**Introduction** Sport motivation among young has been deeply studied as a key element for improving both sports performance and adherence to the physical activity practice from the tenets of Achievement Goal and Self-Determination Theories. The aim of this study was to analyze the influence of the perceived motivational climate, task-involving (T) or ego-involving (E) over the basic psychological human needs satisfaction, competence (C), autonomy (A) and relatedness (R). **Methods** Perceived Motivational Climate in Sport Questionnaire (PMCSQ-2) and Psychological Needs Satisfaction in Exercise Scale (PNSE) were administered to 131 young basketball players. We used a linear regression analysis to study the effects of T & E on the satisfaction of C, A & R. **Results** Regression analyses showed that C ( $R^2 = 0.14$ ;  $p < 0.001$ ) was positively predicted by T ( $\beta = .43$ ;  $t = 5.18$ ,  $p < 0.001$ ) while no relation was found between E and C ( $t = 1.56$ ,  $p > 0.05$ ). A ( $R^2 = 0.05$ ;  $p < 0.01$ ) was predicted by E ( $\beta = .26$ ;  $t = 3.10$ ,  $p < 0.01$ ) and non by T ( $t = 0.68$ ,  $p > 0.05$ ). Lastly, R ( $R^2 = 0.25$ ;  $p < 0.001$ ) was predicted by T ( $\beta = .49$ ;  $t = 5.85$ ,  $p < 0.001$ ) while no relation was found between E and R ( $t = 1.82$ ,  $p > 0.05$ ). **Discussion** Results agree with most existing literature (Ntoumanis and Biddle, 1999). Relation between T with C and R (Cox & Ullrich French, 2010; Escartí & Gutiérrez, 2001) is consistent with the predictions of the AGT; in task-involving settings, it is more likely that the individual holds in the task, focuses on the intrinsic rewards of learning and maintains high perceptions of competence and relatedness, as there is no comparisons among subjects. No previous references have been found about relation found between E and A. However, we must take into consideration that when subjects feel identified with the action they do, their perceived autonomy grows (Moreno, 2006). It makes sense that the sample, formed by players participating in the highest competition league at those ages, could feel well-identified with the features of E, where competition is emphasized. **References** Cox, A., & Ullrich-French, S. ### **EFFECTS OF TWO DIFFERENT TYPE OF AEROBIC EXERCISE ON LIFE SATISFACTION AND BECK DEPRESSION LEVEL**

Atan, T., Cicek, G., Imamoglu, O., Yamaner, F., Gullu, E., Unlu, C.

*Ondokuz Mayıs University*

**Introduction** The positive effects of regular aerobic exercises on increasing self-confidence, getting away from negative thoughts, regular sleep and adapting to stress, decreasing depression risk, and life quality are dealt with. The aim of this study was to search the effect of the two different type of eight-week aerobic exercises on Life Satisfaction and Depression level according to sedentary women. **Methods** The groups were formed by total 56 voluntary sedentary women. 25 of them (age;  $33.44 \pm 4.51$  years, height  $158.76 \pm 5.88$  cm) were separated as an aerobic-step group and the rest 31 women (age;  $34.87 \pm 4.80$  years, height  $157.25 \pm 5.49$ ) were separated as an aerobic-core group. The groups were made to do aerobic-step or aerobic-core exercises at a severity level of 60-70 percent of their heart beat rate for 60 minutes in 4 days during 8 weeks. Before and after the exercise programme, Life Satisfaction Inventory and Beck Depression Inventory were applied to the experimental subjects. For the statistical analysis "student t" test and "paired t" test were used. **Results** Body weight and Depression level of each group after the exercise decreased compared to the ones before exercise ( $p < 0.01$ ). Life Satisfaction level of both groups increased after two-month exercise ( $p < 0.01$ ). The Body weight, Life Satisfaction and Depression level measured before the start of the two-month exercise did not show meaningful difference between two groups ( $p > 0.05$ ). But when the values after two months were compared, it was found that the Depression level of the group doing aerobic-step exercise was statistically lower than that of the group doing aerobic-core exercise ( $p < 0.01$ ). Body weight and Life Satisfaction level measured after two months did not show meaningful difference between those two groups ( $p > 0.05$ ). **Discussion** By studying the link between depression and exercise in many researches, it has been revealed that regular exercise is useful for mental disorders (Salmon, 2000). It has been revealed that exercise could be used both directly and collaterally in the treatment of low and bland severity of depression, and that exercise is good way of response to control or prevent depression and it is as curative as drugs. (Dun et al., 2005; McAuley et al., 2003). According to these studies, this supports the results obtained from this research, and aerobic exercise increase the life satisfaction scores in women and decrease the symptoms of depression. However, aerobic-step exercise has been observed to decrease the level of depression more than aerobic-core exercise. **References** Salmon P. (2000). *Clinical Psychology Review*, 21, 33-61. ## MOTIVATIONAL PROFILES AND PERFORMANCE IN YOUNG ELITE FOOTBALL PLAYERS: A PERSON-ORIENTED APPROACH

Zuber, C., Zibung, M., Conzelmann, A.

*Institute of Sport Science (ISPW)*

**MOTIVATIONAL PROFILES AND PERFORMANCE IN YOUNG ELITE FOOTBALL PLAYERS: A PERSON-ORIENTED APPROACH** Introduction The influence of motivational variables on athletic performance is undisputed. What is unclear, though, is how the motivational system must be constituted in order to promote performance as much as possible. In terms of motivational psychology, this raises the question how the motivational constructs Self-Determination, Hope for Success (HS), Fear of Failure (FF) and Achievement Orientation interact with each other (Conroy et al, 2007). This holistic approach leads to a person-oriented methodology that studies how patterns of such variables affect the development of performance (Bergman et al., 2003). Methods A sample of 95 young, male football talents (MAge = 12.26, SD = 0.29) were questioned concerning their self-determination, HS and FF as the facets of their achievement motive, and their competitive orientation. Their athletic performance was assessed a year later by national youth team coaches, using a 2-step scale (1= low level of performance, 2= high level of performance). The clusters found (Ward, squared Euclidian distance) were examined in terms of the transition probabilities between the performance categories. Results Four clusters are identified (52.85 % explained variance). The "high achievement motivated" athletes are found to move into the group of high-performance players at a higher-than-random frequency (odds ratio = 1.3). "Extrinsically motivated" athletes, display a higher-than-random transition into the lower performance category (OR =1.5). No higher-than-random paths were observed among those "fearful of failure" and those "intrinsically motivated and not achievement-oriented". Discussion The results indicate the importance of specific sets of variables for the medium-term development of performance among young talents in competitive sports. Further longitudinal studies are needed in order to decide whether the patterns of variable can contribute to talent selection and promotion in the longer term too. References Bergman, L.R., Magnusson, D. & El-Khoury, B.M. (2003). Studying individual development in an interindividual context. A person-oriented approach. Mahwah, N.J: Erlbaum. Conroy, D. ## MOTIVATION AMONG BASKETBALL PLAYERS: DIFFERENCES ACCORDING TO THE COMPETITION.

Franco, E., Coterón, J., Sánchez, G., Refoyo, I.

*Technical University of Madrid*

Introduction Adolescence is a key period to become regular practitioners of physical activity or to completely abandon it. Existing literature has set the importance of the context where activity takes place as a factor which can predict many other motivational outcomes. The aim of this study was to analyze differences that young basketball players show in the perception of important motivational variables from the tenets of Self Determination Theory according to the league they take part in. Methods Psychological Needs Satisfaction in Exercise Scale (PNSE), Sport Motivation Scale (SMS) and the Intention to be Physically Active Scale (IPAS) were administered to 204 young basketball players. One factor ANOVA was used to find possible differences among players belonging to preferred federated (PF), federated competition (A) and municipal sport games competition (MSG). Scheffé post-hoc tests were used to compare groups. Results Differences were found in future intention to be physically active (I;  $F=3.41$ ,  $p < .05$ ) and in relatedness (R;  $F=3.47$ ,  $p < .05$ ). Post-hoc test revealed PF players ( $M=4.49$ ;  $SD=.57$ ) scored higher in I than MSG ( $M=4.18$ ;  $SD=.73$ ). Also, PF players ( $M=3.93$ ;  $SD=.58$ ) got higher scores in R than F ( $M=3.64$ ;  $SD=.61$ ) and MSG ( $M=3.65$ ;  $SD=.44$ ). No differences were found in the rest of variables: competence, autonomy and intrinsic motivation ( $p > .05$ ). Discussion PF players showed higher scores both in I and R. Existing literature (Carpenter, et al., 2002 & GarcíaCalvo, et al., 2010) has shown a relation between R and adherence to the physical activity, which, in our study, could be reinforced by the higher level of I in PF sample. These players have chance of promoting to elite basketball teams which could explain their higher levels of I due to an extra-motivation. Furthermore, players from this league spend more time together due to longer training sessions, travels, etc. which can improve the quality of their friendship and so, support feelings of R (Cox, et al., 2008). It seems that players from different competitions have disparate motivational profiles and which thus should receive adapted interventions. References Cox, A., Smith, A., & Williams, L. (2008). ## THE MOTIVATION OF YOUTH SPORT PARTICIPANTS

Chaves, A., Carbinatto, M.V., Ferraz, O.L.

*Universidade Federal do Triângulo Mineiro/ Universidade de São Paulo*

Introduction According to Murray (1983), the differences of motivation can explain different types of involvement in an activity. Currently, the investigation of motivational processes among youth sport participants has been to adopt a goal perspective approach (DUDA, 1992). Two major goals have been found to exist in achievement situations (WHITE, DUDA and KELLER, 1998), i.e., task or ego orientation. Methods In this study took part 62 youth sport participants, 12 girls (mean age of  $12.77 \pm 1.2$  years) and 50 boys (mean age of  $13.8 \pm 2.4$  years), participants of modalities struggles, futsal, swimming, artistic gymnastics and volleyball. All subjects volunteered to participate in the study. We used the questionnaire the Task and Ego Orientation in Sport Questionnaire - TEOSQ (DUDA and NICHOLLS, 1992), translated, adapted and validated by Hirota and De Marco (2006), where we can identify whether the individual is ego oriented or task oriented. The internal consistency of the task and ego orientation subscales was determined by Cronbach's Coefficient Alpha and an average orientation of each to identify the motivational orientation of participants. Results The results obtained by Cronbach's Coefficient Alpha task orientation reached a value of 0.81, while the ego orientation a value was 0.71. We recorded the following average,  $4.28 \pm 0.19$  and  $2.44 \pm 0.14$ , respectively, task orientation and ego, showing results consistent with existing literature. There was no significant change for the different sports. Conclusion The results showed that participants are task orientation, i.e., they are self-determined, self-confident, creative and cooperate more with the group. References DUDA, J. L. ### **PREDICTING PSYCHOLOGICAL NEED THWARTING AND AMOTIVATION: COACHES ALSO EXPERIENCE THE DARK SIDE**

Alcaraz, S., Viladrich, C., Torregrosa, M.

*Universitat Autònoma de Barcelona*

**Introduction** Coaches play a key role in the psychological development of the athletes they train. Given the crucial importance of coaches, recent research has studied their feelings and motivations within sport environment (e.g., Stebbings et al., 2012). Depending on the influence received from the environment, coaches' experiences can be either positive or negative, as in the case of athletes (e.g., Bartholomew et al., 2011). Framed in the Self-Determination Theory (e.g., Deci & Ryan, 2000), the aim of this work is to present a model in which we assess the coaches' negative experiences. Specifically, we hypothesize that pressures from the social environment would thwart coaches' basic psychological needs, which in turn would lead them to feelings of amotivation. **Method** One hundred and forty-nine coaches (Mage = 27.75, SD = 8.79, range = 15-52, 94% male) responded to our multi-section questionnaire. The coaches trained football (82%) or basketball (18%). **Results** All the analyses were carried out using Mplus 7.0. First, we compared the measurement models obtained with the confirmatory factor analysis (CFA) approach and the exploratory structural equation modelling (ESEM) approach. For each instrument, we chose the one that fitted better to the data. Then, the structural equation model (SEM) was tested. Fit indices of this model showed a good fit to the data:  $\chi^2(226) = 375.142, p < .001, CFI = .955, TLI = .950, RMSEA = .067$ . The results revealed that perceptions of the environmental pressures were a positive predictor for coaches' psychological need thwarting, which in turn positively predicted their amotivation. **Discussion** Our work confirmed a model that examines the dark side of coaching. Thus, when a coach perceives pressure from the social environment (e.g., club managers), he/she feels their psychological needs thwarted. When this situation occurs, the coach will probably experience a sense of amotivation. Future research should include other influences from the social environment to test the conditions in which the coaches would have positive (i.e., psychological need satisfaction, self-determined motivation) or negative coaching experiences. **References** Bartholomew, K. ### **THE WHAT, WHY AND WHERE OF EXERCISE BEHAVIOR: EXPLORING ASSOCIATIONS BETWEEN PHYSICAL ACTIVITY QUANTITY, INTENSITY, ENVIRONMENT AND MOTIVATION.**

Welch, A.S., Banks, A.K.

*Johnson State College & Iowa State University*

**Introduction** High rates of physical inactivity and associated health problems mean that understanding physical activity (PA) behavior patterns is a public health priority. Self Determination Theory research has demonstrated that intensity, duration and frequency of PA are all positively associated with more autonomous reasons for exercise (Duncan et al., 2010), but little attention has been given to where those activities take place. Furthermore, exercise in environments with natural features has been shown to provide physical and mental health benefits (Pretty et al., 2005). Thus, the purpose of the present study was to explore the relationships between PA environments, behaviors, and motivations, with emphasis on differentiating nature-based and outdoor PA. **Methods** Participants were 849 physically active US adults (M age = 43.5 years; SD = 11.1) who completed an online survey including the 7-Day Physical Activity Recall questionnaire to assess PA behaviors (modified to assess PA location) and the Behavioral Regulations in Exercise Questionnaire-2 to assess motivations. **Correlations** between motivations (intrinsic, integrated, identified, introjected, external, amotivation), PA environment (%outdoor, %nature), moderate (MPA; METS) and vigorous (VPA; METS) intensity, duration (minutes), and frequency (days/week) of PA were analyzed. **Results** Percentage of physical activities that took place in nature (%nature) had small but significant positive correlations with intrinsic ( $r = .08; p < 0.05$ ), integrated ( $r = .08; p < 0.05$ ), and identified regulation ( $r = .07; p < 0.05$ ), but no associations with exercise behavior variables. In contrast, %outdoor was inversely associated with VPA ( $r = -.16; p < 0.01$ ), integrated ( $r = -.11; p < 0.01$ ), identified ( $r = -.10; p < 0.01$ ), and introjected regulation ( $r = -.13; p < 0.01$ ). MPA and frequency of PA had significant positive associations with % outdoor. Consistent with other research, positive correlations between autonomous regulations and VPA were observed ( $r = .27$  to  $.30; p < .01$ ), but MPA was negatively associated with all autonomous regulations. **Discussion** Those who engage in more nature-based activities are regulated by more autonomous motivations. Incongruous associations between % outdoor, MPA and autonomous motivations may be explained by outdoor work-related physical activities being reported as moderate intensity activities. Careful consideration should be paid to the assessment of type and location of PA in the search to understand PA behavior. **References** Duncan, L. R., Hall, C. R., Wilson, P. M., & Jenny, O. **ATTITUDES TOWARDS DOPING: A COMPARISON AMONG DIFFERENT SPANISH OLYMPIC CYCLING NATIONAL TEAMS**

Morente-Sánchez, J., Freire, C., Zabala, M.

*Faculty of Sport Sciences, University of Granada (Spain)*

ATTITUDES TOWARDS DOPING: A COMPARISON AMONG DIFFERENT SPANISH OLYMPIC CYCLING NATIONAL TEAMS Morente-Sánchez, J. Freire, C.1, & Zabala, M.1,2 1 Faculty of Sport Sciences, University of Granada (Spain) 2 Spanish Cycling Federation, Madrid (Spain) Introduction According to Morente-Sánchez and Zabala's systematic review about doping attitudes, beliefs and knowledge in elite athletes [1], there were no previous specific studies that assessed attitudes towards doping in elite athletes by means a validated scale. The aim of this study was to know and compare the attitudes towards doping among different Spanish Olympic cycling national teams using a validated tool. Methods A total of 72 Spanish national team cyclists, (mean age: 19.67±4.72 years) participated in the study. The gender distribution was 70.1% males (n=51) and 29.9 % females (n=21). The total sample was divided into four groups according to the 4 different Olympic cycling disciplines: Mountain bike -MTB- (n = 18; 83.3% men), Bicycle Moto Cross -BMX- (n = 12; 100% men), Track -TRA- (n = 9; 77.8% men) and Road -ROA- (n = 33; 54.5% men). Descriptive design was carried out by means of a validated questionnaire, Performance Enhancement Attitudes Scale (PEAS) [2] of 17 questions using a Likert scale from 1 (Strongly Disagree) to 6 (Strongly Agree) for different statements that supported the use of doping in sport. Mean value ± Standard Deviation was obtained for each item and Mann Whitney test for independent variables with Bonferroni post hoc was carried out. Results Regarding results from PEAS for the whole sample, mean score (1-6) was 2.13±0.55 and a overall score (17-102) was 36.12±9.39. Taking the different analyzed groups into account, mean and overall scores were, respectively: MTB: 1.80±0.43, 30.28±6.92; BMX: 2.50±0.62, 42.46±10.74; TRA: 2.54±0.71, 43.22±12.00; ROA: 2.06±0.39, 34.91±6.62. Regarding mean score and overall score significant differences were observed between MTB and BMX (p=0.001; p=0.002, respectively) and between MTB and TRA (p=0.002; p=0.003, respectively). Discussion According to PEAS, higher scores represent a more lenient attitude toward doping. Cyclists of the Spanish Olympic national teams, in general, are not tolerant in relation to doping, though BMX and Track riders were little more permissive attitudes towards doping than MTB and road. These scores are relatively far from non-elite confessed doping users have also been assessed (46.8±13.32, [3]; 46.8±13.32, [4]) however, a deep analysis and monitoring of this sample appears necessary. **A PROGRAM OF EMOTIONAL AWARENESS TRAINING AND IMPLICATIONS FOR COACHING EDUCATION**

Schoen, C., Gallo, J.A.

*Salem State University*

Introduction Emotions as a precursor to performance served as the focus of recent research in tennis using an IZOF framework (Schoen & Gallo, 2010). Our preliminary investigation focused on identifying optimal emotions with our athletes using Hanin's (2000) model. We found the following: athletes at the Division III Collegiate level (United States college athletics) have difficulty identifying their emotions; they also failed to recognize how emotions influenced performance and reported feeling mainly negative emotions along with low confidence in prematch and practice challenge match situations more often than positive emotions or confidence. Methods Accordingly, the sport psychology practitioner working with the team developed and implemented a training program throughout the 2011-2012 training and regular season to 1) increase emotional awareness along the lines of Mayer & Salovey's (1997) ability model, 2) practice problem-focused and emotion-focused coping strategies with the athletes, 3) measure first serve percentages to gauge how emotional coping strategies correlated with performance, and finally 4) to emphasize greater team building steps designed to improve intrateam support and cohesion. The team consisted of 8 players, ranging in age from 18-24 (with an average of 7.4 years competitive playing experience) who responded to surveys asking them for self-reported measures of anxiety and confidence before every match and practice challenge scenarios designed to replicate pressure situation in competition. First serve percentage was also measured periodically starting in pre-season and throughout the regular season. Results Improvement in recognizing various emotional states was observed using a content analysis of players' survey responses as indicated by the number and variety of emotional states identified prior to performance, an increase in first serve percentage over the course of the season, and a team climate that was by all measures much more positive and supportive compared against prior observations and data collected from the Schoen and Gallo (2010) study. Discussion Practical implications for coaching education practices will be addressed in terms of selection of team captains (emotional leaders), an emphasis on a higher character team climate as underscored with a team philosophy of mutual on and off court intrateam support, and finally emotional management skills that transcend intercollegiate tennis and transfer to academic performance and/or professional performance after the termination of competitive tennis with this population. **ACUTE ACETAMINOPHEN INGESTION IMPROVES TIME TO EXHAUSTION DURING EXERCISE IN THE HEAT**

Mauger, A.1, Taylor, L.2, Harding, C.2, Foster, J.2, Castle, P.C.2

*(1) University of Kent; (2) University of Bedfordshire*

Introduction: In thermoneutral conditions core temperature (T<sub>core</sub>) is usually maintained within a physiologically acceptable range of ±1 °C. However, when environmental temperatures exceed 30 °C, human mechanisms of heat loss are compromised and the subsequent rise in T<sub>core</sub> has been shown to negatively effect exercise capacity and performance. The analgesic and antipyretic acetaminophen is

effective in the reduction of Tcore in febrile patients. It has also been shown to reduce Tcore by up to 0.22 °C in afebrile stroke patients. Given this observation, the aim of this study was to assess the efficacy of acetaminophen in moderating the metabolically driven rise of Tcore during exercise in the heat. Methods: 10 physically active male adults (age: 21 ± 1 yrs, height: 184 ± 8 cm, weight: 72 ± 15 kg, VO2max: 44 ± 6 mL•min<sup>-1</sup>•kg<sup>-1</sup>) completed a graded exercise test, a familiarisation time to exhaustion and two time to exhaustion trials (TTE) in hot conditions (30 °C, 50%rh) at a fixed power output equivalent to 70% VO2max. In the TTE trials, subjects ingested either 20 mg/kg lean body mass of acetaminophen or a placebo control in a randomised, cross-over design. During TTE trials Tcore, skin temperature (Tskin), RPE, heart rate and thermal sensation were recorded. Results: Subjects cycled for significantly longer (t9 = -2.34, p < 0.05) following ingestion of acetaminophen (1164 ± 722 s) when compared with the placebo trial (964 ± 547 s). This was accompanied by a significant reduction in Tcore (~0.15 °C), Tskin (~0.5 °C) and TSS (~0.5) in the first 60% of the TTE (p < 0.05). No significant difference in RPE was observed between the conditions (p > 0.05). Discussion: The primary finding of this study was that acetaminophen reduced core and skin temperature during fixed intensity exercise in the heat, which may have contributed to an improved time to exhaustion. Acetaminophen is believed to act through penetrating the blood-brain barrier where it reduces levels of prostaglandin E2 through the inhibition of cyclooxygenase. Whilst this mechanism serves to reduce fever by reducing the elevated hypothalamus' thermoregulatory set-point, it is unclear how this may reduce an exercise-induced elevated core temperature.

### EFFICACY OF HEAT MITIGATION STRATEGIES USING MAGNITUDE-BASED INFERENCE

Tan, P.1, Lee, J.2,3,4

1: Nanyang Technological University, 2: DSO National Laboratories, 3: National University of Singapore, 4: Nanyang Technological University

**INTRODUCTION** The rapid rise of body core temperature (Tc) when exercising in the heat often results in an impairment of exercise capacity and performance (Galloway & Maughan, 1997; Parkin et al., 1999). Heat mitigation strategies used to counteract the debilitating effects of heat strain include behavioural alterations, aerobic fitness (AF), heat acclimation/acclimatization (HA), pre-event cooling (PC) and fluid ingestion (FI). This review objectively scored and ranked the effectiveness of each heat mitigation strategy using magnitude-based inferences (Hopkins et al., 2009). **METHODS** A computer-based literature search was performed using the electronic databases: PubMed, SPORTDiscus and Google Scholar. After applying a set of inclusion and exclusion criteria, a total of 75 studies were selected for evaluation. Each study was assessed according to the intervention's ability to lower Tc before exercise, attenuate the rise of Tc during exercise and extend Tc at the end of exercise. Hedges' g values were calculated based on the differences in mean Tc values, standard deviations and the number of subjects in each study at each of the three phases of Tc. Thereafter, weighted averages (Turner & Bernard, 2006) were calculated for each strategy. **RESULTS** For the lowering of Tc before exercise, HA (g=0.78) was found to be the most effective, followed by AF (g=0.69), PC (g=0.40) and FI (g=0.26). FI (g=0.63) was the most effective strategy in attenuating the rate of rise of Tc, then HA (g=0.26), PC (g=0.07) and AF (g=-0.38). To extend the limit of Tc at the end of exercise, AF (g=1.21) was found to be most influential, followed by PC (g=-0.08), HA (g=-0.11) and FI (g=-0.31). The heat mitigation strategies in order of effectiveness are: HA (g=0.47), AF (g=0.21), FI (g=0.16) and PC (g=0.15). **CONCLUSION** While behavioural alteration is perhaps the most important and effective heat mitigation strategy, HA was found to be the most effective in terms of a strategy's ability to favourably alter Tc, followed by AF, FI and lastly, PC. This knowledge will be useful for athletes, coaches, backroom staff and occupational labourers for determining the priority in which these strategies should be employed, especially when resources are limited. **REFERENCES** Galloway SD, Maughan RJ (1997). *Med Sci Sports Exerc*, 29 (9), 1240-1249. ### ADOLESCENT PERFORMERS' PERSPECTIVES OF MENTAL TOUGHNESS AND ITS DEVELOPMENT.

Mahoney, J.W.1,2, Gucciardi, D.F.3, Mallett, C.J.1, Ntoumanis, N.2

1: UQ (Brisbane, Australia), 2: UoB (Birmingham, United Kingdom), 3: CUT (Perth, Australia)

**Introduction** Over the past decade sport psychology researchers have attempted to clarify what is meant by the term mental toughness. Despite a burgeoning body of research, previous literature has only examined a homogeneous sample when attempting to define and conceptualise mental toughness. For example, researchers have typically limited their investigations to adult, male, elite, team sport athletes. Further, researchers have offered insight into how mental toughness is developed, but have yet to embed such findings in established theory on human development. In light of previous research, the aim of the current study was to compare adolescents' perspectives of mental toughness and its development across different performance contexts. Bronfenbrenner's (2001) bioecological model was also explored as a possible underlying theory useful for interpreting participants' perspectives pertaining to mental toughness development. **Method** Eighteen adolescents (9 girls, Mage = 15.6 years) from three performance contexts (i.e., sport, academia, and music) and identified by informed others as being mentally tough, participated in focus groups and 1-1 interviews. **Results** Ten personal resources – persistence, high self-expectations, optimistic thinking, forethought, social intelligence, support seeking, self-belief, drive, disciplined focus, and heightened-awareness – emerged from the discussions as comprising mental toughness. Importantly, whilst this group of resources is partially different to findings from past research, no meaningful differences were observed between performance contexts in the current study. Participants considered three higher-order factors as contributing to the development of mental toughness: supportive social agents, critical incidents, and curiosity. Supportive social agents were further categorized by encouragement, autonomy, challenge, and role modeling, whilst critical incidents were categorized by early successes, varied experiences, and failures and setbacks. Curiosity was not categorized further. Participants' perspectives resonated strongly with Bronfenbrenner's bioecological model, with minor omissions. **Discussion** We concluded that mental toughness is: a concept applicable across performance contexts; different between adolescent and adult performers; and underscored by the bioecological model. Future research could support our findings by conducting quantitative research exploring the relationship between the personal resources and developmental factors that emerged in our study. **References** Bronfenbrenner, U. (2001). *International encyclopedia of the social and behavioral sciences*, 6963-6970. Elsevier, New York.

### THE EFFECTS OF 6 WEEK ACSM INTERVENTION ON STANDARD CARDIOVASCULAR MEASUREMENTS IN SEDENTARY OLDER MEN.

Ratcliffe, J.I, Sculthorpe, N.I, Herbert, P.2, Baker, J.I, Richards, J.3, New, K.I, Grace, F.I

*Uni West of Scotland*

Institute for Clinical Exercise and Health Science, University of the West of Scotland, Hamilton, Scotland ML3 0JB 2University of Wales, Trinity Saint Davids, Camarthen Campus, Camarthen SA31 3EP 3 Institute of Sport and Physical Activity Research, University of Bedfordshire, Bedford MK41 9EA Introduction The American College of Sports Medicine (ACSM) recommends a weekly exercise dosage of 150 minutes for adults (Garber et al., 2011) in order to improve and ensure long term physiological wellbeing. However, there is a lack of supporting evidence for the efficacy of these recommendations in older adults. The present study set out to examine the effect of a 6 week intervention using the ACSM guidelines on cardiovascular measures in sedentary older males. Methods Participants consisting of untrained older males (UT, n= 22, 62.4±5.4 yrs) underwent 6 weeks of training in accordance with the ACSM's guidelines for the development and maintenance of cardiorespiratory fitness (≥30 min.d-1 on ≥5 d.wk-1 for a total of ≥150 min.wk-1). UT underwent telemetric measurement of heart rate (HR) maximal heart rate (HRmax) and heart rate reserve (HRR) and auscultatory measurement of systolic and diastolic blood pressure (SBP, DBP) and resultant mean arterial pressure (MAP) and rate pressure product (RPP). Measures were taken at baseline (Pre) and following 6 weeks of training (Post). At both time points UT were compared with a group of master athletes (MA, n=17, 60.4±5.2 yrs) who acted as a positive control. Data were analysed using SPSS v 20 software using a mixed design ANOVA. Simple effects were investigated using a paired samples t-test. The alpha level was set at 0.05. Results UT had a significant fall in resting SBP and DBP (p<0.05) with subsequent reductions in RPP and MAP (p<0.05). HRmax and HRR significantly increased from Pre to Post (p<0.05). At Pre UT had significantly higher SBP, DBP, MAP, and RPP with lower HRR (p<0.05). Following 6 weeks training none of these variables were significantly different from MA. Discussion These data suggest that the ACSM guidelines are effective as a short term exercise intervention in improving cardiovascular function in older sedentary populations. The magnitude of change was such that cardiovascular measures following the 6 week intervention in the previously long term sedentary older participants were not distinguishable from age matched masters athletes. This suggests that the ACSM guidelines are an effective method of improving the cardiovascular health of an ageing sedentary population. References Garber, C. E., Blissimer, B., Deschenes, M. et al. 2011. Med Sci Sports Exerc, 43, 1334-59.

### THE EFFECTS OF A 6 WEEK ACSM INTERVENTION ON AEROBIC FITNESS IN SEDENTARY OLDER MEN.

Herbert, P.2, Ratcliffe, J.I, Sculthorpe, N.I, Baker, J.I, Richards, J.3, Grace, F.I

*Uni West of Scotland*

Institute for Clinical Exercise and Health Science, University of the West of Scotland, Hamilton, Scotland ML3 0JB 2University of Wales, Trinity Saint Davids, Camarthen Campus, Camarthen SA31 3EP 3 Institute of Sport and Physical Activity Research, University of Bedfordshire, Bedford MK41 9EA Introduction A low aerobic capacity can heavily impact an individual's quality of life, and is widely regarded as a risk factor for cardiovascular disease. The American College of Sports Medicine (ACSM) recommends a weekly exercise dosage of 150 minutes for adults (Garber et al., 2011) in order to improve and ensure long term physiological wellbeing. However, there is a lack of supporting evidence for the efficacy of these recommendations in older adults. The present study set out to examine the effect of a 6 week intervention using the ACSM guidelines on aerobic fitness in sedentary older males. Methods Participants consisting of untrained older males (UT, n= 22, 62.4±5.4 yrs) underwent 6 weeks of training in accordance with the ACSM's guidelines for the development and maintenance of cardiorespiratory fitness (≥30 min.d-1 on ≥5 d.wk-1 for a total of ≥150 min.wk-1). At baseline (Pre) and following 6 weeks of training (Post), participants performed an incremental exercise test to exhaustion (VO2max) on a cycle ergometer (Wattbike UK). Breath-by-breath analysis (Metamax II, Cortex, Leipzig, Germany) enabled measurement of gas exchange variables, including VO2max, absolute VEmax, VT as a % of VO2max. At both time points UT were compared with a group of master athletes (MA, n=17, 60.4±5.2 yrs) who acted as a positive control. Data were analysed using SPSS v 20 software using a mixed design ANOVA. Simple effects were investigated using a paired samples t-test. The alpha level was set at 0.05. Results UT experienced significant increases in VO2max (p<0.01), absolute VEmax (p<0.05), and VT expressed as a % of VO2max (p<0.05). At Pre, UT had significantly lower VO2max, absolute VEmax, maxO2 pulse, and power at VO2max (p<0.01). Although significant increases in VO2max, absolute VEmax, and VT expressed as a % of VO2max occurred after 6 weeks of training in UT, MA still maintained significantly superior values for these variables at all measurement points. Discussion These data suggest that the ACSM guidelines are effective as a short term exercise intervention in improving aerobic fitness in older sedentary populations. The benefits of participating in a continuous exercise training programme, following standard guidelines, may present a powerful method of health promotion and treating age associated functional decline. References Garber, C. E., Blissimer, B., Deschenes, M. et al. 2011. Med Sci Sports Exerc, 43, 1334-59.

### DIFFERENCES IN ACTN3 GENOTYPE IN SPANISH FEMALE SWIMMERS

Díaz-Ureña, G., Muniesa, C.A., De la Calle, L.

*European University of Madrid*

Introduction Performance depends on different factors, among them, the genetic factor. The ACTN3 R577X gene is associated with power and velocity performance in elite athletes. Therefore, the purpose of this study was to analyse the differences in ACTN3 R577X genotype between sprint female swimmers compared to middle-distance and non-athletes females. Methods The sample of this study is composed of 39 female elite swimmers (20 sprinters) and 166 non-athletes females. All swimmers participated at least in one Absolute Spanish Championship in swimming pool. Genomic DNA was isolated from buccal epithelium or peripheral blood, and genotyping was performed in the Genetics Laboratory of Universidad Europea de Madrid, Spain. We compared genotypic frequencies among sprint (50m and 100m), middle-distance (>200m) and non-athletes females using a Pearson Chi-Square test. When the assumptions were not met, it was calculated p value with Monte Carlo approximation. Results The genotype frequencies of the ACTN3 R577X polymorphism in the different study groups were: Non-athletes (RR:31,9%; RX:48,2%; XX:19,9%); Sprint swimmers (RR:40,0%; RX:45,0%; XX:15,0%); and Middle-distance swimmers (RR:26,3%; RX:47,4%; XX:26,3%) There were no significant differences in genotype frequencies among all groups ( $\chi^2(4) = 1,26; p > 0,05; IC95\% \text{ for } p: 0,874-0,887$ ). Discussion The results showed no association of the RR genotype with the typology of swimming competition. Chiu et al. (2011) studied the ACTN3 genotype frequency in elite Taiwanese sprint swimmers and observed that the frequency of the ACTN3 R-allele was significantly higher in elite sprint female swimmers (< 400 m) compared to the general population. References Chiu LL, Wu YF, Tang MT, Yu HC, Hsieh LL, Hsieh SS. (2011) ACTN3 genotype and swimming performance in Taiwan. Int J Sports Med: 32: 476-480.

**THE CATALAN SPORTS OBSERVATORY. THE DATA OF SPORT IN THE SPOTLIGHT**

Gomez Ribas, J., Munoz Bover, L., Serra Payeras, P., Nasser, J.P., Camps Povill, A.

*Institut Nacional d'Educació Física (INEFC)*

Introduction The Catalan Sports Observatory (<http://www.observatoridelesport.cat>) is an initiative of the Secretariat General of Sports of the Generalitat of Catalonia. INEFC and other institutions involved in sport are in charge of its development. It is aimed at individuals and organizations involved in the field of sport to provide them information about the evolution of sport in Catalonia. The Observatory is part of the definition of sport that the European Sports Charter offered in May 1992, and provides data of both sport performance and the extra-curricular sport activities, sports activities with the elderly, adapted physical activities, etc... Methodology The information is provided by six broad dimensions that incorporates the overall sports phenomenon: Sport participation, Organisations and facilities, The economy of sport, Training, research and professions, International renown and Legal and Political framework. Information can be acquired in two different ways according to the dimension approached: - Information from existing sources (surveys, yearbooks, reports ...) that others have collected in our region and that we adapt to our formats using a secondary method. - Information generated by the Observatory on topics for which there was no information, along with other organizations that establish the methodology that will be implemented in the study to be carried out. The main method that has been used in these researches is the standardized surveys, which was conducted face to face with those individuals involved. Results The Observatory discovered 206 indicators and it currently has 234 with an expected increase to 250 by emptying several studies with other agents. It has presented 22 communications in national and international conferences, exhibiting 12 research studies and has participated in 26 events related to sport. In recent years the Centre has received 67 inquiries from various publics, private and individuals to whom they have provided with some information. The website has received almost 90.000 visits since its inception and has begun to develop trends, such as the dimension of sports participation, which discusses the evolution of the number of sport licenses in Catalonia and Spain. The number of licenses has increased a 12% in recent years, from 545.946 athletes in 2006 to 611.991 in 2011. It also explains the evolution of the number of elite athletes who have dropped a 16% between 2007 and 2011, decreasing from 553 to 461 athletes. Discussion Through these methods, the Observatory aims to disseminate these trends of the evolution of the sports phenomenon that show what the behavior of the different aspects analyzed in recent years was, and predict what direction sport will take in the future in its various aspects.

**MODERNITY AND THE REGULATION OF BODIES: ELIAS MEETS FOUCAULT**

Martins, C.

*UNESP*

This paper seeks to reflect on the possibility of a meeting ground where Michel Foucault and Norbert Elias' thought comes together around the issue of the regulation of drives and bodily practices within modernity. Such drives – among which we highlight the use of force and violence, as well as the acceptable regulation of their release and applications – have been the object of particular procedures within the modern era, whether seen in relation to individuals or from to the social body. Several chapters in the history of the body in modernity may be considered emblematic and relevant to the search for satisfactory and socially acceptable compromises to the problem of the governing and self control of the different drives, forces and conflicts originating in the bodies of individuals constituted through social practices. These drives – among which we could give particularly salience to the use of force and violence, as well as to the acceptable regulation of the way the latter are released and applied – have been the object of particular procedures in the modern era, whether seen from the perspective of individuals or approached from the angle of the social body. Approaches that are particularly worthy of merit may be found in the Michel Foucault's history of the emergence of disciplinary and bio-political practices and Norbert Elias' work on the socio-genesis of modern sport, both exemplary as distinctive theoretical contributions. The processes these thinkers describe and identify are, in origin, development and ramifications, phenomena that can be periodized in terms of the "long duration". In this article, we intend to look at possible points of convergence in the contributions that these two authors make to our thought on the regulation of bodily practices and impulses within modernity. For such purposes, we will construct an overview of problems of the political management of bodies and populations within modernity, from the perspective of the "civilizing process". Both of these authors, each with the singularity of his own thought, made enormous contributions to the critical diagnosis of the role of different forms of regulation and self-governance of the functions and practices of bodies within modernity. Our purpose here has been to establish the possible convergences between them, while attempting to articulate them within a broad and complex panorama of the issues at stake.

**EXCHANGE PROGRAMS/INTERNATIONAL LEISURE COOPERATION IN THE AREA OF THE NATIONAL RESEARCH GROUPS CONTEXT**

Marinho, A.1, Santos, P.M.2, Moletta, A.F.2, Bahia, M.C.3, Alves, C.4

*1: UDESC (Santa Catarina, Brazil), 2: UFSC (Santa Catarina, Brazil), 3: UFPA (Pará, Brazil), 4: UNIRARAS (São Paulo, Brazil)*

EXCHANGE PROGRAMS/INTERNATIONAL LEISURE COOPERATION IN THE AREA OF THE NATIONAL RESEARCH GROUPS CONTEXT Introduction The higher education internationalization process, which includes academic mobility programs and other international cooperation actions, often workable by research groups (GP), is not a novelty. However, the theorization in many specific subject areas, such as leisure, is still not largely explored in this scenario (Lo Bianco, 2009). Therefore, the intent of this study is to deliberate on exchange programs/international cooperation in the line of leisure developed by Brazilian RGs. Methods We conducted a descriptive exploratory research with quantitative and qualitative approach in two phases: initially, we performed a mapping of GP in the leisure area in Brazil, registered in the database 'Directory of Research Groups' of the National Council of Scientific and Technological Development (CNPq). We found 211 RGs related to leisure. In the second phase, the representatives of these groups were invited, via email, to answer a questionnaire. Fifty-four researchers took part of the study, signing a consent form. Data were analyzed using descriptive statistics and content

analysis technique. Results Nine RGs who develop international programs in the line of leisure were found. These groups are centered in public higher education institutions and are distributed in the Southeast, Northeast and Southern regions of Brazil. International programs are associated with shares in New Zealand, Israel, Canada, Colombia, Spain, Portugal, Germany and France. Three groups develop only specific actions such as visits of professors and renders international collaboration for the development of scientific materials. The other groups coordinate consolidated exchanges programs and various actions of international cooperation by means of agreements with institutions abroad and financing of development agencies like CNPq, ERASMUS Program, Fundación Carolina and the Sports Ministry. Discussion This study revealed the existence of updated proposals that are challenging and promising which may Grant contribution to multiculturalism and for professional training in the area. Although some groups have reported only the development of certain actions of international cooperation, Duca et al. (2011) stresses that such initiatives can enable new alliances between researchers and thus facilitate the process of internationalization of a particular area. References Lo Bianco AC (2009). *Revista latino-americana de psicopatología fundamental*, 12(3), 445-453. Duca GFD, Garcia LMT, Silva KS, Nascimento JV (2011). *Revista Brasileira de Educação Física e Esporte*, 25(4), 607-617.

### THE ROLE OF SPORTS COMMUNITY FOR QUALITY OF LIFE IN STRICKEN AREA FROM DISASTER

Takahashi, S.

*Tohoku Gakuin University*

Introduction Most of the north part of Japan was severely hit by the Great East Japan Earthquake two years ago. Now, residents in stricken areas are recovering from the disaster. Under such situation, to maintain physical and mental health is important in order to achieve recovery early. In recent years, it was found the social capital may be a useful factor in the maintenance of physical and mental health. Social capital is composed by cognitive component and structural component, in further structural component is distinguished to some communities such as neighborhood association and other communities (sports, recreation, hobby, culture community). Given exercise have effects on the prevention of life style related disease and mental illness, the sports community might be more effective component than neighborhood association and hobby and culture community. Therefore, the purpose of this study was to compare effect of sports community for quality of life (QOL) with it of other communities in Sendai city that is the stricken area. Methods Questionnaires were distributed to 2000 people who aged 20 and older in Sendai city by mailing method. We received 477 valid questionnaires. QOL was measured by the WHO-QOL 26 and summed to calculate a score ranging from 0 to 100. Cognitive social capital was measured by trust (low/high). Structural social capital was measured by membership in 1) neighborhood association (Yes/No), 2) sports community (Yes/No), and 3) hobby or culture community (Yes/No). Effects of three types of structural social capital were compared by ANCOVA with individual confounders (gender, age, income, education attainment, smoking habit, drinking alcohol habit, physical activity, and cognitive social capital). Results ANCOVA results revealed high levels of neighborhood association (regression coefficient = 2.98, SEE = 1.33,  $p = 0.025$ ) and sports community (regression coefficient = 6.25, SEE = 1.51,  $p < 0.001$ ) significantly were associated with better QOL. Association between culture community and QOL was not significant (regression coefficient = 0.63, SEE = 1.87,  $p = 0.738$ ). Discussions We found that the positive effect of sports community on QOL was also higher than effects of neighborhood association and hobby or culture community, after adjusting for confounders including physical activity. Sports community may particularly contribute to enhance mental health as well as physical health in the stricken area.

### A COMPARISON OF PUBLIC-PRIVATE PARTNERSHIPS IN CONSTRUCTING PROFESSIONAL SPORTS FACILITIES BETWEEN THE UNITED STATES AND TAIWAN

Lee, K.W., Lee, P.C., Yang, C.W., Fang, C.C., Yu, C.H.

*National Taichung University of Education (NTCU)*

Introduction Sports complexes is widely perceived as giving cities a competitive advantage in attracting new businesses, residents, and tourists. Moreover, cities seek to associate themselves with professional sports teams and facilities, and often pay a premium to do so (Long, 2012). Therefore, this research based on research questions that concern the partnership models that U.S. and Taiwan governments used to promote private sectors in building sports complexes. Methods The document analysis was used to collect research data from three professional sports facilities in the U.S. and two facilities in Taiwan. Public construction, land and infrastructure cost data is largely drawn from primary sources, including local and state governments. Results In Taiwan, the public-private partnership of constructing professional sports facilities was Build-Operate-Transfer model (BOT). In the partnership, all the constructing costs belonged to private sector's responsibilities. The government then commissioned the operation of the facility project to the same private institution. Upon expiration of the operation period, the facility ownership and the right to operate reverted back to the government. In the U.S., the constructing projects benefited from numerous government incentives and other forms of economic assistance. The most substantive of these financing tools were tax credits, bonds, and tax-increment financing, along with other loans. Discussion The research question was concerned with the similarities that existed in the partnerships between the U.S. and Taiwan. The findings revealed that the facility projects were undertaken jointly by public and private entities, where there is significant and direct financial participation by both partners and where responsibilities are formalized in a legal contract. These are fundamental tenets of public-private partnership (Crompton, 2004; Murray, 2009). Moreover, those projects were publicly administered but within a framework that allowed for private finance, design, operation, and possibly temporary ownership of a building or real property. The findings also verified previous research that participants in sports facility deals can be categorized as public partners that include municipal, county, state, and other public institutions, and private partners that include team and other private entities. Among public partners, municipal governments are the most active public participants in sports facility financing (Long, 2012). References Crompton, J. (2004). Beyond Economic Impact: An Alternative Rationale for the Public Subsidy of Major League Sports Facilities. *Journal of Sport Management*, 18(1), 40-58. Long, J. (2012). ### AN AUTOETHNOGRAPHIC EXPLORATION OF CANCER AND ALCOHOLISM WITHIN A FATHER/SON RELATIONSHIP

McInch, A.

*University of Gloucestershire*

Several autoethnographic studies have explored the parent/child relational identity that has been affected by homophobia (Adams, 2006), Alzheimer's Disease (Fox, 2010) and absent parents (Jago, 2006). The aim of this study was to explore a father/son relational

identity that has been long affected by alcoholism and more recently cancer. In adopting an embodied autoethnographic methodology, three body narratives are presented that explore the highly contextual tensions and dilemmas that both illnesses have inflicted on the relationship. The findings suggested that the metaphorical discourse used in the text is a result of a sporting, relational identity shared by father and son. The findings also positively confirmed an ethical ideology that likened the author to Frank's (1991) Communicative Body, one that shares experience[s] as result of one's own adverse circumstances. On a journey of understanding the self, the author also came to realise that a reflexive way of knowing was also for self preservation as well as others and that all identity can be considered as relational. Directions for future research are provided.

### **BIGGER MUSCLES AND MORE SEX: AN ALTERNATIVE INTERPRETATION OF YOUNG MEN'S USE OF ANABOLIC STEROIDS**

Christiansen, A.V.

*Aarhus University*

Over the last decade the use of anabolic androgenic steroids (AAS) in gyms and fitness centers has received increasing attention from policy makers, stakeholders and the media. However, the use has not declined. Prevalence measurements from Scandinavia, Europe, USA and Australia indicate that between 1-4 per cent of the male population have experiences with AAS and similar drugs (e.g. Barland & Tangen 2009; Hoare & Moon 2010; Johnston et al. 2010). Scholars have generally explained the use of AAS as a consequence of a cultural preoccupation with body and appearance. In recent years a theory on 'a masculinity in crisis' has been added to this (Klein 1993; Pope et al. 2000). But the rather uniform prevalence data challenges the explanatory power of the 'culture and crisis hypotheses'. Building on long qualitative interviews with AAS using young Danish men this paper evaluates the 'culture hypothesis' in relation to theories on evolutionary psychology (e.g. Kenrick et al. 2004; Konner 2003). The ambition is to provide the basis for a more solid understanding of the use of AAS in and around gyms, and by that potentially contribute to improved education and policy on the area. ### **COMPARISON OF SPORT HABITS BETWEEN HUNGARIAN AND US SOLDIERS SERVING IN AFGHANISTAN**

Molnár, A.H., Ditrach, R., Balogh, L., Orban, K., Soter, A.

*Institute of Physical Education and Sport Sciences, University of Szeged, Szeged & HDF Medical Center, Budapest*

Introduction: Ordinary people do not know much about everyday lives of soldiers serving in foreign countries. This is one of the reasons why they cannot imagine how burdensome it could be, especially for a longer period of time, without having a holiday, or how those soldiers spend their leisure time between duties. Aims: A comparison study about the sport habits of soldiers serving at an operational area in Afghanistan. Methods: A multiple-choice type, anonymous survey was used. The questionnaires were filled in by the soldiers of the Hungarian Defence Forces (n = 48) and the United States Ohio National Guard (n = 46). Results: Before the mission majority of US soldiers did team sports and played different ball games. Besides these, Hungarian soldiers did several individual sports previously. In the mission body building became the most popular type of movement among the soldiers of both nations. There were no professional athletes among US soldiers before the mission. Most of them did sports as hobbyists. Half of the Hungarian soldiers were amateur athletes earlier and there were a few professional sportsmen. After the mission, almost all soldiers of both nations became hobbyists, only a few Hungarian amateur athletes remained. Before the mission or in the operational area Hungarian soldiers spent more time on doing physical exercises in their leisure time. Conclusions: Soldiers serving in foreign countries have national particularities regarding their sport habits during deployment. Soldiers serving in mission spend a significant proportion of their leisure time improving their physical condition. Limited sport facilities simplify the sport habits of the soldiers. In this aspect, soldiers of the two nations become uniform. Results of this survey seem to be useful in the process of pre-deployment preparation of soldiers. These results would help the top-level missions of the soldiers at the operational area.

### **THE DOUBLE ARTICULATION OF THE RELATIVE AGE EFFECT ON SWEDISH FOOTBALL PLAYERS**

Petersson, T.

*Dep. of Sport Sciences*

Introduction In a study including all children born 1984 within the Swedish Football Association, the Relative Age Effects (Cobley et al 2009) are documented on all levels of the selection systems (Peterson 2011). Even the selection of players who had been rejected by the selection system, but still became elite players, was heavily influenced by relative age effects. Methods Three empirical materials are used in the study. The first one is a longitudinal study, where 1117 individuals were selected from 46 teams in 31 football clubs in a strategic sample based on sex, the clubs position in the Division System and their geographical and demographical location. Both quantitative and qualitative methods were used. Two methods are used to measure the Relative Age Effect on the selection of individuals on different levels of the selection systems - Index and Odds Ratios. The second material is the official statistics of the Swedish Football Association, mostly regarding the cohort of 1984, during 1999-2009. The third empirical material contains data about all 61 men and women born 1984, who 2009 belonged to the Swedish football elite, playing in Sweden or abroad. This information was obtained mainly through club home pages after the season of 2009. Results In 2009, at the age of 25, there were 61 players (46 men and 15 women), born 1984, playing abroad, in the first division for men and for women, or in the second division for men, in Sweden. 27 out of 61 players did not belong to the group of players picked by the selection system. The system did not manage to find more than half of the males (23-23) who would play professional football at the age of 25. For the women the system found 11 out of 15. Discussion The 1984 cohort's contribution to the Swedish football elite was 61 individuals. If all potential talent in a cohort in the moment of birth was to be transformed into

"confirmed Elite" in adult age, the distribution of days of birth for the "confirmed Elite" should correspond to that of the entire cohort. The results presented in this article indicate that the selection system of Swedish children- and youth football for the cohort of 1984 was heavily influenced by relative age effect. In 42.6% of the cases the positions were filled with individuals that should not have been there, as a result of Relative Age Effects. Out of the individuals identified as future elite players by the selection system, half of the men and one fourth of the woman were not to belong to the "confirmed elite". They were replaced in the elite football by individuals who had been rejected by the selection system, because of relative age effects, and left to creating a carrier for themselves outside the system. These empirical findings suggests that the Swedish football elite is not created by the selection system, it is rather created in spite of it. References Cobley S, Baker J, Wattie N, McKenna J. (2009). *Sports Med*, 39 (3): 235-256 Peterson, T (2011) *SISU Idrottsböcker*.

#### **THE RELATIONSHIP BETWEEN SCHOOL SPORTS AND IDENTITY FORMATION: SOCIALIZATION OR SELECTION?**

Pot, J.N., Schenk, N., van Hilvoorde, I.M.

*VU University Amsterdam*

It seems common knowledge that school sport participation leads to all kinds of social and educational effects (Coakley, 2009), such as school bonding and long-term sport participation. However, it may also be the case that students with a certain predisposition, sometimes referred to as sporting capital (Wheeler, 2011), are more inclined to participate in school sports. The present study used a longitudinal design to investigate whether participation in an elementary school sport competition actually brings about changes in children (socialization hypothesis), or whether children with a certain predisposition are more inclined to participate in the competition (selection hypothesis) (Brandl-Bredenbeck & Brettschneider, 1997). In a survey of 304 students, student identity was used as an indication of school bonding and sport identity was used as an indication of sporting capital and long-term sport participation. The results of the study showed that boys and girls with a strong sport identity are more inclined to participate in the school sport competition, but that participation in the competition did not alter their sport identity. No relationship existed between participation and student identity. In contrast to commonplace assumptions about the socializing effects of school sport participation, the present study suggests that a selected, predisposed group of children tends to participate in school sports. This indicates that effects related to school sport participation may already have been present before participation started. The absence of socializing effects of a school sport competition can be explained by findings of other studies (e.g., Birchwood et al., 2008; Wheeler, 2011) that suggested that (sporting) capital is mainly transmitted through the family. ### THE INFLUENCE OF HYDROTHERAPY IN INDIVIDUALS WITH DUCHENNE MUSCULAR DYSTROPHY.

Honório, S.I, Batista, M.I, Martins, J.2, Cardoso, J.2, Dias, M.I, Honório, G.3

*Higher School of Education, Torres NOvas-Portugal and University of Beira Interior - Covilhã*

Objective: To determine whether hydrotherapy is beneficial in terms of functional mobility in individuals with Duchenne muscular dystrophy evaluated by EK Functional Motor Scale, and its influence on BMI and percentage of fat mass. Methods: The sample contained seven individuals, males, six of which did not practice hydrotherapy and other individual obtained hydrotherapy classes once or twice a week for 45 minutes. Was applied the EK scale was applied and non-parametric tests of Wilcoxon and Mann-Whitney. Results: The variables analyzed were hydrotherapy, values of functional motor scale EK, BMI and percentage of body fat by testing the influence of these on the first. The results showed that as the BMI value increases, so is the percentage of fat mass higher, and thus brings major motor limitations to individuals, which means higher values on the EK scale. Conclusions: There were no statistically significant differences and there was a decreasing tendency of EK values in the individual with classes, compared to those who didn't practice, with these being higher. The values of correlation between the BMI and EK variables are considered 'Fairly Good', though there were no statistically significant differences. When comparing the variables% MG and EK, there are values considered 'very good', since the increase of one raises the other with a statistical significant value of 0.006.

### THE RELATION BETWEEN PHYSICAL ACTIVITY HABITS, THE HEALTH-PROMOTING LIFESTYLES AND ACADEMIC ACHIEVEMENTS OF PHYSICAL EDUCATION AND SPORTS STUDENTS

Koz, M., Aisabi, S.R., Mert, E.

*ANKARA UNIVERSITY*

Introduction Existing information shows that activities of physical education, health-promoting lifestyle behaviors and physical activities contribute to academic achievement. However, it is not very clear what the relationship is between the physical activities, health-promoting lifestyle behaviors and academic achievements of the students of the Physical Education and Sports(PES). Purpose The purpose of this research is to determine the relationship between health-promoting lifestyle behaviors, physical activities and academic achievements of the students studying at the School of PES and to explain the influencing factors. Methods The research was conducted with the participation of 91 students aged 18-25 studying during the 2011-2012 academic year at the Ankara University School of PES. The physical activity habits and health-promoting lifestyle behaviors of the students were measured with the International Physical Activity Questionnaire (IPAQ), (long form), along with the Healthy Lifestyle Behaviors Questionnaire (HLBQ), while their academic achievements (AA) were determined through obtaining the student's grade scores averages from the Student Information System (SIS). AA was analyzed from the aspects of departments (Teaching Education, Sports Management, Coaching Education), activity level (active and very active), places of living (with family, dorms, lodging houses and houses), working condition (working or not working in any kind of job), sportsmen with and without licenses. Results Fifty one (56%) of the students participating in the study were evaluated as active, while 39 (42.9%) were assessed as very active. From the aspect of physical activity values, significant differences were found between students living with their families and those living in dorms and also between students living in lodging houses and those living in dorms. It was determined that students living in lodging houses had higher values of physical activities, while the students living in dorms had lower values ( $P < 0.05$ ). A significant negative relationship ( $r = -0.23$ ) was found between exercise, which is a subscale of HLBQ and grade scores average. Significant differences were seen between the total HLBQ scores and students of the departments of Physical Education and Sports, and Sports Management ( $P < 0.05$ ). It was observed that students of the department of Physical Education and Sports Teaching had gained high points. Significant differences were also found in self-actualization, nutrition, interpersonal relations, stress management, health responsibility and exercise points between departments ( $P < 0.05$ ). Conclusion Results show statistically there was no relationship between physical activity habits, the health-promoting lifestyles and academic achievements in physical education and sports students.

### RELATIONSHIP BETWEEN THE FUNCTIONAL CLASSIFICATION AND PERFORMANCE IN WHEELCHAIR BASKETBALL MALE PLAYERS

Gil, S.M.I, Yanci, J.I, Otero, M.I, Olasagasti, J.2, Badiola, A.I, Bidaurrazaga-Letona, I.I, Iturricastillo, A.I, Granados, C.I

*University of the Basque Country (UPV/EHU)*

Institutions 1Department of Physical Activity and Sport, Faculty of Physical Activity and Sports Science, University of the Basque Country, UPV/EHU 2Gipuzkoa Adapted Sport Federation Acknowledgements We would like to thank Salto Bera-Bera for participating in this study and also the Department of Physical Activity and Sport (UPV/EHU) for the financial support Introduction The aim of this study was to analyze the performance of wheelchair basketball (WB) players with regard to their anthropometric parameters, functional classification and training history. Methods 14 WB male players (age  $33.07 \pm 7.75$  years, body mass  $75.8 \pm 20.82$  kg and sitting height  $86.8 \pm 6.67$  cm) belonging to a team of the Spanish national WB third division league participated in this study. Players were classified according to the Classification Committee of the International Wheelchair Basketball Federation (IWBF): class 1 (n=1), class 1.5 (n=2), class 2 (n=3), class 2.5 (n=1), class 3 (n=2), class 3.5 (n=2), class 4 (n=1) and class 4.5 (n=1). Their training history was recorded ( $5.71 \pm 4.17$  years). The following measurements were performed: Anthropometry (body mass, measured in kg; sitting height, in cm; sum of skinfolds, in mm: subscapular + tricipital + abdominal + suprailiac) and performance tests: sprint, measured in s (5 m and 20 m without the ball, and 5 m and 20 m with ball, 20 m with ball); agility, in s (T-test and Pick-up test), strength (handgrip in kg, maximal pass) and medicinal ball throw, both in m) and endurance (Yo-Yo intermittent recovery test adapted to 10m). Pearson's or Spearman's correlations were performed between the measured parameters, IWBF class and training experience. Results Positive significant relationships were observed between the IWBF class and sitting height ( $r=0.768$ ,  $p=0.004$ ), body mass ( $r=0.683$ ,  $p=0.014$ ), handgrip ( $r=0.566$ ,  $p=0.05$ ), maximal pass ( $r=0.625$ ,  $p=0.04$ ) and medicinal ball throw ( $r=0.685$ ,  $p=0.02$ ). Training experience was significantly correlated with the sprint test 20 m with ball ( $r= -0.617$ ,  $p=0.043$ ) and the agility T-test ( $r= -0.645$ ,  $p=0.032$ ). Body fat was not correlated to performance. Conclusions In this group of WB players

the IWBF class was related to the strength tests. Thus, players with lower levels of disability performed better than more disabled players. Not only disability, but also body size may have influenced the results in the strength tests. However, in the more skillful tests, such as the sprint with ball and the agility, most experienced athletes in wheelchair training had better performance, independently of the disability. On the other hand, unlike other sports body fat did not (negatively) correlate with performance, maybe due to the fact that disability and skill are more important in this particular sport. ### CHANGE OF DIRECTION ABILITY IN WHEELCHAIR BASKETBALL PLAYERS

Yanci, J.I, Granados, C.I, Badiola, A.I, Otero, M.I, Olasagasti, J.2, Bidaurrazaga-Letona, I.I, Iturricastillo, A.I, Gil, S.M.I

1 Department of Physical Activity and Sport, Faculty of Physical Activity and Sports Science, University of the Basque Country, UPV/EHU, Vitoria-Gasteiz, Spain. 2 Guipuzcoa Adapted Sport Federation

**Introduction** The aims of the present study were to determine the reliability and reproducibility of the agility T-Test and to determine the change of direction ability (CODA) measured by the agility T-Test in wheelchair basketball (WB) players. **Methods** 16 WB players (33.12 ± 7.36 years, 71.89 ± 21.71 Kg and sitting body height 86.07 ± 6.82 cm) belonging to the Spanish national WB third division league participated in this study. The agility T-test previously used in able-bodied (AB) players (Pauole et al., 2000) was performed on alternate days. A photocell (Migrogate Polifemo Radio Light, Bolzano, Italy) was used to record the time. The coefficient of variation (CV = SD/Mean\*100) (Atkinson et al., 1998) and the intraclass correlation coefficient (ICC, test-retest) was used to assess the T-Test reliability and reproducibility. **Results** Good reproducibility values (ICC = 0.74) were showed in T-test. The mean result of this test was 16.96 ± 1.14 s. The results according to the International Wheelchair Basketball Federation (IWBF) class in agility T-test were 17.01 ± 0.34, 16.37 ± 0.88, 15.13, 15.74 ± 0.16, 18.82 ± 0.08, 17.33, and 17.30 ± 0.02 s for the 1-4.5 IWBF class, respectively. **Discussion** In this study, T-Test with WB players showed good reproducibility values. This reproducibility could be considered good because it has yielded a value greater than 0.70 (Coppieters et al., 2002). In our study, the CV was 2.58% in the T-test showing an optimal assessment of reproducibility. Similar findings have been observed in other T-design tests (Sassi et al., 2009) in AB players. These results indicate that the T-Test can be used in the evaluation of the training programs in WB players. **Acknowledgments** The authors would like to thank Bera-Bera wheelchair basketball players and coaches for the opportunity to carry out this investigation. **References** 1. ### SPRINT PERFORMANCE IN WHEELCHAIR BASKETBALL PLAYERS

Yanci, J.I, Granados, C.I, Badiola, A.I, Otero, M.I, Olasagasti, J.2, Bidaurrazaga-Letona, I.I, Iturricastillo, A.I, Gil, S.M.I

1 Department of Physical Activity and Sport, Faculty of Physical Activity and Sports Science, University of the Basque Country, UPV/EHU, Vitoria-Gasteiz, Spain. 2 Guipuzcoa Adapted Sport Federation,

**Introduction** The aim of the present study was to determine the generic sprint performance measured by 5 m and 20 m tests and the specific sprint capacity measured in the same distances with ball, in wheelchair basketball (WB) players. **Methods** 16 male and female WB players (33.12 ± 7.36 years, 71.89 ± 21.71 Kg and sitting body height 86.07 ± 6.82 cm) participated in this study. The subjects undertook a sprint running test consisting of three maximal sprints of 20 m (Vanlandewijck et al., 1999). Time was recorded using photocell gates (Microgate, Polifemo Radio Light, Bolzano, Italy). The timer was activated automatically as the volunteers passed the first gate at the 0.0 m mark and split times were then recorded at 5 m and 20 m. The maximal sprint test with ball was performed using the same protocol and material, adhering to the International Wheelchair Basketball Federation (IWBF) rules for dribbling (De Groot et al., 2012). **Results** The mean results of the 5 m and 20 m sprint test in WB players were 1.87 ± 0.21 s and 5.70 ± 0.43 s, respectively. For the 5 m and 20 m with ball, the mean results were 2.10 ± 0.30 s and 6.59 ± 0.61 s, respectively. **Discussion** In this study, the mean velocity in 5 m was better than the results obtained by De Groot et al., (2012), in Premier league, Tournament A and Tournament B wheelchair players (2.4 s, 2.5 s, 2.6 s, respectively). Comparing to the values obtained in 20 m sprint, our results were also better (3.8%) than reported by Vanlandewijck et al. (1999) in national and worse (5.3%) than in international WB players reported by Chapman et al. (2010). Concerning to the sprint 20 m with ball, the values reported in our study (6.59 s) were better than those obtained by De Groot et al., (2012) in Premier League players (7.00 s), Tournament A (7.40 s) and Tournament B (8.70 s). In any case, it is difficult compare the results of different studies that have measured sprint time in WB players because they differ in the method of measurement. **References** 1. ### EFFECTS OF EXPERIENCE OF WHEELCHAIR BASKETBALL ON PSYCHOSOCIAL ATTITUDE IN YOUNG PEOPLE

Yoda, T.I, Kawanishi, M.2, Kanou, H.3, Matsuo, T.3

1:Dokkyo University (Soka, Japan), 2: Kinki Health Welfare University (Japan), 3:Rikkyo University (Niiza, Japan).

**Introduction** Recently, adapted physical activities including wheelchair sports are conducted for non-disabled people to facilitate their interaction with disabled players. It can improve to understand the disabled and promote normalization (Tripp et al., 1995). Wheelchair sports have come to be known in Japan these days, however, it is still insufficient for generalization. The aim of this study was to investigate about the effects of experience of wheelchair basketball on young people's awareness of the wheelchair and disabled sports, as a first step to introduce wheelchair basketball to university students to make them recognized wheelchair basketball as just one kind of sport. **Methods** We conducted a program in which 82 non-disabled university students experienced wheelchair basketball. The program included orientation, practice to control wheelchair, and games for 1 hour. Before and after the program, subjects were asked to answer the question about their awareness of the wheelchair and wheelchair sports, disability and disabled people, and mood by marking "strongly think (1) ", "somewhat think (2) ", "somewhat not think (3) " or "not think at all (4) ". Then we analyzed subjects' each answer was

scored from one to four to compare awareness before and after the program. Results To the question "is a wheelchair a special vehicle of disabled people?", the score increased from  $1.88 \pm 0.82$  to  $2.83 \pm 0.83$  ( $p < 0.05$ ). The score of the question to "Do you feel challenged to sit in a wheelchair as a non-disabled?", was  $2.50 \pm 0.95$  before and  $3.20 \pm 0.81$  after the programs ( $P < 0.05$ ). "Do you think wheelchair sports is the sport for the disabled?", the average score changed  $2.07 \pm 0.84$  to  $2.95 \pm 0.91$  ( $P < 0.05$ ). "Do you think that anyone can enjoy wheelchair sports regardless of disability?", before was  $2.13 \pm 0.80$ , after was  $1.43 \pm 0.65$  ( $P < 0.05$ ). For the question "Do you feel charm for wheelchair sports?", subjects answered more positive after the program ( $1.54 \pm 0.74$ ) than before ( $2.12 \pm 0.85$ ) ( $P < 0.05$ ). Discussion After participants played wheelchair basketball, their impressions of wheelchair sports and disabilities positively changed. The view that a wheelchair is a vehicle for a disabled person is reduced by experience of this program and it is thought that the specialty of wheelchair was wiped away. Similarly, subjects had less negative image of disability. In addition, it became clear that a participant's awareness is changing that it is a sport which can be enjoyed regardless of the existence of disability. The experience wheelchair sports with disabled people can make participants' awareness changed positively (Yasui, 2004). These results suggest that the experience of wheelchair basketball could affect participants' attitude toward not only wheelchair sports itself but also disability in general. References Tripp A., French R., Sherrill C. (1995). *Adapt Phys Activ Q*, 12, 323-332. Yasui T. (2004). *Japanese Journal of Adapted Sport Science*, 2(1), 25-30.

### **PHYSICAL ACTIVITY LEVELS IN CHILDREN WITH AUTISM**

Gallo-Salazar, C., Ruiz-Vicente, D., García-Pastor, T., Soriano, M.L., Mampaso, J., Theirs, C., Moraleda, E.

*CAMILO JOSE CELA UNIVERSITY*

Introduction Although social impairments are the defining feature of Autism spectrum disorders (ASDs), motor functioning is lower than in non-ASD peers (Bhat et al., 2011). The aim of the current study was to investigate physical activity levels in ASD children throughout accelerometer data. Methods Fifty-three ASD children (40 boys and 13 girls) from three Special Schools in Madrid were recruited for this study. The average age was 11,9 3,4. Consent forms were signed by their parents before the study. A desensitization program was necessary for the children to accept the accelerometers. Participants wore a portable triaxial accelerometer during waking hours, except bathing or water activities, throughout a 7-d assessment period (5 weekdays, 2 weekend days). Accelerometers were worn on the hip secured by an elastic waist belt. Results Boys were physically more active than girls, mostly sedentary and vigorous-intensity. No significant differences were found between weekday and weekend values ( $P > 0,05$ ). The physical activity average was 9663 step counts weekday and 10135,7 on weekends. No significant correlations were found between physical activity variables ( $P > 0,05$ ). Discussion It was observed that boys' physical activity levels reach the official recommendations, while girls' physical activity levels don't. Thus, boys values were higher than observed in other foreign studies (Feehan et al., 2012). Previous studies affirm that sport practice levels decrease from childhood to adolescence (Macdonald et al., 2011). This descent was not present in our study likely because these Special Centers teach physical education. References Bhat, A. B., Landa, R. J. y Galloway, J. C. (2011). #### **VALIDITY OF BLOOD LACTATE MEASUREMENTS USING PORTABLE LACTATE ANALYZER ; LACTATE PRO AND LACTATE PRO2**

Ebi, Y.1, Nakagaki, K.1, Kon, M.1, Zhong, H.1, Kobayashil, Y.1

*1:Japan Institute of Sports Science*

Introduction Measurement of blood lactate is a common practice to assess and monitor exercise performance in sports physiology laboratories worldwide. Graded exercise tests (GXT) and Wingate anaerobic power test (WT) are also accepted as valid and reliable testing protocols to evaluate metabolic capacity. Blood lactate measurements in GXT and WT are often carried out using portable lactate analyzers. However, more information is not clear about the validity of LP2. The purpose of this study was to evaluate the validity of blood lactate measurements using two types of portable lactate analyzer, the Lactate Pro (LP) and Lactate Pro2 (LP2). Methods Blood samples were taken from fingertips of 5 male athletes ( $18.4 \pm 0.5$  yr) immediately after each of two different exercise protocols, a GXT using a cycle ergometer and a 90s WT. For the purpose of this investigation, the BIOSEN C-Line (BI), a highly-accurate lactate analyzer, was used as the benchmark measure. The order of blood sampling analyses was BI first followed by the two portable analyzers in random order. The validity of each lactate analyzer was determined using a linear regression coefficient and 95% limits of agreement of a bias between the lactate analyzer (i.e., LP or LP2) and BI. Results The regression coefficient for LP2 (0.965) was closer to 1 compared with that for LP (0.859). The limits of agreement were -2.9 to 4.2 for LP and -3.0 to 3.4 mmol/l for LP2. However, at low blood lactate concentration ( $< 5$  mmol/l), the coefficient for LP (1.070) was closer to 1 compared with that for LP2 (0.861), and the limits of agreement at low blood lactate concentration were -0.6 to 0.4 for LP and -0.6 to 0.7 mmol/l for LP2. Discussion The validity of Lactate Pro2 at low blood lactate concentration was lower compared with Lactate Pro. However, the validity of higher concentration values with LP2 was greater compared with LP. References David B Pyne, Tanya Boston, David T Martin, Andrew Logan. #### **TO WHAT EXTENT COULD THE ANTIOXIDANT CAPACITY ENHANCE PROFESSIONAL SOCCER PERFORMANCE?**

Gutierrez-Manzanedo, J.V., Castro-Maqueda, G., Gravina, L., Ponce-Gonzalez, J.G.

*University of Cadiz*

Introduction Some results suggest that oxidative stress is markedly up-regulated by a soccer game, probably as a part of the exercise-induced inflammatory response, and is accompanied by a marked deterioration of anaerobic performance for as long as 72 hours. However, it remains unknown the effect of the oxidative stress responses on professional soccer performance. Hence, the main aim of this study was to determine the effects of circulating levels of oxidative stress and antioxidant status markers on soccer performance after mid-season in professional soccer players in three different teams belonging to the 3rd Spanish Division. Methods Three teams belonging to the third Spanish Division during the season 2010-2011 were involved in this study: Team A (n=23), Team B (n=21) and Team C

(n=21). Body composition, VO<sub>2</sub>max, Total Antioxidant Status (TAS) and ratio of reduced glutathione (GSH) and glutathione disulfide (GSSG) were measured at the beginning of the season (PRE). TAS and GSH/GSSG ratio were repeated just at the mid-season (4 months) as well as standings for each team (POST). Results All teams showed similar age, height, weight, BMI and % of body fat at PRE. The VO<sub>2</sub>max at PRE for team A, B and C were 58.5±4.5; 57.2±4.8 and 55.4±4.6 ml/kg/min, respectively (A vs C, p<0.05). The ranking position just in mid-season and at the end of the season were 2nd and 1st for team A, 5th and 5th for team B and, 12th and 14th for team C, respectively. Team A showed higher values of TAS and GSH/GSSG ratio at PRE compared to team B and C (p<0.05). Moreover, team B had higher GSH/GSSG ratio at PRE compared to team C (p<0.05). All teams reduced their TAS and GSH/GSSG ratio after mid-season compared to PRE (p<0.05). The differences in TAS and GSH/GSSG ratio were higher in team C compared to A and B (p<0.05), while team B showed a trend to be higher than team A (p=0.09 and 0.08, respectively). The differences in TAS and GSH/GSSG ratio were inversely correlated with wins (r=-0.52; p<0.05), and directly correlated with losses (r=0.34 and 0.56 respectively, p<0.05), and with the ranking position at mid-season and at the end (r=0.43 and 0.56 respectively, p<0.05). Moreover, differences in GSH/GSSG ratio was inversely correlated with VO<sub>2</sub>max and scoring goals (r=-0.30 and -0.42, respectively, p<0.05). Finally, VO<sub>2</sub>max was correlated positively with wins and inversely with losses (r=0.27 and -0.28, respectively, p<0.05). Conclusion Our results suggest that oxidative stress is markedly upregulated after mid-season of professional soccer league, and were more accentuated in the team with lower standings. Hence, aerobic and antioxidant capacity seem to be crucial for soccer performance.

### EFFECT OF ONE MONTH OFF-SEASON ON THE ANTIOXIDANT CAPACITY OF ELITE SOCCER PLAYERS: DIFFERENCES BETWEEN MALE AND FEMALE PLAYERS.

SCHOOL OF NURSING

Institutions: 1Department of Physical Education and Sport, University of the Basque Country, UPV/EHU. 2Department of Nursing, UPV/EHU. 3Athletic Club de Bilbao. 4University of Cape Town, South Africa. Introduction Playing a soccer match can produce oxidative stress in both males and females<sup>1</sup>. Different antioxidant status responses have been shown following a soccer game and during recovery<sup>2</sup>. However, little is known about the effect of the off-season period on the antioxidant capacity in soccer players. The aim of this study was to analyse the impact of one month off-season in the plasma markers of oxidative stress in male and female elite players. Methods Two elite teams from the Athletic Club of Bilbao participated in this study: Male Elite Team (24 ± 3, n=15) and Female Elite Team (25 ± 5.1, n=14). Blood samples were obtained at the end of a competitive season (T1) and 1 month afterwards, at the beginning of the next season (T2). During that month, soccer players were off-season. Serum levels of Total Antioxidant Status (TAS, mmol/l), Reduced Glutathione (GSH, μM), lipid peroxidation (MDA, μM) and protein oxidation (carbonyl, nmol/mg) were measured, as well as the activity of antioxidant enzymes: Superoxide Dismutase (SOD, U/ml), Glutathione Peroxidase (GPx, nmol/min/ml) and Catalase (CAT, nmol/min/ml). Paired T-Student Test was used for the statistical analysis. The significance level was set at p<0.05. Results The Male Team showed higher level of TAS in T2 (0.85±0.1 vs 1±0.5, p<0.01), MDA (11±7.8 vs 34±20, p<0.01), CAT activity (37±17 vs 103 ± 23, p<0.001), and lower SOD (0.16±0.05 vs 0.08±0.04, p<0.01), GSH (1464±142 vs 748±142, p<0.001) and carbonyl (0.36±0.08 vs 0.15±0.05, p<0.001) comparing to T1. The Female Team also presented higher activity in T2 of CAT (17±7 vs 54±18, p< 0.001) and MDA (16±12 vs 51±32, p< 0.05), but lower GPx (121±21 vs 93±23, p< 0.05) and protein carbonyl (0.3±0.05 vs 0.13±0.03, p< 0.001). Moreover, in T1 the activity of SOD (p<0.05) and CAT activity (p<0.001) were significantly higher in the Male Team than the Female Team. In T2, male players showed lower SOD (p<0.05) but higher CAT (p<0.001) and TAS level (p<0.001) than female players. Conclusions One month off-season provoked similar effects in the antioxidant capacity in both elite soccer teams. Male and female players showed higher catalase activity although higher lipid peroxidation and lower reduced glutathione was observed after this month. The lower amount of carbonyl in both teams demonstrates that the cumulative effects of oxidative stress disappeared after this period off-season. Only the Male Elite Team presented higher total antioxidant status. References 1Andersson H, et al. Scand J Med Sci Sports. 2008; 23:1-9. 2Fatouros I, et al. ### SAGITTAL SPINAL CURVATURES AND PELVIC INCLINATION IN STANDING OF HIGHLY-TRAINED CANOEISTS

Vaquero Cristóbal, R.1, Muñoy, J.M.2, Alacid, F.1, López-Miñarro, P.A.3

1. Catholic University of San Antonio (Murcia); 2. University of Almería; 3. University of Murcia

Introduction Systematic sport training may generate specific spinal adaptations depending on the postures adopted during training. The canoeing discipline of sprint paddling is basically a repetitive movement of the upper segments and trunk for long periods. Canoeing is characterized by kneeling on one knee in the canoe and performing dynamic strokes on one side only. The stroke requires significant flexion and rotation of the trunk and a slight lateral inclination. This may influence the sagittal spinal curvatures (López-Miñarro et al., 2011). For this reason, the purpose of current study was to describe the thoracic and lumbar postures and pelvic inclination while relaxed standing in young canoeists. Methods Sixty-nine highly-trained young canoeists (mean ± SD, age: 16.19 ± 2.27 years) participated in this study. The Spinal Mouse system (Idiag, Fehrltdorf, Switzerland), was used to measure sagittal spinal curvatures (thoracic and lumbar spine) and pelvic inclination in a relaxed standing position. The subject assumed a relaxed position, with the head looking forward, the arms hanging by the side, the knees normally extended, and the feet shoulder-width apart. Results The means (± standard deviation) for thoracic and lumbar curvatures and pelvic inclination in relaxed standing were 45.20 ± 8.23°, -29.75 ± 7.91° and 13.88 ± 6.27°, respectively. Discussion Some differences in spinal curvatures between sports have been associated to specific positions and movements during the training. In the current study, canoeists showed a trend to thoracic hyperkyphosis in standing whereas the lumbar curve presented a neutral posture. These results are in concordance with a previous study in kayakers (López-Miñarro et al., 2010). López-Miñarro et al. (2011) found that canoeists adopt a lumbar flexed posture and reduced thoracic kyphosis at the catch phase of the stroke. The increased thoracic kyphosis in standing might be more related to growth variables and spinal posture in the daily activities than to the specific position in the canoe. Wojtyś et al. (2000) reported that a high exposure of intensive athletic training might increase the risk of developing a hyperkyphosis posture in certain sports. The increase in spinal curvatures might also be due to loss of disk height, which would tend to reduce the length of the anterior column of the spine, thereby increasing thoracic kyphosis and lumbar lordosis. Postural training should be included in the training program of canoeists to improve the thoracic posture in the standing position. References López-Miñarro PA, Muñoy JM, Alacid, F. (2010). Physical performance is influenced by several factors, including body composition, biological maturity status, level of habitual physical activity, and muscular strength. It is known that genetic endowments play a key role in many of these factors related to performance: many recently discovered polymorphisms that may affect sports performance have been described in animal or other human based models. In this study, in line with previous researches, we investigated the probability that there is a strong association between polymorphism and performance. We compared genetic profile analysing various polymorphisms on sixty professional Italian soccer players, considered "power-oriented athletes" and thirty sedentary volunteers. Samples of venous blood were obtained by standard clinical procedures and anticoagulant-treated blood was used to prepare genomic DNA. The polymorphic sites were scanned using PCR-RFLP protocols with different enzyme. Being an elite athlete is a complex attribute that may result from the combined influence of hundreds of genetic polymorphisms. For this reason it is difficult to identify with association studies, that is, studies showing between-group differences in the genotypic/allelic frequency of a given polymorphism. We analysed specifically genetic polymorphisms in the PPAR $\alpha$ -PPARGC1A-NRF2 (A/G; C/T) pathway; moreover, we examined that the ACTN3 polymorphism, that has functional significance in muscle function and metabolism. The odds ratio (OR) of power-oriented athletes compared with the sedentary control group has shown a variation of genotype distribution of the analysed polymorphisms: in fact professional soccer players possess "theoretically" a genetic background that is more suitable for mitochondrial biogenesis.

## THE EFFECTS OF N-ACETYLCYSTEINE SUPPLEMENTATION ON INFLAMMATORY AND PERFORMANCE RESPONSES FOLLOWING REPEATED FOOTBALL MATCHES DURING A SIMULATED MICROCYCLE

Fatouros, I., Draganidis, D., Barbero, J.C., Chatzinikolaou, A., Mohr, M., Stampoulis, T., Ermidis, G., Douroudos, I.I., Jamurtas, A.Z., Avloniti, A., Giannakidou, D.

*DEMOCRITUS UNIVERSITY OF THRACE*

The major thiol-disulfide couple of reduced (GSH) and oxidized glutathione (GSSG) regulates major intracellular signaling pathways regulating inflammation and recovery following exercise-induced injury. On the other hand, antioxidant supplementation may hamper exercise-induced cellular adaptations and performance. The aim of this study was to investigate how thiol-based antioxidant supplementation affects inflammatory and performance responses following repetitive games during a simulated in-season microcycle. A double-blind, 4-group design was utilized. 40 high-level football players were randomly assigned to one of four groups (N=10/group): a) placebo match group, received placebo and participated in football matches (PM), b) control training group, received placebo and participated only in training but not in matches (PT), c) NAC match group, received NAC (20 mg/kg/day) and participated in football matches (NM), d) NAC training group, received NAC and participated only in training but not in matches (NT). Three days following an initial 8-day preparatory period consisting of daily training, CM and NM played the first match. The second match took place 3 days after the first match and the third match was performed 4 days after the second one (Sunday-Wednesday-Sunday matches). In between matches, players from all groups participated in daily training according to an in-season training model. NAC and placebo was administered throughout the experimental period. GPS technology was used to measure performance during each match and each training session. Blood samples were collected and repeated sprint ability (RSA) was measured before and three days after the preparatory period, before each match, immediately post and 2h after each match as well as daily after each match (for three days after the last match). Blood was analyzed for inflammatory markers (creatine kinase activity, c-reactive protein oxidative stress markers, adhesion molecules). Data analysis revealed that NAC supplementation maintained a higher GSH/GSSG ration, reduced inflammation following each match and contributed to a faster performance recovery following the first and the second match. Furthermore, NAC increased high-intensity efforts during the first match compared to placebo. These results suggest that thiol-based antioxidant supplementation may induce a faster recovery following repeated football matches during a weekly microcycle.

## Biomechanics

### THE VELOCITY AND TRAJECTORY OF LEG MOVEMENT IN JUDO DURING THROWING TECHNIQUES

Rexhepi, F.1, Ferunaj, P.2, Vehapi, Sh.3

*Faculty of Physical Education, University of Tetovo*

1: Faculty of Physical Education, State University (Tetovo) 2: Faculty of Physical Activity and Recreation, Sports University (Tirana, Albania) 3: Faculty of Physical Education, AAB University (Pristina, Kosovo) Introduction Judo is a combat and Olympic sport emphasizing in throwing and dynamic footwork, where osoto gari and sasae tsurikomi ashi are two of the most effective throws. The coaches of this sport always focus on maximum efficiency with minimum effort during the early phase of throwing teaching (Imamura, Misaki, Alan, & Rafael, 2007). This study aim to compare (1) the velocity of attacking foot, and (2) the velocity of blocking foot, as well as movement trajectory of both feet during throwing performance by black belt master of Judo. Method A black belt master (age = 31 y; mass = 74 kg; height = 1.68 m) served as the tori (thrower) and ten subjects (age = 29  $\pm$  2.34 y ; mass = 68  $\pm$  3.46 kg ; height = 1.64  $\pm$  1.36 m) served as uke (fallers). Two throws, (1) osoto gari and ( 2 ) sasae tsurikomi ashi were executed against ten uke in consecutive way. Velocity performance and trajectory of both tori's leg movement, (1) attacking leg and (2) supporting leg, was assessed by the APAS system of bio mechanic analyses. Results The results showed greater linear velocity in anteroposterior direction of attacking foot in osoto gari ( $v=5,065$  m/s) than sasae tsurikomi ashi ( $v=4,47$ m/s). Considering the trajectory of foot joint, was found a anteroposterior displacement of 102,37 cm in osoto gari vs. 83,37 cm in sasae tsurikomi ashi. While in mediolateral direction the foot displacement in osoto gari was 36,26 cm, and in sasae tsurikomi ashi was 8,85 cm. Discussion The results of this study showed that in those throwing technique of Judo where attacking (cutting) leg performs actions like cutting the opponent leg or other part of his body, linear velocity of foot and knee joint is greater than the techniques where role of leg is blocking or supporting, and as consequence, force applied to opponent's body is higher. In addition, in contest situation, the fast movement of the thrower do not let enough time for the faller to react (Harter and Bates, 1985). These data can help the judo coaches to understand the importance of velocity training of lower limbs for improving performance of their students during the competition. References Imamura, R. during competitive and non-competitive condition. Journal of sport science and Medicine , 15-22. Harter, R.A. and Bates, B.T. (1985). Kinematic and temporal characteristics of selected judo hip throws. In: Biomechanics in Sport II. Do not insert authors here

## ANKLE JOINT MOMENT IS SUBSTANTIALLY UNDERESTIMATED WHEN MEASURED WITH CLASSICAL ERGOMETERS MOUNTED WITH A UNI-DIMENSIONAL FORCE SENSOR

Simoneau, E.M., Toumi, A., Gillet, C., Leteneur, S.

*Université de Valenciennes et du Hainaut Cambresis*

**Introduction** Assessment of mechanical properties of ankle joint muscles during isometric and/or dynamic conditions is usually performed to estimate, for instance, the impact of a (re)training program, of an immobilization or of aging. This assessment is usually achieved by means of either specific ankle ergometers or by means of isokinetic ergometers. For all these devices, moment developed at the ankle joint is measured via either a pedal connected to a unidirectional (1D) force sensor (generally placed away from the axis of rotation of the ergometer) or either by a pedal connected to a 1D torque sensor placed at the axis of rotation of the ergometer. However, plantar-flexion (PF) actions are systematically accompanied by inversion and supination actions. This means that a multi-dimensional effort is measured by ergometers mounted with a 1D force (or torque) sensor. While a 1D sensor allows to assess the moment exerted around the transverse X axis, it cannot allow to assess moments during PF that can be exerted around the sagittal Y and longitudinal Z axes. One can then assume that such ergometers should underestimate the maximal resultant moment that can be recorded at the ankle joint. Then, the purpose of this study was to determine whether the ordinary use of a 1D force sensor, compared to a 3D sensor, can provide a reliable assessment of PF moment. **Methods** Ten healthy male volunteers took part in this investigation. Ankle PF maximal voluntary isometric contraction moments (M<sub>Amax</sub>) were measured using a new and validated ankle ergometer mounted with a 3D force sensor (force-torque sensor – Sensix, Poitiers-France). All measurements were performed in the sitting position with the dominant lower limb extended and with the ankle joint at 90°. M<sub>Amax</sub> was calculated as follows: 1D\_ M<sub>Amax</sub> = Fz\*d and 3D\_ M<sub>Amax</sub> = (M<sub>Ax</sub><sup>2</sup> + M<sub>Ay</sub><sup>2</sup> + M<sub>Az</sub><sup>2</sup>)<sup>0.5</sup> with M<sub>Ax</sub> = M<sub>Ox</sub> + Fy\*h – Fz\*d; M<sub>Ay</sub> = M<sub>Oy</sub> – Fx\*h; M<sub>Az</sub> = M<sub>Oz</sub> + Fx\*d; F and M<sub>O</sub>: forces and moments recorded at the origin of the 3D force sensor (O); d: Y distance between O and the ankle joint center of rotation (A); h: Z distance between O and A. **Results** Paired t-test revealed a significant effect of the number of dimensions of the force sensor (1D vs 3D) on the assessment of maximal ankle joint moment: 1D\_ M<sub>Amax</sub> (100.5 ± 19.1 N.m) was significantly lower than 3D\_ M<sub>Amax</sub> (159.8 ± 40.3 N.m) (p<0.001). **Discussion** The results showed that the use of a 1D, instead of a 3D, force sensor significantly underestimated (-37%) the resultant ankle moment exhibited by the plantar-flexors. Since ergometers classically used in clinical and biomechanics research are usually built with a 1D force (or torque) sensor, care must be taken when assessing muscle actions that are characterized by multi-dimensional components.

## BIOMECHANICAL ANALYSIS OF GAIT IN PREGNANCY AND POSTPARTUM: A LONGITUDINAL STUDY

Santos-Rocha, R.1,2, Branco, M.1,2, Aguiar, L.2,3, Vieira, F.2,3, Veloso, A.P.2,3

*1: CIPER (Lisbon, Portugal), 2: ESDRM-IPS (Rio Maior, Portugal), 3: FMH-UTL (Lisbon, Portugal).*

**Introduction** The purposes were to quantify the kinematic variables and mechanical load exerted on the structures of the lower limb during gait, and compare it between the first (1T), second (2T), third (3T) trimesters of pregnancy and in the postpartum period (PP) in 8 women. **Methods** A longitudinal three-dimensional analysis was performed. Kinematic data: 10 infrared high-speed cameras (Qualisys, 200Hz). Kinetic data: 2 Kistler platforms (1000Hz). Qualisys Track Manager software was used. Markers setup: Cappozzo (1997) for lower limb; CODA (Charnwood Dynamics) protocols for pelvis segment. Women walked a distance of 10m between two points, barefoot in a straight line at a natural and comfortable speed (Falola 2009; Huang, 2002), for 3 min. **Results** Significant differences were found in the following variables. Double limb support time and right foot support time between the 4 periods. Kinematic variables in sagittal plane: 1st and 2nd peaks of hip joint. In the ankle, 3rd angle peak in 3T (right leg). In the frontal plane, 1st peak of hip joint in 3T (right leg). In ankle joint, 2nd peak, increase in foot eversion in 3T (right leg). Ground reaction forces (GRF) in the 1st and 2nd peak of anterior and posterior GRF, specifically with a higher brake in PP (both legs) and, a decrease in propulsion in 3T (left leg). Joint moments in the 1st peak of ankle joint, increase of adductors participation in the 3T (transverse plane, left leg). Joint power analysis showed a decrease of hip abductors mechanical energy production, 3T (left limb). **Discussion** While walking in at a self-selected pace, the pregnant woman needs to promote stability of the body (Lymberry & Gilleard, 2005) increasing double and right limb support time. Kinematic data presents more changes in hip, probably because it's near of the abdominal of the pregnant woman, however ankle joint also presents changes in the angle movement. GRF presents differences in the 1st anterior posterior peak but it is only relevant between 1T and PP, which may indicate that PP should also be the focus for more studies. Vertical GRF showed that late pregnancy present less impulse. Joint moments only reveal a higher participation of foot adductors and the joint power only presents less mechanical production in hip abductors. Hip and ankle joints seem to have the major changes and therefore the ones with an overload on lower limb (Foti, 2000). **References** 1. Cappozzo A et al (1997). IEEE Trans. ## DEVELOPMENTAL DIFFERENCES IN TENDON HYSTERESIS: IMPLICATIONS FOR PAEDIATRIC MOVEMENT EFFICIENCY?

Waugh, C.M.1, Blazevich, A.J.2, Korff, T.1

*1Brunel University, London, UK; 2Edith Cowan University, Perth, Australia.*

**INTRODUCTION.** Children are less efficient than adults when performing cyclic motor tasks such as walking; however, the mechanisms underlying such differences are not fully understood. One mechanism that may contribute to age-related differences in task efficiency is the tendon's dissipative properties, as low tendon hysteresis values have been previously linked with higher movement efficiency in adults [1]. The aim of this study was to determine Achilles tendon hysteresis in prepubertal children and compare with that of adults. **METHODS.** Achilles tendon hysteresis was obtained in eight prepubertal children (6.0 ± 0.6 years) and eight adults (24.3 ± 2.8 years) from maximal isometric plantarflexion contractions. Tendon elongation was measured using ultrasonography and peak plantarflexor moment using dynamometry. Tendon elongation due to ankle rotation was accounted for using a combination of 3D motion capture and anthropometry. Tendon force was calculated as the ratio of plantarflexor moment and Achilles tendon moment arm, which was obtained by means of the tendon excursion method. The slopes of the ascending and descending phases of the force-elongation curves (normalised to peak force) were fitted to second-order polynomials. Achilles tendon hysteresis was calculated as the difference between the areas under the ascending and descending portions of the force-elongation plots. Statistical differences in hysteresis values between children

and adults were examined using an independent t-test. Statistical significance was accepted at  $p < 0.05$ . RESULTS. Mean ( $\pm$ SD) hysteresis values for children and adults were  $40.2 \pm 13.7\%$  and  $26.1 \pm 7.0\%$ , respectively. These findings were statistically different ( $p = 0.022$ ). CONCLUSION. Our results demonstrate that the dissipative properties of the Achilles tendon are different between children and adults, which expand upon previously demonstrated differences in other tendon viscoelastic properties between these populations [2]. It is possible that decreases in Achilles tendon hysteresis with age may influence movement efficiency in children as they develop, which is an important area of future research. ### **KINEMATIC DIFFERENCES OF TWO TYPES OF SCULLING ACTIONS IN DISPLACEMENT**

Arellano, R.1, Gomes, L.2, Taladriz, S.1, Lopez-Contreras, G.1, De la Fuente, B., Cienfuegos, J.3, Morales, E.1, Domínguez-Castells, R.1

1:FSS-DEFD-UGR (Granada, Spain), 2:UFVVF (Petrolina, Brasil), 3:CAR (Sierra Nevada, Spain)

**Introduction** Sculling is a basic propulsive action with four hand movements: outward, supination, inward and pronation (Arellano et al., 2006). Analysis 3D showed a zigzag path, where hand displacement is mostly forward, with strong hand rotations during the direction's change (Arellano, 2011). The study aim was to know the effect on kinematic variables of the use of normal and power sculling in displacement. **Methods** Twenty-three subjects participated in the study. Each performed two 20m trials using a normal sculling [NSc] (arms and elbows fixed close to the water surface making and angular displacement of forearm and hand) and power sculling [PSc] (moving arm, forearm and hand, inward and outward). A linear encoder tethered to the swimmer's belt allowed intra-cyclic speed [V] (m/s) recordings (200 Hz) synchronized with video cameras (HD - 60Hz) to measure sculling frequency [f] (Hz). The average speed and sculling frequency were calculated during six sculling cycles and the sculling length [L] (m/cic) from the equation:  $L = V/f$ . Results No significant differences were found between trial mean V [NSc =  $0.48 \pm 0.09$ , PSc =  $0.47 \pm 0.08$ ,  $t = 0.83$  ( $p = 0.42$ )] Meanwhile f and L were statistically different [fNSc =  $1.32 \pm 0.17$ , fPSc =  $1.10 \pm 0.13$ ,  $t(22) = 7.57$  ( $p < 0.01$ ), LNSc =  $0.36 \pm 0.07$ , LPSc =  $0.43 \pm 0.07$ ,  $t(22) = -5.44$  ( $p < 0.01$ )]. Low correlation values were obtained between variables [r (NSc,V,f) =  $0.454$  ( $p = 0.05$ ) and r (PSc,V,f) =  $0.300$  ( $p > 0.05$ )]. **Discussion** The type of sculling action studied did not affect average velocity, however the sculling frequency and length were modified. The longer hand's displacement observed results in slower frequencies, a more similar hand path action plus bigger arm muscles contribution, more similar to the formal strokes than the normal sculling with a more analytical and isolated hand/forearm movement. It is recommended to apply this type of power sculling on stroke technique development instead of normal sculling even though further studies should be performed. **Acknowledgement:** Project funded by Spanish Ministry of Science and Innovation, VI National Plan for Research, Development and Technological Innovation (I+D+i) 2005-2008, Ref: DEP2009-08411. **References** Arellano, R. ### **EFFECTS OF ACUTE MODERATE HYPOXIA ON PERFORMANCE AND BIOMECHANICAL PARAMETERS IN 50-M FRONT CRAWL IN ELITE SWIMMERS**

Mercadé, J.J.1, Morales, E.1, Argüelles, J.2, Domínguez, R.1, De la Fuente, B.2, Feriche, B.1, Barrero, A.3, Chaverri, D.3, Iglesias, X.3, Rodríguez, F.A.3

1: Faculty of Sports Science, University of Granada (Spain), 2: High Performance Centre of Sierra Nevada (Granada, Spain), 3: INEFC-Barcelona, University of Barcelona (Spain)

**Introduction.** Exposure to acute moderate hypoxia induces a significant cardiovascular and metabolic response short after the ascent. However, performance during short high-intensity exercise seems not to be affected by altitude exposure. To our knowledge, only one study has analysed the effect of altitude on swimming technique (Mercadé et al., 2006). We aimed to analyse the effects of acute moderate altitude exposure on performance and biomechanical parameters of a maximal 50-m front crawl swimming test in elite swimmers. **Methods.** 27 elite swimmers performed two 50-m front crawl test at normoxic (N) conditions and 72 h after arrival to a real altitude hypoxic (H) environment (2320 m, CAR of Sierra Nevada, Spain). Tests were performed at 50-m indoor pools and were recorded with three lateral video cameras (50 Hz), two placed underwater and one outside the water. Final time (T50), swimming speed (V), stroke rate (SR), stroke length (SL), and stroke index (SI) were assessed on each trial. Results. T50 time was non-significantly faster ( $-0.5\%$ ,  $p > 0.05$ ) in H ( $27.78 \pm 2.11$  s) than in N ( $27.91 \pm 2.07$  s). Although mean swimming speed did not change ( $-0.3\%$ ,  $p > 0.05$ ), the start time (0-15 m) improved after the ascent ( $2.06 \pm 0.18$  and  $2.13 \pm 0.19$  m·s<sup>-1</sup> in N and H, respectively,  $p > 0.05$ ). SR and SL non-significantly decreased in H compared to N ( $-0.2\%$  and  $-0.7\%$ , respectively,  $p > 0.05$ ), leading to a decrease in SI ( $1.5\%$ ,  $p > 0.05$ ). **Discussion.** Exposure to acute moderate hypoxia seems not to have a significant effect on performance in a 50-m maximal test. The slight, non-significant improvement in T50 might be due to an increase ( $+3.2\%$ ) in speed in the first 15 m. Previous studies have reported an increase in performance in throws, jumps and other force-velocity actions when they were executed at altitude (Levine et al., 2008). Similarly, an increase in jump power on the starting blocks might have led to longer flight time and distance during the swimming start. In conclusion, acute moderate hypoxia does not affect sprint swimming performance and technical variables in elite swimmers acutely exposed to moderate altitude. The slight changes observed in the starts suggest that training in H may be a complement to improve this particular race component. **References** Mercadé JJ, Arellano R, Feriche B (2006). *Revista Portuguesa de Ciências do Desporto*, 6, supl. 2, 148-150. ### **HIGH-LEVEL WHEELCHAIR BASKETBALL SPRINT PERFORMANCE ASSESSMENT REGARDING PLAYING POSITIONS USING A LASER SYSTEM**

Ferro, A.1, Villaceros, J.1, Pérez-Tejero, J.1, Aguado, R.2, Graupera, J.L.3

1: Polytechnic University of Madrid; 2: Autónoma University of Madrid; 3: Alcalá de Henares University. Spain.

**Introduction** The wheelchair optimization and training processes have been evolved during last years but there is limited knowledge for elite wheelchair basketball (WB) players profiling in their preparation to a major competition (Goosey-Tolfrey, 2005). Sprint tests are used by coaches to assess the quality of velocity in their players and to make decisions on the best possible distribution of players in the different positions (Pérez et al., 2010). However, the measuring instruments used are not always accurate enough to help them in their deci-

sion-making. The purpose of this study was to identify and quantify kinematics variables that define the quality of velocity in WB players from different playing positions (guard, forward and centers), using laser system. Methods Eleven men, WB players of the Spanish National team, took part in a 3 series of 20 m sprint test. Distances were measured in real time by a laser system Biolasersport® (Ferro, 2012, Ferro and Floria, 2010) using a LDM301-Jenoptik type 1 Laser at 200 Hz. Average velocities ( $V_m$ ), maximum velocities ( $V_{max}$ ), relative maximum velocities ( $RV_{max}$ ), time to achieve  $V_{max}$  ( $TV_{max}$ ) and its relative value ( $RTV_{max}$ ) over sections (0-3, 3-5, 5-10, 10-15, 15-20 m) were analyzed. Several one-way ANOVAs were applied using as factor the playing position (3 levels) and the dependent variables. The ICC ranged between 0,96-0,99 for all  $V_m$  and  $V_{max}$ . Results There were no significant differences were found in  $V_{m0-20}$  between playing positions but there were significant differences in  $V_{max0-3}$  between centers and guards (3.36,  $s=0.23$  m/s, 3.31,  $s=0.12$  m/s;  $P=0.37$ ) and forwards and guards (3.36,  $s=0.21$  m/s, 3.31,  $s=0.12$  m/s;  $P=0.001$ ). The  $V_{max5-10}$  was higher in guards than in forwards (4.68,  $s=0.23$  m/s, 4.37,  $s=0.23$  m/s;  $P=0.007$ ). The  $TV_{max0-5}$  between centers and guards (1.60,  $s=0.18$  s, 1.67,  $s=0.10$  s;  $P=0.036$ ) and forwards and guards (1.64,  $s=0.21$  s, 1.67,  $s=0.10$  s;  $P=0.006$ ) were higher in guards. And the  $RTV_{max0-5}$  was higher in guards than in forwards (33.59,  $s=1.44$  %, 30.90,  $s=2.94$  %;  $P=0.012$ ). The  $TV_{max3-5}$  was significant higher in guards than in forwards (0.52,  $s=0.08$  m/s, 0.45,  $s=0.16$  m/s;  $P=0.015$ ). Discussion There were specificity kinematics variables regarding playing positions in the sprint test lower than 5 m. The guards were slower than the centers and forwards; they achieved higher peak velocity in the 3-10 m although it was later than the rest of the players. This results seen related with the guards role developed in competition matches. Finally, to identify the velocity qualities of WB players in on-court sprints, more accurate systems, like laser, are needed. References Coutts, K. D. (1994). *J. Rehabil Res Dev*, 31(2), 138-143. ### THE BIOMECHANICS OF ATHLETIC EXHAUSTION OF THE LOWER LIMB AND ITS RELATIONSHIP WITH THE SKILFUL PERFORMANCE OF COMPOUND SKILLS IN FOOTBALL.

Ahmed, H., Habib, H.

*Sport Kinesiology Department, Faculty of Sport Education, Mansoura University, Egypt*

The biomechanics of athletic Exhaustion of the lower limb and its relationship with the skilful performance of compound skills in Football  
Introduction: The state of exhaustion is one that is a common occurrence in all forms of athletic performance. Physical exhaustion can arise in a number of circumstances in relation to both training and competitive circumstances. Professional team sport athletes who are required to play a number of games over a period of weeks will often complain of a Hard training, especially when the individual components are repetitive, can occasionally result in a similar Physical fatigue. Physical exhaustion is also used to describe the testing processes used to calculate skilful performance measures which is a powerful indicator of endurance sport fitness. This research aims to identify the impact of athletic exhaustion on biomechanical movements for the joints in the lower limb during performing compound skills by the junior football player. Methods: Method: study used the descriptive method through using 3-D biomechanical analysis, and kinematographic analysis. Sample: study was applied to a sample of (6) junior football players selected intentionally from Mansoura Sports Club. Tests: The researchers used the following physical tests: Standing Balance Test - Illinois Agility Test - Quadrant Jump Test - Vertical Jump Test Isometric Leg Strength Test, in order to identify the level of exhaustion in addition to skill tests as well (receive and pass – receive and kick). The researchers used the pre- and post- measurement before and directly after the match and before the players could recover. Tools: In addition, they used the 3-D Motion Analysis by using a 250 Frame/second SportsCam then conducting the kinematographic analysis by using the Simi Motion software. Result & discussion: •The most important results were that the averages values of the biomechanical variables and the physical measurements confirm a decrease in the post-measurement test than the pre-measurements in all the skill performance phases. •Also, the time of performing the two skills under study was shorter in the pre-measurements, which confirms in general that the research sample was significantly influenced by exhaustion. •There is a significant correlation between the physical and the biomechanical variables expressing exhaustion. •In addition, there is a correlation between the physical and biomechanical variables and the skill performance phases in terms of post-measurement, which influences on effectiveness of the skilful performance skills of the compound skills in football for the research sample.

### RELATION BETWEEN SHOULDER AND ELBOW JOINT TORQUE AND MOTION RANGE IN BASEBALL THROWING AND RISK OF SHOULDER AND ELBOW INJURY

Tanimoto, M., Yoshioka, S., Setoguchi, Y., Hirashima, M.

*Kinki University*

Introduction Shoulder joint torque and motion range in baseball throwing are considered to have relation with the risk of shoulder and elbow injury. Purpose of this study is to investigate the relation among shoulder joint torque and motion range in baseball throwing, shoulder isometric muscle force and static motion range, and the risk of shoulder and elbow injury. Method Twelve baseball pitchers affiliated with the baseball club of the University performed maximum speed ball pitching with motion capture kinematics and kinetics analysis, isometric muscle force tests of shoulder inner rotation, and motion range tests of shoulder external rotation and horizontal abduction. The relation among the kinetic characteristics of throwing, the physical characteristics, and the risk of shoulder and elbow injury was investigated. Shoulder tensile force, shoulder shear force and elbow inversion torque in throwing were as the estimative index of shoulder and elbow injury risk in throwing. Result Shoulder inner rotation torque in throwing has strong correlation with elbow inversion torque ( $R^2=0.869$ ,  $P<0.001$ ). Shoulder horizontal adduction torque in throwing has strong correlation with shoulder shear force ( $R^2=0.871$ ,  $P<0.001$ ). Motion range of shoulder external rotation in throwing has correlation with elbow inversion torque ( $R^2=0.403$ ,  $P<0.05$ ). Motion range of shoulder horizontal abduction in throwing has strong correlation with shoulder shear force ( $R^2=0.784$ ,  $P<0.001$ ). "Upper arm power type group" defined as the top six subjects with large upper arm torque (amount of shoulder inner rotation and horizontal adduction) in throwing have larger elbow inversion torque ( $P<0.1$ ) and larger shear force ( $P<0.05$ ). Conclusion These results suggested that throwing motion without strong upper arm torque and with larger shoulder motion range may decrease the risk of shoulder and elbow injury in throwing. ## ACCELEROMETRY OUTPUT DURING WALKING AND RUNNING AT DIFFERENT SPEEDS – INFLUENCE OF ACCELEROMETER PLACEMENT

Overgaard, K., Wissing, M.K., Larsen, R.G.

*University of Aarhus*

Background: Accelerometers are often used to measure physical activity and it is important to investigate the validity of the output. It has been suggested that accelerometer placement on the thigh rather than the conventional hip-placement provides a better suited output for detecting activity-types such as walking, running, cycling and stair climbing (1). It is not known, however, if a thigh-placement will yield accelerometry output that is related to the speed of walking or running as is the case for hip placement. Objectives: To compare the accelerometry output from accelerometers placed on the hip and thigh, respectively, during walking and running at various speeds. Methods: 6 healthy subjects (3 m, 3 f, age  $24 \pm 2$  y,  $175 \pm 7$  cm,  $72 \pm 11$  kg) volunteered for the study. Tri-axial accelerometers (Actigraph GT3X+) were fixed with adhesive on the right anterior mid-thigh and on the right hip. Subjects performed several 3 min trials of treadmill walking (3, 5 and 7 km/h) and running (7, 10 and 12 km/h). Accelerometer output was stored as counts per 10 s epoch in each of the three axes. Then, a vector magnitude (VM) was calculated as an index of movement intensity. Mean VM values from each individual during treadmill trials were used for further analysis. Results: Accelerometer outputs (VM) were significantly higher from thigh-placed devices than from hip-placed devices at all walking and running speeds. Using both hip- and thigh-placed accelerometers, there was an approximately linear increase in VM with increases in walking speed from 3 to 7 km/h and a linear regression fitted all subjects with a high correlation coefficient (Hip:  $r = 0.98$ ; Thigh:  $r = 0.97$ ). Also during running, VM increased linearly with increasing speeds, but the correlation was stronger for thigh-placed devices ( $r=0.91$ ) than for hip-placed devices ( $r = 0.60$ ). For hip-placed accelerometers, the linear regression slope was lower for running trials (7-12 km/h) than for walking trials (3-7 km/h). In contrast, similar slopes of the regressions lines were found for walking and running when using thigh-placed accelerometers. Conclusions: Thigh-placed tri-axial accelerometers provide output, which is highly correlated to speed of locomotion and a single common regression line can represent both walking and running at speeds from 3 to 12 km/h. The conventional hip-placed accelerometers give output that is less strongly correlated to speed of locomotion at higher speeds. These preliminary results suggest that a thigh-placed rather than a hip-placed accelerometer may provide a more accurate representation of human locomotion at higher speeds. 1. ## INFLUENCE OF DORSIFLEXION SHOES ON JUMP PERFORMANCE

González-Millán, C., Salinero, J.J., Abián-Vicén, J., Del Coso, J.

*University Camilo José Cela*

Introduction Sports shoes can modify sports kinematics and signify an advantage/disadvantage for physical performance. Dorsiflexion sports shoes were designed to increase jumping capacity by means of a lower position of the heel in relation to the forefoot, favouring additional stretching of the ankle plantar flexors. Results in previous studies using dorsiflexion shoes are contradictory (1, 2). The aim of this study was to compare a dorsiflexion sport shoe model with two conventional sports shoes in a countermovement jump test. Methods The sample included 35 young and active participants that performed a countermovement jump test with three different volleyball sport shoes, one with dorsiflexion (Springboost, with  $2^\circ$  of dorsiflexion) and two conventional sport shoes (Asics and Kipsta) on a force platform (Kistler Quattro Jump, Switzerland). Participants also evaluated perceived comfort while they wore the shoes. Results In comparison to the conventional shoes, dorsiflexion sports shoes were not effective for improving peak power and jump height ( $P = .841$ ). However, there were significant differences in the way the force was manifested during the jump test: in dorsiflexion shoes peak power was reached quicker ( $P < 0.05$ ). Dorsiflexion also reduced the speed but increased the force at peak power ( $P < 0.05$ ). The drop of centre of gravity in push off was lower with dorsiflexion sport shoes ( $P < 0.05$ ). The comfort perceived by participants was better with conventional sports shoes than with dorsiflexion shoes ( $P < 0.05$ ). Discussion The higher ankle flexion induced by dorsiflexion shoes was offset by a lower drop during push off to propitiate optimal ankle flexion. Dorsiflexion produces a modification in the muscle activation pattern during a maximal jump (3) since peak power was obtained with higher force and lower speed. However, as a practical application for sports performance, dorsiflexion does not mean an improvement in peak power or jump performance. Moreover, dorsiflexion decreases the comfort perceived by participants. References 1. Faiss R, Terrier P, Praz M, Fuchslocher J, Gobelet C, Deriaz O. ## TWIST BIKE ATLANTIC ® - A NEW BIOMECHANICAL EFFICIENCY CHALLENGE

Zaccaria, D., Gualea, M.R., Di Palma, F., Rottenbacher, C.

*University of Pavia*

INTRODUCTION Twist Bike Atlantic is a innovative bicycle with a new propulsion system in which the pedals run on a rectilinear trajectory very similar to a step movement. The aim of this study was to examine differences in cycling efficiency between a traditional bike (B) and a Twist Bike (TB). METHODS One trained male cyclist (22 years, 71.3 Kg, 174.1 cm) completed an incremental  $\text{VO}_2$  max test (100W+20W/min) to ascertain his Ventilatory Threshold (VT) and a Lactate Test (80W+40W/3 min) to assess his OBLA on a cycle simulator Computrainer Racermate ®. In both cases we have obtained similar results (VT and OBLA at 185W-166 bpm). Subsequently Oxygen Consumption ( $\text{VO}_2$ ), Heart Rate (HR) and forces exerted on the pedals have been recorded in different incremental tests (80W+40W/4 min) with TB and B with comparable gear ratio in order to guarantee the same wheel metric development and effort and to compare them properly. The tests were performed at two different load levels corresponding to a light/medium (LE) and a heavy exertion (HE). A bi-dimensional 5-bar linkage model of the lower limb/crank system in the para-sagittal plane has been applied both to the TB and the B. In this way the internal actions of the muscles are not directly detected but are reduced to an equivalent system, made of three moments acting on hip, knee and ankle, that can be calculated by the measurements of external forces, with a method known as "link-segment modeling", using an inverse dynamics procedure. RESULTS The metabolic efficiency ( $\text{VO}_2/\text{W}$ ) with TB is more advantageous than with a traditional bicycle at LE. Absolute values of  $\text{VO}_2$  and HR were lower compared with the same power level on a B. At HE all physiological values were higher with low levels of exercise sustainability. Biomechanical results suggest that in general the hip and the knee moments are higher with B than with TB pedaling while the ankle moment is lower with B due to the fact that TB prototype was equipped with a non oscillating pedal.

CONCLUSION Cycling efficiency with TB seems to be higher limited to light loads This results might be interpreted as a lower metabolic commitment determined by the use of different muscle groups in number and type. Further studies are necessary to advance this area of knowledge for a better understanding of this innovative bike. REFERENCES Hull ML, Jorge M. ### ACUTE EFFECTS OF BAREFOOT OR MINIMALIST RUNNING ON 3-D KINEMATICS AND LOWER LIMB EMG ACTIVITY

Donne, B.1, McCallion, C.1, Fleming, N.2

1 Trinity College Dublin, 2 Indiana State University

Introduction Athletes running barefoot adopt a forefoot strike, increase ankle plantarflexion, possibly increase knee flexion and display greater plantarflexor muscle activity, but less activity of tibialis anterior. Research comparing shod and barefoot running biomechanics is limited. Only two studies have examined running biomechanics in minimalist shoes (Squadrone & Gallozzi, 2009; Bonacci et al., 2013) and neither examined muscle activation patterns. Methods Competitive, habitually shod male middle-distance athletes (n=14; age 25±6 yr) completed a randomised series of 6 by 5-min treadmill running bouts, at 2 individualised velocities (70 and 85% of best 5-km time) in 3 scenarios; barefoot, in minimalist and traditional shoes. Three dimensional hip, knee and ankle joint kinematics, spatiotemporal variables and foot strike patterns were recorded. Surface EMG data, recorded from tibialis anterior (TA), medial gastrocnemius (GA), vastus lateralis (VL) and biceps femoris (BF), were temporally and amplitude normalised across stride duration and dynamic maximal EMG, respectively. Results Transitioning from running in traditional to minimalist footwear, or barefoot, did not instantly change running biomechanics. A mid-foot strike was adopted in all conditions at both velocities. No significant differences were recorded in EMG activity of TA, GA or VL. However, some motor pattern plasticity was identified via significant differences in spatiotemporal variables, joint kinematics and EMG activity in BF. From 0 to 10% of the stride, EMG activity of BF was significantly higher barefoot vs. shod (13.3±4.0 vs. 16.5±3.9%; P<0.05). Time to peak BF activity was significantly longer in shod and minimalist conditions vs. barefoot (674±15 and 672±16 vs. 650±16 ms, P<0.05). At both investigated velocities; stride duration, flight time and contact time were significantly shorter (P<0.05), and stride frequency significantly increased (P<0.05) comparing barefoot with shod and minimalist scenarios. Significant footwear effects were detected for hip and ankle angles at initial contact, maximum ankle angle, and hip and knee ROM. The majority of these kinematic differences were most likely due to the cushioned sole allowing for a stronger push-off. Discussion Research reporting biomechanical differences in participants with lengthy experience in barefoot or minimalist running (Squadrone & Gallozzi, 2009) suggests that a familiarisation period is required. Consequently, athletes should probably gradually transition from running in traditional shoes to either barefoot or minimalist running. References Bonacci J et al. ### ANALYSIS OF VARIOUS BODY DEPLOYMENT STRATEGIES ON TANGENTIAL AND PERPENDICULAR VELOCITY OF SKIS DURING A TURN IN ALPINE SKIING

Coulmy, N., Antichan, F., Hintzy, F.

Fédération Française de Ski

ANALYSIS OF VARIOUS BODY DEPLOYMENT STRATEGIES ON TANGENTIAL AND PERPENDICULAR VELOCITY OF SKIS DURING A TURN IN ALPINE SKIING Antichan, F.1-2, Coulmy, N.1, Hintzy, F.2 1 : FFS (Annecy, France), 2 : LPE (Le Bourget du Lac, France) Introduction: In alpine skiing, gravitational force is the main contributor to increase and maintain speed. Nevertheless, the work developed by a skier's muscles may provide effective energy. Meyer et al (2012), have quantified the average total work produced by the skiers during a turn cycle. This work represents approximately 1.5% of the corresponding potential energy change during the turn. This amount should not be neglected as it can make a significant difference in terms of performance due to the possible transfer between potential energy and kinetic energy. The purpose of the study was to measure the effect of various deployment strategies on tangential and perpendicular velocity of skis. Methods: The performances of 2 ex members of the French ski team were analyzed through 8 runs with 7 complete turn during a 20m giant race simulation. 4 runs were performed with an extension during steering phase (stratext) and 4 runs were accomplished in a spontaneous position (stratref). The performance of 1 ex member of the French ski team was analyzed through 5 runs with 10 complete turns during a 20m giant race simulation followed by 12 complete turn during a 13m slalom race simulation. 3 runs were performed with different muscular contraction instruction (eccentric, concentric and plyometric muscle contraction) and 2 runs were accomplished with different body placement instruction (diagonal trajectory, pelvis rest) Tangential velocity of ski was measured with optical navigation sensors Vlink (Novaq, USA) fixed in each ski (Kirby 2009). Pressure distribution on the plantar surface was measured by the use of the bilateral insole measurement system "Pedar" (Novel, Germany). Data were synchronized with a specific software (videomesure). Turn was split into 4 significant zones: transition zone, steering zone, gate crossing zone, glide zone. Results: The results showed that the movement strategy of flexion-extension produced differences concerning the kinetic of the turn. Concerning the different muscular contraction instruction the results showed an increase of the tangential velocity in some case (+4%) during a turn and an acceleration of 7% between the steering phase and the gate crossing zone. Discussion: Extension motion and eccentric muscular contraction seem to increase tangential velocity. This result can be explained by the reduction of inertial moment. However, the pressure under the ski is higher with this strategy. Under certain conditions, it could be negative for the performance in alpine skiing. These interpretations are subject to certain limitations as the number of subjects used in the study was small. Reference: Kirby R (2009). *ILCSS, St Christoph, Austria*. ### INDIVIDUAL MUSCLE THICKNESS AND POSTURE SHOULD BE CONSIDERED WHILE EVALUATING A STANDARD VALUE FOR MUSCLE HARDNESS

Murayama, M.1, Kuwada, K.2, Uchiyama, T.2, Yoneda, T.3

1 Keio University, 2 Keio University, 3 Juntendo University

Introduction Changes in muscle hardness are commonly evaluated for medical rehabilitation and conditioning in the field of sports medicine. However, the standard values of muscle hardness in the resting position have not yet been proposed. It is cumbersome to set a standard value for muscle hardness because various techniques are currently being used to evaluate muscle hardness. Recently, we proposed a modified 2-layered spring model that was proposed by Horikawa et al. for evaluating muscle hardness (1993) (Murayama et al. 2008, 2012). In brief, we compared the hardness values of the upper and lower limbs with the subjects in a standing position. These

values were calculated using 5–30% muscle thickness (MT), and we observed that the muscle hardness value E should be calculated using approximately 15% MT in the standing position. However, the feasibility of using any other body part to calculate these normalization values has not been established. The purpose of the present study was to identify a relevant distortion range for evaluating muscle hardness by considering MT in the supine or prone positions and to propose standard values for the biceps (BS), quadriceps (QS), and triceps surae (TS) muscles. **Methods** This study included 257 college students who volunteered to participate in the study. The subjects were instructed to assume a supine, or prone position. In the supine position, they lay on their back on a bed (for BS and QS muscle hardness evaluation). In the prone position, they lay on their stomach on the bed (for TS muscle hardness evaluation). We measured the MT and the subcutaneous tissue thickness by using ultrasonography. A muscle hardness meter was used, which was attached to a stage controller system. The muscle hardness meter could be shuttled linearly on the belly muscle for approximately 25 mm at 40 mm/s by using the stage controller system. **Results & Discussion** According to our previous studies (Murayama et al. 2008, 2012), muscle hardness (E value) was calculated using 15% MT; 15% E. The mean 15% E values and standard errors (SE) in the supine and the prone positions were as follows: (1) BS,  $24.5 \pm 7.1$  kPa (men: m) and  $30.7 \pm 11.0$  kPa (women: w); (2) QS,  $42.6 \pm 13.8$  kPa (m) and  $66.2 \pm 31.9$  kPa (w); and (3) TS,  $50.9 \pm 15.1$  kPa (m) and  $49.5 \pm 13.3$  kPa (w). Significant differences were observed in the muscle hardness values of each muscle between the male and female subjects. In our previous studies, no significant differences were observed between men and women in the standing position. Furthermore, the hardness of the TS muscle was greater in the standing position ( $128.7 \pm 42.7$  kPa (m) and  $119.1 \pm 29.4$  kPa (w)) than in the prone position. Therefore, we suggest that posture and gender should be considered while evaluating muscle hardness. **References** Horikawa et al. (1993) *Med Biol Eng Comput* 31, 623-27. Murayama et al. ### NEUROMUSCULAR AND KINETIC CHARACTERISTICS OF KENYAN DISTANCE RUNNERS DURING HOPPING

Sano, K., Kunimasa, Y., Oda, T., Akiyama, M., Toyoda, Y., Oda, H., Nicol, C., Komi, P.V., Locatelli, E., Ito, A., Ishikawa, M.  
*Osaka University of Health and Sport Sciences*

**Introduction** The recent years have demonstrated the great success of the east African runners in general and that of the Kenyan runners in particular. Sallin (2003) suggested that one of the possible reasons for their high mechanical efficiency could be the special biomechanical make-up of these runners in their structures and interaction of muscle-tendon unit (MTU). Therefore, this study was designed as an attempt to examine if the elite Kenyan middle and long distance runners possess "such biomechanical qualities" that would help identifying reasons why they are consistently demonstrating performance of excellence in top level international competitions including the World Championship and Olympic Games. The purpose of this study was to examine the characteristics of the neuromuscular behavior together with kinetics during hopping exercises. **Methods** 10-elite Kenyan (KENYAN) middle- and long-distance runners and height-matched control subjects (CTRL) participated in this study. Subjects performed the repetitive maximal hopping exercises. The following parameters were measured during hopping: the medial gastrocnemius (MG) muscle fascicle and tendon length (LAT\_GAS) by musculo-skeletal ultrasonography, the ground reaction force, electromyography (EMG) for MG and soleus and tibialis anterior (TA) together with kinematics for longitudinal direction by high-speed video camera. **Results/ Discussion** The results clearly showed that KENYAN jumped significantly higher than CTRL. The contact time was shorter in KENYAN than in CTRL. The impulse ration of the push-off/braking impulses was significantly greater in KENYAN than in CTRL. The MG and TA averaged EMGs during the preactivation and contact phases were significantly smaller in KENYAN than in CTRL but not the SOL averaged EMG. Although the Achilles tendon stretching and shortening amplitudes were smaller in Kenyan than in CTRL, these results clearly indicate that KENYAN specific muscle-tendon characteristic together with lower EMG activities in KENYAN is likely to have contributed to the effective hopping performance and it may imply that there can be a specific fascicle-tendon behavior to utilize elastic energy effectively. **References** Sallin B. ### RELATIONSHIP BETWEEN THE ACTIVATION LEVEL AND PRETENSION OF THE MUSCLE, AND ITS EFFECTS ON THE MECHANICAL CHARACTERISTICS OF KNEE EXTENSORS

Hegyi, A., Péter, A., Négyesi, J., Tihanyi, J.

*Semmelweis University, Faculty of Physical Education and Sport Sciences*

**Introduction** It has long been documented that a linear relationship exists between activation and tension level of the muscle under isometric contractions (Bigland & Lippold, 1954). Between the pretension and the extent of the following dynamic work also a linear relationship can be detected (Mungiole & Winters, 1991). The aim of this study was to explore whether the activation level or the pretension influences primarily the positive dynamic work. We hypothesized that when muscle is released at low pretension level the velocity of the subsequent concentric contraction will be low, but it can be compensated with maximum activation of the muscle resulting in maximum concentric contraction velocity. **Methods** Nine young ( $19.89 \pm 0.78$  yrs) subjects were measured in Multicont II dynamometer after warm-up. The maximal voluntary isometric contraction (MVC) of knee extensors was measured at 60 degree of knee angle. After reaching 100, 80, 60, 40, 20 % of MVC (QR100, 80, 60, 40, 20) the knee was released from static position and the knee extension started automatically. The pretension was reached in two different ways: with no time constraint (NTC) and with the shortest possible time (SPT). During the contractions the activation level of the isometric phase (rmsEMG) was measured at vastus lateralis (VL) muscle by telemetric EMG. Angular velocity ( $v$ ) and -acceleration ( $\beta$ ) were defined from 60 to 50 degrees at each concentric contractions. **Results** At NTC a significant ( $p < 0.01$ ) linear relationship was established between rmsEMG and pretension level. At SPT no significant relationship was observed between activation and pretension level. There was also a linear relationship between pretension level and  $v$  or rather pretension level and  $\beta$ , whereas in SPT the mechanical work was significantly greater at QR60, QR40 and QR20 compared to those in NTC ( $p < 0.01$ ). **Discussion** Our results indicate that the pretension and activation levels ought to be separated, because these are not related at maximal activation. The amount of positive work in NTC depends mostly upon the amount of elastic energy stored in the patellar tendon since pretension and activation of the muscles increased parallel. In SPT positive work was almost the same at all pretension level, so it can be concluded that maximum activation level is the dominant factor in producing work. However, it should be noted that the difference between the work generated without pretension and work estimated at different pretension level indicates the contribution of elastic energy stored during isometric contraction. **References** Bigland B, Lippold OC. ## KINEAMTICS, GROUND REACTION FORCE AND EMG COMPARISON OF OVERGROUND AND NON-MOTORIZED TREADMILL

Kashiwagi, Y.1, Hirano, T.1, Yamagishi, M.1, Akitake, H.1, Hakamada, N.2, Funato, K.3

1: Graduate school of Health and Sport Science, Nippon Sport Science University, 2: Japan institute sports science, 3: Nippon Sport Science University, Tokyo, Japan

**Introduction** Motor drive treadmill is used by endurance training or exercise and measurement evaluation of a laboratory test such as Oxygen uptake (VO<sub>2</sub>Max). But a difference of stride length, step frequency and knee joint torque were reported by comparison of motor drive treadmill and overground in many research. Recently non-motorized with curve inclination-type treadmill (Curve :woodway) in a runway. However, there are few reports of the influence that special configuration (curve inclination) gives to human body during running movement of this treadmill and effective for practical use to training. The purpose of this study was to compare the kinematic, ground reaction force (GRF) and electromyography (EMG) parameter of non-motorized treadmill running (NR) to those of overground running (OR).

**Methods** Eight health young subjects (age:23.6±2.0yrs, BH:170.8±2.7cm, BW:67.0±8.9kg) ran 30m indoor overground and non-motorized treadmill was attached on force plate at 3m/s and 5m/s. Motion capture (VIOCN MX20 Oxford :200fps) and GRF(Kistler:1kHz) and Bipolar surface EMG (Noraxon :1.5kHz) data for three steps were recorded. As for the running velocity adjustment, as for OR photo cell, NR let velocity curve feed back to a subject. EMG affixed it to lateral gastrocnemius (GA), tibialis anterior (TA), a gluteus maximus (GM), vastus lateral (VL), vastus medialis (VM), rectus femoris (RF), biceps femoris (BP), erector spine (EP) which calculated average integrate EMG (iEMG) of three steps. Lower limb joint angle, GRF (Vertical:Fz, Horizontal:Fy) and EMG data were compared with between NR and OR. Results and Discussion Step frequency was significant difference of between NR and OR in both conditions (3m/s: NR 2.80±0.16 VS. OR 2.59±0.53 Hz p<0.001, 5m/s: NR 3.21±0.25 VS. OR 2.80±0.11 Hz p<0.001). Fz first impact was not observed in OR compared with NR. Statically significant difference in Fz peak force and Fz impulse were identified in 5m/s condition (Peak force:3.08±0.43VS.:3.34±0.34N/BW, p<0.05, impulse:0.320±0.027 VS.0.355±0.018N · sec/BW, p<0.001). Erector spine of NR was indicated tendency higher muscle activity than OR.

**Conclusion** Non-motorize treadmill (curve) was indicated that has high Step frequency and lower COM displacement running form. By Fz first impact lower, reduce an injury risk of a knee, and running training is enabled. References Wank, V., Frick, U. and Schmidtbleicher, D. (1998) *Int. J. Sports Med.*, 19: 455-461. ## IN VIVO MEASUREMENT-BASED ESTIMATION OF THE TRICEPS SURAE MUSCLE-TENDON UNIT LENGTH CHANGE DURING ANKLE JOINT MOVEMENTS

Iwanuma, S.1, Hashizume, S.1,2, Akagi, R.3, Kanehisa, H.4, Yanai, T.1, Kawakami, Y.1

1: Waseda university (Tokorozawa, Japan), 2: JSPS Research Fellow (Tokyo, Japan), 3: Shibaura Institute of Technology (Saitama, Japan), 4: NIFS in KANOYA (Kanoya, Japan)

**Introduction** The muscle-tendon unit (MTU) length is an important parameter that influences its mechanical functions. The triceps surae MTU length has been estimated on the basis of the equation derived from cadaveric measurements using ankle joint angle as an independent variable (Grieve et al., 1978; Hawkins and Hull, 1990). This estimation method is questioned by a recent in vivo study (Iwanuma et al., 2011) indicating that foot deformation caused by ankle joint movement affects the displacement of insertion of the MTU. Additional independent variables should therefore be included to improve the accuracy of the MTU length change estimation. This study aimed to newly develop a prediction equation of the triceps surae MTU length change, taking into consideration foot deformation during ankle joint movements.

**Methods** Healthy young women (n = 10) and men (n = 10) volunteered as subjects. Using a magnetic resonance imaging scanner, sagittal images of the right foot were obtained at rest and during contractions at 10° dorsiflexed, neutral, 10° and 20° plantar flexed ankle positions. The contraction levels were set at 30%, 60% and 80% of the maximal voluntary contraction of isometric plantar flexion. The triceps surae MTU length changes were determined as the displacement of the calcaneal tuberosity on sagittal plane. A multiple regression equation analysis (forced entry method) was used to develop an equation for estimating the triceps surae MTU length change. As the independent variables, the orientation of posterior segment (the line connecting the anterior vertex of talus and calcaneus tuberosity) relative to the longitudinal direction of tibia, the length of the posterior segment and the displacement of the anterior vertex of talus were measured in each condition.

**Results and Discussion** The regression analysis produced an equation with r<sup>2</sup> of 0.968 and the standard error of estimate of 1.5 mm (13.0%). The changes in the triceps surae MTU length estimated by the newly developed equation were similar to those obtained by in vivo measurements. Bland-Altman plot did not show a systematic error of the developed equation. These results indicate that the present equation is useful to estimate the change in the triceps surae MTU length during various ankle joint movements. ## QUANTIFICATION OF IMPACTS IN ARTISTIC GYMNASTICS WITH ACCELEROMETRY: AN APPROXIMATION

Sanchez de los Santos, L., Grande Rodríguez, I., Campos Granell, J.

UNIVERSITY OF VALENCIA

Intensity and volume of training in Artistic Gymnastics are increasing as the sooner athlete's age of incorporation creating some disturbance in them. Intensity is commonly measured through impacts and impulses registered by force platforms which suppose a medium-large size and difficult access device for coaches during training sessions. In contrast, accelerometers are smaller, non-invasive and easy-access devices than those ones. The aim of our study was to find the relation between impacts measured with force plate and accelerometers to assess accelerometers values that could be useful to quantify the intensity of gymnast training. Seven female (n=7) gymnasts performed three sets of jump test (SJ & CMJ) and landing test (LT). Accelerometer was fixed on the gymnast's lower back. Peak vertical ground reaction force (N; %BW) and vertical acceleration (m·s<sup>-2</sup>) during take-off and landing phases as variables were collected to establish a significant correlation between both. There was no significant correlation between vertical force and vertical acceleration values of each test. Results could be influenced by different study limitations as the sample size or the location and sample rate of the accelerometer. This study showed an initial approximation for further research works. It is required to solve some limitations in order to assess that accelerometers, as small and unobtrusive devices, could be a valid and reliable tool for quantifying the intensity of training sessions in Artistic Gymnastics.

## EFFECTS OF A SIMULATED GAME ON STRENGTH, ELECTROMYOGRAPHY AND PERFORMANCE OF THE KICK IN FUTSAL PLAYERS.

Milioni, F.1, Santiago, P.R.P.2, Vieira, L.H.P.2, Barbieri, R.A.1, Gomes, F.P.3, Santos, J.W.3, Pereira, M.P.1, Da Silva, A.S.2, Papoti, M.2

1: UNESP (Rio Claro – Brasil), 2: USP (Ribeirão Preto – Brasil), 3: UNESP (Bauru – Brasil).

**INTRODUCTION** Futsal is composed by intermittent motor actions, however, there are no reports in the literature about studies assessing the influence of the game on biomechanical and performance variables of finishing kick. Thus, the aim of this study was to analyze the peak force (PF), electromyography (EMG) and peak ball speed (PBS) pre and post a simulated game of futsal. **METHODS** Eight participants performed three maximal voluntary isometric contractions (MVC) of 5 s duration and 1 min interval, sitting 90° angle at the hip and knees, pre and post of futsal game simulation. During the MVCs, EMG was monitored from vastus lateralis (VL) and biceps femoris (BF), as well PF. The game was simulated in 4 periods of 6 min. At the beginning, at the end of 2nd period, before the 3rd period and at the end of the game, a set of three finishing kick from 10 m to goal was performed and monitored by lateral video recording. The blood lactate concentration ([Lac]) was monitored in every event mentioned. **RESULTS** Significant differences were found pre and post game for VL for the integrated EMG (iEMG ( $\mu\text{V}\cdot\text{s}$ ), pre=1858.79 $\pm$ 534.70, post=1619.10 $\pm$ 570.48; p=0.004) median frequency (MF (HZ), pre=63.79 $\pm$ 5.40, post=66.58 $\pm$ 7.53; p=0.027), and PF (N) (pre=906.00 $\pm$ 145.77 post=808.63 $\pm$ 93.58; p=0.044). The PBS (km/h) were 93.88 $\pm$ 6.65, 97.29 $\pm$ 7.67, 98.19 $\pm$ 11.89 and 102.77 $\pm$ 15.36 obtained in the 1st, 2nd, 3rd and 4th sets, respectively, and were not significantly different. The average [Lac] was 3.85 mmol/l. **DISCUSSION** The drop of the PF agrees with the findings of Krstrup et al., (2011) in similar protocol with soccer. The same behavior was observed for the iEMG of VL, however, no significant differences were found in PBS, possibly because the participants, even in a decreased muscle activation scenario, still be able to increase the fast twitch fibers recruitment (Miller et al., 2012) to kicks execution, evidenced by a significant increase in MF of the VL. These findings may also be result of reduced intensity of the game simulation, because the average values of [Lac] were lower than found by Castagna et al., (2009), or familiarization with the tasks (MVC and finishing kicks). In conclusion, it is possible that neuromuscular activation (iEMG) reflects directly the peak force capacity, evidenced by a decrease in both at the post game, and the increase of MF, together with the effects of familiarization with tasks and underestimated intensity of game, may have caused the PBS maintenance. **REFERENCES** Krstrup et al., (2011). *Eur J Appl Physiol.* 111(12):2987-95. ## TRUNK STABILITY DIFFERENCES BETWEEN KAYAKERS, JUDOKAS AND RECREATIONAL ATHLETES

López-Valenciano, A., Elvira, J.L.L., Barbado, D., Juan-Recio, C., Montero, C., Vera-García, F.J.

*Sports Research Centre, Miguel Hernandez University of Elche*

**Introduction:** Although unstable sitting and sudden trunk loading paradigms have been successfully used to assess trunk stability (TS) in pathological populations (Dieën et al., 2010), they have not been used to study the influence of sport practice on TS. The aim of this study was to compare the effect of practicing judo, kayak and recreational physical activities on TS. **Methods:** 12 judokas, 6 kayakers and 16 recreational athletes took part in this study. A battery of static and dynamic tests was performed to measure trunk postural control and dynamic stability while sitting on stable and unstable seats placed on a force plate (Kistler 9286A). Postural and dynamic sway were assessed by analyzing the mean radial error of the COP displacements. In order to measure the trunk response to sudden and unexpected trunk loading in anterior, posterior and lateral directions, the angular displacement and the stiffness of the trunk were calculated for the first 150 ms. In addition, trunk flexor and extensor muscle condition were measured by isokinetic dynamometry (Biodex®). Peak torque and maximum work, and final fatigue ratio, were calculated to assess trunk muscular strength and endurance, respectively. **Results:** Kayakers showed lower mean radial error in unstable dynamic balance tasks and lower trunk stiffness in anterior sudden loading (p<0.05) than judokas and recreational athletes. In addition, judokas and kayakers showed higher trunk flexor endurance (p<0.05) than recreational athletes. **Conclusion:** The kayakers showed better results in unstable dynamic balance tasks and lower stiffness after loading, which could be related to the efforts they do regularly to maintain balance on the kayak. These results support those of Reeves et al. (2006), who observed that an increase of trunk stiffness may impair postural control on unstable sitting. **References:** Dieën JHv, Koppes LJ, Twisk J. (2010). *Spine* 35, 812–817. Reeves NP, Everding VQ, Cholewicki J, Morrisette DC. (2006). *Exp Brain Res* 174, 694-700.

## RELATIONSHIP BETWEEN CORE STABILITY VARIABLES: TRUNK POSTURAL CONTROL AND DYNAMIC STABILITY, TRUNK RESPONSE TO SUDDEN LOADING AND TRUNK MUSCLE STRENGTH AND ENDURANCE

Vera-García, F.J., Elvira, J.L.L., Barbados, D., Lopez-Valencia, A., Juan-Recio, C., Montero, C.

*Sports Research Centre, Miguel Hernández University of Elche (Alicante), Spain.*

**Introduction:** The importance of core stability in athletic function and injury prevention is being increasingly recognized (Borghuis et al., 2008; Kibler et al., 2006). However, the assessment of core stability is very complex as it requires the combination of different variables (Borghuis et al., 2008), as for example, trunk postural control, trunk dynamic stability, trunk response against sudden perturbations and trunk muscle strength and endurance. The aim of this study was to analyze the relationship between all these variables. **Methods:** 26 recreational male athletes took part in this study. A battery of static and dynamic tests was performed to measure trunk postural control and dynamic stability while sitting on stable and unstable seats placed on a force plate (Kistler 9286A). Postural and dynamic sway were assessed by analyzing the mean radial error of the COP displacements. In order to measure the trunk response to sudden and unexpected trunk loading in anterior, posterior and lateral directions, the angular displacement and the stiffness of the trunk were calculated for the first 150 ms. In addition, trunk flexor and extensor muscle condition were measured by isokinetic dynamometry (Biodex®). Peak torque and maximum work, and final fatigue ratio, were calculated to assess trunk muscular strength and endurance, respectively. **Results:** Significant correlations were not found between most of the variables. However, higher trunk stiffness and lower angular displacement against anterior sudden loading correlated with a higher mean radial error of the COP displacements during a dynamic test on unstable sitting (circular trajectory). In addition, higher maximum work during the trunk flexor and extensor dynamometric test correlated with a lower angular displacement of the trunk against lateral sudden perturbations. **Conclusion:** The lack of relationship between most of the variables that have been associated to core stability confirms the complexity of its evaluation and indicates that many different measures are needed to explore all the components of core stability in recreational athletes. **References:** Borghuis J, Hof AL, Lemmink KA. (2008). *Sports Medicine* 38, 893-916. Kibler WB, Press J, Sciascia A. (2006). *Sports Medicine* 36, 189-98.

### EFFECTS OF LONG-TERM DETRAINING ON PHYSICAL FITNESS AND BODY COMPOSITION IN JAPANESE JR. YOUTH SOCCER PLAYERS

Ishizaki, S.1, Yasumatsu, M.2, Nishikawa, S.3, Inayama, T.4, Togari, H.3

*Shibaura Institute of Technology 1), Rikkyo University 2), Heisei International University 3), Tokyo Metropolitan University 4)*

**Introduction** It has often been pointed out in the previous studies that regular training generally improves physical fitness (Helgerud et al., 2001). On the other hand, there is little literature researching especially on detraining in adolescent soccer players. Therefore, the purpose of this study was to investigate physical fitness and body composition during long-term detraining in Japanese Jr. youth soccer players. **Methods** Thirty male Jr. youth soccer players (age;  $14.4 \pm 0.5$ yr, height;  $165.4 \pm 6.1$ cm, body mass;  $52.5 \pm 5.9$ kg, %fat;  $11.8 \pm 4.1$ %) volunteered to participate in this study. Subjects were assigned to either a training group (TR;  $n=19$ ) or a detraining group (DT;  $n=11$ ). TR group did about two-hour training six days in a week, on the other hand, DT group did physical education classes (50min/times) only twice a week. Before and after the training and detraining period (from August to February, 7 months), subjects underwent the following fitness tests: squat jump (SJ), countermovement jump (CMJ), countermovement jump with arm (CMJWA), and 6 jump (6J) using a jump mat (multi jump tester, DKH, Japan), 30m sprint test using a photocell gate (coach's monitor, Brower, USA), and Yo-Yo test level 1. In addition, height and body composition were measured with a body composition analyzer (BC-305, TANITA, Japan) before each test. **Results & Discussion** In both groups, height and body weight were significantly increased after experimental period. Body fat (%) in the TR group was not significantly changed after the experimental period, whereas it significantly increased in the DT group (from  $12.4 \pm 3.9\%$  to  $14.7 \pm 5.0\%$ ,  $p < 0.05$ ). In the DT group, SJ, CMJ, CMJWA, and 6J were significantly decreased after the experimental period ( $p < 0.05$ ), on the other hand, those in the TR group were not significantly changed after the experimental period. The difference in sprint time before and after the period was significant in both groups ( $p < 0.05$ ). Running distance for Yo-Yo level 1 test in the TR group was significantly improved from  $1931 \pm 287$ m to  $2476 \pm 332$ m ( $p < 0.05$ ), whereas that of the DT group was significantly decreased from  $1902 \pm 320$ m to  $1392 \pm 311$ m ( $p < 0.05$ ). In addition, there was significant difference between the TR and DT groups ( $p < 0.05$ ). These results suggested that long-term detraining affected several aspects of physical fitness and increased %fat in the case of Japanese Jr. youth soccer players. **References** 1. ### PERIODIZATION: A SIMPLIFIED MODEL

Silva, F.T.1, Silva, I.L.2, Aragão, T.3

*1: University Center of Estácio-Ceará - Brazil, 2: University of Porto – Faculty of Sport – Portugal, 3: Origo treinamento individualizado - Brazil*

**Introduction** The system of periodization of the training proposed by Russian scientist Ph.D. Leev Pavlovitch Matveev, in the 50s, based on the theory of General Adaptation Syndrome, became a reference among the coaches of the era, popularizing up worldwide. Some models appear to resolve particularities in each context. According to Gomes (2002) starting in 1970, when it starts the questioning of the classical models of planning, new proposals appeared and an expansion of knowledge in this area. The principles of sports training should be respected by the coach to develop a periodization, and this should know well the concepts of energy systems predominant in the sport to be trained, the theory of general syndrome and supercompensation. **Methods** The proposal adapted by Silva, F.T. starts in the 80s, is called simplified model by the author, by objective form connecting the tasks. Using file formats, the macrocycle similarly to classical model, may to plot the days, periods and phases, however it is proposed mesocycle controls where motor skills are indicated along with the methods and means of training, in this control still show up the location execution training tests indicating chosen. **Discussion** In a study by Dantas et. al (2008) the index of comprehensiveness - IABRAN (in Portuguese) - was demonstrated among authors studied Verkoshanski (2.68), Matveev (3.80), Bompa (3.2), ATR (2.93), Forteza (2.73), only the periodization model of Matveev (Classical) presented a suitability very good. Most studies, including this one, the simplified model of periodization were supported on Traditional System of Periodization. **Conclusion** The proposed application of the simplified model allows objectively its monitoring and control, even for coaches still with little experience, is indicated for the beginner or amateur level of competition. And also is possible use this planning of training focused on health. **References** Dantas, E.H.M. Abrangência dos Modelos de Periodização do Treinamento Esportivo. *Revista Brasileira de Ciência e Movimento*, Vol. 16, No 4. 2008. GOMES, A.C. ### FEMALE'S 100 METRES RUNNING DYNAMICS

Babic, V., Blazevic, I.

*University of Zagreb*

**Introduction** Sprinting speed has certain dynamics constantly changing throughout the sprint race phases. The velocity curve of top-level sprinters running over the 100m course are already well known, but no one has yet evaluated the sprinting activity of female athletes who have not been trained for sprinting. Therefore, the quality and development of these abilities is becoming even more interesting for training practice. The aim of this study was to determine the 100m running dynamics of female athletes as well as differences of different quality groups. **Methods** The participants were 78 physically active females (age (mean $\pm$ SD)  $20.1 \pm 0.74$  years; height  $167.75 \pm 7.35$  cm; body mass  $60.07 \pm 7.28$  kg). Measurement was conducted by means of an electronic measurement device. Dynamics of sprinting over 100m has been observed across ten segments of ten metres each. The hierarchical cluster analysis (Ward, 1963) has been used to determine relatively homogeneous female groups of different sprinting characteristics (seconds (mean $\pm$ SD) G1  $16.48 \pm 0.21$  (N=9); G2  $14.81 \pm 0.21$  (N=18); G3  $15.28 \pm 0.24$  (N=22); G4  $13.11 \pm 0.37$  (N=8); G5  $14.07 \pm 0.26$  (N=21)). The segment of maximum sprinting speed has been determined for each analysed group. The values of maximum sprinting speed have been reduced by the standard deviation typical for each group. Differences between groups have been analyzed by the ANOVA. **Results** The following segments of sprinting dynamics over the 100m course are known: starting acceleration (0-30m), achieving maximum sprinting speed (30-60m), maintaining maximum sprinting speed (60-80m) and deceleration. In this study more segments have been found: 8 in groups 1 and 2; 7 in group 5; 6 in group 4 and 4 in group 3. The length of particular segments has varied. In starting acceleration, which is a very dynamic part of sprinting, two

segments have been obtained in all observed groups (0-20m). The segment of achieving maximum sprinting speed has become the segment of maintaining maximum sprinting speed which is 20m long in groups 1 and 5 (20-40m) and in groups 2 and 4 (40-60m) whereas in group 3 it is 30m long (20-50m). Discussion According to the length of the segment of maximum sprinting speed, it is possible to conclude that all these groups haven't got efficient running techniques and according to the competition activity, it imposes higher demands on specific sprinting speed endurance. The present study is the first one on females in which the obtained and presented results indicate a quite different structure of running dynamics, although, to be fair enough, certain researchers have pointed to different velocity curves during the course of the 100m sprint event, except in case studies observing world-class sprinters. We assumed that the determination of running dynamics over 100m, performed by the track-and-field's criteria in non-sprinting examinees, would contribute to establishing certain sprinting regularities. In other words, we have tried to indicate the facts that might limit the progress in learning how to sprint over short courses.

### **SOCCER TRAINING PROGRAM TO IMPROVE TECHNICAL SKILL IN OLISTIC VISION**

Nughes, E., Di Tore, P.A., Raiola, G.

*università degli studi di salerno*

Introduction Team sport activity is composed of conditional, technical, tactical features of performance and uses the periodization to put in practice strategies, methods and teachings to develop the individual and collective group skills, to aim to the best goals. (Manno 2002). The periodization includes the division of the training year in specific periods with well-defined aims. (Raiola, 2012) The matter of the research is to verify the conditional improvements reached by the training time and the performance peak close to the competitive time. Method The research has been carried out on two athletes, who have been subjected to several athletic tests. The Tests have been carried out: At the beginning of the preparatory period, At the end of the loading period, At the end of the transformation period (which coincides with the beginning of the competitive period), those tests allowed us to see the improvements reached on different phases of periodization; improvements achieved through the training proposed, based on a gradual load increasing. Results All tests have shown improvements on both the athletes: in the strength peak test (1 Repetition Maximum in half-squat) the athlete n°1 went from 80 kg to 124 kg of the preparatory period of the competitive period, while the athlete n°2 increased from 81 kg of the training period to 114 kg of the competitive period; for the Cooper test the athlete n°1 went from 2960 meters covered by the run-up to 3440 meters on the competitive period, while the athlete n°2 from 2234 meters to 3013 meters on the same period. Discussion The research results show both the athletes improved their conditional skills, and reached the performance peak on the transformation period ending, that coincides with the competitive period beginning. So, the criterion of the gradual loading and the training complexity allows the nervous system to arrange itself progressively and gain improvements, from a quantitative point of view (Oliveira). For this research and for the future mainly, my studies are drawn from the training led by the coach José Mourinho and his staff, through the years. The objective of future researches will be to collect scientific data not only quantitative, as in this, by performing new tests to show the improvement reached using these training methods also from a qualitative point of view. References Manno R. (2002) L'allenamento della forza. Utet, Italy. Oliveira R. / a planificação, programação, e periodicidade do treinamento em futebol. ### **PILOT STUDY ON FOOTBALL PERIODIZATION IN OLISTIC WAY**

Nughes, E., Rago, V., Raiola, G.

*università degli studi di salerno*

Introduction The research is based on the concept of periodization in the annual training program according to ecological-approach in an olistic vision (Raiola 2012). The subject developed focuses on the concept of periodization, which means the division of the training season in specific periods with clearly defined aims. The goal of the study is to detect the improvements we are at different stages of periodization, that are expected to reach their peak in the competitive period (Bompa 2005) The study has been conducted on the activity of two 22 years old males athletes of a Soccer Team of University Portuguese League to aim the difference. Methods It is utilized an experimental approach by the test of Maximum Strength, Endurance, the Cooper's test and BMI, which helped us to evaluate the improvements of physical performances at different stages of periodization. At the base of periodization, there is the "principle of progressivity of cargo and physiological adaptation". The exercises during the strength training are designed in order to reproduce the technical model in soccer such as tracing movements similar to it, to be executed repeatedly, in order to facilitate the learning. The imitation of technical skills involves the chain of muscles in a way similar to the one used in the analyzed discipline. The exercises and training methods, therefore, must be directed to the movements or the situation that emulate in the match, so as to increase the discharge of motor neurons and to induce the muscles to express athletic movements made of high power and speed. Results From the data obtained we can see how both players have got improvements to all conditionals aspects of in question, especially about the VO2 max test (Cooper test) where the player n.3 from preparatory phase to agonistic has improved 270 meters, and the player n.4 has improved 490 meters. Discussion From the data obtained we see how both athletes, as desired, they reach the peak at the end of the processing period (which coincides with the beginning of the agonistic period). This simple quantitative research is a base for new future studies to be carried out on several samples and with new evaluation tools to validate training further upon the principle of progressivity of the load. ### **FOSTERING LIFE SKILLS IN ADOLESCENT ATHLETES: LEARNING SITUATIONS REPORTED BY COACHES IN TWO SPORT CONTEXTS**

Trottier, C., Migneron, E., Robitaille, S.

*Laval University*

Introduction Sport participation should not only promote an active lifestyle and develop motor skills in adolescent athletes, it should also foster life skills development (Côté & Fraser-Thomas, 2007). The purpose of this study was to explore how coaches in two different sport contexts gain their knowledge about life skills and the strategies to teach them in adolescent athletes. Methods The authors conducted a qualitative multiple-case study (Yin, 2009). Semi-structured interviews were held with 24 coaches working in school sport (12 basketball coaches) and amateur sport (12 swimming coaches). All coaches followed a holistic, athlete-centered approach. In the interviews, coaches described how they learned to teach life skills. The discussions were guided by Werthner and Trudel's (2006) model, such that the

coaches' learning processes are categorized into three types of learning situations: (a) mediated, (b) unmediated, and (c) internal. The authors transcribed the interviews, analyzed them deductively and inductively and conducted cross-case analyses. Results The data analysis sheds light on the diverse learning situations in which coaches have gained their knowledge. The results reveal that coaches in the two sport contexts learn principally through internal learning situations, specifically through retrospective reflection-on-action. Discussion Generally, the coaches in this study seek learning proactively, following an individualized learning process. The main results are discussed in light of the literature on life skills in sport, positive youth development, and coaching education. These new findings extend the discussion on coaching development. References Côté, J., & Fraser-Thomas, J. (2007). Youth involvement in Sport. In P. R. E. ### **MOTOR IMAGERY AS A TOOL TO IMPROVE ARTISTIC GYMNASTIC PERFORMANCE.**

Scassillo, I., Di Tore, P.A., Raiola, G.

*università degli studi di salerno*

**Introduction** The motor imagery is a cognitive process of mental simulation of actions in absence of movement (Jeannerod, 2006). There are two methods to improve skills learning through motor imagery: in first person and in third person (Rymal, 2009). The biological basis on which the motor imagery theory is founded, is formed by: mirror neurons. The aim wants to evaluate the effects of motor imagery practice in training (Rizzolatti, Sinigaglia 2006). The aim is to verify the effects and the potential benefits of motor imagery. (Raiola, 2012). **Methods** It is an experimental approach and it consists of two steps: 1) To administer the questionnaire (Curry et al. 2004). The participants are asked to evaluate the sensation of their own motor act and then their mate's one in accordance with valuation methods of Italian federation of artistic gymnastics. The data will be compared with those of judge/technician. 2) The means used in the second part of the study is the video recording. The participant are given the vision of their own motor gesture that will be stopped and the participant are asked a final forecast of the performance result. The data will be compared with those of judge/technician. The objective is to evaluate if there is assonance between the data. **Results** By the data it is observed a more effective internal evaluation and also an improvement in the performance on about 80% of the gymnasts that performed the round-off flic; with reduction of error of from 1 to 2.5 points. In a time of 6 months. In accordance with the judgment of a technician/judge. **Discussion** In this study two basic aspects of the performance are examined: the motor execution and the motor imagine. Both share the same neuro-motor mechanism: the motor imagery. Concerning the woman artistic gymnastics, it can be useful during the training and the race. So providing the athletes and trainers of a means which uses the motor imagery as a possible application for the improvement of the performance. So in conclusion, the study aims to provide a standard training feasible on a large scale to train the cognitive and physical abilities of an athlete and provide a support tool in the race in order to improve performance, optimize time and to reduce the margin of error. **References** Curry, L.A., & Maniar, S. ### **DECISION MAKING IN EDUCATION OF GOALKEEPER IN FOOTBALL**

Scassillo, I., Verde, G., Raiola, G.

*università degli studi di salerno*

**Introduction** Decision making is a cognitive process through which an athlete elaborates fastly exteroceptive and proprioceptive informations related to the space-time situation that he is currently living, extrapolating just those useful to motor action (Raiola, 2008). The stages that individuals use to transform inputs into output are three: Stimulus identification, Answer selection and Answer planning (Schmidt & Wrisberg, 2000). The time taken to transform the input into output is said reaction time. The aim of this study is monitoring and evaluation of three phases: initial, intermediate and final; two different methods to train the goalkeeper with the use of the applications of decision making theory. **Methods** It is an experimental approach and it uses worksheets. It is formed by two steps: in the first step where coach will shoot 36 penalties (12 high, 12 low and 12 at half-height) giving informations to goalkeeper at first using a verbal language (shouting... "I'm shooting at your right" or "I'm shooting to your left") then a paraverbal language ("if coach lift right arm he will shoot penalty at goalkeeper right side whereas if coach lift left arm he will shoot penalty at goalkeeper left side" or "if coach lift right arm he will shoot at goalkeeper left side whereas if coach lift left arm he will shoot at goalkeeper right side"); in the second step goalkeeper must prove to keep 25 penalty shot by 5 different players. **Results** By the data collected in the three different steps it is observed an improvement of skills to oppose and to neutralize a penalty and it is observed an improvement of skill to filter the informations taking only the useful for the own motor act for 80%. **Discussion** So providing the goalkeeper trainer, especially the beginners, a new means, which uses the process of decision, training methodology that aims to increase goalkeeper decision making in a critical moment such as a penalty. The efficacy of this study can be recognized in contexts motor-sports at all levels. The objective of future researches will be to collect scientific data not only qualitative, as in this, by performing new tests to show the improvement reached using these training methods also from a quantitative point of view. in order to implant a training program appropriate to improve the motor skills of goalkeepers. **References** G. ### **ACUTE PHYSIOLOGICAL RESPONSES TO SIMULATED GAMES WITH DIFFERENT DEFENSIVE FORMATIONS IN TEAM HANDBALL: 6-0 VS. MAN-TO-MAN**

Meletakos, P., Nikolaidis, P.T.

*University of Athens*

**Introduction** Although 6-0 and man-to-man defensive formations in team handball (TH) are widely used, there is little information with regard to their physiological impact. Therefore, the aim of this study was to examine the acute effect of two simulated games, one using 6-0 and the other man-to-man, on measures of neuromuscular performance in young TH players. **Methods** Eleven TH field players (experience 4.3±0.7 yr, training 6.5±1.6 h.wk<sup>-1</sup>, age 15.1±1.0 yr, weight 73.7±9.7 kg, height 1.77±0.07 m), all members of an academy of a

first league club, played two 20-min simulated matches (separated by two weeks). They were tested before and after each match for handgrip strength (HS), squat jump (SJ) and 20-m Sprint (acceleration phase 0-10 m, Sprint0-10, and maximum speed phase 10-20 m, Sprint10-20). Results The formation 6-0 resulted in the decrease of Sprint (+0.08 s, 95% CI (0.03; 0.12)), Sprint0-10 (+0.05 s (0.01; 0.10)) and Sprint10-20 performance (+0.03 s (0; 0.05)), while the man-to-man formation caused decrease in HS (-3.1 kg (-5.2; -1.0)). Comparing the two formations, the 6-0 had larger effect on Sprint performance (+0.07 s (0.01; 0.12)), while the man-to-man had a larger effect on SJ (+1.4 cm (0; 2.7)). The formation 6-0 and man-to-man resulted in similar mean (179.8 vs. 180.0 bpm) and maximal heart rate (193.7 vs. 196.0 bpm). Conclusions The findings of this study indicate that the choice a defensive formation in TH may result in different physiological responses that are associated with neuromuscular performance. Knowledge about the physiological impact of each formation can help coaches to optimize the use of the various formations during the game and to use them during training in order to elicit different physiological responses.

### **CLIFF DIVING PERFORMANCE: A MODEL TO EVALUATE IMPACT AND TECHNIQUE FOR VIDEO TRAINING**

Napolitano, S., Tursi, D., Raiola, G.

*University of Salerno*

Do not insert authors here Introduction The sport of cliff diving was born fifteen years ago, and has gained enormous success. Beginning in 2013, in light of the World Swimming Championships, the Italian Swimming Federation (FINA) has added this sport among the official swimming disciplines present in the competition. This highly spectacular sport complies particular motary and psychological abilities, which are not possible to train for lack of specific sports facilities. In competitions, the starting platforms are at a height of 25-28 meters, and the impact with the water is at a high velocity that stimulates the entire body in little time (Richard G., al 1967). The goal is to calculate the impact with the water, its form and the hypothetical consequences on the body using video training (Yuan Xiong, ed al 2004) . Methods This study uses three distinct approaches: a case study of single performances, the descriptive research for the contribution of the evaluation of the analyst, and the constitution and elaboration of the data for the contribution of the physics expert. The model consists in the total of three performances of three international competitions: • 2 Red Bull Cliff Diving World Series competitions • 1 World Championship competition The single dives were analyzed, compared with overlapping displays of the performances, the analysis and decoding of the video given by the analyst and the technical expert in the field on water entry with Kinovea software. This specific software was used for simulations...data of coefficient of water impact and entry. Results For each dive impact incidence and eventual consequences on the athlete were calculated. For each athlete both the positive and the negative aspects of their performances were located. The evaluation of the data collected (each single dive for each single athlete, total nine dives each) allowed an individual hypothetical model to use pre-competition. Discussion The results can be used by the athletes themselves, using the video education method, and by technical trainers for training, for the analysis and specific evaluation during competitions according to learning skills theory (Raiola 2012). Furthermore, a more in depth study will be able to demonstrate the danger and the consequences on the athletic organism in Olympic competition. Keyword: video analisi, Kinovea, videoeducation, videodidactics REFERENCES Yuan Xiong, Yi Zhang A Learning-based Tracking for Diving Motions Proceedings of the Third International Conference on Image and Graphics (ICIG'04) 0-7695-2244-0/04 \$20.00 © 2004 IEEE Richard G. ### **STUDY ON POSTURE IN RELATION TO DISEASE-WELLNESS IN FEMALE WATER POLO**

Napolitano, S., Cerrotta, M., Tursi, D., Raiola, G.

*University of Salerno*

Do not insert authors here Introduction The study examines the postural effects on the wellness and the performance of fourteen professional female water polo athletes. (Téczy T Á 2006) There are no written studies on water polo, probably because it is assumed that there is no pain because Archimedes's formula opposes the force of gravity. Currently athletes carry out exercises to compensate and to avoid any eventual pain that then disappears when they are out of the water according to motor control and learning theory (Raiola 2012). The aim is to understand the phenomenon in professional athletes using a tridimensional analysis of the surface of the torso and the baropodometric platform. Methods and Materials This consists in examining the "3D" surface of the torso of fourteen professional water polo athletes, participants in the Italian Championship in the A1 series, and the data of the baropodometric platform. This data highlights curves that will then be considered with regards to athletic performance and well being. The data of performance and well being of the athletes is collected by a trainer for each single athlete. The study was carried out at the specialized center CORPORA of Gricignano (CE) with the following apparatus: "Formetric Spinometer". This allows the morphological 3D image of the torso, with extreme accuracy (error below 0,2 mm), speed, and safety thanks to the radiation free equipment. The postural Formetric check-up supplies a series of indicators which together give a detailed evaluation of the subject's posture. For each athlete a synthesis chart was elaborated, showing a 3D reconstruction of the surface of the torso and the individualization of specific postural parameters with the data collected by the trainers on the athlete's performance and well being. This data was elaborated using a statistic model of linear regression Results The evaluation of the data shows no existent correlation between cases with pseudo pathological curves and their state of well being and performance. While athletes with a near perfect exam often complained about occasional pain. Discussion There is a paradox regarding affection, performance and pain; in some cases it is low, while in some cases, it is the opposite. The results of the Archimedes's principle and the force of gravity probably produce physiological adjustments in water. Keyword: Spinometria Formetric, postura, performancesw REFERENCES Teczely, T., Á, (2006), Investigation of postural stability, reaction time and body measures in basketball players, Acta Physiol Hung. 2006 Jun ;93 (2-3):107-16 17063622 Raiola G (2012), La complessità dello studio in ambito educativo sportivo, Pensa, Lecce, Italy

### **VIDEO ANALYSIS OF ARMSTROKES IN FEMALE WATER POLO: EVALUATION AND INCIDENCE OF THE BALL DURING SWIMMING**

Tursi, D., Napolitano, S., Di Tore, A., Raiola, G.

*University of Salerno*

Introduction Water polo is a team sport which alternates moments of high intensity where players, with and without possession of the ball, jump, throw, and moments of low intensity and pauses. But, it is also a contact sport where athletes battle against adversaries,

withhold and push them. (Smith, 1998; Van der Wende, 2005). Swimming plays an important role in water polo, as it is used during most of the game. "Water polo consists of high intensity bursts of sprinting, interspersed with short periods of low to moderate intensity swimming." (Hohmann A & Frase R, 1992). Under this aspect the swimming preparation is therefore a determining aspect. Swim training conditions play a constant role in order to obtain the best results (Raiola et al, 2011). The goal of this study is to evaluate the transport incidence of the ball during high intensity swimming, so we are able to supply trainers with useful elements regarding training methodology to use. Materials and Methods The approach to this study consists of two distinct methods: the case study for the technical contribution and evaluation for the analysis of single performances, and theoretic argumentation to elaborate a complete picture in which we define the data. Eleven high level athletes were recruited (participants of Italian championships of the A1 series), and they were tested in 300 Quick Race, once swimming with the ball, and once without. An average was calculated for each athlete, the fastest and the slowest with, and without, the ball. Furthermore, each athlete was filmed in order to analyze the angle of the arm strokes. The analysis was conducted separately for each athlete and each test. Results The data of the athletes' fastest and slowest average times was collocated in charts and histograms, and a linear graph was created comparing the two tests (with and without the ball) of each single athlete. Discussion The data collected shows that swimming in possession of the ball does not always have a negative effect in high intensity swimming. The result can be read in correlation to the athlete's history: high level athletes do not undergo any significant time variation, players that have a professional swimming history noticeably worsen their times, and athletes with a background in water polo improve their times. The video analysis shows a notable difference in the angles of the arm strokes. The results demonstrate how this study can be used as a valid instrument to help trainers use training strategies aimed to improve particular abilities that were analyzed in a unique way and therefore create a specific training regimen to improve performance. ### **FOSTERING LIFE SKILLS DEVELOPMENT IN HIGH SCHOOL AND COMMUNITY SPORT: A COMPARATIVE ANALYSIS OF THE COACH'S ROLE**

Trottier, C., Robitaille, S.  
*Laval University*

Introduction Researchers largely agree that the coach is the most significant shaper of values and life skills in adolescent athletes (Danish, Fazio, Nellen, & Owens, 2002; McCallister, Blinde, & Weiss, 2000). Therefore, the aim of this study was to gain a deeper understanding of coaches' perceptions of their role in the development of life skills in adolescent athletes in two different sport contexts. Method A qualitative multiple-case study (Yin, 2009) was conducted. Semi-structured interviews were held with 24 coaches working in school sport (12 basketball coaches) and amateur sport (12 swimming coaches). All coaches followed a holistic, athlete-centered approach. Coaches described the life skills they taught, their motivations, and the strategies they used to foster life skills development in practice. Interviews were transcribed, then analyzed deductively and inductively, followed by cross-case analyses. Results First, results revealed that the coaches taught many common life skills between the two contexts, notably self-confidence and respect. Second, two main motivations for teaching life skills emerged: athletes' needs and coaches' personal values. Third, the most often cited teaching strategies were general discussions, established rules, individual and specific interventions, goal setting, feedback, maintaining high expectations, and modeling. Fourth, the most frequent transfer strategies were specific discussions, followed by asking athletes to apply life skills in other life areas. Certain results are specific to each of the sport contexts: distinctions between high school sport (basketball) and amateur sport (swimming) are identified and discussed. Discussion The main results are discussed in light of the literature on life skills in sport and positive youth development. The considerable similarities between coaches in the two contexts are discussed in terms of methodological considerations: (a) participants' profile, (b) participant selection criteria, and (c) interview type. Finally, a question is raised, with implications for future research avenues: does a holistic, athlete-centered approach outweigh the influence of sport context on how coaches teach life skills? ### **CHANGES IN PERCEIVED MOTIVATIONAL CLIMATE IN SPORT AMONG YOUNG FOOTBALLERS**

Nunes, N., Severino, V., Gonçalves, C.  
*University of Coimbra*

Introduction The athletes' perceptions of their coaches' behavior contribute significantly to the knowledge of the training climate, oriented to mastery or performance. This study aims to analyze the effects of different types of guidance on the perceptions of the climate of two groups of young soccer players. Methods Twenty-two soccer players, aged 13-14 years completed the Perceived Motivational Climate in Sport Questionnaire-2 prior to the first practice in preparation for a tournament, and before the last game. Meanwhile, the under-13 team (n=12) was given a mastery approach by the coach, and the under-14 team (n=10) a performance approach. Results At the baseline, Kruskal-Wallis Test showed no differences between the groups, except for Punishment ( $p=0.05$ ), with the under-13 group presenting higher mean scores. Comparing 1st to 2nd moment, only Cooperative Learning showed significant differences ( $p=0.02$ ), with the under-13 presenting the higher scores. In all the variables the mean scores decreased for both groups, except Punishment which showed a moderate increase. Discussion The under-13 team results on the second time, where were instilled task behaviors and attitudes, were higher in the categories of Cooperation, Importance in Team and Effort/Improvement, related to task orientation. On the other hand, the values of ego orientation categories decreased on average. These results are supported by studies of Seifriz, Duda & Chi (1992), Smith et al. (2005), and Torregrosa et al. (2008), who reported that a motivational climate task oriented relates to a coach who provides many guidelines, encouraging positive feedback after the success or failure in performance, supporting the players and not ignoring the error. The results for the under-14 team on the second time, instilled with ego behaviors and attitudes, were higher in the categories of Punishment and Inequality, related to ego orientation. As for the values relating to the categories of task orientation, dropped from first to second stage of data collection. These findings are supported by studies of Seifriz, Duda & Chi (1992), Smith et al. (2005), and Torregrosa et al. (2008), which state that a climate ego oriented is associated with a high amount of negative feedback, punishment, lack of support, results and individual performance overvaluation. Conclusion The deliberate orientation of the training climate is perceived by the athletes in the same direction as suggested by the coach. Hence, the context of practice can be manipulated by the coach in a negative or positive sense. References Seifriz J. Duda J, Chi L. (1992). *Journal of Sport & Exercise Psychology*, 14, 375-391. ### **FEET PLACEMENT FOR BACK CORNER SHOTS IN ELITE SQUASH**

Vučković, G., James, N., Murray, S., Hughes, M.D.

*University of Ljubljana, Faculty of sport*

Introduction Movement in squash is, along with racket skills, the most important technical criteria for good performance. Movement consists of proper positioning around the T area (Vučković et al., 2009), movement towards the ball, positioning to play the shot and movement back to the T area. Although positioning has a direct influence on shot selection and accuracy this aspect of players' movements has never been analysed in detail. Methods Six matches played by professional players at the 2010 and 2011 British Grand Prix Squash tournaments were analysed. This consisted of three times two matches played by players in top 8, 9 to 24 and 25 to 50 on world rankings. The SAGIT software system was used to determine shot location and feet positioning. This analysis was restricted to the back corners of the court as these areas account for the majority of shots and only when playing straight and crosscourt drives and straight drop shots as these account for the vast majority of shots. Feet positioning was classified according to which foot was closest to the sidewall at the time the ball was struck (left, right or both). Data was processed in Microsoft Excel and transferred to IBM SPSS statistics package (v19, SPSS Inc., 2010) for analysis. Repeated measures ANOVA were used to determine differences between world ranking levels foot placements and court locations. Results Significant interactions between world ranking level and feet positioning were found for shots played from both back left ( $F = 14.45$ ,  $df = 4, 117$ ,  $p < .001$ ) and right corners of the court ( $F = 2.66$ ,  $df = 4, 117$ ,  $p < .05$ ). Top 8 and 25 to 50 players had similar patterns of feet positioning when playing shots in the back left corner (backhand). They used the traditionally correct (right) foot forward 61% (top 8) and 63% (25-50) of the time. Players ranked 9 to 24, however, played most of their shots with both feet parallel to the sidewall (42%), much higher than the top (19%) and lower (21%) ranked players. In the back right corner (forehand) the pattern was more similar for all groups although the top 8 players hit the ball off the (supposedly) incorrect foot 71% of the time, as did the other two groups 64% (9 to 24) and 67% (25 to 50). Discussion These findings suggest that players are able to perform better (according to conventional coaching practice regarding feet positioning) on their backhand side compared to the forehand side. However given the high proportion of so-called incorrect feet placements on both sides of the court it is unlikely that these elite players consider the traditional feet positioning model to hold true for all situations. The determinants for feet positioning are not known but the time available to play the shot is likely to be a significant factor. Further detailed analysis is needed to determine which parameters affect feet placement and to determine if the coaching manuals currently used to teach squash need updating. References Vučković, G., Perš, J., James, N. and Hughes, M. (2009). *J Sports Sci*, 27, 8, 863-871.

### **VIDEO-ANALYSIS AS DIDACTIC AND EVALUATION TOOL IN THE TECHNICAL LEARNING IN YOUTH FUTSAL**

Polidoro, L., Bianchi, F., Raiola, G.

*University of Salerno- Italy*

Introduction Futsal is a sport where the time variable is very important in the control of motor learning process (G. Raiola, 2012). It is particularly suitable to the development of motor skills unique to the technical characteristics of the game, such as the rules and the field of play for which the time to analyze, evaluate, elaborate, and execute is limited when compared to other team sports (Schmidt & Wrisberg 2008). Futsal is particularly adapted for children, ages 8-10 years, who are learning the specific techniques of play. Furthermore, motor imagery, through the proposition of visual image, may be learned if it is included in the weekly educational planning. The purpose of the study is to verify and compare if members of a sample, exposed to the video projection of model videotapes are better at learning specific techniques (Menichelli R., 2010), compared to a control group, who has not seen any videotape. Methods The sample group will meet at the sports facility 30 minutes before the control group. The team will be exposed to the video projection of three technical gestures, chosen from the game fundamentals: 1. Control of the ball: oriented ball control with the bottom foot (called 'stop by sole'); 2. Driving the ball, moving the ball with the sole; 3. Shooting: tip shoot After they watched the videotapes, the sample group will reproduce the same technical skills observed in videos during the workout, and they will be recorded by camera for next assessments. Results After analyzing the data from the first phase and dividing the group into two homogeneous micro-groups, we compared the findings of the second phase of evaluations, highlighting the improvements of each members of the sample in comparison to the starting point. By reading the data, it was also possible to appreciate the clear improvement in the average of the sample group (+7.4%) compared to the control group (+2.1) tracing a hypothetical trend for the third and last evaluation phase. In particular, the second assessment showed a significant improvements, particularly in players who showed a good skills level already in first phase (+11%). Discussion The data could be explained by a higher relevance of the 'ideomotor' system especially in players who have a good basic technical ability and therefore less correction in the adaptation phase of technical gestures, after viewing the executive technician model. The data trend suggests further improvements and technical refinement in those who have shown significant progress in the second stage of evaluation, with a remarkable difference between the sample group and the control group (> 5%). ### **EMG RESPONSES TO DYNAMIC MUSCLES ACTIONS PRIOR TO A SPRINT START**

Smirniotou, A., Kesoglou, I., Paradisis, G., Argeitaki, P., Pillianidis, T., Tsigkanos, G.

*Kapodistrian University of Athens*

Introduction The efficiency of a sprint start depends on the execution of explosive and powerful movements. Improved temporal sequencing of muscle activation and enhanced fast twitch fibre recruitment may contribute to optimal sprint start (Smirniotou et al., 2012). Prior to the starting action the production of a more powerful muscular contraction may maximize motoneuron excitability which expected to benefit the sprint start (Ross et al., 2001). Therefore, the purpose of this study was to investigate the EMG activity of selected lower limb muscles during "jumping" and "skipping" as two common powerful functions prior to a sprint start. Reaction time and 2,5m time were also recorded. Methods 7 recreational sprinters performed 4(2\*2conditions) maximal 10m sprints starts on a running track. Randomly, each subject performed 2s of tuck jumps (1st cond.) or quick skipping (2nd cond.) prior to each sprint start. 20min interval was set between the two conditions. Surface electrodes used to recorder the EMG activity from gastrocnemius lateralis (GA), bicep femoris (BF) and

rectus femoris (RF) muscles of the right leg. The amplified EMG signals were low pass filtered (10Hz). EMG signals magnitude was quantified using the average root mean square (RMS) value of the full wave rectified EMG activity. A 200ms moving window used to analyze the data between the onset and the offset of EMG activities. The EMG activity was accessed by using the DELSYS EMG system, Myomonitor IV wireless Transmission (Delsys Inc). Reaction time (RT) was measured (ReacTime, Lynx USA) as well as times at 2.5m was recorded using photocells (Microgate, It.). Statistical methods were employed, included means and standard deviation ( $\pm$ SD). RMS values for GA, BF and RF were considered for analysis. MANOVA used to investigate the interactions of the variables. All data were analyzed using SPSS 20.0 Results There was not statistically significant difference between tuck jumps and quick skipping. RF activity and RT trend to be different between the two conditions. EMG activity of RF during tuck jumps was  $136.75 \pm 45.6$  mV in contrast to quick skipping which was  $180.35 \pm 75$  mV. Furthermore RT was  $0.216 \pm 54$  s post to tuck jumps and  $179 \pm 41$  s post to quick skipping condition. Discussion The results of the study indicate that tuck jumps and quick feet provide similar activation level. Therefore tuck jumps is a dynamic action that incorporates a slow stretch shortening cycle (SSC) in contrast to quick feet that emphasizes more on quickness (fast SSC) (Schmidtbleicher, 1992). Thus, further research needs to investigate the optimal type of activation prior to a sprint start. Ross A et al (2001) Sports Med 31(6):409-425 Schmidtbleicher D (1992) Training for power events. pp. 169-179 Smirniotou et al (2012) Book of Abst., ECSS Bruges, Belg.

## PERFORMANCE ANALYSIS OF AEROBICS GYMNASTIC IN TEACHING METHOD AND EVALUATION APPROACH TO IMPROVE DIDACTICS

Giugno, Y., Di Tore, A., Raiola, G.

*University of Salerno*

**Introduction** The Aerobic Gymnastics is a complex sport and the movements are performed continuously, intensely at high speed with the musical accompaniment. Gymnastics may be globally defined as any physical exercise on the floor or apparatus that promotes endurance, strength, flexibility, agility, coordination, and body control. One can directly assess the overall performance to the naked eye, but is not able to assess the individual elements of movement and technical aspects. The video analysis indirectly, through the ability to stop and review the various stages of movement several times, facilitates the evaluation. The aim of this study is to verify whether the use of video analysis in daily training activities can facilitate the evaluations of the coaches. 'The performance analysis can enable the accurate analysis and explanation of the evolution and dynamics of a historical phenomenon and motor sports'. Methods 4 female athletes will be evaluated using the tabs in the Code of Points with annotations for deductions (0.10 slight error, mean error 0:20, 0:50 fault) and after 30 sessions in two different ways. The athletes are divided into two groups: 1) Control which continues to be evaluated with the traditional forms, 2) Experimental which is evaluated through the use of two cameras, one placed opposite to the athlete and the other one on the side, which apply the points of repelle on specific anatomical points. At the end all the athletes will be traditionally evaluated and one will compare the assessments to highlight the difference between the two groups. Results The athletes in the experimental group improved at 0.30 and 0.40 compared to initial assessments made without the video analysis and compared to the control group. The experimental group compared with the control group has a better final evaluations in the matter of execution and cleanliness of the gesture. Discussion Probably the rapidity of correction of the act requested by the coach after watching the video and the subsequent execution of the athlete support proper execution. This new training methodology may be also tested on athletes, in order to allow a self-assessment through the measurement of the movie and the subsequent correction of performance so that it can better understand the errors committed and implicitly suggest the correction. The simultaneous use of video analysis by athletes and coaches during the training could further improve the result.

## COMPOSITE MODEL OF UNIVERSAL K-1 FIGHTER SUPER HEAVYWEIGHT

Kapo, S., Radjo, I.

*Faculty of Sports and Physical Education, University of Sarajavo*

**Introduction** Martial arts, as part of total sport specific human movement articulation are special phenomenon with enormous number of elements from different anthropological sphere (Shim, 2003). This article is directed toward identification of parameters that explain real situational positioning of all fighters that come to K-1 Grand-prix tournaments in Tokio 1993-2004 Methods Several competent judges, with extra precise methodology that includes detailed and repeated overview of DVD recorded matches, register 102 types of situation aspects. Each fighter that came to Tokyo was described with each of 102 definitions, which become variables. Data were analyzed with special algorithm (Bonacin 2006.), that allows initial data rescaling to universal bounds (1 – 5). For each entity data were summarized. We register 8 fights on each of 12 tournaments and get 96 entities described with 96 individual parameters derived from 102 variables. Each entity was marked with specific X number (1-96) for numeric or graphical position determination. We calculate level (L) of entity on specific tournament with formula  $L = X - \text{INT}((X-0.5) / 8) * 8$ . Calculated L represents position like in 1993. Year of Grand-prix tournament was easy calculated as  $Y = 1993 + \text{INT}((X-0.5) / 8)$ . Results and discussion Using the simple operation of multiply associating of these values of intensity with oblique saturation of previous step results in a unambiguous model of the universal K-1 fighter with maximized features that will ensure success in combat. Such an operation frames the mass, height and experience just as the most important, and equally almost all other tactical and psychological characteristics with projections at level higher than 0.90. With slightly lower intensity, but still very high are also technical characteristics, whose intensity ranges between 0.70 and 0.88. The values of some technical actions and attack types (0.40-0.65) are mediocre, while of the lowest values are rare kicks, unsportsmanlike moves, injuries and other very specific actions. (< 0.40). Specifically, it has been noticed that there are indeed 4 levels for practicing this sport and that these levels are superior to each other, as well as that each of mentioned levels represents really just an inevitable content that each K-1 fighter must immanently integrate in its widest repertoire of behaviors. Conclusion The results show that the constructed composite can be described as: brash, aggressive, skilled and dangerous. These four characteristics must be possessed by each fighter aiming to be successful, as they represents the immanent part of fighter and equally, the characteristics integrated in developing phases influenced by sport training processes. **MEASUREMENT OF LIMBS' ACCELERATION IN TABLE TENNIS USING WIRELESS SENSORS NETWORK SYSTEM**

Chen, Q.

*China Institute of Sport Science*

**Introduction** In Table Tennis, some coaches are eager to acquire the information of player limbs swing's force during the training. But it is difficult to collect the real data of force directly during their movements. However, the acceleration data can be measured easily, and used to assess player's force. The Wireless Sensor Network technology is applied to develop a system to meet the requirement of Table Tennis Coaches. **Methods** Our design is to measure the acceleration data of the athletes' arms while they are swinging. By using of the acceleration data, the upper limbs' force can be evaluated. For example, a three-axis acceleration sensor node is fixed around player's wrist, when they swing upper limbs, the acceleration data are collected. According to Newton's second law  $F=ma$ , obviously, the more the acceleration of wrist is, the more force will put on the shot. **Results** The Wireless Sensor Network technology's main features include the intelligent collection node, automatic network organization, self-management according to the protocols, programmable, wireless mesh network route, two-way signal transmission, etc. This developed measurement system by this MSN technology, more than two acceleration sensor nodes could be available inside this system and could be fixed on different positions of players' limbs to acquire the acceleration data. And not only the acceleration data, but also many other kind of digital signals, such as video signals, pressure force, and angular acceleration. In a test for China Table Tennis male player by this system, the maximum acceleration of his left wrist is 20.62g. **Discussion** Although this system's idea originate from the requirement of Table Tennis, the second prototype has been used in tennis, discus, shot. Due to the miniaturization and lightweight of the sensor node, and multi-nodes available in networking, more than one position's acceleration of players' body can be collected synchronously. And the players' movement video shot by DV and Basler high speed camera could also be collected synchronously in this system for players' action performance analysis. **References** Halit Eren.(2008). ## Health and Fitness

**PHYSICAL ACTIVITY QUANTIFICATION IN ELDER WOMEN.**

Gallo-Salazar, C., Ruiz-Vicente, D., García-Pastor, T., Salinero, J., Pérez-González, B., Mediavilla, L.

*CAMILO JOSE CELA UNIVERSITY*

**Introduction** In view of the society's life expectancy increasing, mostly common in women, and the benefits provided by regular physical activity in elder people (Aoyagi & Shephard, 2009), new physical activity initiatives and programs are being taken into consideration. The aim of the study was to make quantification of the physical activity made by elder women and to measure the impact of a structured physical activity program over that physical activity. **Method** A quasi-experimental ex-post-facto design was used in this study, with a sample of 76 women aged 56-84 years (72.01 ± 5.28) from Alcobendas. Taking part, or not, in a structured physical activity program was included as independent variable as well as the age (plus-70 group, under-70 group) and the body-mass index (BMI). Physical activity levels were measured by means of triaxial accelerometers during a whole week. **Results** Women on structured physical activity program showed higher physical activity levels than sedentary women on weekdays (271608 ± 116937 vs. 191816 ± 83865 counts;  $P < 0.05$ ). The number of moderate-intensity physical activity minutes of plus-70 group was significantly higher than under-70's in both weekdays (40,30 ± 27,00 vs. 28,1 ± 22,20 min/day;  $P < 0.05$ ) and weekends (34 ± 26,40 vs. 21,9 ± 21,60 min/day;  $P < 0.05$ ). No significant differences were found ( $P > 0.05$ ) regarding the body-mass index. **Discussion** Women enrolled on structured physical activity programs were physically more active than sedentary counterparts. Besides, elder women were more active in the weekdays than in weekends, as previously noted by other authors (Togo et al., 2008). The amount of moderate-intensity physical activity was lower on elder women by increasing age. **References** Aoyagi, Y., & Shephard, R. J. (2009). **THE EFFECT OF REGULAR PHYSICAL EXERCISE ON BODY COMPOSITION AND PHYSICAL FITNESS IN MIDDLE-AGE ADULTS COMMUNITY**

Martins, P.F.O., Camargo, V.T.N., Silva, V.L.B., Momesso, C.M., Cury-Boaventura, M.F.

*Institute of Physical Activity and Sports, Cruzeiro do Sul University*

**Introduction** The prevalence of obesity has markedly increased in many parts of the world becoming a global epidemic and has been associated with chronic disease such as cardiovascular disease and diabetes. The main causes of obesity are related to nutritional imbalance and lack of regular physical activity. The present study aimed to investigate the effect of Physical Exercise Program (PEP) on body composition and physical fitness in middle-age adults community. **Methods** One hundred thirty one middle-age adults (81,67 % female and 18,32 % male) were randomly recruited. The average age was 50 ± 4 years old. The PEP was performed during 50 minutes in low to moderate intensity for 6 consecutive months, three and two times a week in the following modalities: hydrogymnastics, swimming or gymnastics. We evaluated body mass, height, upper limbs circumferences (forearm, arm, thorax, waist and abdomen), lower limbs circumferences (hip, thigh and calf) (Lohman et al., 1988), percentage of fat mass (Lukaski, 1987), number of arm flexion in 1 minute (ACSM, 2006), lumbar and lower limbs strength and percentage of maximum oxygen consumption estimated by 1 mile test (Kline et al., 1987) before and after 6 months of PEP implantation. **Results** The participants evaluated were classified: 28 % eutrophic, 42 % overweight and 17 % obese I, 9 % obese II and 3 % obese III. The PEP reduced the percentage of fat mass, circumferences of upper limbs (except left forearm) and hip by approximately 5 - 10 % ( $p < 0.05$ ). In addition, PEP induced increase lower limbs circumferences by approximately 1 - 3 %. We also observed an improvement in the number of arm flexion (16.5 to 19 repetition), lumbar strength (45.3 to 50 kg), lower limbs strength (42 to 56 kg) and percentage of maximum oxygen consumption (15 to 28 %) ( $p < 0.05$ ). **Discussion** The PEP implantation reduced

upper limbs circumferences, percentage of fat mass decreasing the risk to cardiovascular disease and increased in physical fitness that also benefit their quality of life. In conclusion, the improvement of body composition and physical fitness in middle-age adults demonstrate the importance of implementing and keeping up health promotion and physical activity programs in community with high prevalence of overweight and obese. ### ECG PARAMETERS CONCATENATION DURING BICYCLE ERGOMETRY

Vainoras, A., Slapsinskaite, A., Sendzikaite, E.

*Lithuanian University of Health Sciences*

**Introduction** One of the problems to apply complex system theory is the difficulty to understand how different systems of human body or different fractal levels in one system interacts [1]. Adaptation of human body to physical load is an actual task in sports and clinical medicine. Frequently bicycle ergometry test is used to evaluate the functionality of the human body. The aim of work was to evaluate interconnections between some ECG parameters [2] – RR, JT and QRS intervals, to reveal differences in adaptation to load in sportsmen, sprinters (S) and physically inactive (N) groups using new matrix analysis technology. Differences in the changes of the concatenations between intervals (RR;JT) and (RR;QRS) can reveal features of adaptation to load in different groups. **Methods** The standard stress test method of bicycle ergometry work was used. Only males participated in the experiment that consisted of the provocative incremental protocol where the maximal load was 250 W (50 W/min). The evaluation of cardiovascular system reactions was made with the ECG analysis system "Kaunas – Load". The investigated contingent consisted of 10 sportsmen, sprinters (S) ( $M \pm SD = 20.1 \pm 2.23$ ), and physically inactive (N) ( $M \pm SD = 22.5 \pm 1.7$ ) groups. The analysis of concatenations [2] of these ECG parameters – RR and JT, RR and QRS during 5 minutes of the load and 5 minutes of recovery was made. **Results** In both groups during the load the concatenation of (RR/JT) was increasing while the concatenation of (RR/QRS) was decreasing. In the observation of groups dynamics observed differences were – the concatenation of (RR/JT) in the group S was increasing higher ( $M \pm SD = 0.11 \pm 0.02$ ) comparing with group N ( $M \pm SD = 0.08 \pm 0.01$ ). The concatenations of (RR/QRS) in N ( $M \pm SD = 0.42 \pm 0.09$ ) group were decreasing more comparing with S ( $M \pm SD = 0.23 \pm 0.07$ ) group. **Discussion** Interrelation (RR;JT) could be related to activation of body metabolic features it show higher adaptation for S group than for N ( $p < 0.05$ ). This concatenation could serve as an indicator for sportsmen functional state evaluation. Concatenation (RR;QRS) could reflect interrelation between regulatory systems and sportsmen, S group keep it in more stable position than N group (difference between S and N groups,  $p < 0.05$ ). This parameter can be used for evaluation of heart function stability during high loads and to follow up persons overtraining effects. **References** 1. Bruce, J. W. *Where Medicine Went Wrong. ### EFFECTS OF PHYSICAL ACTIVITY, GENDERS AND BMI CATEGORIES

Alves, D., Martins, R.A.

*Universidade de Coimbra*

**Introduction** Obesity and sedentary behaviors are two universal concerns and its consequences raise several questions on the application and physical activity programs, as well as its impact according to Body Mass Index's (BMI) categories and gender. **Methods** The sample was comprised by 39 participants, with ages between 40 and 75 years old ( $60 \pm 8.9$  years). 25 were women and the remaining 14 male. The intervention program was called by Physical Activity Initiation Program's (PIAF), and comprised 2 weekly sessions, during 8 weeks focusing on the reduction of the cardiovascular risk factors. The data was analyzed with statistics correlation methods and multivariate comparisons, with software SPSS. **Results** At the end of the PIAF participants had reductions on the waist ( $0.001^{**}$ ), hip ( $0.032^*$ ) and abdominal circumference ( $0.000^{**}$ ), increased cardiorespiratory fitness ( $0.025^*$ ), HbA1c ( $0.042^*$ ) and HDL-C ( $0.021^*$ ). Men had higher distance in 6 minute walking test ( $0.005^{**}$ ), higher cardiorespiratory fitness ( $0.005^{**}$ ) and waist/hip ratio ( $0.000^{**}$ ). Between BMI categories, differences were found in the following variables: diastolic arterial pressure ( $0.003^*$ ), resting HR ( $0.037^*$ ), and LDL-C ( $0.022^*$ ). **Discussion** The results agree with others, specifically with the increase of  $VO_{2max}$  in about 0.29MET in two months' time. This increase seems to be related with other variables of the cardiovascular health, such as abdominal girth, systolic arterial pressure, triglycerides, glycaemia and HDL cholesterol (Lee et al., 2010). Literature suggests benefits on HbA1c after 6 months of exercise (Hansen et al., 2009). The short duration of the PIAF (2 months) could contribute to explain the lack of positive effects, as well as the absence of dietary control. Lastly, the literature shows an influence in the BMI categories (Mekary et al., 2010) and in gender (Jekal et al., 2001). Though the results are in line with each other, in the variance analysis, none of the factors, by themselves, explained the differences found. More studies are necessary to understanding how the BMI categories and the gender can mediate the impact of exercise on cardiovascular risk. **References** Hansen D, Dendale P, Jonkers RAM, Beelen M, Manders RJF, Corluy L, Mullens A, Berger J, Meeusen R, Van Loon LJC (2009). *Diabetologia*, 52:1789-1797 Lee DC, Artero EG, Sui XC, Blair SN (2010). *J Psychopharmacol*, 24 (Supl. 4), 27-35. ### EFFECTS OF A HYPOPRESSIVE METHOD TRAINING ON WAIST CIRCUMFERENCE, WAIST-HIP RATIO AND BODY MASS INDEX ON WOMEN

Soriano-Segarra, M.L.I., González-Millán, C., Carmona, L.

*Camilo José Cela University*

**Introduction.** Body mass index (BMI), waist-hip ratio and waist circumference have been used in recent decades as predictors of cardiovascular risk. The Abdominal Hypopressive Technique (AHT) is a method created in the 80's by Dr. Marcel Caudriez in the field of postpartum rehabilitation to improve the pelvic floor muscles (Bernardes et al., 2012), although other potential effects may include a reduction in WC. **Objective.** The aim of this study was to analyze the effects of hypopressive training on waist circumference as a ways to recommend it also as a method for modifying cardiovascular risk preserving pelvic floor muscles in women. **Methods.** We performed a randomized, controlled, evaluator-blinded, intervention study of two months duration in 42 women, 21 per group (mean age 42, SD 9). Women in the study group were given 3 30-minute sessions of AHT per week on alternate days (Mon-Tues-Thurs) for eight weeks. Controls were indicated to continue normal life. All patients were examined at baseline and after two months. The effects variables were the difference in

waist circumference, waist-hip ratio and BMI, before and after 2 months of follow-up. Measurements were taken by an investigator blinded to the assigned group. The mean difference was compared between groups with Student's test and 95% confidence intervals (CI) were estimated for the differences of means. Results. Subjects were comparable at baseline in terms of age, BMI, waist-hip ratio and waist circumference. After 2 months, the AHT group had reduced its waist circumference in -2.54 cm (95% CI: -1.85 to -3.24), while it was no evident or increased in the control group, being the difference of means -3.39 cm (95% CI: -4.35 to -2.43;  $p < 0.001$ ). The same occurred with the waist-hip ratio [differences of means -0.03 (95% CI: -0.03 to -0.02;  $p < 0.001$ )]. BMI showed no difference between groups [differences of means -0.12 (95% CI: -0.31 to 0.06;  $p = 0.179$ )] Discussion. Waist circumference and waist-hip ratio, but not BMI, may be significantly reduced by hypopressive exercises for 2 months. The effect on other cardiovascular risk factors and on general cardiovascular fitness and health outcomes would need further study, but our results support the benefit of a women specific training on the reduction of waist circumference while preserving pelvic floor. ## EXERCISE BEHAVIOR AND SCHOOL GRADES IN JAPANESE JUNIOR HIGH SCHOOL STUDENTS

Nakajima, T., Morita, N., Sagawa, M., Yamatsu, K.

*Hokkaido Institute of Technology*

Introduction: Over the past few years, numerous attempts have been made by scholars and educators to demonstrate the relationship between the physical fitness and the academic performance (Hillman et al., 2008). What seems to be lacking, however, is to consider the school grades of each subjects as the actual academic performance. The purpose of this study is to determine whether the exercise behaviors were associated with school grades as the academic performance in Japanese students. Methods: Participants were 285 (female: 47.4%, mean body mass index [BMI]: 19.4+/-3.4) 1st grade (7th grade in USA style) students of public junior high school near Sapporo area in Japan. All students and their parent completed the questionnaires about the exercise behavior. BMI and academic performance (school grade) were received from school records. The sum total of the 9 subjects grades (Japanese, social studies, math, science, English, music, arts, home economics/vocational-technology, physical education) were used as academic performance score. Results: Using ANCOVA that controlled for several covariates (gender, BMI, household income, mother's education), exercisers every day (grades: 32.9+/-5.6) had significantly better school grades than exercisers less than 2 days per week (29.2+/-5.9,  $p < 0.05$  after bonferoni modification). Also, exercisers more than 3 hours in weekend (33.2+/-5.4) had significantly better school grades than exercisers less than 1 hour in weekend (30.5+/-6.2,  $p < 0.05$  after bonferoni modification). No difference between more exerciser and less exercisers in weekday was found. Conclusions: These results suggest that more exercise frequency and more weekend exercise practice may have an affect on the school grades as the academic performance among Japanese junior high school students. Acknowledgements: This study was supported by Challenging Exploratory Research (ID: 12852590) and Scientific Research B (ID: 12863511) from Grants-in-Aid for Scientific Research in Japan. ## THE EFFECTS OF RESISTANCE, AEROBIC AND COMBINED TRAINING AND DETRAINING ON MUSCLE PERFORMANCE AND BLOOD LIPID PROFILE IN CORONARY ARTERY DISEASED PATIENTS

Panayiotou, G.1, Volaklis, A.K.2, Tokmakidis, P.S.2, Douda, E.2, Toubekis, G.A.3, Smilios, I.2, Makris, A.1, Jamurtas, A.4

*1: European University Cyprus (Cyprus), 2: Democritus University of Thrace (Greece), 3: National and Kapodistrian University of Athens (Greece), 4: University of Thessaly (Greece)*

Introduction Every year an increasing number of individuals are diagnosed suffering from coronary artery disease while this disease is the number one cause of death worldwide. For combating the risk factors of coronary artery disease many investigations recommended as important factors the exercise training and the avoidance of sedentary life style (Tully et al., 2005; Booth et al., 2012). Methods 60 males with coronary artery heart disease were randomly assigned into the resistance exercise group (n=11), the aerobic exercise group (n=18), the combine exercise group (n=16) and the control group (n=15). The three exercise groups carried out 8 months of resistance, aerobic or combine training consisting of 3 exercise sessions per week. Before the beginning of the study, after 4 and 8 months of training and after 1, 2 and 3 months of detraining knee extensors peak torque, serum triacylglycerols (TG), total cholesterol (TC), high-density lipoprotein cholesterol (HDL), low-density lipoprotein cholesterol (LDL) were measured. Results By the forth and eighth month, all training modes increased muscle strength and favourably affected blood lipid profile compared to the control group. More specifically, after 8 months of training, resistance, aerobic and combine training increased knee extensors torque by 40.3%, 7.7% and 24.8% respectively. In addition, resistance exercise decreased TG, TC and LDL by -10.8%, -9.4% and -6.5% respectively and increased HDL 8.4%. Aerobic exercise decreased TG, TC and LDL by -13.6%, -9.1% and -6.6% respectively and increased HDL 9.5% while combine exercise decreased TG, TC and LDL by -16.1%, -12.6% and -8.2% respectively and increased HDL 8.9%. In contrast, after the detraining period, a reversed action occurred in muscle strength and blood lipid profile. Discussion The purpose of the present investigation was to compare the effects of three types of chronic exercise on muscle performance and blood lipid profile in aged patients suffering from cardiac artery disease. It was found that muscle strength has been increased mainly by resistance and combined chronic exercises, with the former to cause the greatest alterations as it was expected. Lipid profile indices were positively affected by all training modes of training. However, combined exercise appears to be the most effective mode of exercise for inducing favourable changes on blood lipids profile. ## 1-YEAR WORKSITE STRUCTURED EXERCISE PROGRAM IMPROVES ACTIVE BEHAVIOR ESPECIALLY AT VIGOROUS INTENSITY

Jimenez, A.1,2, Herraes, P.2, Duarte, A.2, Westerbeek, H.1, Garcia, O.2

*1 Victoria University (ISEAL), 2, Catedra de Investigacion Sanitas Wellbeing-UEM, European University of Madrid*

Introduction Addressing diet, physical activity and exercise in the workplace environment has the potential to improve health status of workers; contribute to a positive and caring image of the company; improve staff morale; reduce staff turnover and absenteeism; enhance productivity; and reduce sick leave, health plan costs and workers' compensation and disability payments. Structured exercise

interventions are particularly effective to improve musculoskeletal fitness levels and as a result health and quality of life, but evidences coming from long-term specific interventions delivered at the worksite are very limited. Methods A group of employees (n=200) completed a 1-year structured exercise program (SEP) at the worksite organized with a linear periodization model, in 4 mesocycles of 12 weeks each one. Participants were randomized in one of the 4 different groups: control group (n=46), 2-days per week (n=51), 3-days per week (n=49), and more than 3-days per week (n=54). A comprehensive fitness test protocol was applied at the beginning, after 6 months of intervention and at the end of the year, after proper familiarization process before the initial testing. Testing included a complete health screening, fitness levels, lipids profile, fasting glucose, physical activity reported by IPAQ and directly measured by accelerometer (Mywellness key, Technogym, Forly, Italy), perceived wellbeing (SF-36), job performance and job satisfaction. The specific fitness testing included VO2 max test (modified Balke protocol), maximal strength (leg press, lat pull and bench press) and flexibility (sit and reach). Results Total activity (MET-min/week) showed a significant reduction in the inactive group ( $p < 0.05$ ), while there were not significant differences within the active groups. Regarding potential differences identified in the type of PA, it is especially important the fact that vigorous PA increased in all active groups, but only significantly in the 3-days/week SEP, while we found a significant reduction in moderate PA in all active groups ( $p < 0.05$ ), and non-significant changes in low intensity PA ( $p > 0.05$ ). Total sedentary behaviour/sitting time increase in the inactive group, but not significantly, and it was significantly reduced in all active groups, especially in the 3-days/week ( $p < 0.05$ ). Discussion A strong commitment to integrate PA and exercise into the lifestyle is challenging for the most of the sedentary population, and despite the multiple benefits supported by evidences, time limitation is always a critical perceived determinant factor for individuals to engage. Previous analysis of the same study reported improvements in cardiovascular risks factors and perceived wellbeing in the active groups, without significant differences based on the frequency of exercise (2-days, 3-days or more than 3-days/week). Our study shows how exercise could provide a more effective use of the time allocated for PA, helping the participants to modify intensity and duration to optimize health benefits.

### APPLICABILITY OF SEGMENTAL BIO-ELECTRICAL IMPEDANCE ANALYSIS FOR ESTIMATING SKELETAL MUSCLE VOLUME IN PREPUBERTAL CHILDREN

Ohta, M.1, Midorikawa, T.2, Hikiyama, Y.3, Masuo, Y.4, Sakamoto, S.4, Kawakami, Y.4, Kanehisa, H.5, Fukunaga, T.5

1: Kanazawa Seiryō University, 2: J.F. Oberlin University, 3: Chiba Institute of Technology, 4: Waseda University, 5: National Institute of Fitness and Sports in KANOYA

Background The skeletal muscle volume (SMV) is closely related to physical functions, and it increases rapidly during growth stage (Fukunaga et al 1989). There is an increasing interest in the use of bioelectrical impedance analysis to assess body composition (Miyatani et al. 2000, Ishiguro et al. 2006). However, information about the applicability for predicting SMV in children is limited (Fuller et al. 2002). Objective To investigate whether segmental bio-electrical impedance (BI) analysis is usefulness for predicting the total and segmental skeletal muscle volumes in prepubertal children. Methods Ninety-five healthy Japanese children (58 boys and 37 girls, mean age 10.5 yr) volunteered under permission of their parents to participate in this study. Contiguous MRI images with a 1-cm slice thickness were obtained from the first cervical vertebra to the lateral malleoli. SMV was obtained by summing digitized cross-sectional area for each body segment, i.e., arm, trunk, thigh and lower leg, with the separation between segments based on anatomical landmarks visible in the scanned images. The electrical impedance for each body segment was measured by a BI apparatus (500 $\mu$ A, 50kHz). BI index was calculated as the ratio of the segment length squared to the impedance. Results and Discussion The total SMV measured by MRI, was 8604.5 $\pm$  2551.1 mm<sup>3</sup> for the boys and 7671.2 $\pm$  2609.6 mm<sup>3</sup> for the girls. Ratios of the SMV of arms, trunk, thighs and lower legs to total SMV were 9.5%, 36.0%, 40.6%, and 14.0%, respectively, and had no significant sex-related difference. The total and segmental SMV were significantly correlated with the related BI index with the correlation coefficients of 0.775 to 0.903 ( $p < 0.01$ ). This result agrees with the findings of the previous study (Fuller et al 2002). There was no significant difference between the measured and estimated SMV values. The SEE expressed relative to the mean FFM were 6.7 - 8.2%. Thus, the current results indicate the applicability of BI analysis for predicting SMV in children. However, because significant systematic error was found in the Bland-Altman plot, further study is needed to clarify the factors producing the errors of estimate for developing prediction equation for SMV in children. ### EFFECTS OF PHYSICAL EXERCISES IN 2 TYPE DIABETES PATIENTS ROULE OF WHOLE BODY VIBRATION

Lucchetti, C., Nart, A., Biancalana, V.

Sez. Scienze Motorie, Università degli Studi di Urbino

Introduction International literature showed aerobic and resistance training, used in therapy of diabetes, are able to improve both metabolism and incidence of diabetes. This is tanks to more sensibility of muscle cells to the insulin. This presentation is a 12 weeks study on 2 type diabetes patients working with aerobic and resistance training. Patients were divided into 2 groups: the first one worked with aerobic training and Whole Body Vibration, the second one with aerobic and resistance training. Methods A total of 21 patients, 12 males and 9 females, were recruited. They were divided into 2 groups: Vibration Group VG n= 10, Resistance Group RG n= 11. People had a specific activity program: 1 hour session for 3 times in a week. Each session had the following structure: VG: 15 minutes aerobic training (30-40% HRR during 1st month, 40-50% 2nd month, 50-60% 3rd); 6 minutes Vibration session in the 1st month, 9 min in 2nd, 12 min in 3rd; 15 minutes aerobic training (30-40% HRR in 1st month, 40-50% in 2nd, 50-60% in 3rd); 6 minutes Vibration session in the 1st month, 9 min 2nd, 12 min 3rd. Total 30 min aerobic exercise and 12, 18, 24 min of Vibration session. Each aerobic training was on treadmill and bike (50 %). Each vibration session (Vertical Vibration Platform) had 6 different static iteration with breaks between exercises: Squat, Lunge R/L, Biceps Curl, Triceps Dip, Push Up, Abdominal Crunch. RG: 30 minutes aerobic training (30-40% HRR during 1st month, 40-50% in 2nd, 50-60% 3rd); Stretching break; 30 min of Progressive Resistance Training. The exercise engaged pectoral, dorsal and abdominal muscles in the 1st session; quadriceps, knee flexors, abdominal muscles in the 2nd session; pectoral, dorsal, abdominal in the 3rd. Work was 60 % of one repetition maximum during 1st month, 65% in 2nd and 70% in 3rd. Results All patients ended training. Results were: Group Weight T0 T1 BMI T0 T1 VO2max T0 T1 HbA1c T0 T1 RG 90,18 88,31 32,29 31,95 18,04 19,02 7,61 7,39 VG 93,26 90,51 32,94 31,99 31,31 37,28 8,56 7,88 All items are better in T1 then T0. Patients felt better in daily live activities and had an high satisfaction in training. Statistic Analysis: Values are statistically significant: VO2max RG/VG .000; HbA1c RG/VG .083. Discussion VG went better then RG to demonstrate WBV is a good instrument with benefit no more weights to improve exercise. WBV has no abnormal stress of bones, ligaments, joints and short training sessions too. References American Diabetes Association Guide Lines (2006). **RELATIONSHIP BETWEEN PHYSICAL ACTIVITY BEHAVIOR AND HEALTH RELATED RISK FACTORS IN JAPANESE ADULTS**

Kimura, Y.1, Mizunuma, T.2, Ikegami, T.2, Ohki, K.3, Nakagawa, N.4, Hisatomi, M.1, Yamazaki, S.5

*1:Research Center for Fitness and Health Sciences, 2: Saga Univ., 3: Showa Women's Univ., 4: Sanno Univ., 5: Ishinomaki Senshu Univ.*

Introduction Current evidence suggests that physical activity (PA) levels, time spent in sedentary behavior (SB) and sleep duration are all independent risk factors for health status and chronic diseases (1, 2). The aim of this study is to assess the relationship between PA, SB and sleep and various health related risk factors in Japanese adults. Methods Of the 65 participants, 42 (64.6 %) were women. Mean±SD age was 60.6±7.9 yrs., and the age range was 54 to 80 yrs. Mean body mass index (BMI) was 25.1±2.8 kg/m<sup>2</sup>. Participant's height, weight, BMI, % body fat, waist circumference, blood pressure (BP), bone mass (Quantitative Ultrasound method, AOS-100NW, ALOKA) and lower extremity muscle strength (3) were measured at the outset. PA levels were measured using a triaxial accelerometer (Active style Pro HJA-350IT, Omron Healthcare Co., Ltd) for 7 days. Associations between time spent in SB, and time in light intensity AP (LIPA, 2.0–2.9 METs; metabolic equivalents) and moderate-to-vigorous PA (MVPA, 3 METs or more), and health related risk factors were analyzed using correlation coefficients. Results The mean proportion of time in SB, LIPA, MVPA and sleep duration over a 24 hour period were 47%, 22%, 3% and 28%, respectively. Increased time in LIPA was associated with reduced BMI ( $r=0.06$ ), % body fat ( $r=0.05$ ), waist circumference ( $r=0.06$ ) and systolic ( $r=0.2$ ) and diastolic BP ( $r=0.2$ ) (all  $p<0.05$ ), while increased time in SB was associated with increased systolic ( $r=0.07$ ) and diastolic BP ( $r=0.2$ ) (all  $p<0.01$ ). Increased time in MVPA was associated with reduced % body fat ( $r=0.1$ ) and increased bone mass ( $r=0.2$ ) and lower extremity muscle strength ( $r=0.2$ ) (all  $p<0.01$ ). No significant associations were observed between time in bed and sleep duration with the health indicators. Discussion Although PA research often focuses on moderate and vigorous intensity activity, a new focus on SB has evolved over past year, showing that SB is a distinct risk factor for health independent of PA. On the other hand, even LIPA have been shown to have favorable health effects, at least in older adults. Lifestyle focusing on moving people from less SB to any level of intensity of PA could be useful for health promotion. From the results of this study, it is suggested that increased time spent in LIPA as well as MVPA and less sedentary time were all associated with reduced risk for health related disease. **ASSESSMENT OF SEDENTARY BEHAVIOR DURING FREE LIVING IN OBESE ADULTS**

Larsen, R.G.1, Rasmussen, C.2, Maindal, H.T.2, Overgaard, K.2

*Aalborg University [1], Aarhus University [2]*

Background: Emerging evidence indicates that sedentary time, independent of overall physical activity level, is associated with increased risk of developing cardiovascular disease and mortality. These findings highlight the need for tools that accurately quantify sedentary time during daily living. Compared with direct observations, Actigraph GT3X (AG; ActiGraph LLC, Pensacola, FL) and activPAL (AP; Physical Activity Technologies, Glasgow, Scotland) have demonstrated good capability of quantifying sedentary time [1,2]. However, these studies were limited to 6-10 hours of observations, and it is not known whether there is agreement between AG and AP measures of sedentary time when monitoring is extended to several days of free-living. In addition, little is known about the congruence between these objective measures of sedentary behavior and a self-reported estimate of daily sedentary time. Objectives: To compare estimates of sedentary time obtained from AG and AP during 7 days of free-living, and to compare these estimates with self-reported daily sedentary time in a population of obese, non-exercising adults. Methods: 16 obese (BMI: 32.3 ± 4.7 kg/m<sup>2</sup>; Mean ± SD) men and women who did not engage in regular exercise (VO<sub>2peak</sub>: 23.2 ± 4.1 mL/kg/min) volunteered for the study. The participants wore AG and AP on the right side of the hip and mid-thigh, respectively (attached by non-allergic adhesive tape), while maintaining regular activity patterns for 7 days. For AG, sedentary time was derived using the 100-counts-per-minute cut point in 10-s epochs, whereas AP provided an inclinometer-based measure of time spent lying/sitting (i.e., sedentary behavior) in 10-s epochs. After the 7-day period, participants provided a self-reported estimate of daily sedentary time. Results: Measures of sedentary time during waking hours were highest in AG (13.0 ± 1.5 hr,  $p<0.001$ ), and higher in AP (10.0 ± 1.6 hr) than by self-report (8.1 ± 3.2 hr,  $p=0.03$ ). Measures of daily sedentary time from AG and AP showed a significant correlation ( $r_2 = 0.41$ ,  $p<0.001$ ), but there were no correlations between self-report and AP or AG measures of sedentary time. Conclusion: While there was a correlation between AP and AG data, the absolute difference in sedentary time between these methodologies warrants further investigation. Although we did not include a criterion measure, our results suggest that sedentary time is underestimated using self-report. These preliminary findings further highlight the necessity of developing and implementing tools for objective assessment of sedentary behavior. **ANTHROPOMETRIC MEASURES AND PHYSICAL FITNESS TESTS: ARE THEY ALWAYS RELATED?**

Raccuglia, M.1, Bianco, A.1, Spina, S.1, Alesi, M.2, Pepi, A.2, Palma, A.1

*University of Palermo*

The association between the selected anthropometric measures such as height (H), weight (W), hip circumference (HC), waist circumference (WC), waist/hip ratio (WHR), wrist circumference (WRC) triceps skinfold (SFTR) and the test of physical fitness is well known. Physical fitness tests, such as sit-up (SU), push-up (PU) and squat (SQ) are widely used to evaluate local muscular strength and endurance performances. These tests have the advantage of predicting performance on more measures of muscular strength and endurance (Esco M.R. et al., 2008). Several other aspects are related with the results on this battery's tests and are associated in different ways according to the gender. The purpose of this study was to investigate whether anthropometric measures were related with physical fitness tests and how this fitness tests affected each other on gym's practitioners males and females. The selected health-related anthropometric variables were measured on one hundred healthy subjects (51 men and 49 women) who attended fitness centres. Sit-up test (SU), Push-up (PU) and Squat test (SQ) were also performed in this order. The subjects were asked to perform the maximum number of repetitions for each test. The battery's test also included the Appley scratch test (AS) to evaluate the mobility of the scapulohumeral joint both right (ASRG) and left (ASLF). Through the software Statistica 8.0 (Tulsa, USA) has been conducted the data analysis. A p value less than 0.05 was considered statistically significant. The sample was stratified by gender. The 51 men had an age of 27,4±10,2, height (cm) 173,6±7,0, weight (Kg) 71,5±9,2, WHR (cm) 0,96±0,04, SFTR (mm) 12,7±5,2, WRC (cm) 17,1±0,9. The 49 women had an age of 29,8±10,2, height (cm) 162,7±7,0, weight (Kg) 58,7±8,2, WHR (cm) 0,88±0,05, SFTR (mm) 22,7±6,0, WRC (cm) 15,2±1,8. Men showed a significant negative correlation between ATRG and PU -0,46, ATLF and PU -0,40, ATRG and age -0,53, ATLF and age -0,64, PU and SFTR -0,66, PU and HC -0,49, PU and WC -0,46 and a significant correlation between WRC and HC 0,60, SFTR and WC 0,57, WRC and W 0,78. Women showed a significant positive correlation between SQ and Pu 0,59, SQ and PU 0,52. This pilot study showed that the scores obtained in these tests are related

to each other and with a parameter little considered within the fitness or joint mobility. In fact, the subjects that are able to perform more reps in push ups have more negative values in ASRG and ASLF. The women's group show that the results of SQ and SU, and the scores obtained in SQ and PU are associated. The findings indicate also that the selected anthropometric variables are related with SU, PU and SQ, specially PU and SFTR as regards man. Furthermore, in man joint mobility decreases with increasing of age. The evidence provided by this study can be used by trainers and coaches in the use of SU, PU and SQ for both conditioning and muscular endurance assessment. Therefore, conditioning directed at improving these anthropometric measures would yield a more inclusive conditioning program.

## EFFECTS OF PHYSICAL EXERCISES IN 2 TYPE DIABETES PATIENTS ROLE OF WHOLE BODY VIBRATION

Lucchetti, C., Nart, A., Biancalana, V.

*Sez. Scienze Motorie, Università degli Studi di Urbino*

Introduction International literature showed aerobic and resistance training, used in therapy of diabetes, are able to improve both metabolism and incidence of diabetes. This is tanks to more sensibility of muscle cells to the insulin. This presentation is a 12 weeks study on 2 type diabetes patients working with aerobic and resistance training. Patients were divided into 2 groups: the first one worked with aerobic training and Whole Body Vibration, the second one with aerobic and resistance training. ## THE EFFECT OF GENTLE SKIN STIMULATION ON AUTONOMIC NERVOUS ACTIVITY AFTER AEROBIC EXERCISE

Hoshikawa, H., Sawazaki, K., Yoshida, S., Miyamura, T.

*Tokoha University*

[Introduction] Early recovery of parasympathetic nervous activation after exercise has meaningful effect in the field of athletic sports and healthy promotion. Hoshikawa et al. (2012) observed that non-invasive gentle skin stimulation induce early heart rate (HR) recovery after 30-s supramaximal pedaling exercise. Although this HR response would be attributed to parasympathetic nervous activation, no direct evaluation of autonomic nervous activity has been done in their study. Therefore, the purpose of this study was to investigate the effect of gentle skin stimulation on autonomic nervous activity after aerobic exercise [Methods] Seven healthy male college students were participated in this study. They pedaled at 50 W for 2 minutes and then at 75% of their maximal oxygen uptake for 5 minutes three times: with two types of non-invasive skin stimulation (SS1, SS2) and with no skin stimulation(NSS) in randomized order. Immediately after the exercise, they were instructed to be at rest at supine position for 15 minutes. The mechanical stimulation by either elastomer microcornes (SS1, Hotta et al., 2010) or no microcornes (SS2) was applied to inner thigh skin at a frequency of approximately 1 Hz for 10 min after exercise. R-R intervals during recovery period were measured by a heart rate monitor (RS-800CS, Polar). Using these R-R intervals, the root mean square of sequential deviations (RMSSD) in the time domain and high frequency power in normalized units (HFn.u.) in the frequency domain were calculated. [Results and Discussion] Although the RMSSD for SS1 and SS2 during recovery period is higher as compared with NSS, these were no significant difference among three conditions (SS1, 19.4±14.2 ms; SS2, 18.0±13.2 ms; NSS, 11.9±5.6 ms). Likewise, the HFn.u. showed no significant difference among three conditions (NSS, 27.1±25.2; SS1, 31.2±21.3; SS2, and 31.3±12.9). These results seems to be due to highly individual variation for response to skin stimulation. One of the variation factors is thought to be shorter exercise duration. Further research would be necessary for examining the validity of exercise intensity and duration used in this study, as well as individual variation to skin stimulation. ## CARDIOVASCULAR RISK FACTORS ANALYSIS ON MILITARY MEN OLDER THAN 35 YEARS OLD

Lucas, O., Raimundo, A.

*Universidade de Évora*

Introduction The increasing prevalence of cardiovascular risk factors is mainly due to habits acquired during one's life. However, military training has physical aptitude as one of its main objectives. The objective of the data analysis was to analyze the practiced physical activity, which is the most active age group and if the intensity of the physical activity influences the various parameters being analyzed. Methodology This evaluation focuses on some cardiovascular parameters like the incidence of family history, medication, smoking habits and blood pressure/heart frequency measurements; data from blood tests to examine the biochemistry; body composition through weight, height, abdominal perimeter and, through DXA, body fat; and with accelerometry the physical activity level has been determined. Results Sedentary physical activity is significantly greater during weekends instead of moderate and intense levels, which occur mainly during work-days. People who are between 45 and 54 years old are the ones who takes more anticholesterolemic medicine and also the one who show the best HDL values. The sedentary level of physical activity is positively and directly related with weight, which presents an inverse correlation with moderate physical activity, and also body fat parameters and abdominal perimeter. The highest

prothrombin time levels and sedimentation speed are associated with sedentary physical activity. However, even though HDL levels are significantly greater when intense physical activity is practiced, this also creates higher values of INR. Intense physical activity is also responsible for some ischaemic heart disease, reflecting an increase in CK-MB values. Discussion The abdominal perimeter proved to be a better predictor of intra-abdominal fat than the BMI. The youngest age group showed really high values of PCR, protein being a contributing factor for heart disease risk (Albert, Glynn & Ridker, 2003). The relation between physical activity and fat was inverse (Cederberg et al, 2011), while HDL results were better as physical activity increased (Gordon-Larsen et al, 2009). Physical activity intensity above average show little to no benefits (Aadahl, Kjær & Jørgensen, 2007), just like the increase of circulation CK-MB however, sedentary ones showed more changes when it came to coagulation. Balanced physical activity was moderate when it came to benefits/disadvantages. ### **PHYSICAL FITNESS, PHYSICAL ACTIVITY BEHAVIOURS AND WEIGH STATUS IN PRIMARY SCHOOLCHILDREN OF SOUTHERN SPAIN: THE HAFICA STUDY.**

Jimenez-Pavon, D.1,2, Gómez-Leiva, J.A.2, Moreno-Domínguez, M.A.3, Palma-Reina, M.2

*University of Zaragoza*

**Do not insert authINTRODUCTION** Physical fitness and activity behaviours have been related with weight status (WS) in national and international context using representative samples. However, specific information on schoolchildren of southern Spain is not available; and to know this information would be useful in order to promote future interventions. The present study was conducted (1) to examine the relation of physical fitness and activity behaviours with WS in schoolchildren of southern Spain providing gender-specific information. **METHODS** The current report is based on cross-sectional data from the Healthy lifestyle; physical activity, fitness and nutrition in preschool and school children (HAFICA). A total of 558 children (293 girls) with a mean age of 10.5 years and valid data for weight, height and waist circumference, whose examination took place in Córdoba (Spain) during 2009 were included. Physical fitness measurements included cardiorespiratory fitness (20m shuttle run test) (CRF), muscular strength (handgrip and standing long jump tests) and speed agility (4x10m shuttle run test). Active travel to school, sport participation and sedentary behaviours at home were registered using a self-reported questionnaire. Weight, height and waist circumference (WC) were measured and body mass index (BMI) was calculated. Multivariate general lineal models were used after adjusting for age and family affluence. **RESULTS** Boys had significantly higher physical fitness levels than girls (all  $p < 0.001$ ). No differences in activity behaviours by gender were found. The 54% and 45% of boys and girls, respectively, had 3 or more videogame consoles at home, while the 11% of boys and 5% of girls spent 7 or more hours/week playing videogames ( $p < 0.001$ ). Obese boys and girls had significantly lower handgrip relative to weight, standing long jump, speed agility and CRF performances than their normal weight peers (all  $p < 0.01$ ), except for speed agility in girls. When WC thirds were used instead of BMI categories the results did not change. The 70% of the obese girls did not use a physically active transport to school. Finally, those children participating in sport activities after school had significantly higher standing long jump and CRF than those children do not involved in any sport activity (all  $p < 0.01$ ). **DISCUSSION** Physical fitness, particularly muscular strength and CRF, is related with lower WS in schoolchildren of southern Spain. In girls, an active travel to school is related with lower WS. These findings suggest that physical fitness and activity are important tasks, more than sedentary patterns, in preventing obesity in schoolchildren. Then, sport activities and higher physical activity levels should be promoted at those ages in order to prevent or fight again the epidemic of obesity. **ors here**

### **FACTORS LEADING TO REGULAR EXERCISE IN COMMUNITY-LIVING MIDDLE-AGED AND OLDER PEOPLE WITHOUT REGULAR EXERCISE EXPERIENCE**

Kozakai, R., Ando, F., Kim, H.Y., Lee, S., Yuki, A., Shimokata, H.

*Hokusho University*

**Introduction:** A number of people who had not engaged in regular exercise earlier in their lives started regular exercise in middle age and older in our previous study. Little is known about what contributes to engagement in regular exercise in middle-aged and older people except for the influence of exercise experience. The purpose of the present study was to investigate the primary factors for regular exercise in community-living middle-aged and older people without regular exercise experience. **Methods:** Data was obtained from the National Institute for Longevity Sciences - Longitudinal Study of Aging (NILS-LSA). Inclusion criteria for the present study were as follows: participants who participated in the 4th and 5th study of NILS-LSA, who had completed the questionnaire of regular exercise throughout a person's lifetime, who had never had regular exercise before their first participation and who had participated at least twice during the 1st to 5th study of NILS-LSA. The subjects of this study were 98 men and 166 women aged 40-79 years at the first participation in NILS-LSA. Health and lifestyle factors such as hypertension, smoking status, body mass index, education, self-rated health, depression and grip strength were examined as the primary factors for regular exercise. Cox proportional hazards models were used to analyze the independent effects of health and lifestyle factors on engaging in regular exercise. Both the unadjusted model and the adjusted model for age were performed in men and women separately. Significant probability levels were considered to be less than 0.05. **Results:** The mean length of follow-up was 6.6 (range: 2.0-8.0) years. The participants who started regular exercise during the follow-up were 26 men (26.5%) and 49 women (29.5%). For women, more grip strength (20kg and above) was significantly associated with starting regular exercise (hazard ratio: HR 2.73, 95% confidence interval: 95% CI 1.08-6.90). Adjustment for age did not change the estimate, but slightly decreased the HR and widened the CI (HR 2.47, 95% CI 0.95-6.40). Among men, there were no significant associations of health and lifestyle factors with starting regular exercise in either model. **Discussion:** Of those who had never had regular exercise in earlier life, women who had 20 kg or more in grip strength were more likely to start regular exercise. Although health motives such as advice from doctors positively influence exercise engagement beyond middle age, health problems were reported as the most common barrier to physical activity. The association between physical conditions and exercise engagement is still controversial. Our finding that having a certain amount of grip strength is associated with starting regular exercise in middle age and older even without regular exercise experience in earlier life may help to understand the relationship between physical condition and the inducement to engage in regular exercise.

## PHYSICAL FITNESS LEVELS AND CHILDHOOD OBESITY BETWEEN RURAL AND URBAN CONTEXTS

Martins, J., Honório, S., Batista, M., Cardoso, J., Costa, A.M.

*University of Beira Interior - Covilhã; Higher School of Education of Torres Novas, Portugal*

**Objective:** this work is aimed at knowing the level of physical aptitude and its degree of association, regarding an urban and a rural area, in children from the primary education schools. **Methodology:**the sample consisted of six schools from the primary education of the county of Fundão: Santa Teresinha school (a central school), and the schools of Valverde, Fatela, Enxames, Alcaria and Peroviseu (peripheral schools). The sample has been selected in order to have a certain number of pupils from a peripheral area and another one from a central area of the city. The total sample is represented by 161 pupils, 76 are female and 85 are male and they are aged between 6 and 10. 85 come from an urban area and 76 come from a rural area. The analysis of the physical aptitude had as a reference the battery Prudential Fitnessgram (2002). **Results:** According to the results obtained in the anthropometry, boys and girls from rural areas are heavier and taller than the boys and girls from urban areas. Regarding the BMI and body fat, it is males in rural areas that show a higher number of pupils in the healthy zone. As far as females are concerned, it is the urban area that has more pupils in that zone. It was also noticed that there are a huge percentage of girls from the rural area in the thin zone. In the differentiation between genders, boys have better results in physical aptitude and obesity levels. Regarding the influence of the living area, there are obviously better results in the urban area than in the rural area. Our study reveals that there are significant differences in the physical aptitude tests when they were applied at two different moments. **Conclusions:** After the analysis and interpretation of the results, we can conclude that boys and girls coming from rural areas are taller and heavier than the ones from urban areas and that they exhibit a lower body mass index. When defining the percentage of subjects classified in the "healthy zone", the BMI numbers in boys from rural areas that are in the healthy zone are higher than those of boys from urban areas. Regarding girls, the ones from urban areas as well as those from rural areas have almost the same percentage in the healthy zone. Concerning fat, it is males in the rural areas that have more pupils in the healthy zone. As for girls, the ones from the urban areas have better results in the three zones, being the healthy zone that has a higher percentage of girls. In the relationship between the genders, boys have better results in the levels of physical aptitude and obesity. In the relationship between the areas, the urban one shows better results. The existence of two periods of analysis allowed us to notice an improvement in all the tests.

## ESTROGENS AND TESTOSTERONE HORMONES, AS RESPONSIBLE FACTORS FOR CHANGES IN LIPID PROFILE AND BODY COMPOSITION IN MALE ELITE ATHLETES

Costa, M.1, Raimundo, A.1,2, Crespo, C.3, Maynar, M.3

*1:UE (Évora, Portugal), 2:CIDESD (Portugal) 3:UE, (Cáceres Spain)*

**Introduction** The practice of physical activity and a balanced diet have been identified as strategies to acquire cardiovascular benefits. This study attends to determinate the changes in hormones, testosterone (T) and estrogen (E2) levels, as a result of regular practice, vigorous physical activity and its influence on body composition and lipid profiles in male athletes, since this gender has a higher prevalence of cardiovascular disease. **Methods** In this study where recruited 42 male participants 20 of them professional soccer players (SG) (age 15-28 years) and as control group 22 students (CG) with sedentary lifestyle (aged 18-28 years). The SG workout two times a day, 4 times a week (duration between 60 and 90 minutes each), and competing in football match's at the weekend. The SG is also subject to a medical diet control. Anthropometric evaluation body composition and clinical analysis where used to determinate the lipid profile and the hormone levels. **IPAQ in CG** Results There were significant differences between groups (SG< CG) mainly in abdominal ( $p<0.01$ ), subscapular ( $p<0.001$ ) and thigh ( $p<0.01$ ) skinfolds; hips ( $p<0.001$ ) and waist ( $p<0.01$ ) circumference; in the lipid profile the total cholesterol ( $p<0.01$ : SG< CG), triglycerides ( $p<0.01$ :SG< GC), HDL- C levels ( $p<0.05$ : CG >SG); levels of T ( $p<0.001$ : SG>CG) and E2 ( $p<0.05$ :SG >CG). We noticed a strong correlation ( $p <0.001$ ) between increase physical activity and the levels of T and significant increase among the E2 levels with exercise ( $p <0.05$ ). There's a strong correlation between the increase of T levels and the reduction of subscapular, abdominal skinfolds and waist circumference. **Discussion** The results of the present study suggest that vigorous physical activity have improved the body composition, particularly in the reduction of central fat, in the SG and there lipid profile by increasing the T levels. The findings support that individuals who practice vigorous physical activity in a relation of 'dose-effect' acquire additional benefits which reduces the risk of mortality (Teramoto et al 2009; Tompson et al 2007). **References** 1. ## ACADEMIA DA TERCEIRA IDADE PROJECT : PREVENTION OF DEPRESSION IN THE ELDERLY

Brasil, C.1, Furtado, S.1, Pereira, F.2, Silva, N.4, Furtado, H.1,2,3

*1 Department of Healthy Aging and Life Quality of Rio de Janeiro City (Brasil), 2 UCB (Rio de Janeiro, Brasil), 3Research Center in Aging (INEPE Rio - UCB - Brasil), 4 UERJ (Rio de Janeiro, Brasil)*

**Introduction** The elderly population in general lives in a lonely manner, with little opportunity for relationships. The practice of regular physical activities promotes behavioral change, which can provide social transformations. The systematic practice of physical exercise is associated with absence or reduction in symptoms of depression or anxiety. The Academia da Terceira Idade project is developed in the Rio de Janeiro City through the Department of Healthy Aging and Life Quality, aiming to promote physical activity by using specialized gym apparel, focusing on aerobic and strength training. The program is meant to maintain and/or improve participants' functional autonomy, fall prevention and the formation of social networks among them. The participation of the elderly in regular physical activity programs can be considered an alternative non-pharmacological treatment of depressive disorder, represented by low economic cost, easily affordable and efficient in preventing functional decline in the elderly. **Methodology** The sample consisted of 285 elderly men and women with an average age of 69.2 years, all project participants Academia da Terceira Idade (ATI), for a minimum period of 3 months. The instrument used to measure depression was the Geriatric Depression Scale (GDS). The data was processed in the Statistical Package for the Social Science 21 program. **Results** The results show that there was no prevalence of depression in the elderly program, with an average of 3.49 points, highlighting that 81% of the sample presented amounts below 4, which characterizes absence of depression. **Discussion** Through the research results show that elderly participants in the project had low levels of depression, suggesting that the exercise program group had a positive response on the need to extend social contacts. The psychological benefits of physical activity programs

are important indicators for the mental health of the elderly, demonstrating the positive results achieved in Academia da Terceira Idade Project

### **EFFECT OF A PILATES MATWORK EXERCISE IN MUSCLE AND FAT MASS**

Vaquero-Cristóbal, R., Alacid, F., Esparza-Ros, F., Muyor, J.M., López-Miñarro, P.A.

*1,2&3.Catholic University of San Antonio (Murcia); 4.UAL (Almería, Spain), 5.UMU (Murcia, Spain).*

Do not insert authors hereIntroduction Some researches have demonstrated a relationship between systematic physical exercise and positive changes in body composition. A few studies have showed that performing a Pilates method modifies both muscle and fat mass. Segal et al. (2004) analyzed the influence of one hour per week of Pilates matwork in body composition. However, no changes in body composition were detected. To date, no studies have analyzed the influence of different Pilates matwork volumes on a sample of women without chronic diseases. For this reason, the objective of this study was to analyze the influence of Pilates Matwork exercise in muscle and fat mass of adult women. Methods Fourteen women (mean  $\pm$  SD, age:  $41.93 \pm 7.27$  years) with an experience of one year in Pilates Matwork participated in this study. They participated in a Pilates Matwork program of one hour, twice a week, during 16 week. A Level 2 anthropometrist certified by the ISAK taken all anthropometric variables. Participants completed baseline measures over one week before starting the exercise program. Post-test was taken over one week after finishing it. Instruments were calibrated in advance to avoid measurement errors. The temperature of the laboratory which the measurements were performed was standardized at 24°C. To determine body composition strategy five components by Kerr (1988) was used. Results Significant differences were found ( $t(13)=3.12$ ;  $p=0.008$ ) in fat mass between pre-test ( $23.29 \pm 3.87$  kg) and post-test ( $21.14 \pm 3.01$  kg). The percentage of muscle mass was slightly increased in the post-test although no significant differences were found (pre-test:  $23.36 \pm 3.00$  kg; post-test:  $24.21 \pm 3.36$  kg) Discussion The main objective of this study was to analyze the changes in muscle and fat mass after 16 week of Pilates Matwork training. Pilates Matwork involves the use of a machine (the reformer) while Pilates classic is performed on the floor with implements. Women showed a significant decrease in fat mass and a non significant increase in muscle mass estimated by anthropometry. These results are in concordance with previous research in Pilates classic mat (Cakmakçi, 2011; Carvalho et al., 2009). However, participants of these studies were novices and sedentary. A physical exercise program with sufficient intensity, duration and frequency may reduce fat mass. The present study demonstrated that Pilates Matwork exercise may influence fat component in active adult women. References Cakmakçi O (2011). *Coll Antropol*, 35, 1045-1050. ### **THE INCIDENCE OF A DISEASE IN PROFESSIONAL SPORTS, DEPENDING ON GENDER AND AGE**

Peric, R.

*Karl Franz Universität Graz, Austria. Institute for Occupational and Sports Medicine in Banja Luka, Bosnia and Herzegovina*

Introduction „Mens sana in corpora sano“has always made us believe that sport is healthy. Doing sports either professionally or as a hobby was a way for humans to be and to feel wholesome. Therefore, the aim of this study was to analyze the relative contribution of sports to a general health profile of athletes. Methods Research was conducted in Institute for Occupational and Sports Medicine in Banja Luka, Bosnia and Herzegovina using health examination of athletes on a semi seasonal basis and results were classified using ICD-10 health care classification system. Total number of 2294 athletes was examined in time period of one years. Results 1843 (80%) were male and 451 (19%) were female athletes. Among male population largest number was between 16 -30 years of age. Total of 1009 (54.7%). At female athletes largest number of examined was younger than 15 years (257 or 56.9%) of age. From total number of both sexes, 1436 (62.5%) had two or three diagnosis and 298 (12%) had more than three. Only 109 (4.8%) were healthy what statistically supports the thesis of this study. Discussion Most common disease diagnosis was revealed in muscular-skeletal and digestive systems and interesting differences in diagnosis occurred between male and female athletes and their ages. Women often suffer from anemia, disturbances of vision and pneumonia, while congenital anomalies, skin changes and injuries are common in male athletes. The fact that only ten most popular sport types were part of this study could lead to discussion stating that this data are not general and only relevant to specific sport types. References The World Health Organization (2010). *International Statistical Classification of Diseases and Related Health Problems*, 10th Revision.

### **TIME-COURSE ADAPTATIONS TO HIGH-INTENSITY AEROBIC INTERVAL TRAINING IN METABOLIC SYNDROME PATIENTS**

Mora-Rodríguez, R., Ortega, J.F., Hamouti, N., Fernández-Elías, V.E.

*University Castilla-La Mancha*

Introduction: Metabolic syndrome (MetS) is associated with a fivefold increased risk for type 2 diabetes and a twofold increased risk for cardiovascular disease (1). Exercise training of enough intensity reduces some of the MetS components. However, which factors are more responsive to exercise and which is the optimal exercise dose remain unresolved. We addressed the monthly progression towards healthy values of MetS components (i.e., waist perimeter, systolic and diastolic blood pressure, blood glucose, triglycerides and HDL-c concentrations) with exercise training. Materials and methods: Forty eight MetS patients (22 men and 26 women,  $52 \pm 8.8$  yrs old) underwent 16 weeks a 3 days per week supervised cycle-ergometer high-intensity aerobic interval training (HIAIT). Each training session was composed of 10 min of warm-up, 4x4 min bouts of pedaling at 90% HRmax interspersed by 3 min at 70% HRmax and 5 min of cool-down (2). MetS components, additional blood metabolites, cardio and metabolic fitness (VO2max and maximal fat oxidation rate (MFO)) and O2 flux from vastus lateralis biopsy were evaluated before, monthly and 48 h after the last exercise session (O2 flux only pre-and-post). Results: After 16 weeks of HIAIT, 29% of the patients reduced MetS factors below three and were thus, momentarily free of the syndrome. Waist perimeter, systolic and diastolic blood pressures were progressively reduced with exercise training ( $P<0.05$ ) achieving  $3.8 \pm 2.9$ ,  $12 \pm 2$  and  $11 \pm 3\%$  respectively, after 4 months of training. HDL-c was progressively augmented up to  $13 \pm 10\%$  after 4 months of training ( $P<0.05$ ). VO2max and MFO monthly increased ( $P<0.05$ ) up to  $22 \pm 15$  and  $36 \pm 25\%$ , respectively after 4 months of training. Vastus lateralis muscle biopsies in seven subjects revealed that mitochondrial O2 flux increased by 61% ( $P<0.05$ ) due to increased mitochondrial content. Glycosylated hemoglobin diminished monthly up to  $3.8 \pm 0.8\%$  after 4 months of training ( $P<0.05$ ). However, blood triglycerides and fasting glucose concentration were not affected by 4 months of HIAIT ( $P=0.11$  and  $P=0.28$ , respectively). Conclusions: The MetS factors responsive to exercise (waist perimeter, blood pressure and HDL-c) improved without a plateau response. Thus, HIAIT beyond 4 months could potentially reverse to normal clinical values those three MetS factors in all patients. The marked cardio-metabolic fitness adaptations to training could be behind the improvements in MetS factors. 1) Alberti KG, et al. Harmonizing the metabolic syndrome. *Circulation*.

2009; 120(16):1640-5. 2) Helgerud J, et al. Aerobic high-intensity intervals improve VO<sub>2</sub>max more than moderate training. *Med Sci Sports Exerc.* 2007; 39(4):665-71.

### PHYSICAL WORKLOAD ON NECK AND SHOULDER MUSCLES DURING MILITARY HELICOPTER FLIGHT - A NEED FOR EXERCISE TRAINING?

Murray, M.1, Lange, B.1,2, Chreiteh, S.S.1, Olsen, H.B.1, Sjøgaard, K.1, Sjøgaard, G.1

1, *Institute of Sports Science and Clinical Biomechanics, University of Southern Denmark, Odense.* 2, *Department of Anesthesia and Intensive Care Medicine, Odense University Hospital, Odense*

**Introduction** Work-related neck/shoulder pain is a common complaint among military helicopter pilots and crew members. The flight helmet and additional Night Vision Goggles (NVG) place a considerable load on the cervical spine. The aim of this study was to quantify the physical workload on neck/shoulder muscles to assess possible overload that may call for exercise training to improve capacity and prevent neck pain. **Methods** Nine pilots and nine crew members from the Royal Danish Air Force participated in a standardized representative flight sortie encompassing: Patient transportation (A-B flight) and Search and Rescue (SAR flight). A standard helmet was used (1.85 kg). SAR flight was performed with NVG (1.1 kg) and A-B flight was performed +/- NVG. Before take-off, one pilot and one crew member were equipped with 6 wireless electromyography (EMG) sensors bilaterally above m. trapezius (TRA), upper neck extensors (UNE) and m. sternocleidomastoideus (SCM). Maximal Voluntary Isometric Contractions (MVC) was performed for normalization. A modified version of the observational method "Posture Activity Tools and Handling" (PATH) was used for assessing work positions during flights. For every minute, the head position of pilots/crew members were classified as: anatomically neutral (<30° flexed), flexed (>30°), extended (>30°), rotated (>30°) and/or laterally flexed (>30°). **Results** Mean measuring time was for A-B flight: 16.9 ± 5.1 min, for A-B flight + NVG: 22.7 ± 10.8 and for SAR flight: 21.3 ± 11.1. The mean muscle activity in % MVC was highest during SAR flight: pilots 2.9 ± 1.7 (TRA) 12.7 ± 5.2 (UNE) 4.3 ± 2.9 (SCM), Crew members 4.1 ± 3.8 (TRA) 10.5 ± 2.4 (UNE) 2.4 ± 1.5 (SCM). Muscle activity in UNE was significantly higher than in TRA and SCM during all flights, except for crew members when compared to TRA during A-B flight (P = 0.086). For crew members muscle activity in UNE was significantly higher during A-B flight + NVG compared to - NVG (P = 0.021), while no significant difference was found for pilots. Non-neutral head positions in % of SAR flight time were for pilots observed for 88.6% (flexed) and 64.4% (rotated), and for crew members for 93.8% (flexed) and 89.9% (rotated). **Discussion** The mean muscle activity during flights was overall ~10% MVC in UNE and even higher during SAR flight, which is considered a high sustained activity level. Such high workload in combination with the flexed and/or rotated positioning of the head may play a role for the high prevalence of neck/shoulder pain among this occupational group. The present exposure-assessment suggests that strengthening exercises for the UNE, lowering the relative load during flights, could potentially alleviate neck pain.

### REFERENCE VALUES FOR THE PHYSICAL GROWTH OF SCHOOL CHILDREN AND ADOLESCENTS IN BRAZIL CAMPINAS

Camargo, C., Gómez Campos, R., Arruda, M., Hobold, E., Cossio-Bolaños, M.A.

*Universidade Estadual de Campinas UNICAMP*

**Introduction** Physical growth patterns reflect the nutritional status and life, still important to have references in different cultures and ethnicities (Molinari et al. 2004). Therefore, the aim of this study was to compare the CDC international reference -2012 and build reference values for the physical growth of children and adolescents school of Campinas (Brazil). **Methods** The sample consists of 6531 individuals (3315 boys and girls 3.216) with an age range of 6-17 years. Comparisons were made between the means of study and CDC-2012 reference. Body weight-for-age, height-for-age and BMI-for-age percentiles were obtained using the LMS method. **Results** Men have less weight and height relative to the reference (9-17 years) and BMI (11-17 years) (p < 0.01). Women are lower in weight (6-17 years), height (7-14 years) and BMI (11-17 years) (p < 0.01). **Discussion** The World Health Organization has recommended the adoption of growth charts for the United States where there is a standard area (WHO, 1995), although clearly not reflect the growth patterns of different cultures and different ethnic groups (Silva et al 2012), may lead to bias in the assessment of patients, so that the observed secular changes in body size during the past 30 years, suggesting the use of regional standards for assessing the physical growth trajectory of Campinas in clinical settings or epidemiological studies. **References** Molinari L, Gasser T, Largo R. (2004). TW3 bone age: RUS/CB and gender differences of percentiles for score and score increments. *Ann Hum Biol* 31:421-435. WHO. (1995). ### EFFECTS OF HIGH-RESISTANCE TRAINING ON NEUROMUSCULAR ADAPTATIONS AND FUNCTIONAL MOBILITY IN AN ELDERLY POPULATION

Romero-Arenas, S.1, Blazeovich, A.J.2, Alcaraz, P.E.1

1: *UCAM (Murcia, Spain), 2: ECU (Perth, Australia).*

**Introduction** Aging is associated with decreases in muscle mass, muscle strength and muscle power, which can negatively impact activities of daily living in older adults. High-Resistance circuit training (HRC) is a time-efficient training modality that can elicit demonstrable improvements in health and physical fitness (Romero-Arenas et al., 2013). The purpose of the study was to evaluate the effects of 12-weeks of high-resistance training on the neuromuscular adaptations and functional mobility in an elderly population. **Methods** Thirty-seven elderly (age 61.6±5.3 years, height 1.55±0.07 m and weight 71.9±11.2 kg) were randomly assigned to the traditional strength (TS) group (n = 14, 6RM, 1-3 sets), to the HRC group (n = 16, 6RM, 1-3 sets) or to the control group (CG) (n = 7, no training). Training consisted of weight lifting 2 times a week during 12 weeks. Prior to and at the end of the training program, the functional mobility was evaluated with a 'Timed Up and Go' test. In addition, force per unit of active muscle mass (i.e. muscle quality - MQ) was evaluated by the quotient between maximum isokinetic torque (90°•s<sup>-1</sup>) and lean mass of lower-limb via dual-energy X-ray absorptiometry. **Main and interaction effects** resulting from the intervention were analyzed using single or multivariate analyses of variance (ANOVA) with repeated measures (p ≤ 0.05). **Results** After training, muscle quality was increased in both experimental groups (23.9%, p < 0.001 and 20.0%, p < 0.001; HRC and TS, respectively), being established statistically significant differences between experimental groups and CG (p < 0.05). There was significant increase in functional mobility: the time in "Timed Up and Go" test decreased 13.1% in HRC group (p < 0.001) and 7.8% in TS groups (p = 0.012), there was not significant decreased in CG. **Discussion** The HRC training was as effective as TS for improving muscle quality and functional mobility. Thus, HRC training promoted a similar neuromuscular adaptation as traditional training while using a

shorter training session duration. References Romero-Arenas S, Blazevich AJ, Martínez-Pascual M, Pérez-Gómez J, Luque AJ, López-Román FJ, Alcaraz PE (2013). *Exp Gerontol*, 48(3), 334-340.

### **QUALITY OF LIFE EVALUATION ON ELDERLY PEOPLE WHO TAKE PART IN THE ACADEMIA DA TERCEIRA IDADE PROJECT, IN RIO DE JANEIRO CITY**

Brasil, C.1, Furtado, S.1, Pereira, F.2, Cordeiro, R.1,3, Furtado, H.1,2,3

*1 Department of Healthy Aging and Life Quality of Rio de Janeiro City (Brazil), 2 UCB (Rio de Janeiro, Brasil), 3Research Center in Aging (INEPE Rio -UCB – Brasil) Introduction*

Introduction Ageing is a global phenomenon, and in Brazil specially life expectancy had a significant growth, from 43,3 years in 1950 to 68,6 years in 2000, reaching 73,4 years in 2010. To extend longevity and maintain life quality has become this century's great challenge. The city of Rio de Janeiro with the highest percentage of elderlys in the country accounting for 14.9% of its population. Public policies towards this group are a necessity, and so the City trough, Department of Healthy Aging and Life Quality created the Academia da Terceira Idade (ATI) project, aiming to promote physical activity by using specialized gym apparel, focusing on aerobic and strenght training. The program is meant to maintain and/or improve participants' functional autonomy, fall prevention and the formation of social networks among them. Methodology The sample was constituted by 257 people, from both sexes, active, aging  $69,11 \pm 6,8$  years, participants of SESQV's ATI Project. The instrument utilised was the World Health Organization Quality of Life-OLD questionnaire, to evaluate quality of life (WHOQOL-OLD). To analyse statistical data, the chosen tool was the Statistical Package for the Social Sciences, 21(SPSS). Results The average quality of life score was  $61,69 \pm 8,22$ . The highest value was observed in the intimacy domain ( $78,4 \pm 21,5$ ), and the lowest referred to death and dying ( $45,1 \pm 15,2$ ). Linear regression showed good self perception on health issues and improved quality of life scores in 7,3 points. Discussion Results indicate that the Academia da Terceira Idade (ATI) project, developed in the city of Rio de Janeiro, has been achieving its main objectives. Through the interpretation of these informations, SESQV can offer services with various structures of social aid and health care, especially on the identification of the possible consequences of policies about elderly quality of life, adding a clearer comprehension on the investment areas to attain better outcomes in life quality. References Brazilian Institute of Geography and Statistics (IBGE) 2010. Furtado, H. . Physical activity and aging. In: Brasil, Cristiane. (Org.). *Living is the best option: ... Ageing It's part!*. ### **FOURTH AGE'S FUNCTIONAL FORCE: EXTENDING THE INDEPENDANCE OF RIO DE JANEIRO'S ELDERLY POPULATION**

Furtado, H.1,2,3, Brasil, C.1, Lima, N.4, Pereira, F.2

*1 Department of Healthy Aging and Life Quality of Rio de Janeiro City (Brazil), 2 UCB (Rio de Janeiro, Brasil), 3Research Center in Aging (INEPE Rio - UCB – Brasil), 4 UERJ (Rio de Janeiro, Brasil)*

Introduction The intent of an active ageing has become the main groundwork for public policies to the elders. The patterns of physical activity in the brazilian population have begun to be studied recently, having a major role in life expectancy for the older segments. The Qualivida Project is the City trough, Department of Healthy Aging and Life Quality, a gymnastics program to aged people, free and developed in public squares in Rio de Janeiro city. It aims to maintain the daily life activities (AVD), socialization and functional autonomy. The elderly population has the necessity of maintaining reasonable levels of muscular strenght, since the strength decreases with the natural aging process. The loss of muscular mass, and consequently of muscular strenght, is the main responsible for the loss of mobility and functional capacity in an ageing individual. Methodology The sample was constituted by 51 female elderlys from the Qualivida program, homogenised by age group and body mass index, with  $81,8 \pm 1,5$  years e  $26,8 \pm 4,4$  BMI. As na inclusion criteria it was established a minimum if three uninterrupted months in the referred program. The instruments utilised to measure the functional strenght were the Chair stand and the Arm curl from te Sênior Fitness Test. The data was processed in the Statistical Package for the Social Science 21 program. Results In the Chair stand test the obtained value was  $11,2 \pm 3,3$ , and in the Arm curl test it was  $12,9 \pm 3,4$ . Discussion Based on the presented results, it was inferred that the female elderlys that composed the sample group were within the range of the normative indexes in both Arm curl and Chair stand tests. Therefore, the gymnastics program Qualivida was capable of maintaining the group's strenght in physiologically recommended levels. The study verified that, despite having reached advanced ages among the sample, the regular gymnastics program was key to maintain functional autonomy and the AVD. ### **INCIDENCE OF OBESITY AND ITS RELATIONSHIP WITH PHYSICAL INACTIVITY IN RECREATIONAL CLUB GOERS FROM THE CITY OF FRANCA**

Souza, D.G.1, Neiva, C.M.1,2,3, Tonello, M.G.M.1,4, Quemelo, P.R.1, Navas, A.P.1, Zaia, J.E.1, Quintanilha, J.G.1

*1 UNIFRAN (Brazil); 2 UNESP (Brazil); 3 UNAERP (Brazil); 4 UFSCar (Brazil)*

Introduction In the last three decades, several issues related to obesity are being raised to try to better understand its causes, what better way to identify it and how to prevent it, as well as their consequences. All this, because obesity is currently a public health problem worldwide, mainly in industrialized countries. The morbidities associated with obesity are severe, or the psychosocial point of view of either the biological point of view with various metabolic and osteoarticular disorders, among others. The increased prevalence of obesity has been explained by factors such as sedentary lifestyle and changes in food consumption patterns, for example, higher intake of foods with high energy density. Thus, the objective was to investigate the incidence of obesity and its relation to physical inactivity in the club-entertainment city of Franca, Brazil. Methods Study participants were 64 individuals aged between 20 and 50 years ( $35,3 \pm 9,7$ ), leisure club goers from the region of Franca, Brazil. They responded to an International Physical Activity Questionnaire (IPAQ - version 8) and also underwent an anthropometric assessment. In this, we collected the values of weight (kg) and height (m) and calculated the Body Mass Index (BMI). The subjects were divided into two different groups: active (AG) and sedentary group (SG). Results Characterization of physical activity has been observed that in the AG individuals had an average time of  $559,17 \pm 199,82$  minutes. In the comparison between AG and SG, it was observed that the GA presented increased physical activity ( $559,17 \pm 199,82$  minutes) when compared with the GS ( $165,45 \pm 82,47$  minutes), showing a difference of 393.72 minutes from one group to another ( $p0 .001$ ). When analyzed separately, it was observed that the AG presented a lower BMI ( $21,92 \text{kg/m}^2 \pm 2,68$ ) when compared with the SG Group ( $26,54 \text{kg/m}^2 \pm 2,55$ ), which represents a difference of 4.62 points from one group to another ( $p0 .001$ ). Discussion We believe that physically active individuals have a lower level of obesity compared to sedentary individuals, and thus, we can conclude that physically active children have lower risks for cardio-

vascular and metabolic diseases. Sedentary habits are directly related to obesity. References JÚNIOR, J. C. F.; SILVA, K. **Introduction** Obesity as a national public health problem, is a recent event. Despite the reports from the Paleolithic Era on 'burly men', the prevalence of obesity has never appeared in epidemic level as at present, and is advancing rapidly and progressively, without differentiating race, sex, age or social status. In recent years, obesity has ceased to be a mere inconvenience 'aesthetic' and 'sloppiness', despite treated by patients and healthcare professionals, to become an alarming and frightening reality. The substantial increase in the prevalence of obesity is due largely to the two variables are behavioral: low levels of habitual physical activity and sedentary behaviors. This study sought to identify the relation between obesity, usual level of physical activity and sedentary behaviors in students from public schools from city the interior of São Paulo. **Methods** Were used as indicators of obesity the body mass index, fat percentage and waist to hip ratio. The usual level of physical activity was estimated by physical fitness assessed by the Cooper test and questioner. By the same questioner was also estimated the sedentary habits. **Results** It is observed through indicators of adiposity used in the study a different percentage of schools categorized like overweight if considered the normal between the classification criteria. When classified by BMI and fat percentage, the indexes of obesity have reached 10.4% and 7.8% respectively, while for the WHR the index found was higher, 22.1%. Comparing the results between sexes, no significant differences were found regarding BMI and WHR. For the level of regular physical activity we observed that 27.3% of child were in the category of 'active', that is, only just over a quarter of schoolchildren. The school already classified in the categories 'little active' and 'moderately active' represented a value greater than 72. Of the three measures of body fat used in the study, two were highly inverse-correlated with the level of physical fitness: BMI and fat percentage. **Discussion** The level of regular physical activity, assessed by physical fitness has an inverse relation with obesity in schoolchildren. The behavioral factors, assessed by questionnaire, were not correlated with obesity, leading us to conclude that the methodology may have influenced results. **References** RICARDO, G.D.; CALDEIRA G.V.; CORSO A.C.T. ### **INDICATORS OF METABOLIC SYNDROME IN STUDENTS IN HIGH SCHOOL OF PARACATU-MG BARZIL**

Neiva, C.1,2,3, Mello, S.C.O.4, Souza, D.G.3, Fernandes, C.R.2

1-UNESP, 2-UNAERP, 3-UNIFRAN, 4-FACULDADES ATHENAS

**Introduction** Obesity in childhood and adolescence has a very strong predisposition factor for metabolic syndrome. This study aimed at tracking the risk factors for metabolic syndrome in adolescents in a public school and private one in Paracatu-MG. **Methods** Participated in this study 68 high school students, of both sexes, aged between 14 and 20 years of Paracatu-MG. The anthropometric tests were waist hip ratio (WHR), body mass index (BMI), waist circumference (WC), the relationship age weight and nutritional status (old-growth). The following were performed biochemical analyses: fasting blood glucose (FBG), glycated hemoglobin (GH); triglycerides (TG), total cholesterol (Col. Tot) and HDL fractions. Finally it was also evaluated the blood pressure (BP). **Results** All sample evaluated regarding WC, 11% of students are above normal values (Men and Women 80 cm 94 cm). These show us that the WC in isolation, not presented as a factor indicative of risk for metabolic syndrome in students. On the WHR, 22% of students fall within the values considered at risk (Man more than 0.95 and Woman more than 0.80). BMI did not show up as a good predictor for the risk of SM to the Group of students assessed. The FBG was also not presented values of prediction for SM (average 74, 51mg/dl) to 89% of the group evaluated. But by looking at the data, the high glycemic impact matches for students with higher values of weight and waist circumference, which confirms the high body mass and its relationship with the predictors of SM. The HG was not a good predictor of the SM for the age group studied, since 100% of the Group presented normal values (<6%). This can be explained by the fact that the HG presents itself as a good long-term indicator in adult life. The TG were high in 62% of the group studied, representing an early indicator for the SM. These results are even more important when the TG are associated with other variables, such as Col.Tot (19% of the group with high values) and WHR. On the other hand, the HDL presented important predictor role, since more than half of the Group presented values below the normal range, resembling the occurred with Col. Tot. Finally, although BP has brought in the values to indicate SM just in 11% of the group, this variable was shown to be important for the age group, since it was linked to other indicators with WHR, BMI and TG. **Discussion** Of the 68 students evaluated, the association of up to 2 risk factors was clear in 56% of the group while 6.5% have three risk factors into association. This indicates that these students can be framed as early diagnosis of metabolic syndrome. The causes may be different as cited above. And for the prevention and reduction of risk factors, firstly this modification of the sedentary lifestyle and eating habits. **References** Botezelli JD, Cambri LT, Ghezzi AC, Dalia RA, M Scariot PP, Ribeiro C, Voltarelli FA, Mello MA. ### **SIMILAR IMPROVEMENTS IN AEROBIC CAPACITY IN UNTRAINED FEMALES FOLLOWING HIGH-INTENSITY INTERVAL AND MODERATE-INTENSITY CONTINUOUS TRAINING**

Lancaster, R.E.1, Taylor, L.1, Castle, P.1, George, K.2, Oxborough, D.2, Sculthorpe, N.3

University of Bedfordshire

1: Institute of Sport and Physical Activity Research, University of Bedfordshire, 2: Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, 3: Institute of Clinical Exercise and Health Research, University of West Scotland **Introduction** Recent research suggests that high-intensity interval training (HIT) may produce more favourable adaptations to aerobic capacity than moderate-intensity continuous training (MCT) in a variety of populations (Swain and Franklin, 2006). The paucity of data regarding the aerobic response of females to exercise training warrants further study in this population. The aim of this pilot study was to determine whether 10-weeks of HIT, elicits greater improvements in aerobic capacity in untrained females, than isocaloric MCT. **Methods** 27 healthy females undertook assessments of body composition and maximal oxygen uptake (VO<sub>2</sub>max) at baseline, week 4, week 7 and week 10. Participants were

randomly allocated to a no exercise control group (N = 7; age: 21.0 ± 5.2 yr; VO<sub>2</sub>max: 31.4 ± 6 ml/min/kg), or to complete 3 supervised sessions per week of HIT (N = 12; age: 19 ± 2.3 yr; VO<sub>2</sub>max: 34.1 ± 5.4 ml/min/kg) or MCT (N = 8; age: 20.5 ± 3.9 yr; VO<sub>2</sub>max: 31.4 ± 6 ml/min/kg) on a treadmill. HIT consisted of 6 x 3 min high intensity efforts at a running velocity (RV) corresponding to 90% of each individual's VO<sub>2</sub>max, interspersed with 6 x 3 min recovery at an RV of 40% VO<sub>2</sub>max. The intervals were preceded and followed by 4 min 'warm-up' and 'cool down' periods at an RV of 65% VO<sub>2</sub>max. MCT consisted of 44 minutes at an RV of 65% VO<sub>2</sub>max. Protocols were matched for average exercise intensity, distance covered, duration and calories expended (Bartlett et al., 2011). Results VO<sub>2</sub>max significantly increased within HIT and MCT by 4.3 ± 2.2 and 5.2 ± 2.1 ml/min/kg, respectively. No significant differences were observed between groups. % fat mass was unchanged from baseline (HIT: 36.3 ± 8.3, MCT: 39.7 ± 9) to week 10 (HIT: 35.2 ± 7.8, MCT: 38.7 ± 7.3). No changes in any measured variable were observed in the control group. Discussion In healthy untrained females, HIT is equally as effective in increasing aerobic capacity as MCT. However, the suggestion that HIT results in greater increases than MCT does not appear to hold for this population. This does not preclude the possibility that other health benefits may differ between protocols. These results highlight the importance of matching training protocols when comparing their efficacy for improving aerobic capacity and promoting health. ## **RELATIONSHIPS BETWEEN PHYSICAL ACTIVITY LEVELS, BODY MASS INDEX AND SELF-CONCEPT IN YOUTH PEOPLE**

Yuste, F., Nebot, V., Ballester, R., Bermejo, J., Llorens, F., Huertas, F.

*Universidad Católica de Valencia*

Introduction: Self-concept is one of the most researched constructs within the framework of educational psychology, psychology of the personality, and social psychology. Self-concept can be defined as the perception that an individual has of him or herself, with contents that are both descriptive, as well as evaluative (Harter, 2003, 1999). In the field of sport and exercise, physical self-concept is also considered very important. It plays a considerable role in sports performance (Carraro, Scarpa, & Ventura, 2010). The present study aims to investigate the role of physical activity and sports participation on physical self-concept and body mass index (BMI) in adolescents. Method: This research analysed the relationship between physical activity (PA), determined with a questionnaire (PAQ-A), body mass index and self-concept measured by other questionnaire which rates 5 constructs (physical ability, physical condition, strength, physical appearance, and general self-concept) A validated survey about physical self-concept (CAF) was administered in a classroom setting by two members of the research team. It was presented as an opinion questionnaire about the perception of physical self-concept. A test about physical activity levels (PAQ-A) was also administered in classroom. The research team registered weight and height of each participant to determine their BMI. Results: We observed positive relationship between physical activity, BMI and different constructs of self-concept in adolescents. Discussion: The positive interaction between PA and physical self-concept suggests a reciprocal relationship between behaviour and perception. Finally it seems possible to assert that adolescents with systematic practice of sport out of school may present a positive physical self-concept and better BMI than persons without regular practice of physical activity. (2003). *Beyond the debate: Why some adolescents report stable self-worth over time and situation, whereas others report changes in self-worth*. *Journal of Personality*, 71, 1027-1058.

## **PARENT-CHILD PHYSICAL ACTIVITY RELATIONSHIPS USING ACCELEROMETERS. PILOT STUDY WITH GIRLS**

Ribeiro, J., Ramos, J., Santos, M., Pizarro, A., Silva, G., Aires, L., Ferro-Lebres, V., Mota, J.

*Sports Faculty of University of Porto*

Introduction Regular physical activity (PA), in youth, needs to be promoted to prevent obesity and subsequent clustering of CVD risk factors. Influences of parental PA on adolescents' activity level have been studied with discordant results, using different methods, making it difficult to compare the influence of parents in their child PA patterns. In this sense, parents are recognized as one of the factors of influence on physical activity of children and can therefore act to prevent obesity and other health problems. Therefore, the aim of the present study is: I) to verify the levels of PA, analyzing the differences between gender and different ages, and the number of subjects that meet the current recommendations, II) to investigate how the parents PA is related to the PA of their children. METHODS: The sample consisted of two matched parent-child groups: 28 adolescent girls, aged between 12 and 15 years. Parents Group - 28 Adults (father/ mother of the previous group of students), 7 male and 17 female. PA was objectively measured over 7 and 5 consecutive days of monitoring, (respectively the group of students and the group of parents) by accelerometers (MTI Actigraph GT3Xs) and the classification of the level of PA has been performed by Evenson et al. (2008) and Troiano et al (cut-off points. Results The main results showed that there's no significant association (R=0,09; p=0,675) between the levels of PA with parents and girls. Interesting to observe that in girls only 17% achieved the 60 min./day recommendations of moderate to vigorous PA (MVPA), and parents were exactly the opposite, with 96% of the parents achieving the recommended 30 min./day of MVPA. Regarding the prevalence's of overweight and obesity (OB), only 25% of girls presented OB and 63% of the parents have OB. Discussion In this context, it is important the implementation of strategies that contribute to increase the girls MVPA aiming to increase the percentage of girls achieving the MVPA recommendations. At this level, female subjects seem worth special attention. Note also the role modeling of parents in the implementation and maintenance of active and healthy lifestyles in girls, was not sustained. Further studies needs to be implemented, particularly of objective measurements of PA. ## **SPORT AND PHYSICAL ACTIVITY MONITORING AS A TOOL TO PREVENT DISEASE AND TO IMPROVE A WELLNESS**

Giugno, Y., Sole, F., Raiola, G.

*University of Salerno*

Introduction Sport is a key element in the life of all people, it is the medium that allows us to understand the essential values of life and significant. This means that sport is health, not only for those who choose to practice it at a competitive level, but for all those who, having

morphological imbalances due to physical activity can improve their conditions. During the developmental stages is useful if not indispensable adapted physical activity, to promote and maintain growth and physical development as much as possible harmonious and balanced. The purpose is to provide a tool to identify at an early stage incorrect attitudes to develop a work plan adapted. The Baropodometer is a device consisting of a footboard applied with the sensors connected to a computer system. What the system are measuring the reactions on the ground, in standing and in ambulation. In this way, through an examination baropodometric, various parameters are identified, the correct interpretation which allows to evaluate, with high accuracy, the overall behavior of the system tonic postural of the subject compared to the indices of normality. Acquisitions are accurate, instantaneous, repeatable, non-invasive and can reduce the radiographs. Methods The experimental method used is composed of instrumental measurements and anamnesis with the use of the platform baropodometric on a sample of five children aged between 6/14 years to one year. The platform is used to detect incorrect attitudes, measure the deformation generated by the force applied by the foot on the same and any failures during walking. Tests in static and dynamic. It also administered a questionnaire to collect data about the lifestyle. After three months and at the end of the activity will be repeated the tests and the administration of the questionnaire. The data will be compared to individual and group to correlate the lifestyle and the evolution of any paramorphic attitudes and dysmorphic. Results Detect any changes and compare them with data, especially if they have made improvements to the morphological structure. The correlation between motor habits and evolution of the locomotor system. Discussion The purpose is to provide an analysis tool to support the promotion of exercise and sports in developmental age and monitor the occurrence of possible pathologies. The realization of this project aims to improve the physical condition of the children examined in order to promote this process, given the results obtained, in schools and sports centers occupational health and prevention.

### EFFECTS OF INGESTION TIMING OF HYDROGEN-SATURATED WATER ON EXERCISE-INDUCED CHANGES IN OXIDATIVE STRESS MARKERS.

Masataka, K.1, Mitsuya, Y.2, Daisuke, A.3, Katsuhiko, K.1

1: University of Yamanashi (Kofu, Japan), 2: Yamanashi Prefectural University (Kofu, Japan), 3: National Defence Academy (Yokosuka, Japan)

Introduction Acute intense exercise causes oxidative stress. To reduce oxidative stress-induced adverse events during sports, antioxidant supplementation has been well documented. Recent studies suggested that molecular hydrogen had potential as a "novel" antioxidant improving oxidative stress by drinking water with dissolved it (Nagata et al., 2009). However, timing of drinking hydrogen-saturated water is unclear. The purpose of this study was to investigate the effects of timing of water ingestion before or after exercise on exercise-induced changes in oxidative stress marker in humans. Methods Twenty-one healthy men participated in this study and were randomly divided into two groups in a cross-over study design: NW (normal water, n=7), and HSW (hydrogen saturated alkaline electrolyzed water, n=7). They underwent a treadmill-running test (30 min) at the intensity corresponding to their 70% heart rate reserve, and drunk 500 ml of prescribed water within 5 min before (pre ingestion) or after (post ingestion) the test. Serum creatine kinase (CK) and lactate dehydrogenase (LDH) activities, and serum hexanoyl-lysine (HEL), and malondialdehyde (MDA) concentrations were measured before, 2 and 6 h after the exercise. Urinary 8-hydroxy-2'-deoxyguanosine (8-OHdG) contents were also analyzed. Results There were no significant differences in changes in serum CK and LDH activities, and HEL concentration among groups. In pre ingestion, there were no significant changes in serum MDA and urinary 8-OHdG contents after exercise 6 hours after exercise recovery. However, the percent increases in serum MDA concentration and urinary 8-OHdG content from baseline levels in HSW were significantly suppressed compared with NW, 6 hours after exercise in post ingestion. Discussion Our results suggest that hydrogen saturated water has a potential to attenuate oxidative damage after a single bout of severe exercise in humans. About timing of ingestion, we showed that post ingestion reduced oxidative marker compared with pre ingestion in HSW. We speculate that hydrogen has scavenged reactive oxygen species under condition such as exercise. In conclusion, these results suggest that consumption of hydrogen saturated water after exercise may have a beneficial role in prevention of oxidative stress. References Nagata K, Nakashima-Kamimura N, Mikami T, Ohsawa I, Ohta S. (2009) *Neuropsychopharmacology*;34:501-508.

### COMPARISON OF THE PHYSICAL AND HAEMATOLOGICAL CHANGES IN HEALTHY MALE AND FEMALE BLOOD DONORS FOLLOWING DONATION

Kramp, N.L.1, Stangerup, I.1, Ziegler, A.K.1, Grand, J.1, Dela, F.1, Magnussen, K.2, Helge, J.W.1

1Xlab, Center of Healthy Aging, University of Copenhagen; 2Dept. of Clinical Immunology, Hvidovre Hospital; Copenhagen, Denmark

Introduction Being physically active is more important than ever and fitting this into being a regular voluntary blood donor (DK) can be challenging. Therefore a frequent question in blood banks is: "how is my physical performance influenced by blood donation and when can I expect to perform fully again?" In this study we combine the findings from two independent studies to examine if the acute effect and the subsequent recovery after blood donation are different in women and men. Methods Subjects included in the two studies were donors found via a Danish blood bank. At the time of inclusion, they all met the following criteria: age 20-45 years, regular running activity minimum two times/week, normal BMI 18-30, and a p-ferritin  $\geq 40$  micrograms/L. All subjects, 14 women and 19 men, followed the same protocol consisting of two tests prior to donation measuring baseline values, and four tests placed 3, 7, 14, and 28 days after donation. Blood was sampled, an incremental bicycle VO<sub>2</sub>max and a three km treadmill time trial (TT) was performed on each test day. Results Female subjects had the following mean characteristics ( $\pm$ SEM): height (cm) 169.5  $\pm$ 1.7, weight (kg) 61.6  $\pm$ 1.7, age (yrs) 34  $\pm$ 1.91, VO<sub>2</sub>max (mL O<sub>2</sub>\*kg<sup>-1</sup>\*min<sup>-1</sup>) 47.7  $\pm$ 1.71 and male subjects height 182.7  $\pm$ 1.2, weight 82.1  $\pm$ 2.1, age 33  $\pm$ 2, VO<sub>2</sub>max 49.7  $\pm$ 1.7. The height and weight were lower for women than men, but VO<sub>2</sub>max was similar between genders. After 3 days the blood haemoglobin (mmol/L) was decreased by 6.4  $\pm$ 0.1 and 7.9  $\pm$ 0.2 and was returned to baseline after 14 days for women and 28 days for men; VO<sub>2</sub>max was decreased 5.9  $\pm$ 0.1 and 6.5  $\pm$ 0.1, and was returned to baseline after 28 and 14 days in women and men, respectively. And finally TT performance was attenuated by 5.9  $\pm$ 0.1 and 5.1  $\pm$ 0.2, and were normalised after 14 days, in women and men, respectively. Plasma erythropoietin (EPO) increased after 3 days in both groups and was decreased to baseline in men after 28 days, but remained elevated in women. The plasma EPO concentration was significantly higher in women than men in the last three weeks. Plasma 2,3-DPG remained unchanged through the 28 days and was lower in women than men at all sampling times. Conclusion Overall we demonstrate similar recovery of TT in women and men. However, women have a slower recovery for VO<sub>2</sub>max and a faster recovery for blood haemoglobin compared to men. The higher plasma EPO concentration in women contributes to the faster recovery of blood haemoglobin and yet despite of this the VO<sub>2</sub>max remains attenuated longer in women compared to men.

## CHRONIC BEHAVIOR OF THE BLOOD PRESSURE AFTER SWIMMING TRAINING IN HYPERTENSIVE ADULTS

Eleuterio da Silva, J., Dantas, E.H.M.

*University of Coimbra*

**Introduction** Hypertension (HPT) is one of the major health problem throughout the world, affecting about one billion individuals worldwide. It is estimated a prevalence of (HPT) between 22% to 57% (Wolf-Maier et al, 2003). There is few studies involving hypertension and swimming in human beings. Therefore, the aim of this study was to analyse the Chronic behavior of Systolic Blood Pressure (SBP) after Swimming training in hypertensive adults. **Methods** In this investigation, the sample was randomly selected and the subjects were sorted into two groups: the experimental group (EG) and the control group (CG). Thus, the final sample consisted of 30 subjects with mild and moderate hypertension. The EG individuals (n=20) took part in a regular swimming programme consisting of three weekly fifty-minute sessions of training (ST) for 8 weeks, whereas CG individuals (n=10) were instructed not to alter their physical activity and nutritional habits. **Results** At the end of the 8 weeks there was a decrease of 8,82 mmHg in Systolic Blood Pressure (SBP) at rest when compared with the baseline measurements. The Kruskal-Wallis test was used to determine statistical significance ( $p < 0.05$ ). **Discussion** Although some studies (JNC, 2003; AH A., 2003; Pescatello, et al. 2004) recommend swimming as a form of physical activity to be used in the prevention and treatment of hypertension, rare studies involving human beings have verified the relationship between the practice of swimming and hypertension. In relation to the chronic behaviour of arterial pressure at the end of the intervention, there were, on average, decreases of 6.05 % for SBP between the measurements taken before and after the programme. The latest studies aimed at verifying the effects of swimming on hypertension in humans reported results similar to those found in our study (Tanaka et al. 1997; Silva et al. 2009). **References** Wolf-Maier K, Cooper RS, Kramer H, Banegas JR, Giampaoli S, Joffres MR, Poulter N, Primatesta P, Stegmayr B, Thamm M.(2004) Hypertension treatment and control in five European countries, Canada, and United States. *Hypertension*,43:10-17. ## IMPACT OF COMPLIANCE WITH DIFFERENT GUIDELINES ON PHYSICAL ACTIVITY DURING PREGNANCY AND PERCEIVED BARRIERS TO LEISURE PHYSICAL ACTIVITY

Santos, P.C., Abreu, S., Moreira, C., Lopes, D., Santos, R., Alves, O., Vale, S., Silva, P., Montenegro, N., Mota, J.

*Escola Superior de Tecnologia da Saúde do Porto*

**Introduction:** Physical activity (PA) has been reported as a protective factor in pregnant women's health. However, PA generally declines during pregnancy. This study aimed: (1) to analyze PA engagement during the 1st and 2nd trimesters, considering the different guidelines published on PA, (2) to document the individual characteristics associated with the accomplishment of these guidelines **Methods:** A prospective study was conducted with a sample of 133 pregnant women in two stages: at 10-12 weeks' gestation - T1 and 20-24 weeks' gestation - T2. PA was assessed over 7 consecutive days, by accelerometry, during the T1 and T2 evaluation stages. The pregnant women were divided into four groups, according to different PA guidelines (American College of Obstetricians and Gynecologists-ACOG, Centers for Disease Control and Prevention-CDC, American College of Sports Medicine - ACSM and the United States Department of Health and Human Services-USDHHS). Socio-demographic characteristics, lifestyle factors were assessed via questionnaire. **Results:** A large proportion of women (ranging from 32% - USDHHS to 96% - ACOG) did not reach the levels of PA recommended by the guidelines. There were no significant differences between the 1st and 2nd trimesters with regard to compliance with PA recommendations ( $p > 0.05$  for all). However, a decrease in PA levels from the 1st to 2nd trimesters was noted for all recommendations. No associations were found between participants' characteristics (sociodemographic, obstetric and behavioural) and adherence to particular types of guidelines/recommendations in the 1st and 2nd trimesters ( $p > 0.05$  for all). According to the socioecological framework, no statistically significant differences were found in barriers to leisure PA between the 1st and 2nd trimesters ( $p > 0.05$  for all). **Conclusion:** There were no differences between the 1st and 2nd trimesters in compliance with different PA recommendations. Individual characteristics were not associated with PA guidelines' accomplishment.

## IS THERE AN ASSOCIATION BETWEEN DAILY PHYSICAL ACTIVITY AND ALL PHYSICAL FITNESS PARAMETERS IN WOMEN?

Adriana Santos, Z.

*University of Trás-os-Montes e Alto Douro, Portugal*

**Introduction** It has been proposed that usual physical activity, and not only physical exercise, is of great importance for health maintenance. However, most of the daily physical activities don't develop, at least apparently, several components of physical fitness, namely, agility, power or even strength. Moreover, aging effects on physical fitness decline are well described on literature, which are aggravated by social status changes. Particularly between women, leisure time seem to decrease with age which may affect their time in organized physical exercise, although total week physical activity may be maintained. So, this study aimed to verify if there is an association between daily physical activity and physical fitness parameters, between women over 40 years old. **Methods** Thirty seven women over 40 years of age (from 41 to 82 yrs), not suffering from any motor incapacity, participated in this study. Daily physical activity was quantified by IPAQ, Body mass Index (BMI, weigh/height<sup>2</sup>), waist circumference (WC), aerobic capacity (6 min walking test), 30sec chair stand, 8 ft up-and-go, and squat jump (SJ). Descriptive data analysis and Pearson correlation between variables was done in SPSS. Significant level was set at  $p < 0.05$ . **Results** Table 1 resumes average ( $\pm$ SD) values of age (years), BMI, WC, 6min walking, 30 sec chair stand, 8ft up-and-go and SJ. Age (years) 54.64 $\pm$ 9.52 BMI (weigh/height<sup>2</sup>) 28.10 $\pm$  WC (cm) 89.92 $\pm$  IPAQ 797.25 $\pm$  6min walking (min) 594.71 $\pm$ 5,718 30 sec chair stand (sec) 22.51 $\pm$ 5,718 8ft up-and-go (sec) 4,7651 $\pm$ ,94482 SJ (m) 0.147 $\pm$ ,03794 Pearson correlation revealed that age is positively associated with WC ( $r = .490$ ,  $p < .000$ ) and with 8ft up-and-go (sec) ( $r = .628$ ,  $p < .000$ ). An inverse association was found between age and SJ ( $r = -.602$ ,  $p < .000$ ), 30 sec chair stand ( $r = -.548$ ,  $p < .000$ ) and with 6min walking (min) ( $r = -.439$ ,  $p < .001$ ). However, daily physical activity (METs) was not correlated none of the measured variables. **Discussion** As it was expected, our results revealed that an age related decline in general fitness occurs. Moreover, considering the debate existing in the literature about the influence of daily physical activity vs. physical exercise (were a rigorous control of training workload occur) effects on health, our results pointed out that daily physical activity may contribute to health maintenance but is not enough. This study has been founded by FCT through PTDC/DES/121575/2010 project.

## THE EFFECT TO THE LEG MUSCLE STRENGTH OF THE ELDERLY PEOPLE OF AEROBIC DANCE WHO CARRY OUT AT A HOUSE

Nishizawa, T.

*sigakkan junior university*

Introduction> The purpose our study is to investigate the effect of aerobic dance devised to have on leg strength. It is important to understand the influence of aging on muscle strength of lower limb. Resistance training has been shown to be the most effective exercise for improving muscle strength. Therefore, we devised aerobic dance exercise (ADEx) daily can be carried out in for the purpose of preventing loss of muscle strength. Method> Have been conducted in the elderly aerobic dance program was devise; we measured the morphology and muscle strength before and at the end of the exercise movement. 20 recreationally active women aged  $63.66 \pm 6.66$  years volunteered for the study. 2 monitoring periods are set: one is 2 months-period prior to the start of program, the other is 4 months-periods for the exercise. Program of aerobic dancing exercise (ADEx): This ADEx is created by referring to and replacing the steps of the weight bearing training for aged persons conducted by Yamauchi for skeletal muscle which would suffer from extreme atrophy as the age increases. The exercise time of each ADEx is around 10 minutes, with BPM of from 115 to 120. ADEx of different 5levels are made based on the strength and difficulty of the dances. The subjects choose the exercise time, level, and number of performance, based on their health conditions or paces. Morphology measurement: We measured height, weight, BMI, body fat ratio (TANITA Co), around the hip. Physical Fitness Test: We examine the ability to balance the method using one leg standing with eyes open. Muscle strength :Leg muscle function was measured with a Myutasu F1 (Anima Co.) and the maximum isometric forces (F (max)) . The strength of knee flexor muscles, knee extension muscles, hip joint flexor muscles, and hip joint extension muscles are measured Result> Morphological changes due to the exercise were not observed. Ability to balance the effect of time was able to stand on one leg is extended. As for the isometric leg muscular strength, strength of all of the knee flexor muscles, knee extension muscles, hip joint flexor muscles, and hip joint extension muscles has significantly increased with the activity. Especially, the activity has big effect on gluteus Maximus muscle which produces the strength of hip joint extension muscle. Discussion >: 1) Although did not cause muscle hypertrophy, exercise has contributed to the improvement of neuromuscular function. 2)The program caused a significant increase in isometric strength of all kinds. 3) Providing ADEx that can be carried out at home, may lead to the improvement of exercise habits can be expected. The present results provide a program that can be carried out at home, suggested that prevention of loss of muscle strength is possible.

## A WEB-BASED SURVEILLANCE SYSTEM ON ADOLESCENTS' LIFESTYLES AND OBESITY PREVENTION: ASSO-FTB PRELIMINARY FINDINGS. THE ASSO PROJECT.

Thomas, E.1,2, Raccuglia, M.1,2, Patti, A.1,2, Bianco, A.1,2, Mammina, C.2,3, Tabacchi, G.2,3

*1University of Palermo, Sport and Exercise Sciences unit, Italy 2Ministry of Health, The ASSO Project 3University of Palermo, Department of Health Promotion "G. D'Alessandro",Italy*

The ASSO Project (Adolescents and Surveillance System for Obesity prevention), financed by the Italian Ministry of Health, aims to develop a surveillance system structured on adolescents lifestyles. It is a prospective study with online data collection, simultaneous descriptive data analysis and real time report. The ASSO-Toolkit is made of questionnaires, forms and a fitness test battery. The aims of this study is to evaluate the predictive validity, the criterion validity and the reliability of ASSO-FTB, in other words to assess how well the system operates to meet its objectives. The ASSO-FTB consists of 20mSRT (Shuttle Run Test) to estimate cardiorespiratory fitness, the handgrip strength test and the standing broad jump to assess musculoskeletal fitness, the 4x10mSRT to assess motor fitness and last but not least the sit up test to estimate muscle endurance. The project is currently spreading in southern Italy, both in urban and rural territories. A comparison has been made between two schools to evaluate if demographic aspects affect adolescents fitness and ensure that the project itself is reliable and reproducible. Forty male adolescents ( $17,32 \pm 1,0$  yrs;  $175,3 \pm 6,0$  cm;  $72,4 \pm 14,7$  kg; waist circ.  $86,2 \pm 12,4$  cm) attending an urban secondary school and forty-nine adolescents ( $15,86 \pm 1,4$  yrs;  $169,8 \pm 8,9$  cm;  $64,3 \pm 15$ ) attending a rural secondary school voluntarily participated to the study . In a school setting, the standardized procedures were administered by the ASSO-FTB specialist in collaboration with the (PE) teacher. All data collected were updated through the already existing website ([www.assoproject.info](http://www.assoproject.info)) and codified by the dedicated ASSO-FTB server. Participants were significantly higher in BMI compared to data published by Espana-Romeo et al in 2010. As expected, the maximal isometric strength showed no differences between urban ( $35,07 \pm 7,3$  kg) and rural ( $33,7 \pm 10,8$  kg) school respectively. Data that remains in line with what published by Espana-Romeo et al in 2010. The standing broad jump ( $178,07 \pm 26,9$  cm) has evinced less distance than Espana-Romeo study ( $183,4 \pm 32,75$ ),  $p = 0,37$ . On the whole findings show that there is a correlation between handgrip and the 4x10 meter shuttle run test ( $r = -0,7$ ) and between handgrip and standing broad jump ( $r = 0,7$ ) underlining that this last test is better indicative of the upper and lower body muscular strength. The only concern comes from the VO<sub>2</sub> max results, showing a mean value of 24 ml/kg/min. It is still to determine if the 20m shuttle run test underestimates this parameter or if adolescents have at this stage of development a reduced cardiorespiratory fitness. The trial showed that the FTB-system is reliable and reproducible. At this stage ASSO-FTB seems to be able to meet scientific standards. More studies are necessary for the ASSO-toolkit validation. Preliminary results are very encouraging.

## History

### MAX RUBNER <1854-1932> AND HIS CONTRIBUTION TO SPORT NUTRITION

Colombani, P.C., Mettler, S., Pritchard-Peschek, K.

*Swiss Federal Institute of Sport Magglingen*

INTRODUCTION Born in Munich on June 2, 1854 and dying in Berlin on April 27, 1932, Max Rubner is one of the most important physiologists in history. Rubner is renowned for his calorimetric experiments and the discovery of the isodynamic law, which depicts the energetic interchangeability of the energy-delivering macronutrients. His contributions towards physical activity, sport, and sport nutrition have not been equaled since. Rubner was emeritus when he gave a talk on sport and nutrition at the Sportärztetagung 1925, the 2nd congress of the German Medical Association for the Promotion of Physical Activity (Rubner, 1926). Though by then scientific publications on energy expenditure and dietary intake of athletes were available, his presentation was likely the first in the field of sport nutrition at a sports medicine and science congress. As a leading nutritionist of his time Rubner had a comprehensive overview of the entire field of nutritional

research. Thus, his presentation can be considered as the gold standard in sport nutrition of the mid-1920s. SPORT NUTRITION IN 1925 Rubner had serious concerns regarding the presentation of this topic, as nutrition and physical exercise was still a relatively unexplored field. He therefore considered his work as a beginning for future research. Rubner began with topics of general nutrition, and observed that quite often in literature, pseudo-scientific personal opinions were mingled with scientific evidence. He then discussed the energy requirements for muscular work and made the remarkable statement that intense exercise was a pre-requisite for net muscle gain, but that this type of exercise only led to muscle gain when accompanied by sufficient nutrition. Rubner proposed a total «sport proposal» for energy intake of 3472 calories, which could be achieved by consuming 100 g of protein, 100 g of fat and 490 g of carbohydrates. Using a reference body mass of 70 kg, this translates to 1.4 g of protein, 1.4 g of fat, and 7.0 g of carbohydrates per kilogram of body mass. In other words, nearly 90 years later, we are still recommending these same strategies. Rubner closes his presentation with a general discussion on food, covering aspects still relevant today (e.g. vegetarian vs. non-vegetarian diet, meal frequency with increasing energy need, and correct fluid intake strategies). Overall, Rubner's theories in sport nutrition were remarkably modern for such an early period in its development, and despite lacking scientific evidence at the time, they are still valid today. ## **RETROSPECTIVE STUDY OF RESULTS AT SUMMER OLYMPIC GAMES FROM 1908 TILL 2012 IN MEN SWIMMING CATEGORIES**

Vucetic, V., Zekic, J., Sukreski, M.

*Faculty of Kinesiology*

**INTRODUCTION:** Identify trends and factors of change in results of swimmers, holders of gold, silver and bronze medals at the Olympic games since 1908 till 2012, and make an assessment of their future developments. **METHODS:** A retrospective study of the results at the Summer Olympic games in swimming for men since 1908 till year 2012, and an analysis of available data on anthropometry of swimmers, training methods, the technique of swimming, diet, swimming pool equipment and appearance. In this study we will also analyse the holders of gold, silver and bronze medals at the Olympic Games since 1908 till today. **RESULTS:** Improving of results correlate with the length of the Olympic cycle, which we take into account during results analysis. We notice that the improvement of the results increases with the number of Olympic cycle on which some discipline maintain and that the correlation between the improvement and the number of cycles between olympic disciplines is greater than 90%. Results have shown a tendency of slowing down improvement of the results in few last olympic cycles, with the exception of the results achieved in the Olympic Games in Beijing 2008, when the use of high-tech suits significantly improved results and 66 Olympic records were beaten. This trend suggests that we are approaching the biological plateau in terms of improving performance in swimming, and we expect on the basis of this research all the minor improvements of results in each subsequent cycle, with the exception of the use of high-tech suits. In the period of 110 years, since the first Olympic games in Athens to present, the results have improved by a whopping 40% of the initial results, which is a man nearing his maximum speed of movement through the water without technological aids. Many factors have contributed to the improvement of the results, and none of this factors cannot be ignored in the research of the development of swimming and improving results. The importance of each of these factors remains a challenge for future researchers. **CONCLUSION:** Advance in swimming since the first Olympic Games in Athens in 1896 until today is made by great number of changes. We can divide them into changing the way and technique of training, changes in eating habits and dietary supplementation, changes in swim suits and changing conditions and ambient of swimming. **REFERENCES:** 1. ## **REGULATION RESEARCH APPLIED TO EPISTEMOLOGICAL THEORY OF PHYSICAL EDUCATION AND SPORT IN ITALY**

Tursi, D., Di Tore, P.A., Napolitano, S., Raiola, G.

*University of Salerno*

The epistemology of physical education and sport in Italian universities was changed in 1998 by law with the transformation of Higher Education Institute of Physical Education and Sport, called ISEF (Dlgs 178). Previously, ISEF, Italian National Olympic Committee, called CONI, and the National Sport Federations have provided education for teachers, technicians and trainers but neglecting completely the research. The law established two new Academic Fields : Methods and teaching of motor activities, called M-EDF-01 and Methods and teaching of sports activities, called M-EDF-02. These academic fields have been involved to defend the single propriety of the research in a specific academic field. The M-EDF-01 includes the development of theories, techniques and methods for physical education geared to specific age groups; the M-EDF-02 deals with the development of theories, techniques and methods for the training and practice of different sports activities and with the assessment of the performance and the athletic attitudes. Each academic field has the subarea that explains and declares the meaningful of the academic field. In other hand, to recruit the professors in the new field of Physical education and sport it needs many academic fields (D.M. 4 ottobre 2000). The aim is to research the epistemic origin of the Physical Education and Sport. Method is historical and documentary approach. Results are the professors of Physical Education and Sport have to be part of other academic fields, such as Physiology, Biochemistry, Internal Medicine, Physical and Rehabilitation Medicine, General and Subspecialty Pediatrics, Physiology Clinical Biochemistry and Molecular Biology, Experimental Biology, Human Anatomy, Clinical Pathology, Cardiovascular Diseases, Endocrinology, Musculoskeletal System Diseases, Diagnostic Imaging and Radiotherapy, Theories and Science of Education and Social Education, History of Education, Methodologies of Teaching and Special Education, Educational Research, General Psychology, Psychobiology and Physiological, Psychometrics, Developmental and Educational Psychology, Social Psychology, Work and Organizational Psychology, Dynamic Psychology, Clinical Psychology.. In conclusion the professor are the academic fields different from the epistemology origin of Physical Education and Sport and the mix of academic fields that doesn't give a properly epistemological theory also in research activity. **Keywords:** academic fields, motor activities, sports activities, References Gazzetta Ufficiale, 1998, Legislative decree no. 178, may 8th, Roma, Italy Gazzetta Ufficiale, 2000, Ministerial Decree october 4th, Roma, Italy

**EFFECT OF ACUTE AEROBIC EXERCISE ON PGC-1 ALPHA ISOFORMS EXPRESSION IN HUMAN SKELETAL MUSCLE**Bachinin, A.I., Miller, T.I., Popov, D.I.,<sup>2</sup>*1 SSC RF – Institute for Biomedical Problems RAS, 2 M.V. Lomonosov Moscow State University*

Peroxisome proliferator-activated receptor gamma coactivator 1alpha (PGC-1alpha) is a "master regulator" of mitochondria biogenesis in the skeletal muscle. There are at least four transcript variants of PGC-1alpha mRNA. PGC-1alpha-1 is transcribed from the canonical proximal promoter and PGC-1alpha-2, -3 and -4 are transcribed from the alternative upstream promoter. Rodent studies have shown an acute aerobic exercise induced a drastic expression increase of PGC-1alpha-1, -2 and -3 mRNA variants (Miura et al., 2008; Tadaishi et al., 2011). To our knowledge only one study investigated the effect of acute aerobic exercise on expression of two isoforms of PGC-1alpha-1 and -2 mRNA in human skeletal muscles (Norrbon et al., 2011). Recently Ruas J. and coworkers showed the increased expression of PGC-1alpha-4 mRNA and of proteins associated with skeletal muscle hypertrophy in rodent and human skeletal muscle (Ruas et al., 2012). The goal of the present study was to investigate the effect of acute aerobic exercise on expression of PGC-1alpha-1, -2, -3 and -4 transcriptional variants in human skeletal muscle. Seven endurance athletes ( $\dot{V}O_{2max}$  64±8 ml/kg/min) carried 90 min exercise session (61%  $\dot{V}O_{2max}$ ). Biopsies were taken from m. vastus lateralis before, 3 and 5 h after the exercise. The expression of PGC-1alpha mRNA isoforms was evaluated by qPCR. In resting state the expression of PGC-1alpha-2 mRNA was higher and PGC-1alpha-3 mRNA was lower than expression of PGC-1alpha-1 and 4 mRNA isoforms. After acute exercise session PGC-1alpha-2 mRNA isoform showed more pronounced increase of expression than other isoforms. We speculate, that PGC-1alpha-2 isoform has more important functional role, than other transcript variants. The work was supported by M.V. Lomonosov Moscow State University Program of development and by RFBR grant # 12-04-01668-a.

**THE IMPACT OF ANTIOXIDANT SUPPLEMENTATION AND ENDURANCE EXERCISE ON NEURONAL NITRIC OXIDE SYNTHASE EXPRESSION IN SKELETAL MUSCLE OF MICE**

Baum, O., Hoppeler, H.

*University of Bern*

**Introduction** In skeletal muscles, high levels of the nitric oxide (NO) are generated by the catalytic activity of neuronal NO synthase (nNOS) which may interact with reactive oxygen species (ROS). Both radical systems (NO and ROS) represent important signalling molecules involved in many processes in skeletal muscle. Although antioxidant supplementation with or without endurance exercise leads to well-characterised changes in the ROS metabolism, the impact of this treatment on the nNOS/NO system has not been documented so far. **Methods** We administered a mixture of antioxidants (AOX; 140 mg/l of ascorbic acid, 12 mg/l of coenzyme Q10 and 1% N-acetyl-cysteine) via drinking water to 16 C57BL/6 mice. Sixteen other mice received unadulterated tap water (CON). One cohort of both groups (CON-EXE) and AOX-EXE was subjected to treadmill exercise for 4 weeks (16-26 m/min, incline of 5°-10°). The other two cohorts (CON-SED and AOX-SED) remained sedentary. The mice were euthanized 1 day after the last treadmill exercise (approximately 24 h) by an intraperitoneal injection of pentobarbital (300 mg/kg of body weight). The tibialis anterior (TA) muscle was isolated for an analysis of the gene expression of nNOS at the mRNA and protein level by real-time polymerase chain reaction (RT-PCR) and quantitative immunoblotting. **Results** In CON-SED mice, nNOS expression in TA muscle ( $P \leq 0.05$ ) was higher at both the mRNA (+72%) and the protein (+44%) level than in those undergoing treadmill training. Accordingly, mice that were administered with AOX had a higher ( $P \leq 0.05$ ) nNOS expression in TA muscle at both the mRNA (+57%) and the protein level (+24%) compared to those of the CON-SED cohort. In contrast, combination of AOX supplementation and endurance exercise was accompanied by non-significantly lower ( $P > 0.05$ ) expression of nNOS in TA muscle at both the mRNA (-16%) and the protein level (-5%) compared to that in the CON-SED cohort. **Discussion** Endurance exercise and the supplementation with AOX increase the nNOS expression in TA muscle of mice. If both treatments are combined, the up-regulation of nNOS is blunted. These data suggest that the expression of nNOS in skeletal muscles of mice is susceptible to the treatment with AOX at sedentary conditions. This AOX-sensitivity is impaired, if the mice are simultaneously exposed to AOX supplementation and higher rates of contractility (e.g. by endurance training). **References:** Meier P, Renga M, Hoppeler H, Baum O. (2013), *Cell Biochem Funct.* 31:51-59.

**ADRB2 ARG16GLY AND PPARA G/C GENE VARIANTS ARE ASSOCIATED WITH IMPROVED PERFORMANCE FOLLOWING HIGH-INTENSITY INTERVAL TRAINING**

Bishop, D., Voisin, S., Eynon, N.

*Victoria University*

**Background** Individual differences in the response to similar exercise training are a well-known occurrence, and are influenced by both environmental and genetic factors. The beta(2)-adrenergic receptor (ADRB2) Arg16Gly (rs1042713), and peroxisome proliferator-activated receptor alpha (PPARA) intron 7 G/C gene variants are candidates to explain some of this variability in training response due to their role in glucose and fatty-acid metabolism (1-2). We have designed a tightly controlled High-Intensity Interval Training (HIIT) study, and used an innovative, bootstrapping, statistical method (to overcome the relatively small sample size) to investigate the influence of ADRB2 Arg16G, and PPARA intron 7 G/C gene variants on performance outcomes. **Methods** Twenty-four moderately-trained, unrelated Australian males (21.6±0.7y) underwent 4 weeks of supervised HIIT training (3 sessions a week). A graded exercise test was performed pre and post training to assess changes in endurance performance. Genomic DNA was extracted from leucocytes and genotyping was performed using the R-T PCR Taq Man method. A linear model, corrected for age and BMI, was developed for each gene variant to estimate the effects of the genotypes on the changes in peak power, lactate threshold, and  $\dot{V}O_{2max}$ . Resampling was performed 5000 times for each gene variant, and a 95% confidence interval of the regression coefficient was calculated (bootstrapping method). The level of significance was set at  $P < 0.05$ . **Results** ADRB2 Arg16Gly, and PPARA G/C polymorphisms were significantly associated with the training response. ADRB2, Arg/Arg homozygotes showed a higher increase in peak power following HIIT compared with Gly-carriers (Arg/Arg: 28.5 ± 2.9 Watts, Arg/Gly: 12.9 ± 3.1 Watts, Gly/Gly: 16.7 ± 5.3 Watts). PPARA, G/G homozygotes showed a higher increase in heart rate at the lactate threshold, and in peak power, compared with G/C carriers (change in heart rate at the lactate threshold, G/G: 18 ± 3 beats/min, G/C: 3 ± 1 beats/min; change in peak power; G/G: 21.0 ± 3.2 Watts, G/C: 9.8 ± 2.1 Watts). **Discussion** We have confirmed that ADRB2 Gly16Gly genotype is associated with better response to training, as previously shown (1), and found, for the first time, that PPARA G/G

genotype is also associated with a greater response to training. References 1. Sarpeshkar and Bentley. (2010). ### **EFFECT OF ACUTE AEROBIC EXERCISE ON REGULATION OF MITOCHONDRIAL BIOGENESIS, PROTEIN METABOLISM IN SKELETAL MUSCLE OF TRAINED MEN: A TIME-COURSE STUDY**

Popov, D.1,2, Lysenko, E.1, Bachinin, A.1, Miller, T.1, Vinogradova, O.1,2

*1 SSC RF – Institute for Biomedical Problems RAS, 2 M.V. Lomonosov Moscow State University*

Peroxisome proliferator-activated receptor gamma coactivator 1a (PGC-1alpha) is a “master regulator” of mitochondria biogenesis in the skeletal muscle. Previous dose-response studies have shown that an expression of PGC-1a mRNA depends on relative aerobic exercise intensity. To our knowledge no studies of PGC-1alpha expression in relation to duration of exercise were performed. The aim of the study was to investigate the effect of acute exercise duration on regulators of mitochondrial biogenesis (phosphorylation of p38 and AMPK and expression of mRNA of PGC1alpha, PRC, TFAM, TFB2M) and protein metabolism (phosphorylation of p70S6k and eEF2 and expression of mRNA of Myostatin, MuRF1, Atrogin-1) in skeletal muscle of trained men. Eight endurance athletes ( $\dot{V}O_2\text{max}$  64±8 ml/kg/min) carried out three exercise sessions (61%  $\dot{V}O_2\text{max}$ ): 30, 60 and 90 min duration. Biopsies were taken from m. vastus lateralis before, just after, 3 and 5 h after the exercise. The phosphorylation of PGC-1alpha pathway upstream kinases – AMPK and p38 – did not change after 30 min session, but increased to a similar extent after 60 and 90 min session. The expression of PGC-1alpha mRNA was enhanced 3 and 5 h after 60 and 90 min sessions and did not differ between sessions. mRNA abundance of other mitochondrial biogenesis regulators – PRC, TFAM, TFB2M – did not change after all sessions. The abundance of mRNA MuRF1 after 90 min session was higher than after 60 min session, but on the other hand, only 90 min session led to a decreased Myostatin gene expression. There was a tendency for a more pronounced increase of phosphorylation of p70S6k and eEF2 after 90 min session, than after shorter sessions. In conclusion AMPK and p38 kinases activation and PGC1alpha gene expression were increased with elongation of exercise session up to 60 min. 90 min exercise session had higher potential for inducing muscle protein degradation and lower potential for protein synthesis activation than exercise of shorter duration. The work was supported by M.V. Lomonosov Moscow State University Program of development and by RFBR grant # 12-04-01668-a.

### **COMPARATIVE ANALYSIS OF GENE EXPRESSION IN MUSCLE FIBERS OF DIFFERENT TYPES FROM LOCOMOTOR AND RESPIRATORY MUSCLES IN RAT**

Vinogradova, O.1, Borzykh, A.1, Gainullina, D.2, Kuzmin, I.2, Sharova, A.1, Tarasova, O.1,2

*1 SSC RF – Institute for Biomedical Problems RAS, 2 M.V. Lomonosov Moscow State University*

Expression of genes in diaphragm and three different locomotor muscles from hind extremity (m. soleus -S, red and white parts of m. gastrocnemius – RG and WG) of rat were studied by means of real time PCR. Citrate synthase activity in S and RG was found to be much higher than in WG. Correspondingly, level of PGC-1a expression in S and RG was significantly higher than in WG. Transcriptional factors MyoD and myogenin are involved in regulation of myosin phenotype of skeletal muscles in adults. The high expression of myogenin is typical for slow MF, and that of MyoD – for fast MF. In our study the level of myogenin expression in RG was lower than in S, but was higher than in WG, i.e. it was in accordance with MF I content, which was 80-90% in S, 40% in RG and just tiny in WG. Myostatin is a powerful negative regulator of MF growth. The highest level of its expression was found in WG, the 30-fold lower expression was recorded in RG and 150-fold lower – in S. That distribution is in accordance with MF II content in muscles. IGF-1 is a stimulator of muscle protein synthesis. In the locomotor muscles studied expression of IGF-1 mRNA was practically equal. The levels of expression of PGC-1a and myogenin mRNA in diaphragm were in conformity with its myosin phenotype and citrate synthase activity. On the other hand diaphragm was characterized by an unexpectedly high level of MyoD mRNA as well as high content of IGF-1 mRNA and low myostatin RNA. The last two observations seem to indicate the high intensity of protein synthesis in muscle fibers of diaphragm despite their smaller size than in locomotor muscles. Some additional control might exist specifying small size of diaphragm fibers at the background of myostatin low expression and IGF-1 high expression. The work was supported by M.V. Lomonosov Moscow State University Program of development and by RFBR grant # 12-04-01668-a.

### **EFFECT OF MUSCLE DISUSE AND TESTOSTERONE ON AKT/MTOR/FOXO SIGNALING IN MICE**

De Naeyer, H., Lamon, S., Russell, A.P., Everaert, I., De Spaey, A., Vanheel, B., Taes, Y., Derave, W.

*Ghent University*

Introduction Research models of muscle disuse atrophy are often associated with reduced serum testosterone levels (1). Because androgen deficiency is associated with significant muscle loss (2), it is likely that the hormonal changes during disuse contribute to the observed muscle atrophy. Moreover, the molecular mechanism by which testosterone may affect muscle mass during disuse atrophy is unknown. Therefore, we examined the effects of tail suspension on serum testosterone levels, and we analysed changes in gene and protein expression of known muscle atrophy and hypertrophy inducing targets (3). Methods Measurements were made in slow-twitch soleus (SOL) and fast-twitch extensor digitorum longus (EDL) muscles following testosterone administration during 1, 5 and 14 days of tail suspension in male C57BL/6 mice. Serum testosterone levels were assessed by LC/MS. Gene and protein expression were analysed by qPCR and Western blotting respectively. Results Tail suspension resulted in a significant decrease in body mass, muscle mass and serum testosterone levels. Atrophy of both muscles was associated with increases in MAFbx/Atrogin-1, MuRF1, myostatin and REDD1 gene expression and a downregulation of IGF1 gene expression. However, these changes were not paralleled by changes in protein levels. Total Akt and p-p70S6K were unchanged, but p-Akt and total p70S6K were downregulated following hindlimb unloading. Testosterone administration during tail suspension was not associated with changes in body mass, muscle mass, gene or protein expression levels. Discussion Restoration of the testosterone levels did not minimize the loss in muscle mass, which suggest that the lower amount of circulating testosterone levels observed during the unloading process do not contribute to the muscle atrophy. Although studies have shown changes in Akt/mTOR/Foxo (4) signalling following androgen deprivation and treatment, we could not provide evidence that the changes in hormonal levels observed during tail suspension affected these pathways. ### **INFLUENCE OF GLU298ASP POLYMORPHISM IN HEART RATE RECOVERY AFTER EXERCISE**

Sanchez, J., Campuzano, O., Guerra, M., Iglesias, A., Cabedo, J., Alcaide, M., Brugada, R.

*FPCEE Blanquerna (Ramon Llull University)*

Introduction NOS3 gene is localized to chromosome 7q36 (Robinson, Weremowicz, Morton & Michel, 1994) (National Center for Biotechnology Information, 1994). Nitric oxide synthase endothelial (NOS3) plays a crucial role in the production of nitric oxide, a signaling molecule that acts as an important endothelium-derived vasorelaxant factor (Pereira, et al. 2007). It seems that there is an interaction between the sympathetic nervous system and endothelial function, specifically the relationship between the heart rate recovery (HRR) and endothelial function (Hijmering, et al. 2002). Therefore, the aim of our study was to describe the influence of p.glu298asp in the heart rate recovery during the first, second, third and fourth minutes after maximal exercise. Methods The sample was 68 healthy university Spanish students (age, 18-35 years), 17 females and 51 males, all of them were Caucasian for  $\geq 3$  generations (with p.glu298asp = 31 and without p.glu298asp = 37). They performed a treadmill test with an inclination 3%, and speed increment (beginning at 6 km/h and increasing 2km/h every 2 minutes) until exhaustion, maximal heart rate was obtained as well as heart rate recovery immediately after the exercise during the first minute. Treadmill Lifefitness (USA), MP100 System Hardware. AcqKnowledge Software 3.9-Windows XP. Biopac Systems (USA) and Polar T31 (Finland) were used. Descriptives with Mean and Standard deviation were calculated using SPSS 18 package. Results Heart rate peak was 185.2 bpm. The results suggest that subjects with p.glu298asp have a better heart rate recovery during the first (24.19bpm $\pm$ 8.81), second (40.81 bpm $\pm$ 10.01), third (52.77 bpm $\pm$ 12.06) and fourth (66.77 bpm $\pm$ 9.30) minute after maximal exercise. Conclusion Subjects who are carriers of the Glu298Asp polymorphism of the NOS 3 gene have a better cardiac recovery. Our research was only a descriptive study and needs more research to determine the influence of the Glu298Asp polymorphism of the NOS 3 gene in the heart rate recovery. ### **Motor Learning**

#### **DIFFERENTIAL VS. DRILL LEARNING OF THE OVERHEAD BADMINTON SMASH**

Jaitner, T., Kessler, D.

*University of Dortmund*

Introduction Based on Coordination dynamics theories, the differential learning approach propose that a high variability of practise including variation of movement parameters as well as structures results in superior motor learning results in superior performance than repeating the same movement many times during acquisition (Frank et al, 2008). Empirical evidence has been given in various sports disciplines such as passing in soccer or the badminton serve (Jaitner & Schinz, 2012). The purpose of this study was to investigate effects of differential learning on the overhead Badminton smash. Methods 22 Badminton players of regional level of expertise participated in a learning experiment with 12 practice sessions. Subjects were divided into a differential training group (DT) and a control group (CG). Following a theoretical instruction, CG performed drills that were characterized by high numbers of repetitions of the same exercises. Feedback was given by demand in order to support the athletes adaption to the ideal technique. For the DT group multiple variations were implemented including initial positions, range and intensity of motion, rackets and environmental conditions, and no feedback on performance was given. In pretest (PR), posttest (PT) and retention test (RT) two weeks after the posttest each participant performed a Badminton specific drill that consist of 4 forehand overhead smashes from the rear zone of the field followed by a short drop at the net. All smashes must be placed longline as closed as possible to the front and side line. Smashing performance was filmed with a highspeed video camera (200 Hz), and maximal shuttle velocity and release height were determined. The best trials of each subject and test were included for the ANOVA. Results For DT, mean shuttle velocities (SV) increased from pre- to retention test (PR: 55,5m/s; PT: 57,0m/s; RT: 57,40m/s), whereas mean release heights (RH) remained stable (PR: 2,40m; PT: 2,41m, RT: 2,39m). Mean SV of the CG increased from pre- to posttest (PR: 60,7m/s; PT: 60,9 m/s), but decreased afterwards (RT: 59,1 m/s). RH of the CG reached 2,47m (PR), 2,53m (PT) and 2,49m (RT), respectively. ANOVA revealed significant effects only for the SV for factor time ( $p < .05$ ;  $\eta^2 = .158$ ) as well as for the interaction between time and group ( $p < .01$ ;  $\eta^2 = .409$ ). Discussion The DT group improved their smashing velocity sustainably, while drill training showed no positive learning effect. Hence, badminton players at regional level did not seem to benefit from drill training, whereas the highly variable training lead to superior performance. These results are in line with previous studies (e.g. Jaitner & Schinz, 2012) and indicate the importance of movement variations to achieve further adaptations in trained Badminton players. #### **DISRUPTING SWARMING BEHAVIOUR AMONGST JUNIOR FOOTBALL PLAYERS**

Button, C., Stannard, S., Meerhoff, L., Kennedy, G.

*University of Otago*

Introduction: Swarming is a collective behaviour exhibited by groups of biological organisms manifested in many species in nature (Camazine et al., 2001). Swarms display structural order, with the behaviour of individual members integrated on the basis of simple interactional 'rules', such that they can appear to move as a single coherent entity (Merrifield, Myerscough, & Weber, 2006). In this explorative study we aimed to quantify and potentially disrupt the swarming phenomenon in children's soccer. Methods: Three junior (5-6 years old) football teams participated. One team received a constraints-informed training intervention designed to increase skills and tactical awareness. Each team (n=5) completed pre and post skills tests and also two 16 minute games against each other. Overhead

video footage was collected from the games, to measure the players' spatio-temporal distribution on the pitch (15 x 25 m). Swarm variables included interpersonal distance (IPD), surface area of team, stretch index about the team centroid and coherence of velocity profiles. Results: There were soccer skill (i.e., passing, dribbling, shooting) improvements after 8 weeks of training for all three teams. Before the training period there was strong evidence of swarming tendencies as expressed through low IPD ( $3.2 \pm 0.8$  m) and surface area ( $13.6 \pm 5$  m<sup>2</sup>). After targeted training, the swarming behaviour was partially disrupted (i.e., intervention team IPD =  $3.9 \pm 0.7$  m, surface area =  $18.1 \pm 7$  m<sup>2</sup>). Discussion: The behavioural phenomenon of swarming common to socio-biological groups in nature also appears to exist in junior soccer. Groups of players tend to bunch close together and align their heading direction toward the ball as individuals jostle to get close enough to gain ball possession. We are currently comparing real player positional data with simulated soccer data (constructed with NetLogo 5.0: <http://ccl.northwestern.edu/netlogo/>) to ascertain the extent to which children's soccer games adhere to common swarming principles. Future research may compare swarming in different age groups across adolescence to determine when and how this behaviour changes to more sophisticated patterns of play. ### **SELF-CONTROLLED LEARNING OF MOTOR SKILLS: IS THERE A TRADE-OFF BETWEEN COGNITION AND MOTIVATION?**

Bund, A.

*University of Luxembourg*

Introduction Studies have shown that self-control over (at least) one aspect of the practice situation results in a more effective motor learning (e.g., Post et al., 2011). However, this "self-control effect" consistently occurs delayed, i.e. in the retention test. To explain this delay, a model was developed in which a trade-off between cognitive and motivational processes during acquisition is assumed: Compared to externally controlled learners, self-control learners are exposed to a higher cognitive load (due to the need of decision-making) but stronger intrinsically motivated (due to the perception of autonomy). The aim of the present study was to test this model. Methods A sample of 48 young adults (Mage = 23.5) were randomly assigned to one of four groups: 1. Self-control (SC), 2. Yoked (YO), 3. Self-control + Training (SC+T), 4. Yoked + Training (YO+T). Self-control was given over the frequency of augmented feedback. Prior to the experiment, subjects in the SC+T group took part in a training with the objective to reduce the cognitive load during self-controlled learning. Both SC groups were paired with yoked groups. The task was to throw a standard tennis ball to a 1x1m-target with the non-dominant hand. Participants completed two acquisition sessions and a no-treatment retention test 4 days later. Results Data were analyzed in two separate 2 (control of learning) x 2 (training) x 20 (blocks of 10 trials) MANOVAs with throwing accuracy and form as dependent variables. Accuracy: All groups enhanced throwing accuracy during acquisition,  $F(19,836) = 4.36, p < .05, \eta^2 = .06$ . However, the effects of control of learning and training were not significant, both  $F(1,44) < 1$ . Analysis of retention data yielded a significant effect of control,  $F(1,44) = 5.37, p < .05, \eta^2 = .08$ , with the SC groups showing more accurate throws than the YO groups. The effect of training was not significant,  $F(1,44) < 1$ . Form: All groups improved clearly their throwing form during acquisition,  $F(19,836) = 17.26, p < .001, \eta^2 = .21$ . Again, the main effects were not significant, both  $F(1,44) < 1$ . Across retention, the form scores were similar, i.e. the effects of control and training were not significant, both,  $F(1,44) < 1$ . Discussion In view of the fact that the SC groups were (partly) superior to the YO groups in the retention test but not during acquisition, the findings of this study confirm prior research on self-controlled motor learning. However, the SC+T group did not show better acquisition performance than the SC group, which is contradictory to our model. Possible theoretical and methodological reasons are discussed in the poster. References Post, P.G., Fairbrother, J.T. & Barros, J.A.C. (2011): Self controlled amount of practice benefits learning of a motor skill. *Research Quarterly for Exercise and Sport*, 82, 474-481.

### **FUNDAMENTAL MOVEMENT SKILLS AND DAILY PHYSICAL ACTIVITY LEVELS IN PRESCHOOL CHILDREN**

Sasaki, R., Ishizawa, J., Kusuhara, K., Okuyama, S.

*Keio University*

Introduction: Preschool and the early elementary school years are critical to a child's development and mastery of fundamental movement skills (FMS). The process of acquiring FMS occurs through a range of active play experiences and structured activity programs. Recent research among preschoolers has shown that FMS are positively associated with habitual physical activity (2005, 2008). Moreover, FMS are generally not considered to develop naturally in children through a maturational process. As such, these skills need to be learned, practiced, and reinforced (2011). Moreover, the type of FMS acquired differs depending on the movement category (i.e., locomotion, manipulative movements). In this study, we investigated the relationship between FMS and the daily physical activity level of preschool children, and elucidated the status of this relationship in relation to the movement categories. Methods: One hundred forty Japanese preschool children aged 4-6 years participated in this study. Each child performed 5 FMS (25-m run, zigzag run, standing broad jump, overhand throw, and bouncing the ball), with quantitative data obtained for each of these movements. The amount of physical activity was assessed using a triaxial accelerometer (OMRON, HIJ-350IT), which each child wore for a week. We examined the time children spent engaged in moderate-to-vigorous activity (MVPA) and recorded the number of steps during everyday activities. We compared the measurement data between 2 age groups (2 school-year grades) and between genders (boys and girls). We also tested for associations between the MVPA levels and the total FMS score (z-score) or the individual FMS score. SPSS software was used for statistical analysis. Results: We found that FMS were greater among older children than in younger children. The degree of MVPA was slightly higher among boys versus girls. A statistically significant relationship was found between the total score of the 5 FMS and MVPA ( $p < 0.05$ ). However, when the relationship between MVPA and each movement item was assessed individually, some differences were observed. The 25-m run, zigzag run, and standing long jump were associated with the degree of MVPA ( $p < 0.01, 0.01, \text{ and } 0.05$ , respectively), whereas the overhand throw and ball bounce were not associated with MVPA. Discussion: These results suggest that not only sufficient total daily activities but also practical movement experiences are needed to enhance every category of movement skill in children. Each particular movement needs to be practiced to enable mastery of movement skills (Logan et al., 2011) according to the developmental stage, particularly with respect to manipulative movements. ## THE VARIETY AND DEFINITION OF FUNDAMENTAL MOVEMENTS IN PRESCHOOLER'S SPONTANEOUS ACTIVITY

Ryosuke, K., Shohei, K.

*Kobe University*

**Introduction** Children should experience various movements to make the base of motor skill and the future sports habit. Physical activity guideline for young children in Japan indicates the importance to make movements variedly in many plays. We need to evaluate the diversity of children's movements accurately. Japan Sports Science Center (JSSC) (1980) introduced 84 movements such as "climbing" and "rolling", which are fundamental movements of preschoolers. They were ambiguous because JSSC collected only the terms of fundamental movements without field work evidence. Both researchers and practitioners couldn't understand many of the terms which correspond with actual motion of children. The purpose of this study was to ameliorate the concept of fundamental movements of JSSC based on the feature of action and field observations. **Methods** The subjects were 5-year old children who attend a kindergarten in Kobe City, Japan. We took movies of their spontaneous activity and categorized their motion to fundamental movements using the JSSC list. At first we picked out terms which could express observed motions the most accurately from the list. Then we re-categorized the motions into 8 domains, which included "up-and-down movement", "horizontal movement" "posture change" and so on. When the list couldn't express or correspond observed motions accurately, the terms were changed, removed, integrated or divided. Additionally new motions were added to the list. **Results and Discussion** In eighty-four movements of the list, four motions, "cross", "run away", "be carried one's back" and "stamp", were re-categorized into other domains. Seven motions were changed their names, integrated or divided, e.g. "skip / pop" were divided into "skip" and "pop". Ten motions, "ride", "hide", "stop" etc., were removed from the list since they were difficult to define as a single motion. Twelve motions, "jump and down", "running up", "cartwheel" etc., were added newly. Seventy-four motions were defined. For example, "climb" and "shin up", this deference was ambiguity in the list, were distinguished from perspectives whether children intended to support their action by using hands or not. As a result, eighty-two motions were proposed as fundamental movements. Eighteen motions weren't defined because they weren't observed in this study. Moreover very complicate actions that we couldn't express definitely by only the fundamental movements were also observed.

## TASK- AND DIFFICULTY-RELATED ARC EXPRESSION IN THE PRIMARY MOTOR CORTEX AFTER MOTOR SKILL LEARNING

Lin, Y.

*Kaohsiung Medical University*

**Introduction** Transfer of motor learning represents that previously learned motor skill can provide beneficial effects on the acquisition of a more difficult, and related motor skill. The primary motor cortex plays a key role in this transfer of previously acquired experience. However, the alteration of neuronal substrates for this transfer of acquired experience is still unknown. Because immediate-early genes are closely associated with neuronal activities, therefore, the purpose of this study is to investigate the expression of immediate-early genes in the primary motor cortex during the transfer of motor skill learning. **Methods** Male Sprague-Dawley rats were trained on a runway apparatus to acquire the motor skill needed to complete the acrobatic motor skill learning. According to the difficulties to complete the task, the training protocols were defined into easy acrobatic and difficult acrobatic tasks. Animals were divided in 4 groups: control sedentary (C), easy (E), difficult (D), and easy + difficult training (E+D), and were trained to traverse the runway for seven days. At the last day of training, animals were sacrificed and their primary motor cortices were isolated for subsequent analysis of western blot and immunohistochemistry. **Results** The results demonstrated that previously acquired motor skill in the E group may improve the performance of motor skill in the difficult task. Additionally, the expression of activity-related cytoskeleton associated protein (Arc) in the primary motor cortex was significantly different among groups. Expression of Arc was significantly increased in E group compared to C group, whereas no significant changes in Arc level in D and E+D groups compared to C group. The immunohistochemical observation also showed an increase in Arc immuno-positive signals in the primary motor cortex from E group. **Discussion** Arc protein, as an immediate-early gene, has been reported that involved in modulating the consolidation of memory. The expression of Arc protein was increased in primary motor cortex after easy acrobatic training indicates that Arc plays a role in easy acrobatic training. Moreover, the increase of Arc expression was not observed in the motor cortex of rats from D and E+D groups, indicating the difficulty of motor skill has an effect on the expression of Arc. Because the expression of Arc was not significantly different between C and E+D group, indicating Arc protein could not involved in the transfer of previously acquired motor skill.

## GOAL ORIENTATIONS AND SHORT-TERM PERFORMANCE DEVELOPMENT OF PASSING SKILLS IN YOUNG TALENTED SOCCER PLAYERS

de Greef, J.I., van Dijk, M.J.I., Huijgen, B.C.H.2, de Niet, M.I., Platvoet, S.W.J.1, Elferink-Gemser, M.T.1,2

*HAN University of Applied Sciences*

**HAN**, Nijmegen, The Netherlands, 2UMCG, University of Groningen, the Netherlands **Introduction** In soccer the skill of passing the ball under constraints of time and space is fundamental (Ali, 2011). Being able to develop this skill as a talented soccer player to elite level is key. The players development might be affected by dispositional goal orientations, these predict and explain in which manner players engage in both training and competition (Duda, 1992). It is known that players who are highly task oriented show great persistence to master challenging tasks (Van-Yperen & Duda, 1999). Therefore, task orientation might assist in predicting the potential a talented player has to reach elite level. The goal was to examine whether task orientation discriminates talented soccer players in their passing skill development over a short time frame. **Method** Task orientation of 40 youth players (14,3± 1,1yrs) of a national Dutch soccer club was assessed with the Dutch version of the TEOSQ (Van-Yperen & Duda, 1999). Median split of the task orientation scores resulted in two groups: higher task oriented (HT, n=19, 4,5±0,2s) and lower task oriented (LT, n=21, 3,7±0,4s) (p<.05). The two groups were compared on their development on three performance variables (execution, penalty and performance times) on two consecutive trials with 5 minutes in between (T1 and T2) of the Loughborough Soccer Passing Test (LSPT)(Ali et al., 2007). In addition a questionnaire was administered to investigate persistence (range 1 through 6) as a psychological variable. **Results** No significant differences were found in the development of execution (HT=-4,1±3,9s vs. LT=-3,56±3,92, d=0,33), penalty (HT=-6,3±9,7s vs. LT=-1,2±14,3s, d=0,44) and performance times (HT=-10,4±12,7s vs. LT=-4,8±15,2, d=0,44) between groups (p>.05). Scores of persistence were significantly higher in the HT-group (M=5,4±0,4) than the LT-group (M=4,8±0,3)(p<.05). **Discussion** Although the potential of players to develop the skill of passing did not differ between groups, the HT-group tended to outscore the LT-group on all developmental performance variables. In order to differentiate talented soccer players on their potential to develop passing skills over a short time frame future research could focus on the minimum number of repetitions needed to elicit differences. **References** Ali, A., Williams, C., Hulse, M., Strudwick, A., Reddin, J., Howarth, L., Eldred, J., Hirst,

### **INCREASED EEG THETA AND ALPHA ACTIVITY INDICATE SOMATOSENSORY WORKING MEMORY PROCESSES IN DIFFERENTIAL BADMINTON SERVE TRAINING**

Henz, D., Hofmann, M., Schöllhorn, W.I.

*Johannes Gutenberg University Mainz*

**Introduction** Several studies demonstrate higher learning rates in differential compared to classical repetition oriented training (e.g. Schöllhorn, Hegen & Davids, 2012; Schöllhorn, Michelbrink, Welmski & Davids, 2009). To our knowledge this is the first study that addresses the question of the underlying neuronal mechanisms in differential training. In the present study we measured EEG brain activation patterns after differential and classical repetition oriented badminton serve training. **Methods** Eight semi-professional badminton players were asked to perform differential and traditional badminton training in a within-subjects design. Electroencephalographic activity was recorded from nineteen electrodes according to the 10-20 system before and immediately after each 20-minute exercise. Analyses of variance were performed for the data of power density at the theta (4-7.5), alpha (8-13 Hz), and beta (13-30 Hz) band. Results Increased theta and alpha activity was obtained in contralateral parieto-occipital regions in the differential compared to the classical training condition. Beta activity was increased in the classical training condition in prefrontal areas. **Discussion** Results indicate different underlying neuronal processes in differential and classical repetition oriented training with a higher involvement of frontal areas in classical training, and parieto-occipital areas in differential training. While classical training seems to rely on a rather cognitively controlled processing, brain activation patterns indicate somatosensory working memory processes where visual attentional resources are allocated in processing of somatosensory information (Haegens, Händel & Jensen, 2011) in differential training. **References** Haegens, S., Händel, B.F. & Jensen, O. (2011). Top-down controlled alpha band activity in somatosensory areas determines behavioral performance in a discrimination task. *Journal of Neuroscience*, 31, 5197-5204. ### **PRELIMINARY STUDY ABOUT THE VOLLEYBALL TEACHING IN A YOUNG FEMALE TEAM**

Parisi, F., Maccioni, D., Di Tore, P.A., Raiola, G.

*University of Salerno, Italy*

**Introduction** Traditionally Volleyball teaching is given by a coach through drills with a theoretical basis in cognitive approach. The drills are Partial, Varied, Randomized and Mental training and they are described in detail by the coach. They apply to models of Open circuit and Closed circuit motor control and Generalized motor program. In the teaching of physical activities, there is also another approach called "Dynamic-Ecological" where the coach doesn't prescribe exercises but builds a learning setting aimed at the variety of learning (Raiola 2008). It refers to the motor control of the imagination models and the Theory of Freedom Degrees: Reduction, Exploration and Accumulation of freedom degrees (Bernstein, 1967). The objective is testing the learning of certain basic technical skills of volleyball through training based on different scientific paradigms, and comparing the results of different exercises. **Methods** The method is experimental. The work is done with a team of eighteen athletes female under thirteen and it is divided into: PHASE I) Giving exercises for half an hour in each training session. The team is divided into two groups of nine, diversifying roles. The athletes will be evaluated either incoming and outgoing calls through Accuracy Tests about three technical skills: Shot with one hand, Dribble and Bagher. The variation of precision will be evaluated by the coach during the race with descriptors defined for the specific purpose. PHASE II: A) monitoring through detection cards regarding the three technical skills. B) introduction of new exercises related to the three technical skills. C) changing of setting. D) cooperative learning. E) locking exercises and symmetrization of some general movements in order to reduce the wide range of the movement excursions. At the end there is the comparison between the results of the final and intermediate tests. **Results** It is expected that the Dynamic-Ecological approach can find more educational implications than the cognitive one. **Discussion** The Dynamical Systems approach sees the 'human system' as a reality that can self-organize through a 'circular causality'. A body, left to itself, will be able to produce appropriate movements also without practice (Raiola 2008). Finding a positive result in Dynamic-Ecological approach compared to the cognitive one, should be further investigated for the accuracy of the data. **References** Raiola G (2008) Il ruolo della didattica negli ambienti di apprendimento educativo sportivo, Aracne, Roma, Italy Schmidt, R.A., Wrisberg, G., A. ### **THE RELATIONSHIP BETWEEN VELOCITY AND ACCURACY IN HIGH PERFORMANCE TENNIS PLAYERS RELATED TO AGE AND GENDER.**

Urban Infantes, T., Hernandez Davo, H., Coves Garcia, A., Moreno Hernandez, F.J.

*Universidad Miguel Hernández*

**Introduction** Recent studies report that velocity and accuracy are the most important variables to motor performance (Van den Tillaar & Ettema, 2003). Both variables have been analyzed in different sports (Gorostiaga, Granados, Ibáñez & Izquierdo, 2005). Traditionally, higher velocity has been related with lower accuracy. Nowadays, recent works have shown that increases in velocity are not involved in accuracy losses (Van den Tillaar & Ettema, 2006). The aim of this study was to analyze the relationship between velocity and accuracy in elite players with different age range. **Methods** Fifty five elite tennis players (49 male 6 female) took part in this study. The participants were distributed in four groups: 10-12 years (n=21); 14-16 years (n=22); male +18 (n=6) and female +18 (n=6). All participants carried out thirty services towards a target located in the service box. Ball speed (Stalker Pro) and radial error of ball bounces (video digitized) were recorded to assess service performance. One-way Anova and correlation analysis were carried out to analyze the relationship between velocity and accuracy in each group. **Results** Ball velocity did not show clear correlation with accuracy within subjects (only four participants showed a relation, and only two of them in an inverse relation, none from the 18+ group). Players with higher values in velocity showed better results in accuracy in groups 10-12 yr. ( $r = -.512$   $p < .05$ ) and 14-16 yr. ( $r = -.693$   $p < .01$ ). Regarding group analysis, we have not found differences in accuracy between 10-12 yr. and 14-16 yr. groups, but there were differences in ball velocity ( $p < 0.01$ ). Both +18 yr. groups, male and female, showed better accuracy than the other two groups ( $p < 0.05$ ). Ball velocity showed by +18 yr. female group was

---

similar to 14-15 yr. group, and their results were higher in velocity than 10-12 yr. group ( $p < 0.01$ ) and lower than +18 yr. group ( $p > 0.01$ ). Discussion and conclusions We have not found support to the inverse relation between velocity and accuracy. Three of the participants showed better performance with higher velocities, but none of them were from +18 elite group. Player age and gender seems to affect to velocity of services, but this is not that clear regarding accuracy of the services. References Gorostiaga, E.M., Granados, C., Ibañez, J. & Izquierdo, M. ## **GENDER DIFFERENCES IN VISUOMOTOR ADAPTATION**

Mierau, A., Werner, S., Mierau, J., Strüder, H.K.

*German Sport University*

Introduction: It is well documented that gender differences exist for performance and learning across different cognitive domains. However, the relationship between gender and the acquisition of sensorimotor skills is poorly investigated. Therefore, the present study aimed to identify the effect of gender on visuomotor adaptation and intermanual transfer in a tracking task (main experiment). In addition, data from previous adaptation experiments using pointing movements were reanalysed with regard to gender differences (supplemental experiments). Methods: 59 male ( $23.2 \pm 2.1$  years) and 40 female ( $21.9 \pm 1.8$  years) right-handed university students without overt sensorimotor disorders participated in the main experiment. The subjects' task was to track a visual target on a computer screen with their right dominant hand while the visual feedback was first veridical (baseline) and then right-left reversed (adaptation). After the adaptation phase has ended, subjects were asked to switch the hand and to perform the task with their left, non-dominant hand while the visual feedback was still disturbed (transfer). The nature of the supplemental experiments was comparable to the main experiment but pointing was used instead of tracking. Results: An ANOVA with the tracking error as a dependent variable, the within-factor "EPISODE" and the between-factor "GENDER" revealed significant main effects for EPISODE ( $F_{19, 1805} = 111.75, p < 0.001$ ) and for GENDER ( $F_{1, 95} = 4.25, p < 0.05$ ) during adaptation indicating that subject's tracking error decreased with ongoing practice and, more importantly, that men had significantly lower tracking errors than women. The interaction term however, was not significant ( $F_{19, 1805} = 1.11, p > 0.05$ ) indicating that the time-course of adaptation did not differ between men and women. There were no significant effects of gender during baseline and transfer episodes. A similar pattern of results was obtained in the supplemental pointing experiments. Discussion: The results of the present study suggest that different mechanisms are involved during visuomotor adaptation in males compared to females with males probably using more strategic control and thus, adapting faster to the distortion than females. However, men's advantage during adaptation was not retained during intermanual transfer suggesting that the modification of the internal model and thus, visuomotor learning, did not significantly differ between genders.

### **THE RELATIONSHIP BETWEEN FOOT GRIP STRENGTH AND SPRINTING.**

Maruyama, T.1, Yamauchi, J.1,2

*1:Tokyo Metropolitan University, 2:Future Institute for Sport Sciences*

[Introduction] 'How to run fast' is the interest to many people. It has been shown that there is a strong correlation between maximal strength in half squats and sprint performance (Wisloff U et al., 2004). It is known that plantar flexor force is significantly higher in forefoot striking in running (Peal DP et al., 2012). The function of foot strength seems to be important for the sprinting movement during the contact of ground; however, there are no studies about relationships between sprinting and foot grip strength. [Purpose] The purpose of this study was to investigate the relationship between foot grip strength and sprinting. [Methods] Fifty five healthy subjects (age,  $19.2 \pm 1.9$  years; height,  $165.6 \pm 8.5$  cm; weight,  $57.0 \pm 8.8$  kg; BMI,  $20.6 \pm 2.0$  kg/m<sup>2</sup>; body fat percentage,  $18.3 \pm 6.7$ %; mean  $\pm$  SD) were tested for sprinting time and foot grip strength. Sprinting time was measured between 0m and 20m by photocells and analysed in three different distances (0-20m, 0-10m and 10-20m). After the self-paced warm-up, subjects set standing position with barefoot and their supportive leg was on the pressure mat. After the verbal signal, subjects began to run as fast as possible. The maximum voluntary isometric strength of foot grip was measured with by the foot grip dynamometer. Subjects were instructed to place their barefoot with heel stopper on the dynamometer. in standing position. The first proximal phalanx was positioned on the grip bar and the bar was gripped with maximal effort using all toes. [Result and Discussion] The absolute value of foot grip strength correlated with the speed of 0-20m ( $p < 0.01$ ), the speed of 0-10m ( $p < 0.01$ ), the speed of 10-20m ( $p < 0.01$ ). On the other hands, foot grip strength per weight correlated with the speed of 0-20m ( $p < 0.01$ ) and 10-20m ( $p < 0.01$ ), but not with 0-10m. This study suggested that foot grip strength may be important for sprinting, especially in acceleration phase. [Reference] 1. ### **PHYSICAL EXERCISE INDUCES AN INCREASE IN ELECTROENCEPHALOGRAPHIC ALPHA PEAK FREQUENCY**

Gutmann, B., Mierau, A., Hülsdünker, T., Rojas Vega, S., Hollmann, H., Strüder, H.

*German Sport University Cologne*

Introduction: The beneficial effects of exercise on cognitive performance are frequently reported in the literature, while its effects on neural parameters as the individual alpha peak frequency (iAPF), that is positively related to cognitive performance remain largely unknown. Therefore the aim of the present study was to evaluate the effects of different physical exercise protocols on the iAPF. Methods: Electroencephalographic activity was recorded in 12 healthy males before, directly after and 10 minutes after an incremental cycling test (ramp test) until subjective exhaustion and a 30 minutes lasting cycling protocol at 50% of the maximum power output (MPO), respectively. Electrical power values were calculated in the occipital region using fast fourier transformation. The iAPF was determined as the frequency indicating the highest power between 7 and 13 Hz. Results: After the incremental test the iAPF was significantly increased and remained elevated 10 minutes after exercise. In the 50% MPO protocol the iAPF was consistent throughout the measurements. Conclusion: The different

effects of the two exercise protocols on the iAPF might be best explained by their discrepancy in intensity probably indicating the necessity for high intensity exercise to increase the iAPF.

### **THE EFFECT OF FATIGUE ON EMG ACTIVITY OF THE ANKLE PLANTAR-FLEXORS DURING A 30-S CYCLING SPRINT**

O'Bryan, S.J., Billaut, F., Rouffet, D.M.

*Victoria University*

**Introduction** Fatigue-induced decrements in mean power of up to 58% have been reported during a 30-s maximal cycle sprint [1]. Martin and Brown [2] showed the highest reduction of relative power production (-63%) occurred at the ankle joint during this type of effort. This suggests that fatigue is manifested by a decreased ability of the ankle plantar flexors to directly generate and/or transfer power from proximal muscles [3]. The aim of this study was to manipulate the amount of fatigue during a 30-s sprint and to investigate its effect on the activation of plantar flexor muscles, the co-activation of these muscles with knee and hip extensors, and power output. **Methods** On separate days ten male participants randomly performed a 30-s cycling sprint in a fatigue-free state (SCTL) or after cycling for 10min at  $224 \pm 26$ W (SFAT). Mean power output (MPO), normalized integrated electromyography of the gastrocnemius medialis and lateralis (iEMGGAS), and co-contraction indices of the plantar flexors with vastii (CCIV-PF) and gluteus maximus (CCIGMAX-PF) were calculated for both sprints at 5-s intervals. Results MPO declined from 823W to 326W during SCTL and from 705W to 248W during SFAT between the first and last 5-s interval ( $p < 0.05$ ). MPO was lower during SFAT for the last three intervals (-25%, -27%, and -23% respectively). During SCTL and SFAT iEMGGAS (-23 and -25%), CCIV-PF (-45 and -49%) and CCIGMAX-PF (-41 and -44%) decreased over time ( $p < 0.05$ ). iEMGGAS (86 vs. 67%) and CCIV-PF (18 vs. 15%) were lower during SFAT ( $p < 0.05$ ). **Discussion** Decrements in mean power observed in both sprints, were similar with those previously reported [1]. The reduced power output caused by fatigue coincided with a decrease in plantar flexors activation and a lower co-activation between these muscles and both knee and hip extensors. The alterations in plantar flexors recruitment observed in this study can reduce the power generated and transferred by the plantar flexors during a 30-s cycling sprint, as reported by Martin and Brown [2]. **References** 1. ### **IMPAIRED RAPID MUSCLE FORCE CHARACTERISTICS FOLLOWING PLAYING TENNIS IN THE HEAT**

Girard, O., Racinais, S., Christian, R.J., Knez, W.L., Herrera, C.P., Périard, J.D.

*ASPETAR - Qatar Orthopaedic and Sports Medicine Hospital*

**Introduction:** Studies on fatigue in tennis have primarily focused on the contribution of neural and muscular factors as measured from maximal isometric voluntary contractions of lower limb muscles. However, it remains unknown whether match-play tennis results in impaired neuromuscular function during "explosive" muscle actions and to which extent playing in a hot environment may exacerbate this phenomenon. The aim of this study was to assess the time course of changes in rapid muscle force characteristics in response to match-play tennis under severe heat stress. **Methods:** Two experimental tennis matches that consisted of 20 min of effective playing time - separated in two 10 min segments - were played in cool ( $\sim 22^\circ\text{C}$  and 70%RH) and hot ( $\sim 36^\circ\text{C}$  and 35%RH) environments by twelve competitive players (ITF rank 2-3). Maximal explosive force (i.e., with instructions of "hard and fast") and electromyographical (EMG) activity of the vastus lateralis and rectus femoris muscles were measured during brief (5 s) maximal voluntary isometric contractions (MVC) of the knee extensors before, immediately after, 24 h and 48 h after each game. Rates of force development (RFD) and EMG (i.e., Root Mean Square) rise were recorded at time intervals of 0-30, 0-50 and 0-100, 0-150 and 0-200 ms relative to force onset, and were also normalized to maximal force and EMG values, respectively. **Results:** From pre- to post-match, reductions occurred in the peak RFD within the first 200 ms (5 and 21%), MVC force (-9 and -19%) and the accompanying maximal EMG activity in cool and hot conditions ( $P < 0.05$ ). Similarly, absolute RFD at all time intervals was reduced (Cool: -6 to -9% and Hot: -12 to -16%;  $P < 0.05$ ) after both matches, while the rate of EMG rise did not change ( $P > 0.05$ ). MVC force and RFD returned to baseline levels within 24 h and 48 h after match-play in cool and hot conditions, respectively. Normalized RFD and EMG rise remained unchanged ( $P > 0.05$ ) throughout the protocol. **Conclusions:** In competitive players, rapid muscle force capacity (i.e. within the initial 200 ms of the contraction) is impaired after match-play tennis, which might affect functional performance in actions like sprinting and rapid changes in movement direction. In general, larger reductions in muscle force characteristics occurred after competing in the heat, and were accompanied by a slower recovery time course. However, all of the fatigue-induced changes could not be explained by reductions in agonist muscle activation. Additionally, when differences in maximal strength and activation capacity were accounted for, RFD and EMG rise were comparable across conditions.

### **COOLING INDUCED PLANTAR DESENSITIZATION AND POSTURAL CONTROL**

Horiuchi, K., Yamauchi, J.

*Tokyo metropolitan University*

**Cooling induced plantar desensitization and postural control** [Introduction] Cutaneous sensation on the plantar sole plays an important role in postural control. It has been reported that loss of plantar cutaneous sensation induced by ischemic blocking of afferent conduction below the ankle is related to loss of postural control (Wang and Lin 2008). Also, cooling the skin is often used to induce anesthesia. It has been shown that the cooling of plantar sole mechanoreceptors through ice immersion effects to balance control and lower leg muscle activity (Billot et al. 2013). This impairment of postural stability might be related to the decrease in muscle force production of foot after desensitization if foot muscle strength is also required to maintain a whole body balance. However, there are no studies how cooling induced plantar desensitization affects to the double and single leg quiet standing and it is related to the force generating capacity of foot muscle. [Purpose] The aim of the present study was to determine the role of skin in motor and balance control induced by cooling the skin of the foot. [Methods] Twenty young healthy individuals were participated. Postural control was measured with Kistler force plate before and after the 20 minutes of cold water immersion (0 degree). Postural control was assessed during double and single leg quiet standing in open eyes condition for 30 seconds, using force plate to quantify center of pressure (COP) dynamics. The total locus length(LL), area of body sway(ABS) and total locus length per area(LLA) were calculated using the software to analyze the body sway. The room temperature was maintained at 20 degrees. [Results and Discussion] After the cold water immersion, Medial-lateral COP of double and single legs quiet standing and ABS were significantly increased, and LLA was significantly decreased. Impairment of balance control after a desensitization of foot induced by cold water immersion may be also due to the decreased force generating capacity of foot muscle (Horiuchi

and Yamauchi ECSS2013). [Reference] Wang TY and Lin SI, Sensitivity of plantar cutaneous sensation and postural stability. *Gait Posture* 2008; 23(4):493-499. ## **SURFACE EMG DECOMPOSITION OF VASTUS MEDIALIS AND VASTUS LATERALIS IN TRAINED VERSUS UNTRAINED SUBJECTS**

Lindley, S., Vilas-Boas, M., Richards, J.

*UNIVERSITY OF CENTRAL LANCASHIRE*

**Introduction** Much has been published on the functional differences between Vastus Medialis (VM) and Vastus Lateralis (VL) between trained and untrained individuals with work mainly focussed on muscular onset timings using surface electromyography (sEMG). Further exploration of the neuromuscular system can now be achieved by studying large yields of concurrently active motor unit action potential trains (MUAPT's) and their characteristics (De Luca, 2006), using surface decomposition. This study aims to provide insight into the neuromuscular system's mechanism of controlling Motor Units (MU's) in trained and untrained individuals during a fatiguing protocol. **Methods** Trained and untrained individuals were asked to perform a 40 second trapezoid isometric knee extension task at 40% MVC, which was repeated until volitional exhaustion. Surface EMG (sEMG) signals were recorded from VM and VL using five pin surface array sensors. The raw sEMG signals were then inputted into the Precision Decomposition (PD) algorithm (Nawab et al. 2010) which decomposed the sEMG signals into their constituent motor unit action potential trains (MUAPT's). The mean firing rate (MFR) for each detected motor unit was calculated and smoothed using a 3-s Hanning filter. **Results and Discussion** The untrained subject showed an increase in the VM MU firing rates during the isometric knee extension when compared to its synergistic partner VL. The trained subject did not show differences between the synergistic pair of VM and VL, instead exhibited similar MU firing rates for both muscles. The VL behaviour did not significantly differ between the fatigued and non-fatigued state or between the subjects. These findings could infer the VM is an important modifiable factor associated with training. These results, although exploratory, offer insight into the benefits of training and the effect on the neuromuscular control of synergistic muscles at the knee. The ability to conduct surface EMG decomposition is a recent technological advancement that is still being explored. However, these preliminary findings show that the application of this technology to exploring training differences can offer insight into individuals' neuromuscular control. **Conclusions** The study provides some tantalizing findings and thoughts for progression with regards to the differences in neuromuscular control in training. Although exploratory at this time, the reported differences in motor unit firing rates offer some explanation to knee control during fatiguing muscles and the differences between differently trained individuals. Further investigations among individuals with various levels of training could offer further insight into the mechanisms involved

## **THE RELATION BETWEEN MUSCLE LENGTH AND DURATION OF THE M-WAVE**

Shushakov, V., Eigendorf, J., Maassen, N.

*Medical School Hannover, University of Hannover*

**Introduction** During locomotion, the muscle length changes due to changes in force and joint angle. It was shown that there is a relationship between muscle length and spectral parameters of the surface EMG signal (Inbar et al., 1987, Okada, 1987). In this study, we tested effects of change in the muscle length due to joint rotation or voluntary contraction, on the compound muscle action potential (m-wave). **Methods** Subjects performed isometric knee extensions or plantar flexions of different force (10 to 100 % of maximum voluntary contraction (MVC)) and at different joint angles. EMG and m-waves were recorded in m. gastrocnemius medialis (GM) and m. vastus lateralis (VL). **Results** In both muscles we found a relation between changes in the joint angle and the duration of the m-wave. Knee extension from 90 to 70 degrees led to 4.1% decrease in the m-wave duration (n=10, P<0.05) and to 50 degrees – to 8% decrease (n=2). Plantar flexion of 20 degrees resulted in 5.6% decrease in the m-wave duration (n=8, P<0.05). In both muscles the duration of the m-wave positively correlated with the muscle length. Also an increase of the muscle force from 10 to 90% of the MVC led to a 15% shortening of the m-wave. During MVC, the median power frequency of the EMG spectrum (MF) increased in the VL from 80.3 Hz at 90 degrees to 85.1 Hz at 70 degrees but in the GM the passive muscle shortening led to about 15 Hz decrease in the MF. **Discussion** In both muscles, VL and GM, muscle shortening due to passive changes in the joint angle or active isometric contraction led to decrease in the m-wave duration. This findings confirm the results of Arendt-Nielsen et al. (1992) about relationships between muscle length and muscle fibre conduction velocity. In contrast, the decrease in the MF during the muscle shortening in GM contradicts the linearity between mean power frequency and fibre velocity (Arendt-Nielsen et al., 1985). **References** Inbar GF, Allin J, Kranz H. (1987). *Med Biol Eng Comput*, 25, 683-689. Okada M. (1987). *Eur J Appl Physiol*, 56, 482-486. Arendt-Nielsen L, Gantchev N, Sinkjaer T. (1992) *Electroencephalogr Clin Neurophysiol*, 85(3),166-72. ## **THE RELATIONSHIP BETWEEN FOOT GRIP STRENGTH PLANTAR PRESSURE DURING SPRINTING.**

Maruyama, T.1, Yamauchi, J.1,2

*1:Tokyo Metropolitan University, 2:Future Institute for Sport Sciences*

**[Introduction]** We have found the significant correlation between foot grip strength and sprinting speed (Maruyama and Yamauchi ECSS2013). It has suggested that greater toe grip and gentler heel strike are the strategies to catch the ground in walking (Fong DT et al., 2007). Also, it can be speculated that foot strength may be related to the plantar pressure in sprinting. However, there is still unknown the relationship between foot grip strength and plantar pressure in sprinting. **[Purpose]** The purpose of this study was to investigate the relationship between foot grip strength and plantar pressure in sprinting. **[Method]** Thirteen male subjects( age,19.5±1.2 years; height, 170.9±8.0cm; weight, 64.3±5.9kg; BMI, 22.0±0.8kg/m<sup>2</sup>; body fat percentage, 14.0±3.9%; mean±SD) were tested for sprinting time, foot grip strength and plantar pressure in jogging and sprinting. Sprinting time was measured between 0m and 20m by photocells and analysed in three different distances (0-20m, 0-10m and 10-20m). After the self-paced warm-up, subjects set standing position with barefoot and their supportive leg was on the pressure mat. After the verbal signal, subjects began to run as fast as possible. The maximum voluntary isometric strength of foot grip was measured with by the foot grip dynamometer. Subjects were instructed to place their

barefoot with heel stopper on the dynamometer in standing position. The first proximal phalanx was positioned on the grip bar and the bar was gripped with maximal effort using all toes. Plantar pressure in jogging and sprinting were measured by a pressure insole system (Novel pedar-x, Germany). Jogging was self-paced running. The plantar pressure data were evaluated in 8 regions. [Result and Discussion] Significant higher pressure at hallux, lateral toes, 1st metatarsal head and 4th and 5th metatarsal head regions were found in sprinting as compared with jogging ( $p < 0.05$ ), on the other hands, medial mid-foot and heel pressures were significantly lower in sprinting than in jogging ( $p < 0.05$ ). Foot grip strength was significantly correlated with plantar pressure of hallux and lateral toes in sprinting ( $p < 0.05$ ), while no significant correlation was found between foot grip strength and plantar pressure of hallux and lateral toes in jogging. This study suggests that muscle strength of forefoot region can be an important role in sprinting performance. [Referencel 1. Daniel Tik-Pui Fong, De-Wei Mao, Jing-Xian Li, Youlian Hong. (2008) Greater toe grip and gentler heel strike are the strategies to adapt to slippery surface. *J Biomech.* 2008;41(4):838-44.

## **MAXIMUM ISOMETRIC FOOT GRIP FORCE AND MAXIMUM ISOMETRIC FORCE OF KNEE AND LEG EXTENSION MOVEMENT**

Yamauchi, J.1,2

1:Tokyo Metropolitan University, 2:Future Institute for Sport Sciences

[Introduction] Many physical activities are performed with a standing position on the foot and foot bears body weight as it carry the body through daily or sports activities. There are numerous studies on muscle functions of lower limbs; however, only few studies have demonstrated how foot grip force is associated with the force generating capacity of leg. Therefore, the present study was to investigate how isometric foot grip force generation was related to the force generating capacity of leg in middle aged and elderly individuals. [Methods] Thirty-one healthy individuals (63+/-9 years old) were measured the maximum foot grip, knee extension and leg extension forces. For MVC measurement of foot grip force, subjects exerted maximum force for ~3 seconds on a foot grip dynamometer with either sitting or standing position. Subjects also performed the maximum isometric knee extension and leg extension forces. Measurements were repeated three times with at least one-minute rest period between bouts, and the highest value among the measurements was used. [Results and Discussion] Foot grip forces both at the sitting and standing position were positively correlated with both the maximum isometric knee extension and leg extension forces, respectively. Foot grip force at the standing position was a higher correlation with the force generating capacity of leg as compared with foot grip force at the sitting position. The present results indicate that the ability to generate higher foot grip force is associated with a strong leg muscle force. Also, the measurement of foot grip force at standing position is more useful when evaluating the lower limb muscle functions with other leg force measurements.

## **PERFORMANCE AND RECOVERY DURING REPEATED CYCLING SPRINTS: EFFECT OF HYPOXIA SEVERITY**

Christian, R., Bishop, D., Billaut, F., Girard, O.

*ASPETAR - Qatar Orthopaedic and Sports Medicine Hospital, Doha, QATAR, Victoria University, Melbourne, AUSTRALIA*

The aim of this study was to examine the effect of hypoxia severity on an initial bout of short (4-s) repeated cycling sprints and the subsequent recovery of performance during an additional bout of repeated cycling sprints. On separate days, 8 healthy males performed 2 sets of maximal isokinetic cycling sprints (lasting 4-s) at  $120.7 \pm 5.6$  RPM (26 s of passive rest between sprints and 8 minutes of passive recovery under normoxic conditions between sets). The first set consisted of 10 sprints and was completed under normoxia (simulated altitude: 0m), mild (2000m), and severe normobaric hypoxia (4000m). The second set consisted of 5 sprints and was completed under normoxia in all trials. There was a main effect of condition on the mean power output during the first sprint in set 1 (normoxia:  $1205.5 \pm 127.4$  W, mild hypoxia:  $1170.4 \pm 147.6$  W, severe hypoxia:  $1151.1 \pm 123.9$  W,  $p = 0.049$ ). During set 1 both the reduction in total mean power for the 10 sprints ( $959.5 \pm 101.1$  vs.  $1072.3 \pm 137.0$  and  $1046.7 \pm 135.7$ W,  $p = 0.000$ ) and the percentage decrement score ( $16.3 \pm 8.0\%$  vs.  $11.0 \pm 6.9\%$  and  $10.4 \pm 5.2\%$ ,  $p = 0.001$ ) were larger in severe hypoxia compared to normoxia and mild hypoxia, respectively. During sprint 1 in set 2 the mean power output recovered to  $96.3 \pm 5.9\%$  (all conditions compounded) of the mean power achieved during sprint 1 in set 1 with no difference observed between conditions ( $p = 0.811$ ). There was a main effect of condition when comparing the mean power achieved during sprint 1 in set 2 vs. sprint 10 in set 1 ( $119.3 \pm 11.5\%$ ,  $119.9 \pm 15.8\%$  and  $130.2 \pm 10.3\%$  for normoxia, mild and severe hypoxia respectively,  $p = 0.044$ ). During set 2 there was no difference between conditions in the mean power achieved during sprint 1 ( $p = 0.093$ ). During set 2 the mean power for the 5 sprints was reduced in severe hypoxia ( $p = 0.017$ ) compared to normoxia but not mild hypoxia ( $1021.7 \pm 127.4$  vs.  $1079.7 \pm 140.1$  and  $1068.4 \pm 137.5$  W) with a main effect of condition on the percentage decrement score ( $7.2 \pm 4.0\%$ ,  $7.3 \pm 3.3\%$  and  $5.2 \pm 4.2\%$ ,  $P < 0.05$ ). Despite the inability to repeat very short (4-s) cycling sprints being exacerbated during severe hypoxia compared to normoxia (the performance loss was not different between normoxia and a simulated normobaric altitude of 2000m), following 8 minutes of recovery, the initial sprint during a subsequent bout of repeated sprint exercise was not different and recovered to the same level among conditions. However, performance during 5 additional cycling sprints (completed in normoxia) was impaired when the first bout was completed in severe hypoxia compared to normoxia.

### **EFFECTS OF ILEX PARAGUARIENSIS INGESTION ON FAT METABOLISM DURING EXERCISE**

Alkhatib, A.

*University of Greenwich*

Introduction The positive thermogenic and lipid-lowering effects of Yerba Mate (YM), an infusion made from the leaves of the tree *Ilex paraguariensis* are well documented (Bastos et al. 2007). Commonly reported chronic effects of introducing YM into the diet include the reduction in body fat percentage, and the acute effects include increased fatty utilisation in resting conditions (Martinet et al. 1999). However, no study has yet investigated whether and how YM ingestion affects fat utilisation during exercise. This study investigates the acute effects of YM on fatty acid oxidation at different exercise intensities. Methods: Following the institutional ethical approval, thirteen healthy participants (mean + SD: age =  $20.8 \pm 3.4$  yr, height =  $171.8 \pm 10.0$  cm, body mass =  $70.4 \pm 11.3$  kg) gave written consent, and were randomly assigned to exercise in two experimental conditions over a period of two weeks, in double-blind design. During each visit participants ingested either a placebo of hydroxypropyl methylcellulose capsules or 1000 mg capsule of YM. Participants then rested for 60 minutes before completing a cycling ergometer incremental exercise until volitional exhaustion, with power output initiated and in-

creased by 0.5 w.kg<sup>-1</sup> every 3 minutes. Cardiorespiratory gases of oxygen uptake (VO<sub>2</sub>), carbon dioxide production (VCO<sub>2</sub>) and respiratory exchange ratio (RER) were continuously measured, and were used to estimate fatty acid oxidation (FAO) using stoichiometric indirect calorimetry technique (Peronnet and Massicott 1991). A repeated measure ANOVA was applied to detect the effects of YM ingestion on FAO, and paired t-test was applied to detect the effects on maximal exercise performance, significance levels were set at (p<0.05). Results: RER was significantly reduced at all power outputs (p<0.05). FAO was significantly increased (main effect, P<0.05), at all light to moderate exercise power outputs corresponding to RER < 1, in the YM condition compared with placebo condition (0.26 ± 0.09 vs. 0.34 ± 0.10, 0.25 ± 0.12 vs. 0.33 ± 0.11, and 0.16 ± 0.15 g.min<sup>-1</sup> at 36.5, 73.0 and 110.0 W respectively, p<0.05). This increase in FAO was despite no difference in peak VO<sub>2</sub> (38.8±8.4 vs. 38.1±8.7 ml.kg<sup>-1</sup>.min<sup>-1</sup>) or maximal power output (222.3 ± 59.8 vs. 221.8 ± 66.8 W). Discussion and Conclusion: Acute ingestion of YM before exercise enhances fat metabolism during light and moderate exercise intensities, without negatively affecting peak power or peak VO<sub>2</sub>. This is the first study to have demonstrated the YM metabolic effects during exercise. The combined ingestion of YM with exercise may be an effective strategy for optimising fat metabolism during exercise, known to play a role in metabolic weight management. ## FLUID BALANCE OF WELL-TRAINED SWIMMERS DURING VARYING INTENSITY EXERCISE IN AN OUTDOOR ENVIRONMENT

Pritchard-Peschek, K., Colombani, C.P., Mettler, S.

*Swiss Federal Institute of Sport Magglingen*

**Introduction** The current hydration recommendations for aquatic sports are based mainly on those for 'land-based' sports, despite the different methods of heat loss (i.e. conduction and convection) and the immersion of the body in water<sup>1-2</sup>. Currently, limited research exists on the sweat loss of aquatic athletes in outdoor environments across multiple training sessions within a day (i.e. morning and afternoon training) and of varying exercise intensities. It is thought the level of dehydration is not as severe in aquatic sports as in 'land-based' sports<sup>1</sup>, and therefore the fluid intake guidelines may differ for aquatic athletes. The purpose of the present study was to investigate the individual sweat loss of elite swimmers training twice per day in sessions of varying exercise intensity in an outdoor environment. **Methods** Twelve nationally and internationally competitive male swimmers volunteered to participate in this study (mean ± SD age 16.9 ± 2.7 years, mass 71.0 ± 7.8 kg). Data was collected over two days during a two-week training camp in an outdoor 50 m pool prior to a national competition. Each day consisted of two training sessions resulting in two different training conditions: Day 1 (easy-moderate) and Day 2 (easy-hard). Standard fluid balance measurement procedures were followed, and individual fluid intake and sweat loss was calculated. **Results** The 'moderate' and 'hard' sessions elicited body mass losses of 0.24 kg and 0.30 kg, which was significantly greater than the 'easy' sessions (p = 0.01 and p = 0.003, respectively) in which gains in body mass (0.17 kg) were observed. Sweat loss and sweat rate were significantly higher in the 'moderate' session (0.74 L and 0.43 L/h) compared to the 'easy' (0.30 L and 0.17 L/h) session (p = 0.02 and p = 0.02, respectively), neither of which were different to the 'hard' session. Sweat loss and sweat rate were moderately correlated with fluid intake in the 'easy' training condition only. There were no differences between training days in body mass loss or total sweat loss (i.e. Easy-Moderate p = 0.08; Easy-Hard p = 0.52). **Discussion** Overall, athletes were better able to match fluid intake with sweat loss in the 'easy' sessions, resulting in a net gain in body mass. The lack of differences in daily body mass change and daily sweat loss may be due to the large individual variation in fluid intake and sweat loss among athletes, which likely impacted upon the calculations in this study. Nevertheless, sweat rates for swimmers are substantially lower than those reported for 'land-based' athletes, suggesting the need for more specific hydration guidelines for aquatic athletes. **References** 1. ## MICRONUTRIENT INTAKE OF TOP LEVEL MALE AND FEMALE HIGH JUMPERS

Veligekas, P., Bogdanis, G.C., Selima, E., Christofi, E., Pafili, Z.

*University of Athens, GREECE*

**Introduction** Elite male and female high jumpers have a low body mass index (BMI) that would place them at the lower quarter of the general population percentile curve. To maintain a low body mass, high jumpers may consume relatively low energy diets and this may lead to inadequate intake of vitamins and minerals that are important for energy metabolism, hemoglobin synthesis, bone health and immune function. The aim of the present study was to investigate and compare micronutrient intake of top-level male and female high jumpers during the general preparation phase of their training. **Methods** Fourteen elite male and female high jumpers took part in the study (7 males: 1.86±0.03 m, 75.4±1.7 kg, BMI: 21.9±0.7 kg/m<sup>2</sup>, personal best: 2.09±0.08 m and 7 females: 1.77±0.03 m, 58.7±2.1 kg, BMI: 18.7±0.8 kg/m<sup>2</sup>, personal best: 1.68±0.06 m). Participants weighed and recorded their diet for 3 days (2 weekdays and 1 weekend day), during the general preparation phase. Nutrient intake was analyzed using custom-made software based on a standard nutritional database (Food Standards Agency, 2002). Statistical comparisons between male and female jumpers were made using independent t-tests (p<0.05). **Results** Average daily energy intake was higher in male than in female jumpers was 2673±445 and 1984±262 kcal (p<0.05). A low intake (below 50% of daily reference intake-DRI) was found for both male and female jumpers for vitamin D (12% of DRI), vitamin E (34% of DRI) and folate (46% of DRI). Female jumpers had a low iron intake compared with DRI (55% of DRI) and low vitamin B12 intake (~60% DRI). A relatively low intake for both genders was also found for calcium (78% of DRI), magnesium (66% of DRI), zinc (84% of DRI) and selenium (83% of DRI). **Discussion** Exercise training may lead to increased micronutrient needs and thus athletes should consume diets that provide at least the recommended daily reference intakes (DRI) for all micronutrients (ACSM, 2009). In the present study, both male and female jumpers had intakes of vitamins D and E and folate that were all lower than 50% of DRI. Also, iron intake in female jumpers was 55% of DRI and this was combined with low folate (<50% DRI) and low vitamin B12 intake (~60% DRI). These micronutrient deficiencies may be due to the low energy intake and suboptimal diet composition. **References** Food Standards Agency (2002). McCance and Widdowson's *The Composition of Foods*. Cambridge: Royal Society of Chemistry. ACSM (2009). *Med Sci Sports Exercise*, 41(3), 709-731.

## EFFECTS OF A TRANSDERMAL APPLICABLE ARGININE SUPPLEMENT ON THE MAXIMAL AND SUBMAXIMAL BENCH-PRESS PERFORMANCE.

Geisler, S., Streich, D., Diel, P.

*German Sport University Cologne & IST - University of Applied Sciences*

Arginin is a common supplement in weightlifting and bodybuilding. Supplements are usually taken by oral application and therefore have to pass the gastrointestinal tract to be absorbed into the cardiovascular system. The aim of the present study was to determine the potential ergogenic effects of the new transdermally applied arginine supplement AminoSkin Power on maximal and submaximal bench-press performance. 15 sports students with a 1-year minimum of resistance training attended 2 sessions. In a double-blind, crossover design the subjects were randomly assigned to using the placebo in the first and AminoSkin in the second session or counterwise. In each session they had to apply the given unguent on their chest and arms and perform the 1-RM test protocol of the National Strength and Conditioning Association (NSCA) and one set at 80 % 1-RM for maximum repetitions. To maintain high objectivity, specific technical instructions regarding the bench press were given. The achieved weights and correspondent repetitions were protocolled as well as the heart rate was monitored through the whole session. In addition the subjective sensation of a potentially positive effect was obtained. Differences between the placebo and AminoSkin Power were analyzed by dependent T-tests. Neither in maximal performance (difference  $0,89 \pm 4,18$  kg) nor in submaximal performance (difference  $0,64 \pm ,72$  reps) could be found any ergogenic effect of AminoSkin Power compared to the placebo. The heart rate also didn't show any significant difference throughout the whole session and in the 80 % 1-RM set. There is no proof for an ergogenic effect of the transdermal applied arginine supplement, but the obtained data suggests that there might be a positive effect on submaximal bench-press performance. Therefore future studies should focus on the submaximal performance and the effectiveness of transdermal application in general.

## CAFFEINE INGESTION PARTIALLY COMPENSATES THE MORNING REDUCTIONS IN UPPER AND LOWER BODY MUSCLE POWER

Mora-Rodriguez, R., García-Pallarés, J., Ortega, J.F., Fernández-Eliás, V.E., López-Gullón, J.M.

*University Castilla-La Mancha, University of Murcia*

Purpose: To investigate whether caffeine ingestion counteracts the morning reduction in neuromuscular performance associated with circadian rhythm. Methods: Thirteen highly resistance-trained men underwent a battery of neuromuscular tests under three different conditions; i) morning (8:00 a.m.) with 6 mg kg<sup>-1</sup> of caffeine ingestion (i.e., AMCAFF); ii) morning (8:00 a.m.) with placebo ingestion (AMPLAC); iii) afternoon (18:00 p.m.) with 6 mg kg<sup>-1</sup> of caffeine ingestion (PMCAFF) and iv) afternoon (18:00 p.m.) with placebo ingestion (PMPLAC). A randomized, double blind, crossover, placebo controlled experimental design was used, with caffeine ingestion 90 min prior to the test. Body weight, bioelectrical impedance analysis, blood hematocrit and tympanic temperature were measured before a neuromuscular test battery and after a standardized warm-up. The test battery consisted in the measurement of bar displacement velocity during free-weight full-squat (SQ) and bench press (BP) exercises against loads that elicit 25%, 50%, 75% and 90% 1RM load. After recovery cycling peak power was measured during an all-out 4s cycling sprint (1). Results: Before the neuromuscular performance test, body weight, impedance and hematocrit were not significantly affected by time of day. However, body temperature was 0.4°C lower in the morning than in the afternoon despite the standardized warm-up ( $P < 0.05$ ). In the PMPLAC trial, muscle power was similar to the PMCAFF trial in all loads except in 90% 1RM load where caffeine ingestion increase 8% BP and 5% SQ power ( $P < 0.05$ ). In the AMPLAC trial, muscle power was lower than in the AMCAFF trial, at all loads (25%, 50%, 75% and 90% 1RM) in BP and SQ exercises (5.5-9.5%;  $P < 0.05$ ). Similar difference was found between AMPLAC and PMPLAC (5-8.5%;  $P < 0.05$ ). Peak cycling power was not improved by this dose of caffeine ingestion (6 mg kg<sup>-1</sup>) neither in the morning nor in the afternoon. Conclusions: Caffeine ingestion at a dose of 6 mg kg<sup>-1</sup> body weight in the morning (i.e., AM trials) improves upper and lower body muscle power at all loads (i.e., 25-90% 1RM). In the afternoon (PM trials) caffeine has no effect on muscle power, except when working against a high resistance (90% 1RM). Caffeine ingestion in the morning partially reverses the circadian reduction in muscle power. 1. Martin JC, Wagner BM, and Coyle EF. Inertial-load method determines maximal cycling power in a single exercise bout. *Medicine and Science in Sports and Exercise*. 1997;29(11):1505-12.

## A CASE STUDY: NUTRITIONAL INTERVENTION AND BODY HYDRATION/COMPOSITION ASSESSMENT IN ULTRA-ENDURANCE CYCLING EVENT

Lopez-Grueso, R.1, Guerrero-Lopez, F.J.2,3, Sanchis-Chorda, J.4, Ferrando, B.4

*1 Universidad Miguel Hernández de Elche. 2 Instituto de Nutrición Deportiva (IND) Valencia. Spain 3 Universidad Politécnica de Madrid. Spain. 4 University of Valencia. INCLIVA. Dpt. Physiology. Spain*

Introduction The training and competition alter the metabolism and body composition greatly, especially those of long duration in one or several stages, where the energy becomes to be deficient (Weitkunat et al., 2012). There is little research, and this is the aim of this study, focusing on analyzing the effects of a cycling test (1000km non-stop) with an individualized nutritional intervention to assess the hydration and body composition as a response of the organism. Methods A well-trained ultra-endurance athlete developed 1000km non-stop of cycling in a road circuit (4.7km) with a 40-hours of time limit. The nutritional and fluid intake was registered, during the entire test (pre, during -6 measures- and at the end) anthropometry and bioimpedance analysis -BIA- (Z-Metrix®, Bioparhom) were used to determine changes in body mass, skeletal muscle mass and fat mass. In order to quantify hydration status we measured intracellular water volume and urinary specific gravity. Results The athlete consumed a total of 49.6 MJ of energy, 2781 mg of caffeine and 17.3 L of fluids (water, supplements and food contain), equal to 0.44 L/h. The body mass decreased as well as fat mass a 2.2%. The skeletal muscle mass and intracellular water volume decreased until the end too. These changes in body composition by anthropometry and BIA were changed in the same way that urine specific gravity (1005 g/mL to maximum of 1030 g/mL and 1020g/mL at the end). Discussion Our data suggest that is important to consider a nutritional intervention to modulate the body composition to secure physical performance in endurance exercise, decreasing the obvious changes that occur in the body of the athlete in these special events (Knechtle et al., 2009; Rehrer NJ., 2001). ## LIPID STATUS IN A YOUNG MALE POPULATION WITH HIGH-INTENSITY TRAINING

Ortiz-Franco, M.I, García-Hortal, M.I, Molina-López, J.I, Marfínez-Burgos, M.A.I, Sáez-Pérez, L.I, Planells del Pozo, E.I  
of Pharmacy, Institute of Nutrition and Food Technology "José Mataix", Biomedical Research Centre, University of Granada (Spain)

**Introduction** Fat is a highly concentrated energy source and the major source of energy, both resting and during low intensity physical activity. Muscle is the main tissue that burn (oxidizes) fat. Higher rates of fat oxidation occur during aerobic exercise, and using fat for exercise can spare muscle glycogen. Adaptation to aerobic exercise improves fat utilization as an energetic source. The long and short-term unbalanced diet could lead on nutritional deficiencies that alter performance and the optimization of results in high intensity training. Bad eating habits in the studied collective could cause adverse effects, so adequate nutrition is important to control high intensity athletes because their increased energy expenditure requires a huge intake. The aim of this study was to evaluate the nutritional fat status in a young male adult collective trained with high intensity tests. **Methods** This is a cross-sectional study. Twelve men, aged 25.8 ±4.2 years, participated in the study voluntarily. Real nutritional intake was measured with Nutriber software, the anthropometry with bioimpedance TANITA equipment and specific methodology, and the physical condition was tested with practical exercises (2000m run, high jump, a circuit and pull-ups). SPSS 17.0 program was used to determine the bivariate Pearson's correlation between vitamins and other parameters. The aim of this study was to evaluate the nutritional status focused on fat intake in a young male adult collective trained with high intensity tests. **Results** The adequacy (%RDAs) of Energy, Lipid, Protein and Carbohydrates were 76.1%, 80.8%, 219.9%, 63.1%, respectively. Energy and fat intake were significantly correlated with the intake of saturated fatty acids ( $r=0.97$ ;  $p<0.001$  and  $r=0.84$ ;  $p=0.001$ , respectively). The intake of chicken was correlated with the intake of saturated fatty acids ( $r=0.64$ ;  $p=0.026$ ). The intake of butter is directly correlated with saturated fatty acids, cholesterol and the energy intake ( $r=0.60$ ;  $p=0.042$ ,  $r=0.78$ ;  $p=0.003$  and  $r=0.80$ ;  $p=0.002$ , respectively). Chickpeas are directly correlated with saturated fatty acids, fat and energy intake ( $r=0.66$ ;  $p=0.020$ ,  $r=0.61$ ;  $p=0.036$  and  $r=0.73$ ;  $p=0.007$ , respectively). The intake of olive oil is inversely correlated with the lipid profile (saturated, monounsaturated and polyunsaturated fatty acids) **Conclusions** Our results show imbalances in recommended fat intake that could alter lipid status in young athletes and the expected results of high-intensity training. Nutritional assessment as well as monitoring these collectives is necessary to prevent possible negative long term and to further the acquisition of healthy habits **References** Trushina ÉN, Gapparova KM, Mustafina OK, Chekhonina luG, Nikitiuk DB, Kuznetsov VD. *Vopr Pitan.* 2012;81(3):92-6. ## DOPING AND SUPPLEMENT: THE ATTITUDE OF IRANIAN NATIONAL TEAM DOCTORS

Golshanraz, A., Same Siahkalroodi, L., Poorkazemi, L.

*Sport Medicine Federation of Iran*

**BACKGROUND:** Supplement use is common in sport. Burns (2004), reported that 88.0% of the questions athletes used at least one supplements and 58% admitted using more than one type (1). Besides their cost, use of supplements may have side effects on general health and sports performance. Nobody cannot ignore role of team physician in athletes sport achievement. **METHODS** This studies utilized a cross-sectional survey design and cluster sampling. 60 validated questionnaires were distributed among team physicians in 30 different fields of sports. A questionnaire designed to explore physicians' attitude to supplement consumption by athletes, beliefs and knowledge regarding dietary supplements. Mean age of participants was 30 years. **RESULTS** The knowledge of team physician about supplements was good in 79.3%, fair in 65.1%, and poor in 2.3%; whilst 24.7% felt that they have little knowledge. 78.6% stated that supplements are unavoidable part of competitive sports. They thought over than 70% of elite athletes use supplements. Most of them they had experience of inadvertent doping due to supplement contamination with prohibited substances. They expressed athletes like have a recommendation of sport supplements use by nutritionists (27%), team physicians (38.1%), coaches (18%), fitness trainers (16.3%) and pharmacists (12.6%). They cited athletes using supplements based on recommendation (54.7%), brand (24.8%), advertising claims (23%), availability (14%) and price (16%). **DISCUSSION** Our study revealed that many team physicians mentioned that athletes should acquire information from nutritionists, team physicians, coaches, fitness trainers and pharmacists. Whilst, Malinauskas et al. in their study found that 71% of athletes considered coaches the best consultants regarding sports supplements (3). It is evident that team physicians so far can be a reliable information source. So that, sport organizations can schedule educational sessions for team doctors to update their nutrition and supplement information. Subsequently they can transfer the information to athletes for best practice. **REFERENCES** 1- Burns, RD. et al. (2004). ### **NO CUMULATIVE EFFECT OF GRAPE POLYPHENOL WITH EXERCISE ON INSULIN SENSITIVITY IN HIGH FAT FED RATS**

Lambert, K., Thomas, C., Lees, J., Hokayem, M., Fabre, O., Mercier, J., Avignon, A.

*INSERM*

Improvement of insulin sensitivity has been found in rodent and in obese human with polyphenol such as resveratrol. Exercise training is also a well-known therapeutic for insulin resistance. The purpose of our study was to investigate the association of grape polyphenol (PP) with exercise training on the mechanisms of insulin resistance in high fat diet fed rats. We chose a grape seed polyphenol supplementation with a mix of polyphenol in order to be closed to the French nutritional recommendation of eating fruits and vegetables. 40 male Sprague-Dawley rats were used. During 4 weeks they were fed ad libitum with a high-fat diet (HFD) (58% kcal from fat, D12330 Research Diet). Then rats continued the HFD for 8 weeks but they were included in one of 4 groups of 10 rats: HF rats with only the diet, PP rats with a supplementation of PP in drinking water (50mg/g), EXO rats submitted to exercise training on treadmill (1h/day; 5days/week, 10% slope at 30m/min) and EXO+PP rats with exercise training and PP supplementation. Glucose tolerance tests were performed: at rats arrival, after the 4 weeks of HFD and after the 8 weeks of treatments. After sacrifice, soleus muscles and epididymal adipose tissue were incubated with insulin or PBS for 15 minutes at 37°C. Compared to HF rats, exercised rats presented a significant decrease in adiposity illustrated by a significant decrease in leptin. On insulin sensitivity, HF rats presented a higher glycemia compared to trained rats with a significant increase at 90 minutes after glucose injection. The area under the curve for glycemia was significantly increase after 4 weeks of HFD and present a significant decrease only in exercise animals when analyzed by ANOVA, there was no effect of PP alone or in combination with exercise. On soleus, the ratio Akt phosphorylated on Akt on tubulin present an increase only in exercised animals. On adipose tissue, this ratio at this time of analysis was not affected by exercise or PP. Moreover, on muscle, a decrease of inflammation was detected in exercise animals without effects of PP. Training is able to counteract the insulin resistance due to the high fat diet with no benefit of grape polyphenol supplementation on this alteration, at this time of analysis.

### **VITAMIN D STATUS, LEAN MASS AND MUSCULAR STRENGTH IN SEDENTARY SUBJECTS SUPPLEMENTED WITH LEUCINE FOLLOWING A 16 WEEKS EXERCISE PROGRAMME**

Farran-Codina, A.1, Zomeño-Fajardo, D.1, Cadefau, J.2, Brugnara, L.3, Murillo, S.3, Novials, A.3, Cussó, R.1, Lizarraga-Dallo, M.A.1, Palma-Linares, I.1, Antón, A.4, López-Ambatlle, A.5, Reguant, A.5

1; UB (Barcelona, Spain) 2; INEFC (Barcelona, Spain) 3; CIBERDEM (Barcelona, Spain) 4; UPN (Pamplona, Spain); 5; SportVital (Andorra la Vella, Andorra)

Introduction Loss of lean mass and muscular function associated with aging increases with sedentarism and nutritional imbalance. Exercise stimulates muscular protein synthesis and increases muscular strength. On the other hand, an adequate protein intake is necessary for achieving an optimal muscle mass (Solerte et al., 2008). Recently, some evidence has emerged suggesting that vitamin D deficiency increases muscle weakness (Fuller et al., 2011). The objective of this study was to evaluate the effect of a combined routine that included strength and endurance exercises and a post-exercise supplementation with leucine-enriched milk whey protein on lean mass, muscular strength and inflammatory markers in healthy and DM2 sedentary subjects. Methods We performed a clinical, randomized, double-blind study with 35 healthy volunteers (n = 17) and DM2 volunteers (n = 18) that underwent a 16 weeks training program. A subgroup of healthy volunteers received a supplement or a placebo 30 minutes after performing exercises. Each individual was clinically assessed at the beginning and at the end of the exercise programme, including muscular strength, body composition, diet and muscular strength tests. Results and discussion First results obtained to the date showed that all the groups slightly increased their lean mass (between 0,3% and 2,1%) and the leg muscular strength measured with a 1RM test increased (p<0,05) in subjects that received the protein supplement (41,7%), placebo (44,5%) and controls (13,7%). Vitamin D plasma concentration in subjects at baseline was generally quite low, showing levels <30 nmol / L indicative of insufficiency (82% of subjects) or even <20 nmol / L indicative of deficiency (32% of subjects). According to the observations made by other authors (Fuller et al., 2011), these really low plasma concentrations could attenuate the increases in muscle mass. ### **DIETARY HABITS OF JUNIOR RECREATIONAL GYMNASTS**

Ioannidi, V., Theos, A., Maridaki, M.

*national kapodistrian university of athens greece*

Introduction Adherence to Mediterranean diet seems to positively affect components of health-related quality of life in adolescents (Costarelli et al., 2012) and significantly reduce the risk of obesity and arterial stiffness (Lydakis et al., 2012). The purpose of the present study was to assess dietary habits of Greek junior recreational gymnasts. Methods 89 junior recreational (3-4 days/week) gymnasts (age: 8.7 ± 0.2 yrs, body height: 129.5 ± 1.5cm and body weight: 30.4 ± 1.1kg) answered the Mediterranean Diet Quality Index (KIDMED) questionnaire. The questionnaire consisted of 16 questions that assess the adherence to the Mediterranean diet pattern. For each question, the positive answer was rated as +1 and the negative as -1. The total score varies between 0 and 12 and scores between 0-3 are considered poor (low quality diet), scores between 4-7 are considered of medium quality and scores ≥ 8 are considered optimal (high quality diet). Results are presented as mean ± SE. Results According to the Mediterranean Diet Quality Index participants scored 8.3 ± 0.2 and therefore their diet was classified as of an optimal quality. More specifically most of the children (≥ 88%) consume every day breakfast with milk or/and yogurt and serials. In a daily basis they also consume vegetables and fruits, while fish is consumed at least twice a week. Discussion The results of the present study indicate that Greek recreational gymnasts still follow the Mediterranean Diet pattern that is considered to be the best diet pattern in order to maintain a healthy living and promote longevity. ## ANTIOXIDATIVE CAPACITY AND OXIDATIVE STRESS AFTER THREE WEEKS OF STRENUOUS EXERCISE IN YOUNG ADULTS

Lundström, P., Rickenlund, A., Barrès, R., Krook, A., Fritz, T., Zierath, J., Caidahl, K.

*Karolinska Institutet*

**Introduction:** Acute strenuous exercise increases the level of reactive oxygen (ROS) and at the same time eventually decreases the levels of plasma antioxidants. Athletes have an increased production of ROS but they also have an up-regulated antioxidative capacity (AOC). **Aim:** To test the hypothesis that AOC is up-regulated even after a short period of strenuous endurance training. **Methods:** 15 healthy (medium 26 year old) volunteers participated in 3 weeks endurance intensive training with 2 sessions per day, six days a week; intensity targeted to the lactate threshold. After the last training session the participants were asked to refrain from any sport activity during a subsequent 4-weeks post-exercise recovery period. The AOC and the indirect determination of the concentration of ROS were measured at baseline, after training-, and detraining period. **Results:** The total plasma AOC levels decreased significantly during the three weeks of exercise compared to baseline. After four weeks of recovery, the levels had increased but were still lower than baseline. There were no significant changes in oxidative stress after three weeks of training. At baseline oxidative stress was inversely related to fat free mass ( $r = -0.65$ ,  $P = 0.01$ ), hemoglobin ( $r = -0.89$ ,  $P < 0.001$ ), leucocyte count ( $r = -0.66$ ,  $P = 0.01$ ), oxygen uptake ( $r = -0.55$ ,  $P = 0.04$ ) and directly to respiratory quotient ( $r = 0.68$ ,  $P = 0.007$ ). AOC correlated to neither hs C-reactive protein ( $r = 0.64$ ,  $P = 0.02$ ) and the respiratory quotient ( $r = 0.59$ ,  $P = 0.03$ ) were positively related to the relative amount of body fat, while oxidative stress and AOC were not. Oxygen uptake increased, but body fat was not altered during the exercise period, neither was oxidative stress. However, AOC decreased ( $P = 0.004$ ) as did hemoglobin ( $P = 0.006$ ). **Discussion:** Short term high intensity endurance training decreases AOC. The decreased AOC did not fully recover after a detraining period. It seems that AOC rather decreases than increases after a short period of strenuous exercise. Whether the reduction of AOC is due to limited availability of antioxidants or increased consumption induced by ROS remains to be proven. **References:** Davies KJ, Quintanilha A, Brooks GA, Packer L (1982) *Biochem and Biophys Commun*, 107 (4), 1198-205 Chevion S†, Moran DS, Heled Y, Shani Y, Regev G, Abbou B, Berenshtein E, Stadman ER, Yoram, Epstein Y. ## THE INFLUENCE OF MASTIC AND PHYSICAL ACTIVITY AS A FACTOR RELATED TO LIPID METABOLISM, GLUCOSE METABOLISM AND BODY COMPOSITION

Fukazawa, T., Smyrnioudis, I., Konishi, M., Takahashi, M., Kim, H., Sakamoto, S.

*WASEDA UNIVERSITY*

Fukazawa, T.I, Smyrnioudis, I. 2, Konishi, M.I, Takahashi, M.I, Kim, H.I, Sakamoto, S. 1 1:Waseda University (Japan) 2:The Chios Gum Mastic Growers Association (Greece) **Introduction:**In the past several years, mastic gum from Chios-island of Greece has been a very popular and widely used functional food, which has important roles in the treatment of several modern lifestyle-related diseases in Western countries. This study aims at exploring ways in introducing mastic-gum from Chios Island in Greece to Japan with focus on its therapeutic-effect on lipid metabolism, glucose metabolism and body composition. **Methods:**We studied 21 healthy male subjects. Group A ( $n = 7$ ) received mastic powder 5g/day. Group B ( $n = 7$ ) received placebo powder 5g/day. Group C ( $n = 7$ ) received mastic powder 5g/day and additionally, participated in 30-min of walking, 3 times per week as physical activity. The period of the experiment is six months for all groups with an intervention of 3 months. We carried out the following blood test and physical measurement twice, before the intervention of three months and after the completion of the six months experiment. **Blood test:** group of lipid metabolism consists of cholesterol, low density lipoprotein, high density lipoprotein, triglycerides and lecithin-cholesterol acyltransferase. Group of hepatic function consists of serum glutamic oxaloacetic transaminase, serum glutamate pyruvate transaminase and gamma-glutamyl transpeptidase. Group of glucose metabolism consists of insulin and glucose. Group of body composition consists of body mass index, waist circumference, body fat, subcutaneous fat ratio and rate of skeletal muscle. **Results:**Comparing the differences among three Groups: A, B and C and between the two experimental periods: first period (3 months) and second period (3 months). At this stage of our experiment, we focus on the changes observed in the first period before the intervention of 3 months. Concerning Groups A and B, the changes are not greatly seen. However, after comparing group A with group C, there are more changes to be observed. The blood-test indicates that the combination of mastic-gum and 3 times of walking per week has a positive effect on lipid metabolism, glucose metabolism and body composition. **Conclusion:**At the end of the first period of three months, we only observe some slight positive effects of combining mastic intake and physical exercise. Continuing our examination, the data will be compared with those extracted at the end of the second period, six months later (including the intervention period). According to previous studies, we expect that Chios mastic powder could have at least a hepatoprotective role in vivo in humans (Triantafyllou et al., 2007). As this study is still in progress, we aim to observe clear results after the completion of the second period and to examine the functional and medical efficacy of mastic in Japan. **References:**Triantafyllou A., Chaviaras N., Sergentanis T.N., Protopapa E., Tsaknis J. (2007). *Journal of Ethnopharmacology*, 3, 43-49.

## Philosophy and Ethics

### EVALUATION OF WEST-AUSTRIAN COACHES' AND SPORT TEACHERS' KNOWLEDGE REGARDING DOPING IN SPORT

Blank, C.1, Fürhapter, C.1, Leichtfried, V.1, Mair-Raggautz, M.1, Müller, D.2, Schobersberger, W.1

*1:UMIT (Hall, Austria), 2: NADA Austria (Vienna, Austria)*

**Introduction:** Athletes are surrounded by a network of relationships and dependencies. This network has the power to influence the athlete, both, in a positive as well as in a negative way. Important are the right attitudes towards, and qualified education in the field of doping. The aim of the current study was to evaluate the knowledge and attitudes of West-Austrian coaches and sport teachers regarding anti-doping issues and to assess their role in educating athletes/students. **Methods:** An anonymous questionnaire was distributed to coaches and sport teachers of five Tyrolean sport schools ( $n=135$ ). The questionnaire was structured into ten areas of interest, dealing with socio-demographics, knowledge about prohibited substances, attitudes towards doping, own sporting career as well as the contact to athletes. To define the level of knowledge a cut-of point at 80% (retrieved from the literature) of correct answered was set, indicating

good knowledge. Chi-Square tests, student t-Test as well as descriptive statistics were used to analyze the data. Results: 62 respondents returned the questionnaire (response rate 45.9%). 93.5% showed a good knowledge of the World Anti-Doping Agency (WADA) prohibited list. Uncertainties occurred with respect to the side effects of stimulants and anabolic steroids (40.3% bad knowledge each). 58.1% felt well informed about doping matters, mostly through primary and secondary education. Over 97% of the respondents showed a critical attitude against doping and 53.2% discussed the topic with their athletes during training. Yet, for 69.4% doping was not a relevant topic during everyday training even though 48.4% reported a high interest in the topic aside their athletes. 6.5% of the coaches and teachers felt tempted to use prohibited substances during their active career themselves. No significant differences were found with respect to gender, age, years of profession and/or own professional sporting career. Discussion: Findings show a slightly better knowledge of the Tyrolean coaches and sport teachers in regard to doping substances when compared to the studies by Peters et al (2009) and Laure et al (2001). Yet, there are still some gaps in the knowledge especially regarding side effects of anabolic steroids and stimulants as well as nutritional supplements. Although athletes show an interest in the topic by addressing their coaches for information and coaches articulate a strong wish to integrate the topic into the education of their students, only 69.4% consider the topic as relevant in everyday training. ### **RELATIONSHIPS BETWEEN FITNESS AND GUIDANCE OF ATTENTION IN SPORTS INVOLVED AND SPORTS NON-INVOLVED CHILDREN**

Serbetar, I., Kos, L.

*Faculty of Teacher Education Zagreb*

**Introduction** The study intended to assess the relationships of fitness – motor and anthropometric measures and some indicators of attention and whether there are differences regarding guidance of attention between children athlete's and non-athlete's. **Methods** The sample of 56 children (35 athletes) aged 8-11 was assessed. Fitness was measured using the EUROFIT battery comprised from 8 motor tests: hand grip, sit ups, flamingo balance test, sit and reach, standing broad jump, bent arm hang, plate tapping, shuttle run. Body weight and height were also assessed and BMI was calculated. The skinfolds were taken at triceps, biceps, subscapular and abdominal sites and sum of skinfolds was calculated. Guidance of attention was established by questionnaire based on DSM-IV classification (APA, 1996) with ten items included. Items in the questionnaire were like the following: "It is hard to me to maintain the attention when I am doing homework or playing some game." Children answered on Likert scale from 1 – 5 ("never" – "very often"). Results There was no differences in body measures between boys and girls but in motor test boys outperformed girls in sit-ups ( $p=.00$ ) and standing broad jump ( $p=.00$ ), while the girls were better in shuttle run ( $p=.00$ ). Children athletes were significantly better from non-athletes in all motor test and also in sum of attention items. There were no differences in BMI and sum of skinfolds. Mann Whitney U test showed that there was statistically significant differences in 7 of 10 item, favoring children athletes in guidance in attention. Motor tasks were further standardized and summarized in overall motor score. After the same was done with attention items the correlation between motor and guidance of attention scores was computed. Negative but significant value of  $-.43$  was obtained, suggesting the higher the motor scores the lower the attention problems. **Discussion** Similar findings are presented in Adsiz et al. (2012), which proved that children which were more physically active also had higher level of concentration. The same was established by Hillman and others (2009), they found that moderate aerobic exercise could enhance cognitive attention control in period of young adolescence. Akcmlı (2005) also showed that movement exercises positively influence on the development attention and memory. Özdemir (1990) found that children involved in sport have higher level of attention than sports non-involved children. It could be concluded that children sport engagement could lead to increased level of attention as well as possible expansion of academic achievements and learning skills. References Hillman, C.H., et al. (2009). The effect of acute treadmill walking on cognitive control and academic achievement in preadolescent children, *Neuroscience*. 159:1044-1054

### **THE INFLUENCE OF AN ALTERNATIVE EDUCATION PROGRAM UPON STUDENTS' TENNIS LEARNING PROCESSES**

Silva, N., Miranda, M., Santos, R., Resende, H.

*Universidade do Estado do Rio de Janeiro; Universidade Federal de Juiz de Fora; Universidade Salgado de Oliveira; Universidade Castelo Branco*

**Introduction** One of the ways to overcome the label of elite sport of tennis is to show the possibility of its practice adapted to different spaces, alternative materials and participation of a greater number of players in each learning group. Therefore, the aim of the present study was to investigate the effects of teaching tennis, considering the application of the Recreational Game method, on learning of mid-school children during physical education classes. **Methods** The study investigated the effects of an alternative education tennis program upon the learning process of school children between the ages of 11 and 13 years old, at a public school in the city of Rio de Janeiro. Twelve school children with no previous experience of the game participated in 38 lessons aimed at teaching the basic Forehand, Backhand and Serving movements, methodologically worked according to Method of Recreational Sports Game. For the purposes of data collection, a Lawn Tennis Specific Motor Skills Test was developed, validated and applied. The results were analyzed by means of descriptive statistical work and the Student's t-Test was used for dependent samples. **Results** The results indicated that the method employed was effective for the functional acquisition of motor skills and those of the game itself, as well as being an important factor in the motivation of the students. **Discussion** Our results are in accordance with others authors such as Leonardo et al. (2009) and Faria et al. (2006), indicating that learning of team sports can be facilitated through the experience of the pre-sports games, as well as those of Matthiesen et al. (2008) and Matthiesen and Fioravanti (2008), which from experience with track and field modalities, suggest that learning this modalities may have basis in recreational activities, leading to development of basic motor skills. The similarity found in student performance during the game and Skill Specific Tennis Tests suggests that the use of Recreational Game Method in the process of teaching and learning, with application of activities that preserve the characteristics of the end-game, can be an important factor contributing to the acquisition of basic skills, the functionality of the game and motivation for learning. ### THE EFFECT OF PHYSICAL ACTIVITY HABITS AND PHYSICAL FITNESS ON ACADEMIC PERFORMANCE IN ADOLESCENTS STUDENTS

García-Tardón, B., Pertusa, G., Sanz-Frías, D., Salinero, J.J., Perez-González, B., García-Pastor, T.

*CAMILO JOSE CELA UNIVERSITY*

**Introduction** Physical activity (PA) was found to improve cognitive functions in the brain but there is weak evidence of PA habits, fitness levels and academic performance association (Chaddock et al., 2011). The aim of the study was to expand the current existing research on academic and physical education in order to effectively determine the influence PA habits and fitness on academic performance (AP) has among high school students. **Methods** The sample comprised 1,326 subjects, both male and female, between fourteen and eighteen years old ( $15'12 \pm 0'99$ ), enrolled in their second cycle in 13 schools in Leganés (Madrid). We administered fitness test based on FITNESSGRAM: cardiorespiratory fitness by the Shuttle Run test, hamstring flexibility by the Sit & Reach test, and prehensile strength of their forearm flexors by the use of a manual dynamometer. We assessed PA habits with the Assessment of Physical Activity Level Questionnaire (APALQ) (Ledent, Cloes, & Piéron, 1997), and AP based on the number of failed subjects in their most recent scholastic trimester. **Results** Due to weak statistical correlation, the findings must be interpreted cautiously; however, there was found to be a statistically positive but weak correlation between the academic performance and the level of cardiorespiratory resistance ( $r=-0,107$ ;  $p=0,00$ ), and between the academic performance and the level of hamstring flexibility ( $r=0,080$ ;  $p=0,00$ ). These results allow us to infer that a greater number of failed subjects will lower a student's score obtained in both physical tests. **Discussion** Cardiorespiratory fitness results are consistent with previous research on academic performance in children (London & Castrechini, 2011). The findings of the current study showed that cardiorespiratory fitness and hamstring flexibility may have a positive influence on academic performance in adolescent students. **References** Chaddock, L., Pontifex, M. ### DOES PHYSICAL OUT OF SCHOOL ACTIVITY COMPROMISE THE ACADEMIC PERFORMANCE OF YOUTH PEOPLE?

Ballester, R., Yuste, F., Bermejo, J., Llorens, F., Moratal, C., Huertas, F.

*Universidad Católica de Valencia*

**Introduction:** As the focus on academic achievement has increased, the hours of physical education in the school have decreased in Spain. In an attempt to discover how the decline in PA may affect academic achievement, researchers have been studying the effects of PA on cognition and academic achievement in children for more than 50 years (see review of Howie & Pate, 2012). Some studies have found strong, positive relationships between physical activity and cognitive outcomes, while other studies have reported small, negative associations (Fedewa & Soyeon, 2011) Recommendations for appropriate amounts of physical activity for the youth population, have been developed by several organizations and agencies around the world. Although recent reviews have summarized the benefits of regular physical activity on the health of youth and its benefits a more specific approach is indicated. **Method:** The objective of this study was to examine whether there is any relation between the systematic practice of a sport measured with the PAQ-A and the academic achievement in children aged 12-13 years. The sample was composed by children from the lower leagues of a first division team and students from the scholar context,  $n=72$ . **Results:** Our study has found positive relationships between physical activity levels and academic achievement. **Discussion:** This study presents results dealing with the effects of regular physical activity on several health and behavioural outcomes in Spanish school-age youth, with the goal of developing a recommendation for the amount of physical activity deemed appropriate to yield beneficial health and behavioural outcomes. **References:** Fedewa, A.L., & Soyeon, A. ### ECOLOGICAL-DYNAMIC APPROACH IN PHYSICAL EDUCATION ACCORDING TO BERTHOZ THEORIES

Polidoro, L., Di Tore, P.A., Raiola, G.

*University of Salerno- Italy*

In Italy, the school document on physical education (PE) has been changing continuously by the Minister of Education and its last updated (G.U. 2013) is a new educational and didactics model for PE, as well as it happens for the other subjects. New discoveries about the mechanisms of learning skills are highlighting in opposite way to the traditional vision and so a new question on teaching method emerges. Actually, there is not an accurate study about the content of motor control, learning and development in PE, to verify if they are applied teaching method and if these aspects are in current ministerial document for first cycle of education. In this way it needs to integrate psychology and pedagogic aspects in PE according to the body, corporeality theory. Natural sciences and its approach of the physiology of perception offer the educational epistemology on the moving body a description of the functions of specific properties of human beings who can face up the complexity and transfer it to other contexts. Original PE research is carried out by the study of Alain Berthoz, who step by steps, offers a thorough analysis of the concepts of Le Sense du mouvement (Berthoz, 1997) with proactive idea of action, Le decision (Berthoz 2003) with a decision making in movement and Simplexity (Berthoz, 2009) with a mix between complex and simplex. He offers a new vision to help an educational epistemology. The principle of differentiation, anticipation, forecasting, reliability, flexibility are in the dynamics, the expressiveness and the emotional potential of PE. It is a very complex phenomenon which includes corporeity, affectivity and witness and it requires a dynamic vision and multidimensional too. **Methods** is to analyze the documents and to evaluate if the new paradigm is included in document. An integrated method that joins a historical and documentary approach to describe the evolution steps and then to argument and deduct on new discoveries on PE. **Results** do not carry out any particular aspects connected to the new theories. All ministerial documents do not provide any reference of specificity of motor control system and its classification. Furthermore, there are not any innovative elements on didactics and teaching methods. It appears a repetitively traditional corpus of documents updated with general scientific idea that must be changed. PE documents need a changing vision to address a

new approach to didactics according to ecological-dynamic approach (Raiola 2012). References: G U (2013) Indicazioni nazionali curricolo, Poligrafico stato, Roma, Berthoz, A. ### THE EFFECTS OF EXERCISE-INDUCED CHANGES IN CEREBRAL OXYGENATION ON COGNITION IN THE HUMAN PREFRONTAL CORTEX

Kobayashi, K.I, Yamauchi, J.I,2

1:Tokyo Metropolitan University (TMU), 2:Future Institute for Sport Sciences

[Background] An increasing number of human studies have suggested a beneficial influence of aerobic exercise on blood concentrations in the motor region of the brain (Ide et al., 2000, Bhambhani et al., 2007). We have also reported that exercise with moderate intensity increases cerebral oxygenation in the PFC. This increase may be related to an improvement in cognitive performance; however, it is still unclear whether exercise-induced oxygenation hemodynamics affects the cognitive function during and after exercise. [Purpose] The purpose of this study was to investigate the effect of exercise-induced changes in cerebral oxygenation on cognition in the human prefrontal cortex. [Methods] Five healthy individual performed a 9 min modified Flanker test (FT) and a 15 min serial calculation test (UKT) before, during and after exercise. The exercise condition was set at 55% of VO<sub>2</sub>max. During exercise, the participants took the Flanker test 20 min after the start of exercise. Haemoglobin concentration changes such as oxyHb, deoxyHb and totalHb were measured in the prefrontal cortex (PFC) using a multichannel functional optical topography. The number of calculations were counted from the UKT. The reaction time (RT) and the number of errors were analyzed in the FT. [Results and discussion] The oxyHb increased during UKT and exercise, while deoxyHb decreased during UKT. The number of calculations in the UKT increased after exercise. In the FT, the RT decreased during exercise and the number of errors did not change. This indicated that either psychological or physical stress causes an increase in oxygenated haemoglobin in the PFC. It is still unclear how an increase of oxyHb after exercise is related to an improved cognitive performance during and after exercise with moderate exercise intensity. ### RELATIONSHIP BETWEEN DAILY SPONTANEOUS RUNNING DISTANCE AND BRAIN MONOAMINE LEVELS IN RATS

Yanagita, S., Ochiai, H., Takano, Y., Kubota, N., Takeda, K.

Tokyo University of Science

Introduction Spontaneous wheel running is common physical exercise model to enhance physiological and psychological health in rodents. It is well known that daily spontaneous wheel running distance gradually increases over several weeks from starting day of running. Remarkably, it is also known that there is considerable individual variability in the amount of daily spontaneous running distance in the running wheel. Because the amount of physical exercise is an important factor to obtain beneficial effects of exercise, individual differences of daily spontaneous running distance may influence outcome of exercise training. In this study, we examined the effects of difference of daily spontaneous running distance on brain monoamine levels which have crucial role for physiological and psychological benefits in rats. Materials and Methods Male Wistar rats were used in this study. The rats were housed individually in plastic cages with or without an attached running wheel and were randomly assigned to either physically active or sedentary conditions. Physically active rats were allowed voluntary access to their wheels for 4 weeks. Daily wheel revolutions were recorded digitally, and running distance was calculated by multiplying wheel circumference by the number of revolutions. The rats were screened into high runner (HR) or low runner (LR) based on the calculated daily running distance. Furthermore, locomotor activities in the housing space in cages (i.e. activity of other than running wheel) were analyzed using infrared system. We assessed the levels of brain dopamine, serotonin, noradrenaline, and its metabolite using high-performance liquid chromatography (HPLC). This assessment was performed in various brain regions, such as the prefrontal cortex, striatum, nucleus accumbens, paraventricular nucleus of the hypothalamus, hippocampus and central nucleus of the amygdala. We also examine the creatine synthase activity in the soleus muscle, and blood glucose levels to estimate individual training status. Results Four weeks of spontaneous wheel running made the predominant individual variability in daily spontaneous running distance, but not locomotor activities. Brain monoamine levels in HR remarkably differed from that of LR in the several brain regions. Discussion The results of the present study showed that difference in the amount of daily spontaneous running distance influenced monoamine levels in several brain regions related to physiological and psychological benefits. The results of the present study, taken together with numerous studies that have shown that spontaneous wheel running has excellent effects on the maintenance of physical and mental functions, suggest that it is necessary to enhance the ability to engage in spontaneous physical activity in their daily lives.

### EFFECT OF COMBINED TRAINING ON PLASMA VOLUME VARIATION IN RESPONSE TO SUPRAMAXIMAL EXERCISE: EFFECT OF ADVANCED AGE

Sellami, M.1, Ben Abderrahman, A.2, Kebsi, W.1, Bouguerra, L.2, Zouhal, H.1

1 M2S Laboratory, University of Rennes 2-ENS-Cachan, Rennes, France. 2 ISSEP, Tunis Tunisia, University of Manouba.

Introduction Plasma volume variations are known to be affected by several factors such as age (Berthoin et al 2003), physical training (Zouhal et al 2007) and exercise intensity (El Sayed et al 1990). The purpose of this study was to investigate the effect of 13 weeks of high intensity sprint and strength training (HISST) on plasma volume variation (PVV) in response to supramaximal exercise in young and older (middle age) adults male athletes. Methods Twenty-eight male subjects, moderately trained (21.3±1.2 and 40.6±1.9 years) participated on this study. They were divided in four groups as follow: young male experimental group (YE, 21.3±1.1 yr., n= 7), young male control group (YC, 21.9±1.06 yr., n= 7), aged male experimental group (AE, 40.3±1.8 yr., n= 7) and aged male control group (AC, 40.9±1.8 yr., n= 7). Experimental groups performed a HISST two to three times a week during 13 weeks. Before and after the training program, all participants performed a Wingate-test (WT). The hematocrit (Ht) and hemoglobin (Hb) were measured at rest, after a warm-up (15 min, 50% VO<sub>2</sub>max), immediately after WT and after 10 min of recovery. The PVV was calculated using Ht and Hb (Dill and Costill 1974). Results

Before and after HISST, the warm-up induced no significant differences in PVV between AE and YE. However, a significant decrease ( $p < 0.05$ ) in PVV was observed in all groups before and after HISST at the end of the WT. The maximal values registered were  $-12.7 \pm 7.4\%$  in AE and  $-10.8 \pm 3.3\%$  in YE after HISST. Hence, the degree of regression between test and re-test was much more pronounced in YE with a percentage of about  $-2\%$  suggesting the age effect in response to WT. During recovery after HISST, PVV increased in all groups, this increase was significantly high in YE ( $p < 0.05$ ) compared to the other groups. Discussion The similarity of results between YE and AE in PVV after warm-up and after HISST is due probably to the benefit effect of the training program among experimental groups. The higher decrease of PVV in AE observed at the end of WT could mainly be explained by the age effect. The higher increase in PVV during recovery in YE seems to be the result of a metabolic adaptations related to sprint and strength training (Zouhal et al 2007). However, this hypothesis remains to be explained. References Berthoin S, Allender H, Baquet G, Dupont G, Matran R, Pelayo P, and Robin H (2003). *Acta Paediatrica*. 92: 283-290. ## EFFECTS OF A 25 KM ULTRA OPEN WATER SEA SWIMMING TEST ON SALIVARY LEVELS OF HORMONES AND IMMUNITY MARKERS

Tauler, P., Martínez, S., Moreno, C., Martínez, P., Aguiló, A.

*University of the Balearic Islands*

Introduction Several hormones and inflammatory and immunological markers, which are usually determined in blood, can be also measured, in a non-invasive way, in saliva. The aim of this study was to determine the effect of an open water sea swimming ultra exercise test on hormone, C-reactive protein (CRP) and immunoglobulin A (IgA) levels in saliva. Methods Saliva samples were taken from 43 swimmers (32 men and 11 women) participating in the "25 km Cabrera Open Water Race". The race (25 km) was performed between the islands of Cabrera and Mallorca at a constant pace of 3 km per hour. Unstimulated saliva samples were taken before and after the exercise test. Cortisol, testosterone, dehydroepiandrosterone (DHEA), CRP and Ig A were measured in these saliva samples using commercially available ELISA kits (Salimetrics, Newmarket Suffolk, UK). Mean age ( $\pm$ s.e.m.) of participants in the study was  $38.2 \pm 1.4$  years, weight  $74.2 \pm 1.8$  kg and height  $175.3 \pm 1.2$  cm. Participants lost about 3 kg weight during the exercise test. Results Salivary flow rate increased significantly after the exercise ( $p < 0.001$ ). The swimming race induced a significant increase in cortisol levels ( $p < 0.001$ ). However, testosterone concentration decreased after the exercise ( $p = 0.006$ ) and DHEA levels did not change along the study. On the other hand, the competition induced a decrease in both Ig A levels ( $p < 0.001$ ) and Ig A secretion rate ( $p = 0.023$ ). However, no changes were observed in CRP levels. Discussion A decrease in saliva production after exercise is commonly observed due to dehydration. The increase in the salivary flow rate after exercise in the present study could be produced by the marine salt, which is one of the most important stimuli for increased salivation. Increased cortisol levels, together with the reduction of testosterone, reflect the high physical stress and the catabolic environment induced by the high demanding exercise performed. Increased cortisol could result in decreased production of Ig A, inducing a situation of partial immunosuppression. Low levels of IgA after exercise may be responsible, at least in part, for the increased incidence of upper respiratory tract infections which has been observed after several endurance competitions or high intensity training programs. It is noteworthy that the ultra-endurance exercise performed did not induce changes in CRP levels as a component of the habitual inflammatory response to exhaustive exercise. In conclusion, salivary testing allows a non invasive measurement of physical stress and immunosuppression induced by an ultra-endurance exercise test.

## CROSS-VALIDATION OF DIFFERENT PREDICTIVE EQUATIONS FOR AEROBIC CAPACITY BY SHUTTLE RUN 20M IN BRAZILIAN YOUNG MEN.

Ferreira, C.E.S.1,2,3, Maciel, D.G.1, Araújo, D.G.1,2, Dumas, R.J.V.1, Melo, G.F.1,3, Silva, F.M.1,2

1: Curso de Educação Física, Universidade Católica de Brasília (UCB), Brasília, Brazil, 2: Laboratório de Avaliação Física e Treinamento (LAFIT), UCB, Brasília, Brazil, 3: Programa de Pós Graduação em Educação Física, UCB, Brasília, Brazil. INTRODUCTION Cardiorespiratory fitness (CF) makes up the main physical fitness health-related component, also been associated with cardiovascular profiling and used for health promotion policies in different countries. Moreover, CF can be predicting by maximum oxygen uptake ( $VO_{2max}$ ). Indirect tests (IT) provide the possibility of assessment in multiple subjects at the same time at low costs. One of the feasible IT is Shuttle Run 20m (SR20m). However, SR20m uses equations from specific population as proposed by Léger; Léger with velocity adjusted by Kuipers; Barnett. The first two equations are constantly used in Brazil due to be easy to memorize and Barnett's for been recommended recently (Ruiz et al, 2009). So, even with frequent use of SR20m, at this moment, no study has investigated the validity of these equations in Brazilian young men. Thus, the aim of this study was to determinate the validity of three different SR20m equations for estimating  $VO_{2max}$  in Brazilian young men. METHODS To assess aerobic capacity 21 Brazilian young men ( $13.6 \pm 1.0$  years;  $46.3 \pm 8.4$  kg;  $1.6 \pm 0.1$  m) performed SR20m until volitional fatigue. Prior to the test, anthropometric data were collected. During the entire SR20m subjects wore a portable gas analyzer that measure breath-by-breath oxygen uptake. ANOVA for repeated measured was performed to detect differences between measured and estimated  $VO_{2max}$  and the agreement between them by Bland Altman method. RESULTS Only Barnett's equation didn't differ from measured  $VO_{2max}$  ( $p < 0.05$ ). Moreover, the prediction errors (SEE and E) ranged from 4.54 (Léger) to 0.4 ml/kg/min (Barnett). The agreement between measured and estimated was Barnett 0.1, Kuipers 4.6 and Léger -5.3. DISCUSSION Only Barnett's equation estimated  $VO_{2max}$  equal than measured. All the others equations underestimated average  $VO_{2max}$ . Our results are similar than performed with European youths (Ruiz et al, 2009). According to our results, we recommend using the Barnett's equation for the better agreement with gold standard in Brazilian young men. REFERENCES BARNETT, A., CHAN, LYS., BRUCE, IC. ## **RUNNING A 100 KM ULTRA-MARATHON INDUCES AN INFLAMMATORY RESPONSE BUT DOES NOT RAISE THE LEVEL OF THE PLASMA IRON-REGULATORY PROTEIN HEPcidIN**

Kaspruwicz, K., Ziemann, E., Ratkowski, W., Laskowski, R., Kaczor, J.J., Dadci, R., Antosiewicz, J.

*Polish Tennis Association, University of Physical Education and Sport*

Exercise may induce an inflammatory response that may lead to changes in iron metabolism. The aim of this study was to examine the relationship between the inflammation induced by a 100 km run and the level of hepcidin, which is a hormone regulating iron metabolism. Six males, age  $44.5 \pm 13.5$  years, running 100 km. The concentration of the CRP protein, IL-6 and leucocyte count were measured as an index of inflammation. A 100 km run caused a progressive increase in blood IL-6 concentration, which reached the highest values after 75 km. Furthermore, an increase in levels of CRP, a marker of inflammation, was observed after the 100 km run and continued to increase after a 14 h recovery period. Leucocyte number and markers of muscle damage were significantly elevated after the 100 km run. This was accompanied by a decrease in transferrin saturation and an increase in blood haemoglobin and ferritin. Despite all these changes, the 100 km race did not affect blood hepcidin concentration either during the run or after a 14 h recovery period. The study shows that a 100 km run induces an inflammatory response but does not trigger changes in the blood hepcidin level. Thus it can be concluded that changes in IL-6 are not sufficient to increase the blood hepcidin level in runners.

## **RELATIONSHIP BETWEEN FINGERTIP SWEAT AMMONIA CONCENTRATIONS AND POWER FOLLOWING SHORT-TERM SPRINT CYCLE EXERCISE**

Itoh, H.1, Kimura, S.1, Sugimoto, K.1, Sakashita, Y.1, Ohkuwa, T.1, Tsuda, T.1,2, Hisanaga, M.2

*Nagoya Institute of Technology<sup>1</sup>, Pico-Device Co., LTD.<sup>2</sup>*

**Introduction** During short-term sprint exercise, the accumulation of ammonia in working skeletal muscles increases, and effluxes into the blood. Previously, we (Itoh & Ohkuwa 1991) have confirmed that the peak value of blood ammonia concentrations appears in sprints within 15-s. Increasing sweat ammonia excretion have also reported during cycle exercise (Czarnowski & Gorski 1991). However, no one has confirmed changes in the sweat ammonia concentrations after short-term sprint exercise. Therefore, we determined changes in sweat ammonia concentrations after the 10-s supramaximal cycle exercise. Furthermore, we examined whether peak sweat ammonia concentrations would relate with power following the short-term sprint exercise or not. **Methods** Ten healthy male students ( $21.6 \pm 0.2$  years; mean  $\pm$  SE) volunteered as the subjects. The subjects performed 10-s sprint cycle exercise as fast as they could using a Power max-V (Combi wellness Co., Ltd., Japan). Sweat ammonia samples were obtained from the surface of fingertip (forefinger) with a sampling tube containing 5% ethanol. Sweat samples were collected before and 0, 1, 2, 3, 4, 5, 6, 9, 15 min after the 10-s sprint exercise. Sweat ammonia and sodium concentrations were measured by the ion chromatographic analysis. **Results** The peak power and the exercise load of the subjects were  $836.0 \pm 39.9$  watt and  $6.3 \pm 0.3$  kp, respectively. Sweat ammonia ( $\text{NH}_4^+$ ) concentrations increased after the exercise compared to pre-exercise values, and then returned to pre-exercise levels. Similar changes in the ratio of  $\text{NH}_4^+$  to sodium ( $\text{Na}^+$ ) ( $\text{NH}_4^+ / \text{Na}^+$ ) were observed. There was a significant relationship between the peak  $\text{NH}_4^+$  and the power after the exercise ( $r=0.848$ ,  $p<0.001$ ). A significant relationship was also observed between  $\text{NH}_4^+ / \text{Na}^+$  and the power ( $r=0.756$ ,  $p<0.01$ ). **Discussion and Conclusions** The ammonia that appears in the blood during short-term exercise originates from the deamination of adenosine 5'-monophosphate (AMP) to inosine 5'-monophosphate (IMP) in the muscle. This reaction occurs via the purine nucleotide cycle (PNC) and is catalyzed by AMP deaminase (Lowenstein 1972). Ammonia production via the PNC in contracting muscle depends on exercise intensity, and occurs predominantly in fast-twitch muscle fibers (Dudley et al. 1983). On the other hand, previous studies have suggested that part of ammonia formed during exercise was lost with sweat (Czarnowski & Gorski 1991). Thus, in this study, excessive energy demands during the sprint cycle exercise increased the blood ammonia concentrations, and these increased blood ammonia levels might reflect the sweat  $\text{NH}_4^+$  concentrations. Therefore, peak sweat  $\text{NH}_4^+$  and  $\text{NH}_4^+ / \text{Na}^+$  would relate the power after short-term sprint exercise. **References** Itoh H and Ohkuwa T (1991). *Eur J Appl Physiol*, 62, 23-25. ## **EXERCISE IMPROVES POSTMENOPAUSAL DEPENDENT VASCULAR ACTIVITY**

Alkhatib, A., Klonizakis, M.

*University of Greenwich*

**Introduction** The risk of developing cardiovascular disease is well known to rise in women following menopause, and is associated with sedentary lifestyle and reduced cardiorespiratory exercise tolerance. The age-related deterioration in the vasculature integrity has been suggested to accelerate post menopause, and the effects on the vascular endothelial function have been linked with age and menopausal changes (Kirwan et al. 2004, Klonizakis et al. 2013). Recent studies have recommended regular exercise to reduce postmenopausal-related CVD risks including vasomotor and arterial stiffness (Figueroa et al. 2012), and cardiorespiratory exercise tolerance (Earnest et al. 2010). However, no study has yet investigated whether the exercise dependent increase in cardiorespiratory capacity is combined with improvement in endothelial microvascular function. This study aims to test whether and regular aerobic exercise training increase microvascular activity and cardiorespiratory exercise tolerance in postmenopausal women. **Methods** Following obtaining the institutional approval, fifteen postmenopausal women (age =  $53.3 \pm 2.9$ , body mass  $74.4 \pm 15.0$ , height =  $164.9 \pm 5.3$ ) participated in this study and were interviewed about their menopausal status. Participants then completed a cardiorespiratory tolerance test, and were assessed for their upper- and lower-limb vascular endothelial cutaneous vascular conductance (CVC) test using Laser Doppler Fluximetry (LDF), with endothelium-dependent Acetylcholine (ACh) and -independent Sodium nitroprusside (SNP) vasodilation. The exercise training involved eight weeks of discontinuous treadmill running based on each individual's perceived exertion twice per week. **Results** Exercise training improved CVC (e.g. ACh at  $2000 \mu\text{C}_b$  in the forearm  $0.9 \pm 0.4$  PU/mmHg compared with  $2.2 \pm 1.6$  PU/mmHg post-operatively). This was combined with improvement in participants' cardiorespiratory exercise tolerance as indicated by a significant increase in their ventilatory threshold (VT) ( $11.5 \pm 2.1$  vs.  $14.0 \pm 3.0$ ) and the corresponding VT speed ( $4.4 \pm 1.0$  vs.  $5.0 \pm 0.8$ ), all are  $P<0.05$ . **Conclusion** The present study suggests that regular moderate exercise improves menopausal related microcirculatory endothelial function and increases exercise tolerance in postmenopausal women, both are responsible for reducing cardiovascular risk in this high-risk group. **References** Earnest CP, Blair SN, Church TS. ## MUSCLE FUNCTION & PERFORMANCE AFTER MANIPULATION WITH BLOOD METABOLITES IN HIGHLY TRAINED CYCLISTS

Lyngholm, J., Andreasen, J.J., Christensen, P.M., Nordsborg, N.B., Bangsbo, J.

*University of Copenhagen*

**Introduction** Intense exercise with one muscle group compromises subsequent intense exercise performance engaging another muscle group. In the present study it is investigated if the detrimental effects of previous arm-exercise can be localized to the engaged muscle group or if the experienced fatigue is of more central origin. Further, it was investigated if protection from systemic metabolic acidosis would counteract exercise induced deterioration of muscle function and performance in highly trained cyclists. **Methods** On three separate days, cycling performance was evaluated in eight highly trained cyclists (VO<sub>2</sub>max: 70.0±8 ml O<sub>2</sub>/min/kg; Age 30±5 years; Weight 74±10 kg). Randomized manipulations were placebo treatment (PLA), bicarbonate ingestion (NaHCO<sub>3</sub>, 0.2 g/kg) and prior intense arm exercise (ARM). Two exercise bouts were performed (EX1 and EX2). EX1 consisted of 3 min cycling at 85 % aerobic peak power (367±19 W). EX2 was identical to EX1 but followed by a 2 min performance test (PT). EX1 and EX2 were separated by 75min rest. Blood samples were taken from an arm vein at rest as well as 1 min prior to and after each bout. In a subgroup (n=5), quadriceps maximal voluntary contraction (Q-MVC), voluntary activation degree (VAD) and twitch force (TF) was evaluated pre-exercise as well as 1 min after EX1 and EX2. Immediately after, maximal voluntary handgrip force (H-MVC) was determined. **Results** Mean power during PT was less (P<0.001) in ARM (377±39 W) relative to HCO<sub>3</sub> (412±39 W) and PLA (410±41W) with no difference between the latter two. Blood pH were lower (P<0.01) in ARM and higher (P<0.01) in HCO<sub>3</sub> compared to PLA (P<0.001) prior to both EX1 (7.19±0.05 and 7.41±0.01 vs. 7.36±0.02) and EX2 (7.23±0.04 and 7.42±0.02 vs. 7.37±0.02), respectively. Venous blood lactate was elevated (P<0.001) in ARM compared to both HCO<sub>3</sub> and PLA prior to EX1 (14.2±3.3 vs. 0.9±0.2 and 1.0±0.3) and EX2 (10.7±3.8 vs. 1.2±1.4 and 1.2±0.4 mM), respectively. After EX1 blood pH was lower in ARM (7.18±0.05) compared to HCO<sub>3</sub> (7.28±0.02) and PLA (7.24±0.05) (p<0.001). Furthermore in HCO<sub>3</sub> blood pH levels were higher after EX1 compared to PLA (p<0.05). After EX2 no difference in blood pH were observed among trials. Q-MVC performance was lower after EX2 in ARM compared to values at rest. Otherwise, no differences were observed in Q-MVC, VAD, TF or H-MVC for any of the trials after EX1 and EX2 compared to values at rest. No differences were found among PLA, HCO<sub>3</sub> and ARM. **Discussion** As expected ARM had negative effects on PT performance. This could be ascribed to inhibited muscle function since Q-MVC was lower after EX2. Central activation appeared unaffected as illustrated by the unaltered VAD and H-MVC. An increase in blood pH during HCO<sub>3</sub> did not improve PT performance. Thus, blood pH appears to be of limited importance for intense short-term exercise like PT.

## RED BLOOD CELL MORPHOLOGY ADAPTS TO INTENSE, ENDURANCE TYPE EXERCISE

Schumacher, Y.O., Nonis, D., Klodt, F., Pottgiesser, T., Voss, S.

*Aspetar Orthopedic and Sports Medicine Hospital*

**Purpose:** Through the transport of oxygen, red blood cells play a key role in defining the body's endurance capacity. As an adaptation to endurance training, red blood cell mass and plasma volume are increased in trained individuals compared to untrained subjects. However, only little data is available on the adaptation of the morphology of red blood cells to intense endurance training. **Methods:** 15 highly trained endurance athletes underwent 9 days of 3-6 hours of outdoor cycling exercise in a temperate climate (~25°C). Fluid intake was not restricted and carefully monitored. In the morning and the evening of each day, athletes were weighed and standardized venous blood samples were obtained, hematological variables (Hemoglobin concentration (Hb), hematocrit (Hct), red blood cell count, MCV, MCHC, MCH) were determined on an automated cell counter, protein concentration was measured in serum. **Results:** Athlete's weight did not show any alterations, the fluid balance was stable throughout the study period. Hb and Hct decreased significantly over the first 3 days of exercise to remain stable thereafter. MCV increased from the first to the last day of racing (meanΔMCV Day1-Day9 2.3fl, p<0.05), MCHC decreased accordingly (meanΔMCHC Day1-Day9 -2.1mg/dl, p<0.01). The magnitude of the variations was similar in morning an evening samples. Serum protein showed no significant change. **Conclusion:** Our data show a significant, persisting increase in MCV and a decrease in MCHC associated with several days of endurance-type training. This pattern accompanies the exercise induced plasma volume expansion, illustrated by decreased Hb and Hct. Previous research has focused on changes in MCV and MCHC during or shortly after high intensity exercise assuming that an exercise induced increase in osmolality would lead to cell swelling. However, these studies failed to demonstrate any long-term effect. In our investigation, osmolality was not measured, but the literature suggests unaltered osmolality after multi-day endurance exercise, which is confirmed by our observations of stable weight and unaltered protein concentration. Therefore, the physiological mechanisms triggering the sustained changes in MCV and MCHC remain to be explored. The altered MCV after several days of endurance training should be considered when using indirect models for the calculation of plasma volume changes based on Hct. In this context, the stability of MCV might also be used as a tool to assess potentially confounding plasma volume shifts in research settings.

## EFFECTS OF LIPOSUCTION AND EXERCISE TRAINING ON SELECTIVE INFLAMMATION-RELATED ADIPOSE TISSUE CYTOKINES.

Benatti, F.B., Solis, M.Y., Artioli, G.G., Montag, E., Saito, F.L., Painelli, V.S., Lima, F., Roschel, H., Gualano, B., Lancha Jr, A.H.

*University of Sao Paulo*

**Introduction** It has been speculated that the immediate liposuction-induced increase in the ratio of visceral to subcutaneous fat could lead to an increased metabolic risk. The beneficial effects of exercise on adipokine metabolism and the metabolic profile have been well described. Therefore, exercise training could positively impact adipokine metabolism following the surgical procedure. **Objective** To investigate the effects of liposuction on selective inflammation-related adipokines and insulin sensitivity in women (20-35 years; BMI: 23.8 ± 2.2 Kg/m<sup>2</sup>) who were either exercise-trained or not after surgery. **Methods** Thirty-six women underwent a small-volume abdominal liposuction (mean fat aspirate supernatant: 1240.3 ± 363.6 ml). Two months after surgery they were randomly divided into two groups: trained (n=18) and non-trained (n=18). The four-month exercise program consisted of aerobic plus resistance training, thrice a week. Body fat distribution and abdominal visceral to subcutaneous fat ratio (V-S ratio - determined by computer tomography), plasma levels of inflammation-related adipokines, and insulin were assessed at baseline (PRE), two (POST2) and six months after surgery (POST6). Adipose tissue gene expression of inflammation-related adipokines and physical capacity were assessed at PRE and POST6. **Results** V-S ratio equally increased in both groups from PRE to POST2 and POST6 (TR PRE: 0.18±0.04, POST6: 0.27 ± 0.10, p=0.0001; NT PRE: 0.18±0.08, POST6: 0.29±0.13, p=0.0001; within-group comparisons). Adiponectin plasma levels were markedly decreased (TR PRE: 19.3±7.3, POST6: 12.5±4.1, p=0.001; NT PRE: 19.4±8.0, POST6: 12.8±3.9, p=0.001; within-group comparisons) and a small but significant decrement in

adiponectin gene expression in subcutaneous abdominal and thigh adipose tissue was also observed ( $p < 0.05$ , within-group comparisons). Plasma levels of IL-6, TNF- $\alpha$  and IL-10 were unchanged throughout the study in both groups. In contrast, the inflammation-related cytokines' gene expression was significantly increased by 3 to 12 fold in both subcutaneous abdominal and thigh adipose tissue ( $p < 0.05$ , within-group comparisons). Finally, insulin sensitivity and physical capacity were unchanged in the non-trained group whereas it was significantly improved in the trained group at POST6 (data previously published). Conclusion These results indicated that a small-volume liposuction markedly down-regulated the secretion of adiponectin by the adipose tissue whereas it up-regulated the expression of inflammation-related genes six months after surgery in both exercise-trained and untrained women. These findings demonstrated that liposuction may not be free of long-term adverse metabolic effects. Additionally and importantly, although exercise training was incapable of counteracting these potential associated risks as consequence of a liposuction procedure, it improved insulin sensitivity and physical capacity. Thus, health professionals should strongly recommend exercise training as a mandatory intervention following liposuction surgery.

### **NORMALISED METHOD TO QUANTIFY THE OXYGENATION PROFILE OF SKELETAL MUSCLE WITH REAL TIME NIRS MEASUREMENT.**

Rios-Kristjansson, J.G., Gasol, X., Garcia, M.A., Marina, M., Turmo, A., Pages, T., Viscor, G.

*University of Barcelona*

**Introduction:** The real time Near-Infrared Spectroscopy (NIRS) measurement is widely used to monitor the oxygenation profile of an exercising skeletal muscle. The measurement is based on two traces: the concentration of oxyhaemoglobin (O<sub>2</sub>Hb) and deoxyhaemoglobin (HHb). These can simultaneously allow the calculation of the sum (tHb=O<sub>2</sub>Hb+HHb) and the difference (HbDiff=O<sub>2</sub>Hb-HHb). With the minimum of two measuring channels, an absolute value of the tissue oxygen saturation (StO<sub>2</sub>) can be obtained via the Tissue Saturation Index (TSI) (Myers et al., 2009). The main technical limitation of this in vivo measurement is the difficulty in obtaining a calibrated scale. Recommended quantification methods focus on blood flow and volume and oxygen consumption (Van Beekvelt et al., 2002). We want to go further and focus on the quantification of the O<sub>2</sub>Hb and HHb, looking for a reliable correlation between the lowest TSI% obtainable and the lowest O<sub>2</sub>Hb measurable. **Methods:** 11 healthy subjects (9 males and 2 females, aged 27 $\pm$ 8 years) participated in the study. The NIRS instrument (PortaMon, Artinis Medical Systems) was placed on the forearm's m. extensor digitorum. Pressure cuff was placed around the upper arm, and ischemia was induced (240 mmHg), until the decreasing O<sub>2</sub>Hb concentration reached a plateau, and the pressure was relieved. Previous to this a short boot of forearm exercise with (1-3 kg) was performed with isometric muscle concentration during the ischemic application. **Results:** The decrease in TSI and O<sub>2</sub>Hb with arterial occlusion was about 35 AU and 40  $\mu$ M, respectively. The TSI at the ischemic level reaches down to about 30% independent of initial resting TSI level. Although the O<sub>2</sub>Hb concentration reaches plateau at the same time, we cannot assume that actual concentration level has reached 0  $\mu$ M, rather, that the level of available O<sub>2</sub>Hb has. We simplify by using the 40- $\mu$ M decrease and the resting TSI value to estimate the concentration of O<sub>2</sub>Hb and HHb. **Discussion:** The actual O<sub>2</sub>Hb level will never reach zero due to residual critical Mb O<sub>2</sub> partial pressure about 2.75 torr (Bekedam et al., 2009). But the NIRS measurement does not distinguish between Mb and Hb. The 30% TSI value occurs due to; (1) the physical behaviour of microcirculation, capillaries will not be all closed simultaneously; and (2) the affinity of O<sub>2</sub>Hb to haemoglobin maintains residual O<sub>2</sub>Hb. The consistency of this model needs to be tested under distinct conditions, e.g., hypoxic vs normoxic environments, anaerobic vs aerobic exercises. The ischemic arrest is not a new method to evaluate the lowest O<sub>2</sub>Hb concentration, but we propose the above mentioned modifications for a more detailed profiling. **References:** Bekedam, M.A., van Beek-Harmsen, B.J., van Mechelen, W., Boonstra, A., and van der Laarse, W.J. ### **VARIATION OF THE MEDIAL GASTROCNEMIUS PENNATION ANGLE AND TORQUE BETWEEN GENDERS**

André, A.1,2, Castro, M.A.1, Pocinho, M.1, Moretto, D.2, Semedo, N.3, Tavares, P.2

*1Coimbra College of Health Technology, Portugal; 2Faculty of Sport Sciences and Physical Education, University of Coimbra, Portugal, 3 Taekwondo Association of Coimbra*

**Introduction** Muscle pennation angle and fiber length are important parameters of muscle strength. These characteristics of the muscle are changeable according to the functional requirements. Some studies have shown that several factors, like physical activity, gender, age and morphology, can influence the muscle pennation angle. The purpose of this study is to compare the variation of the pennation angle in two conditions, relaxed and maximal contraction of gastrocnemius, a fundamental muscle to the gait, in a sample of man and women. It was also our goal to verify the influence of factors like height, weight and BMI in the variation of the pennation angle. **Methods** The medial gastrocnemius pennation angle was assessed by ultrasound with a 12 MHz linear probe, in rest and in maximal contraction. The evaluation of the gastrocnemius was done in two planes: longitudinal and transversal. The image of the medial gastrocnemius was acquired only in longitudinal plane, to allow the evaluation of the angle between two lines, the fascicle and the deep aponeurosis. Muscle strength was evaluated using an isokinetic dynamometer, BiodexSystem3. 60 subjects, 50% of female and 50% agreed to participate voluntarily on this experiment. Both groups had a similar level of physical activity and subjects with muscle injury were excluded. After a warm up, subjects were asked to remain at rest for a first measurement of the pennation angle. After that the same measurement was performed during a maximal contraction and the torque value was recorded. In both measurements, rest and maximal voluntary contraction, the lower limb was fixed in the same position in order to maintain the same degree of gastrocnemius extensibility. Both limbs for each subject were assessed **Results** Our results showed that the variation of the pennation angle is influenced by gender. Overall, females were found to have lower angles of pennation and force values than males. To find predictors of the difference angle pennate angle of the right leg and the left, we used a linear regression analysis in which prediction model we included the independent variables gender, lower limb pre-existing injury, sport activity, age, height and weight. **Discussion** As expected males present higher values in all variables, with significant differences between the two groups in both states. However, the pennation angle in rest even though remaining higher in males, showed no significant differences when compared to the female rest pennation angle. The differences in morphology by the pennation angle variation between men and women are confirmed in our experiment.

## THE CAPACITY AND HYPOXIC RESPONSE OF SUBCUTANEOUS ADIPOSE TISSUE BLOOD FLOW IN HUMANS

Kalliokoski, K.K., Kaskinoro, K., Kemppainen, J., Knuuti, J., Boushel, R., Heinonen, I.

*University of Turku*

**Introduction** We have recently shown that blood flow in subcutaneous adipose tissue of the leg increases from rest to exercise in an exercise intensity-dependent manner, but only in the vicinity of working muscle (Heinonen et al. 2012). Furthermore, we also showed that adenosine receptor antagonism attenuates this blood flow enhancement at the highest exercise intensity (Heinonen et al. 2012). Here we studied the effects of exogenously infused adenosine on adipose tissue blood flow (ATBF) in order to estimate the blood flow capacity in the adipose tissue. Further, we also wanted to investigate how acute systemic hypoxia affects ATBF at rest or during exercise. **Methods** We measured ATBF in nine healthy young men by positron emission tomography using radiowater tracer. ATBF was measured adjacent to the knee extensors at rest and during dynamic knee extensor exercise, and during two physiological perturbations: while breathing moderate systemic hypoxia (14 % of O<sub>2</sub>) at rest and during exercise, and during intra-arterial (a. femoralis) infusion of adenosine, with a dose which has previously been shown to induce maximal femoral artery blood flow. **Results** Adipose tissue blood flow was  $1.3 \pm 0.6$  ml/100g/min at rest and increased by exercise ( $8.0 \pm 3.0$  ml/100g/min,  $p < 0.001$ ) and adenosine infusion ( $10.5 \pm 4.9$  ml/100g/min,  $p = 0.001$ ), but not by breathing of moderate systemic hypoxic air at rest ( $1.5 \pm 0.4$  ml/100g/min,  $p = 0.16$ ). Adipose tissue blood flow was similar during exercise and adenosine infusion ( $p = 0.23$ ), but vascular conductance was higher during adenosine than exercise. Finally, adipose tissue blood flow during exercise in moderate systemic hypoxia was reduced ( $6.3 \pm 2.2$  ml/100g/min) compared to normoxic exercise ( $p = 0.004$ ). **Discussion** In conclusion, the vasodilatation capacity of human subcutaneous adipose blood flow to exogenous adenosine appears to be at least comparable to that induced by moderate intensity exercise. In addition, reduced blood flow in adipose tissue during exercise in systemic hypoxia is likely a result of sympathetic nervous vasoconstriction activation that works to redistribute blood flow to exercising muscle in a condition of reduced oxygen availability. **References** Heinonen IH, Bucci M, Kemppainen J, Knuuti J, Nuutila P, Boushel R, Kalliokoski KK. (2012) *J Appl Physiol*, 112, 1059-1063.

## EFFECTS OF PEDAL RATE ON PEDAL FORCE AND MUSCLE ACTIVITY DURING CYCLING

Tokui, M.1, Migita, T.2, Hirakoba, K.3

*1: Kyushu-Kyoritsu University, 2: Kurume University, 3: Kyushu Institute of Technology*

**Introduction** The exercise stress in physiological experiment using cycle ergometer was determined by pedal load and pedal rate namely muscle force and contraction velocity. However, the relationship among friction-braked pedal load, pedal force exerted by foot and lower limb muscle activities was unclear. Therefore, the aim of this study was to investigate the effect of pedal rate on pedal force and electromyographic (EMG) activities in thigh muscles during constant load cycling stress tests. **Methods** Ten healthy male volunteers (age,  $21.1 \pm 0.3$  yr; height,  $169.6 \pm 3.9$  cm; weight,  $66.7 \pm 8.4$  kg) were evaluated on a friction-braked cycle ergometer. The subjects performed constant load (1.0 kp) cycling stress tests for 6min in three different pedal rates (40, 80 and 120 rpm) on different days in randomized order. Pedal force and pedal frequency were measured throughout all tests and averaged for 30 sec (from 5 min to 5 min 30 sec). EMG signals of 5 thigh muscles (vastus lateralis, vastus medialis, rectus femoris, biceps femoris, and semitendinosus) were measured similarly. Integrated EMG value (iEMG) of each muscle was normalized by the value at maximal voluntary contraction (%iEMG) and totaled up (total %iEMG). External power was calculated as power to rotate flywheel from pedal load and pedal frequency. Internal power was estimated as power exerted in exercising muscle (Minetti et al., 2001). Total power was evaluated as sum of external and internal power. **Results and Discussions** Despite the fact that pedal load was set in 1 kp on all stress tests, as pedal rate was increased, pedal force and external power were increased. Consequently, even if same pedal load is set, it was revealed that pedal force shows different value if pedal rate is changed in cycling stress test. Total %iEMG was increased with increasing pedal rate, particularly remarkable in 80 to 120 rpm, which was similar to change of internal and total power. In total %iEMG and pedal force relationship, the increasing rate of total %iEMG was greater than that of pedal force. It was therefore shown that the muscle activities would be distributed to power output for faster lower limb rotation in higher pedal rate. Present results suggest that pedal rate could affect muscle force as well as contraction velocity or muscle power output, indicating that setting of exercise stress should be established carefully in cycling experiment. **Acknowledgement** This study was partly supported by a Grant-in-Aid for Scientific Research from The Ministry of Education, Sports, Science and Technology in Japan (# 23570287 to K. Hirakoba). **Reference** Minetti AE, Pinkerton J, Zamparo P. (2001) *Proc R Soc Lond B* 268, 1351-1360

## EFFECTS OF CARBOHYDRATE SUPPLEMENTATION ON VENTILATORY RESPONSE DURING REPETITIVE INTENSE EXERCISE

Yunoki, T., Lien, C.S., Afroundeh, R., Shirakawa, K., Yamanaka, R., Yano, T.

*Hokkaido University*

**Introduction** Decrease in blood pH is known to be one of the factors driving breathing. On the other hand, the effects of blood pH on the ventilatory response during intense exercise (IE) still remain to be investigated in detail. In the previous study (Yamanaka et al., 2012), we examined the effects of blood pH on the ventilatory response during IE, by using repetitive protocol in which the increase in blood lactate concentration ([La-]) and the decrease in blood pH are attenuated with decrease in muscle glycogen content. As a result, since ventilation (VE) and effort sense during IE was increased by the repetition of IE, it was suggested that ventilatory response during IE is independent of blood pH and at least partly associated with effort sense elicited by recruitment of type II fibers in the working muscle. In the present study, we therefore examined the relationship between recruitment of type II fibers, effort sense and ventilatory response by preventing the rise in the recruitment of type II fibers via carbohydrate supplementation. **Methods** Seven subjects performed an IE test in which IE (2 min,  $99 \pm 5\%$  of VO<sub>2</sub>max) was repeated three times (IE1st, IE2nd and IE3rd) using a cycle ergometer at 120-min intervals. Each interval consisted of a 20-min recovery, 40-min submaximal exercise ( $50 \pm 5\%$  of VO<sub>2</sub>max), and a further recovery for 60 min. Each subject ingested carbohydrate (maltodextrin, 1g/kg) after the IE1st and IE2nd. This carbohydrate supplementation was provided in five divided doses at intervals of 20 min with a total of 500 ml of water during the 40-min submaximal exercise and the 60-min recovery before IE2nd and IE3rd. **Results** There were no significant differences in [La-], blood pH, ventilatory response, effort sense, and mean power frequency (MPF) of the EMG measured in the vastus lateralis during IE between the three conditions. **Discussion** It is thought that similar levels of [La-] and blood pH between the three conditions is a consequence of effective carbohydrate supplementation. In addition, unchanged MPF through the three IEs suggests that rise in the recruitment of type II fibers by the repetition of IE, which had been observed in our previous study (Yamanaka et al., 2012), was prevented by carbohydrate supplementation. Although VE during IE was increased by the repetition of IE in our previous study, VE and effort sense in the present study were the same levels in the three IEs. These results reinforce our hypothesis that ventilatory response during IE is associated with effort sense elicited by recruitment of type II fibers. **Reference** Yamanaka R, Yunoki T, Arimitsu T, Lian CS, Afroundeh R, Matsuura R, Yano T (2012). *Eur J Appl Physiol*, 112, 2149-2162.

## BODY HEIGHT OF BASKETBALL PLAYERS IN THE LAST 15 YEARS

Matkovic, B.R., Matkovic, A., Mestrov, M.

*Faculty of kinesiology University of Zagreb*

**Introduction** In basketball the main objective is to score by putting a ball into the basket that is in the hoop with the regular rim height of 305 cm. As early as in 1976 Alexander found that body height is significantly related to success in the game of basketball which means that it is a good predictor for the number of points a player can score, number of rebounds after shot attempts and generally for successful playing. The aim of this study was to analyze changes in body height of basketball players in the period from the year 1995 to 2010. **Methods** According to data from official FIBA webpages body height of players from the first eight ranked teams in European and World championships and Olympic Games from 1995 till 2010 was assessed. The average height was calculated for every team, and number of players taller than 200 cm was evaluated. **Results and discussion** Almost all studies related to body height of both male and female basketball players confirmed the fact that basketball players are on average significantly taller than non-selected population and mostly taller than athletes who compete in other sports. It can also be observed that over years mean values increased, that is, that basketball players today are taller than basketball players who played ten years ago or even before that. Hence, we can conclude that there has been a long-term trend of body height increase in basketball which in recent years partly slowed down. This can be attributed not only to the omnipresent process of acceleration, but also to the process of selection. Namely, it can be seen in youngest players in basketball schools that players who are selected are of above average body height. Malina (1994) in his study concludes that basketball players are in childhood about or above 90 percentiles of population height and are also biologically older. Some 20 or 30 years ago a certain body height of basketball team corresponded to a certain result in a competition (Furukawa, 1974). By analyzing results obtained in European and World championships as well as in the Olympics in the last fifteen years it can be seen that such a trend does not exist today. Nonetheless, it can be seen that there is over 60% of players of a mean body height over 200 cm among the top eight teams while the others mainly ranged between 198 and 200 cm. Furthermore, most teams have 7 to 8 players who are above 2 meters and among winning teams there is rarely a team with less than 6 players above 2 meters. **References** Alexander MJL. ## SCALING RUNNING EFFICIENCY IN RECREATIONAL AND HIGH-LEVEL ENDURANCE RUNNERS: EFFECT ON PERFORMANCE PREDICTION

Tartaruga, M.P.1, Mota, C.B.2, Peyré-Tartaruga, L.A.3, Brisswalter, J.4

*1: UNICENTRO (Guarapuava, Brazil), 2: UFRGS (Porto Alegre, Brazil), 3: UFSM (Santa Maria, Brazil), 4: LAMHESS (Nice, France)*

**Introduction** Among factors affecting the relationship between running efficiency (REff) and middle- or long-distance running performance, some authors have investigated the way by which an athlete's body size affects performance, demonstrating that an indiscriminate use of the unit ml.kg<sup>-1</sup>.min<sup>-1</sup> is inappropriate to compare oxygen consumption between subjects with different body characteristics or performance level. Therefore, the aim of this study was to examine the effect of allometric scaling on the relationship between REff and middle-distance running performance according to performance level. **Methods** The relationship ( $\log y = b \cdot \log x + \log a$ ) between human maximal metabolic rate ( $y$ ) and body mass ( $x$ ) was used for determination of  $b$  (allometric scaling). Thirteen recreational middle-distance runners (male, mean  $\pm$  SD – age: 33.31  $\pm$  8.48 years; body mass: 76.41  $\pm$  8.57 kg; maximal oxygen uptake – VO<sub>2</sub>max: 52.87  $\pm$  4.60 ml.kg<sup>-1</sup>.min<sup>-1</sup>) (G1) and thirteen high-level middle-distance runners (male, age: 25.46  $\pm$  4.23 years; body mass: 62.85  $\pm$  2.67 kg; VO<sub>2</sub>max: 70.41  $\pm$  1.92 ml.kg<sup>-1</sup>.min<sup>-1</sup>) (G2) performed a continuous incremental test to determine VO<sub>2</sub>max and a 6-min running submaximal test at 70% of VO<sub>2</sub>max to assess REff. The performance was assessed from the best performance in middle-distance events. **Results** Significant correlation between REff and performance were found for both groups, however, strongest correlations were observed in the recreational runners, especially when using the allometric exponent (respectively for G1; non allometric vs. allometric scaling ( $b = 0.75$ ):  $r = 0.80$  vs.  $r = 0.86$ ; and for G2; non allometric vs. allometric scaling ( $b = 0.75$ ):  $r = 0.55$  vs.  $r = 0.50$ ), demonstrating that REff could be an important factor to predict middle-distance running performance. **Discussion** These results corroborate with previous studies indicating the role of REff in endurance performance and the interest to identify strategies to improve REff (Daniels, 1985; Bailey and Pate, 1991; Morgan and Craib, 1992; Saunders et al., 2004; Foster and Lucia, 2007). However, in this study, the strongest correlations were observed in the recreational runners, especially when using the allometric exponent, demonstrating the interest of allometric scaling to express efficiency or oxygen consumption in such population. According to Markovic et al. (2007), the recently proposed allometric cascade model by Darveau et al. (2002) may be valid in describing the scaling behavior of metabolic rate in untrained individuals, but not in athletes. **References** Bailey SP, Pate RR. (1991). *Sports Med*. 12, 228-236. **Introduction** The majority of young women use oral contraceptives (OC). Use of OC has been reported to be associated with lower synthesis rates of myofibrillar and tendon collagen proteins. Therefore, we in the present study aimed to investigate whether the adaptive response to regular strength training in muscle and tendon differentiate between OC-users and controls. **Methods** Fourteen healthy young OC-users (24 $\pm$ 1 yrs, fat% 32 $\pm$ 1, 35 $\pm$ 2 O<sub>2</sub>/min/kg) and 14 controls (24 $\pm$ 1 yrs, fat% 32 $\pm$ 2, 34 $\pm$ 2 O<sub>2</sub>/min/kg) performed a 10-week supervised progressive resistance training program (leg extension and leg press). Participation in regular strength training within the last six months was an exclusion criterion. Before and after the intervention period a muscle biopsy was obtained from m. vastus lateralis. Furthermore, muscle and tendon cross-sectional area (CSA) was determined by MR-scans. Maximal isokinetic strength was measured in a dynamometer and 1 RM was determined during leg extension. **Results** Training enhanced muscle CSA ( $p < 0.001$ ) and tendon CSA ( $p < 0.01$ ). A tendency towards a greater increase in muscle CSA was observed in the OC-group than in controls (interaction  $p = 0.066$ ). Analysis of mean muscle fiber type CSA show a tendency towards an increase in type II muscle fiber area ( $p = 0.10$ ), whereas type I muscle

CSA increased in the OC-group ( $3821 \pm 557$  to  $4470 \pm 475$  mm<sup>2</sup>,  $p=0.05$ ), but not in controls ( $3822 \pm 822$  to  $3893 \pm 779$  mm<sup>2</sup>,  $p=0.20$ ) (interaction  $p<0.05$ ). Post hoc analysis indicated that the effect of OC on muscle mass was induced by the OC-users ( $n=7$ ) who use OC containing 30 µg ethinyl estradiol, whereas the response in OC-users taking pills with 20 µg ethinyl estradiol did not differentiate from controls. Both OC and controls experienced an increase in maximal isokinetic strength ( $p<0.001$ ) and 1RM leg extension ( $p<0.001$ ) after the training period. The response in the strength parameters did not differentiate between groups. Conclusion Use of OC during a 10-week supervised, progressive strength training program was associated with a tendency towards a greater increase in muscle mass and a significantly greater increase in type I muscle fiber area compared to controls. Nevertheless, use of OC was not accompanied by a significantly greater increase in muscle strength

### CHANGES IN THE WHOLE-BODY BIOELECTRICAL IMPEDANCE VECTOR INDUCED BY TRAINING IN YOUNG ELITE SYNCHRONIZED SWIMMERS: PRELIMINARY RESULTS

Carrasco, M.1,2,3, Iruñia, A.2, Rodríguez-Zamora, L.2, Iglesias, X.2, Brotons, D.3, Vidal, E.1, Rodríguez, F.A.2

1: FCS Blanquerna, Univ. Ramon Llull (Barcelona, Spain); 2: GRCE, INEFC, Univ. de Barcelona (Barcelona, Spain); 3: SGE, Àrea de Medicina de l'Esport (Esplugues de Llobregat, Spain).

Introduction Synchronized swimming (SS) requires high-volume and high-intensity training that is assumed by young swimmers from an early age. A typical training session may include specific drills, choreography, and physical conditioning exercises, imposing complex physiological demands (Rodríguez-Zamora et al., 2012). Bioelectrical impedance vector analysis (BIVA) is a non-invasive and safe technique for assessing hydration and body composition changes (Lukaski & Piccoli, 2012). This study applied BIVA to the assessment of hydration changes evoked by training sessions in swimmers of different age and competitive level. Method 59 swimmers were divided into 1) pre-juniors (pre-JR): mean age 13.9 (SD 0.9) y, body mass (BM) 47.0 (7.2) kg, height 161.8 (8.2) cm, fat mass 15.1 (4.8) %BM, muscle mass 37.6 (5.0) %BM; and 2) juniors (JR): 16.7 (0.9) y, BM 53.7 (4.9) kg, height 165.8 (5.2) cm, fat mass 18.6 (2.6) %BM, muscle mass 38.8 (3.7) %BM. Anthropometric assessment (ISAK) and BIVA analysis were conducted PRE and POST a typical training session (p-JR 2.5 (0.1) h, JR 4.0 (0.2) h). A multi-frequency wrist-to-ankle BIA meter device (Z-Metrix®, BioparHom Co, France) was used and 50 kHz whole-body BIA vectors were analyzed by the resistance-reactance (R/Xc) graphic method, and Z mean values plotted (Piccoli et al., 1994). Hotelling's T2 test determined differences in the complex localized vector through the 95% confidence and tolerance intervals. Results Changes ( $p<0.005$ ) were observed between PRE and POST in BM (pre-JR: 47.0 (7.2) kg vs. 46.7 (7.3) kg; JR: 53.7 (4.9) kg vs. 53.4 (4.9) kg), R (pre-JR: 530 (46) Ohms vs. 548 (45) Ohms; JR: 503 (33) Ohms vs. 524 (45) Ohms), and Xc (pre-JR: 64.4 (5.4) Ohms vs. 66.6 (4.8) Ohms; JR: 66.0 (2.9) Ohms vs. 70.3 (4.3) Ohms). BIVA showed vector migration from PRE to POST ( $T^2=8.99$ ;  $p<0.05$ ) in JR, whereas no changes were found in pre-JR ( $T^2=1.92$ ;  $p>0.05$ ). Discussion JR swimmers showed a migration of the BIA vector characterized by an increase in length (R) and a decrease in the dielectric mass of soft tissues (Xc), likely as a result of moderate dehydration. In turn, pre-JR showed the maintenance of a good hydration status without significant bioelectrical changes. These preliminary results should be considered by coaches, nutritionists and physicians in order to ensure adequate fluid intake during training in these young athletes. References Lukaski HC, Piccoli A (2012). Handbook of Anthropometry. Springer, 287-305. Rodríguez-Zamora L, Iglesias X, Barrero A, Chaverri D, Erola P, Rodríguez, FA. (2012). PLoS One 7(11), e49098.

### SOCCER REFEREES REPEATED SPRINT ABILITIES

Nedic, A., Rupcic, T., Matkovic, B.R.

Faculty of Kinesiology

Introduction Soccer referees are an integral part of the soccer game. Their job is to regulate the behavior of players and other participants through the implementation of soccer rules. In addition to the principal referee who makes the final decision on the ground, there are 3 assistant referees that may assist in game regulation. To make the most correct decision, the referee must be at the right place and have an overview of the situation which requires excellent physical condition, visual perception, mental ability, focus, willingness and ability to make quick decisions. The aim of this study was to evaluate sprint abilities of soccer referees and assistant referees. Methods The sample consisted of 83 soccer referees, international ( $N=15$ ) and national ( $N=68$ ). On average referees were  $35.5 \pm 3.2$  years old,  $183.1 \pm 6.2$  cm tall and weighted  $83.6 \pm 6.4$  kg. All of the referees were tested with the FIFA High-Intensity Fitness Test that involves 6 x 40m sprints followed by a maximum of 1 minute and 30 seconds recovery after each sprint. Results The average values of all six trials for referees was  $5.75 \pm 0.19$  s (range 5.3-6.1), and significantly better for assistant referees  $5.63 \pm 0.15$  s (5.1-5.9). The average best trial for referees was  $5.58 \pm 0.24$  s, and for assistants  $5.59 \pm 0.11$  s. Discussion During competitive games, referees pass a total of 9-13 km with varying levels of intensity, but approximately at the level of 85 to 90% of the maximal heart rate and respectively 70 to 80% of the maximal oxygen consumption (Weston et al., 2012). Blood lactate concentration was between 4 and 5 mmol/l, but the recorded values were as high as 14 mmol/l. All this leads to the fact that they are subjected to high levels of exertion that can sometimes even exceed those that the players endure. It is also important that they can not be replaced like players so they have to keep pace with the match from the beginning till the end. The results for both referees and assistants are within the FIFA required values. The better results of assistants are in correspondence with the demands of their role – they have to be in line with the ball whenever it is possible to avoid wrong offside judgments due to poor positioning. Krstrup and his colleagues (2002) stated that assistant referees' performance of repeated sprints correlates with the high-intensity players' performance in a soccer game. The differences between the six trials in the sense of fatigue were not noticed. References Krstrup P, Mohr M, Bangsbo J. (2002). JSports Sci, 20(11), 861-871. Matkovic BR, Nedic A. (2012). ### CHANGES OF THE PERFORMANCES FOR HIGH INTENSITY INTERVAL TRAINING BETWEEN PRE AND POST HEME-IRON INTAKE PERIOD OF THE HIGH SCHOOL SWIMMERS

Tomohiro, N.1, Suzuki, J.1, Matsumoto, M.1, Meguro, T.1, Sakai, M.1, Katsumata, M.2

1:Nihon University college of Humanities & Sciences 2: ILS Inc.

This research focused on the examination using high school swimmers as subjects as follows: First, what influence heme-iron intake and training for a short term (for four weeks) would have on high-intensity interval training performance. Second, what affects they would have on lactate level after a cool-down and the change of mood condition before and after training. And the research also centered on what influence the intake of heme-iron brings about to blood constituent including Hb (hemoglobin) and also studied the degree of

changes in swimming records in the competition before and after the period. The result was as follows: 1) The swimming speeds significantly increased in the competition at post-intake heme-iron compared with the ones of the previous competition ( $p < 0.001$ ). 2) The intake of heme-iron significantly increased average swimming speeds at the first and second round lactate tolerance set (LTS, 1 R:  $p < 0.001$ , 2 R:  $p < 0.001$ ). The HR (heart rate), RPE (Rate of Perceived Exertion), and lactate level ( $\Delta$ La after 1 R- before LTS) at the first round were significantly increased, too. 3) Each item of POMS (Profile of Mood States) (Tension-Anxiety: T-A, Depression, Anger-Hostility: A-H, Vigor, Fatigue, and Confuse) significantly decreased in T-A ( $p < 0.001$ ) and D ( $p < 0.05$ ) after training at pre-intake of heme-iron compared with before LTS. Likewise, at post-intake of heme-iron each item of POMS significantly decreased in T-A ( $p < 0.001$ ) and D ( $p < 0.001$ ). This showed that test subjects came to endure more severe training than ever at post-intake of heme-iron. But it was found that psychological condition was kept intact. 4) Hb were significantly increased at post-intake of heme-iron ( $p < 0.001$ ). No significant difference was noted on Hb on blood constituent inspection but, in contrast, PLT (Platelet) ( $p < 0.01$ ) and TIBC (Total Iron Binding Capacity) ( $p < 0.001$ ) significantly decreased at post-intake of heme-iron. This was apparently because the decrease of the training opportunities caused by the conflict of the intake at the latter half with the competition period didn't stimulate red blood cell production. However, conversely, the increase of ferritin was noted in many test subjects, so the further extension of intake period was thought necessary for additional examination in the future. From the above mentioned results, the followings became clear. The high school swimmers who went for the training at post-intake of heme-iron could increase swimming speed through high-intensity interval training even in the short period of 4 weeks. As a result, they could improve their swimming speed in the competition. References Noguchi T, Suzuki J, Shinya K, Takamura A, Sekiguchi K (2009). ### ESTIMATION OF VO<sub>2</sub> KINETICS FROM GRADED EXERCISE TESTS IN SPRIINTERERS

Sentija, D., Vucetic, V.

*Faculty of Kinesiology, University of Zagreb*

**INTRODUCTION** Oxygen uptake kinetics are determined by computation of the time constant, or 'τ' ('tau'), from VO<sub>2</sub> data during square-wave work. In an incremental (ramp) test, presuming a linear increase of VO<sub>2</sub> with increasing intensity ( $dVO_2 / dt = \text{const}$ , for the intensity range below the anaerobic threshold), tau can be estimated from the time delay ( $\tau = \Delta t$ ) needed to reach the VO<sub>2</sub> that corresponds to the steady-state VO<sub>2</sub> (VO<sub>2</sub>ss) at the same intensity (Whipp et al., 1981). Accordingly, we estimated tau in trained sprinters from: 1) single treadmill step tests (with no steady-state) and VO<sub>2</sub>ss, and 2) two step tests with different speed increments, without utilization of VO<sub>2</sub>ss. **METHODS** 24 sprint runners (100-400m) completed 3 incremental treadmill tests to exhaustion with increase in running speed of: 1 km/h each ½ min (T05), 1 km/h each min (T1), and 2 km/h each 4 min (SS). Breath-by-breath VO<sub>2</sub> data were averaged to 30 s, and centered to the corresponding running speeds for T05 and T1. The VO<sub>2</sub>ss values at 8, 10 and 12 km/h were defined as the average VO<sub>2</sub> values in the 4th minute of respective stages in the SS test, and were corrected to account for the VO<sub>2</sub> difference between ramp and step protocols. The time constants ( $\Delta t$ ) were determined from linear regression parameters derived from the VO<sub>2</sub>/running speed relationship in SS, T05 and T1. The analysis was performed within the aerobic speed range (8-12 km/h). The significance of differences between  $\Delta t$  were determined from 1) SS-T1, 2) SS-T05, and 3) T1-T05 test data ( $p < .05$ ). **RESULTS AND DISCUSSION** The VO<sub>2</sub> kinetics, as estimated from  $\Delta t$  determined from SS-T05, SS-T1 and T1-T05 data did not differ significantly ( $49.2 \pm 21.0$  s,  $51.7 \pm 37.1$  s, and  $46.7 \pm 29.1$  s, respectively;  $p > 0.05$ ), and were somewhat slower in T1 and T05 with increasing speed. The per step increase of intensity in T05 (1kmh/30s) is twofold the increase in T1 (1kmh/60s). Therefore, for a certain VO<sub>2</sub>, the  $\Delta t$  between T1 and T05 tests should be equal to  $\Delta t$  between T1 and SS, enabling estimation of  $\tau$  and VO<sub>2</sub>ss. Indeed, the average error of VO<sub>2</sub>ss and  $\Delta t$  estimated from the time delay between T1 and T05 was practically irrelevant (0.1-0.3 ml/min/kg, or 3-5 s). The average  $\Delta t$  values of sprint runners were significantly higher compared to tau values measured directly from square-wave tests in previous studies, and approx. 15-20 s higher than the values determined with the same methodology in endurance runners (Sentija et al, 2012). The high  $\Delta t$  values as measures of VO<sub>2</sub> kinetics of both studies, may be explained by the delay time needed for transportation of blood from working muscles to the lungs (~ 10-20 s). As in endurance runners, high individual variability (many values outside of the physiological range for  $\tau$ , reflecting accumulated effects of high biological variability and technical errors for repeated measurements), precludes the use of this methodology as a reliable procedure for individual determination of VO<sub>2</sub> kinetics. **REFERENCES** Whipp BJ et al (1981). *J Appl Physiol* 50(1):217-21 Sentija D, Vucetic V (2012). *ECSS*, 556-7

### EXHAUSTED EXERCISE PRECONDITIONING MAY CAUSE PLASMA TO PREVENT LIPID PEROXIDATION OF RBC IN VITRO

Sha-Pu, L.B., Jung-Charng, L., Chia-Chih, L., Yi-Ting, P., Chung-Hsiang, Y., Ching-Hui, Y., Shih-Ling, C.

*Chinese Culture University*

**Purpose:** Exercise preconditioning has been known to reduce strenuous exercise-induced oxidative damages. To understand the underlying mechanisms, plasma samples isolated from exhausted exercises were used to investigate the possible protection effect on RBC with or without following hypoxia/reoxygenation. **Methods:** Eight healthy male participants were recruited voluntarily (age:  $28.9 \pm 8.3$  yr, height:  $170.1 \pm 5.9$  cm, weight:  $68.9 \pm 7.4$  kg). Blood samples were collected before (resting, r) and after (post exercise, e) running by Bruce graded exercise testing (GXT). Plasma and RBC were separated and then recombined again into 4 groups: rWB (rWhole Blood), rRrP (rRBC + rPlasma), rReP (rRBC + ePlasma), rRs (rRBC + PBS). All groups were then treated with hypobaric hypoxia at PO<sub>2</sub> = 45 mmHg (H/N) or normbaric normoxia at PO<sub>2</sub> = 152 mmHg (N/N) for 1 hr and then recovered by N/N for 5 min. Data were to compare differences among the groups at indicators including antioxidant enzyme activities, peroxidized lipid (TBARS), lactate, glucose and uric acid. **Results:** As compared to the control group, plasma with exercise preconditioning had significantly increased levels of lactate ( $15.26 \pm 0.73$  mM vs.  $2.88 \pm 0.19$  mM,  $p < .05$ ), glucose ( $120.18 \pm 6.40$  mg/dL vs.  $98.12 \pm 5.09$  mg/dL,  $p < .05$ ) and uric acid ( $5.64 \pm 0.53$  mg/dL vs.  $4.56 \pm 0.48$  mg/dL,  $p < .05$ ). Except for eReP, RBC's TBARS level was significantly elevated in rWB, rRrP, rRs after N/N treatment as compared to rP ( $146.35 \pm 32.48$  nmol/gHb,  $141.97 \pm 34.4$  nmol/gHb,  $148.42 \pm 29.8$  nmol/g Hb vs.  $59.72 \pm 16.31$  nmol/gHb,  $p < .05$ ) or eP along ( $146.35 \pm 32.48$  nmol/gHb,  $141.97 \pm 34.4$  nmol/gHb,  $148.42 \pm 29.8$  nmol/gHb, vs.  $50.53 \pm 21.33$  nmol/gHb,  $p < .05$ ). However, this protection effect contributed to eP cannot be observed in groups after H/N treatment. All antioxidant enzyme activities among the groups were not different in both N/N and H/N treatments. **Conclusion:** Plasma with exhausted exercise preconditioning may reduce RBC peroxidized lipid damages but may not in hypoxia and reoxygenation. Further studies are needed to explore the role of uric acid in this reaction.

## THE ABILITY OF LOG-LINEAR ANCOVA TO DETECT CARDIORESPIRATORY DEFICIT IN OVERWEIGHT SUBJECTS

Draper, S.B., Potter, C.R.

*University of Gloucestershire*

**Introduction** There has been much debate over how to most appropriately scale peak aerobic power (VO<sub>2</sub>peak) in groups of subjects differing in body size. This issue is particularly pertinent when seeking to determine relative cardiorespiratory (CR) fitness in overweight (OW) subjects. The problems associated with assessing CR fitness in OW subjects was highlighted recently by Potter et al. (2013), who showed that a group of OW children could be considered to exhibit either superior (absolute VO<sub>2</sub>peak), similar (VO<sub>2</sub>peak divided by mass raised to the power 0.67) or reduced (scaling VO<sub>2</sub>peak in direct proportion to body mass) fitness when compared to non-overweight (NO) subjects depending on the scaling approach taken, despite the VO<sub>2</sub> kinetics data indicating a clear CR impairment in the OW subjects (mean response time [MRT] was significantly longer in the OW subjects). However, these authors did not attempt to compare VO<sub>2</sub>peak data between NO and OW subjects using log-linear analysis of covariance (log-ANCOVA). The aim of this study was to investigate the ability of log-ANCOVA to detect VO<sub>2</sub>peak differences in OW and NO children. **Method** Eleven OW (age 11.8 (0.4) y; BMI 25.8 (3.4) kg.m<sup>-2</sup>) and 12 NO (age 11.8 (0.4) y; BMI 25.8 (3.4) kg.m<sup>-2</sup>) participated. These groups differed significantly in MRT to moderate intensity exercise (43.5 (10.7) vs. 36.3 (5.3) s) and subjects completed a cycle ramp test (12 W.min<sup>-1</sup>) to ascertain VO<sub>2</sub>peak (ml.min<sup>-1</sup>). The VO<sub>2</sub>peak data were first log transformed and then adjusted VO<sub>2</sub>peak values were compared using ANCOVA (having ensured the regression slopes were not significantly different,  $p=0.529$ ). Results Log-ANCOVA revealed a non-significant VO<sub>2</sub>peak difference between groups ( $p=0.629$ ). **Discussion** Despite the presence of a CR deficit in the OW subjects (as evidenced by their slower VO<sub>2</sub> kinetics), log-ANCOVA suggested similar cardiorespiratory function in both groups. As has been previously demonstrated with alternative scaling methods (Potter et al. 2013), the use of VO<sub>2</sub>peak to assess CR fitness in OW subjects, even using log-ANCOVA, may be misleading and actually disguise CR impairment in OW subjects. **References** Potter CP, Zakrzewski JK, Draper SB, Unnihan VB. (2013). *Int J Obesity* 37,101-106

## MAXIMUM LACTATE STEADY STATE AND 4 MMOL/L LACTATE THRESHOLD IN ROWING

Grabow, V.

*University of Dortmund*

**Introduction** Maximum lactate steady state (MLSS) during a longer lasting load (30 min) characterizes the load threshold that is covered mainly by aerobic energy supply. The individual MLSS can be determined by a series of repeated tests at different load levels. Hence, these procedures are very time consuming and need normally several days for testing. In the past many concepts and corresponding tests have been developed which propose to estimate the MLSS by using just a single test (Heck, 1990; Marees de, 2003). This study compares the MLSS test with a multiple step test on a rowing ergometer. **Methods** 11 top elite rowers (age 20.1 ± 1.9 years, height 189.7 ± 9.6 cm, weight 86.7 ± 9.8 kg) of national level participated in this study. Submaximal three step tests (step duration 8 min, resting time between each step 30 s) were performed on a Concept II rowing ergometer (type C) with slides at the beginning and six weeks later at the end of the study. Average power output (P (W)), average stroke rate (SR (1/min)), heart rate (HR (1/min)) and post exercise ear capillary blood lactate (LA (mmol/l)) were measured. By interpolation the power output at 4 mmol/l LA (P<sub>4</sub>) was calculated. Between this two step tests - with a delay of one week - a second test series with gradually adapted load was performed to determine the MLSS on identical ergometers (duration 30 min at constant load; LA samples at 2nd, 4th, 8th, 10th, 14th, 18th, 22nd, 26th and 30th min). In accordance to Beneke (1995) the first 30 min load was recommended in the range of 3 mmol/l LA. In case of an equilibrium of the MLSS the given load was increased of 10 W (3-4% of P), in case of a non equilibrium respectively an increase of the LA the load was decreased of about 10 W. **Results and Conclusions** P<sub>4</sub> was in the range of 289 ± 35.2 W in average, P at MLSS reached a mean of 264 ± 32.6 W in average. Corresponding LA was 2.3 ± 0.6 mmol/l after 8 min (MIN = 1.5, MAX = 3.4 mmol/l) and at the end after 30 min at 2.7 ± 0.7 mmol/l (MIN = 2.2, MAX = 3.7 mmol/l). Lactate values at MLSS were without exception lower than 4 mmol/l, however between both values a high significant correlation was found ( $R^2=0.90$ ). By regression analysis, MLSS could be estimated from P<sub>4</sub> using the following formula:  $MLSS = 0,88 \times P_4 + 10$ . The standard estimation error was 10.0 W (3,8%), and therefore within the range of precision of measurements for the estimation of MLSS. Hence, with regard to the small sample size the lactate threshold at P<sub>4</sub> seems to allow a precise estimation of the MLSS in elite rowing. **References** Beneke R. ## AEROBIC CAPACITY AND INCREASE IN BODY CORE TEMPERATURE DURING GRADED EXERCISE TESTING

Rakovac, M., Sentija, D., Babic, V., Marsic, T.

*University of Zagreb, Faculty of Kinesiology*

**Introduction** Persons with higher aerobic capacity were shown to have a greater increase in body core temperature than persons with low aerobic capacity during sustained submaximal exercise at similar relative intensities (Mora-Rodriguez et al, 2010). The aim of this study was to determine the relationship between some indicators of aerobic capacity (maximal oxygen uptake (VO<sub>2</sub>max), maximum speed (V<sub>max</sub>), speed at the ventilatory anaerobic threshold (VT<sub>2</sub>), as well as heart rate at VT<sub>2</sub> (HRVT<sub>2</sub>)) and the rate of temperature rise (Tr, delta temp/delta t) in different intensity zones during a graded treadmill exercise test. **Methods** The participants were 32 physically active males (age (mean±SD) 26.5±6.6 years; height 179.2±5.0 cm; body mass 76.8±8.1 kg). Graded treadmill exercise test with speed increments of 0.5 km/h each 30 sec was performed, in controlled thermoneutral conditions, until volitional exhaustion. Ventilatory parameters, heart rate and rectal temperature (measured at 8 cm from anal sphincter) were registered throughout the test. The first and the second ventilatory thresholds (VT<sub>1</sub> and VT<sub>2</sub>), delimiting three intensity zones (low, moderate, and high intensity), were determined by the V-slope method. Tr was calculated for each intensity zone (Tr<sub>1</sub> below VT<sub>1</sub>, Tr<sub>2</sub> between VT<sub>1</sub> and VT<sub>2</sub>, Tr<sub>3</sub> above VT<sub>2</sub>). Pearson product-moment correlation coefficients were used to determine the relationship between zone specific Trs and indicators of aerobic capacity (VO<sub>2</sub>max, V<sub>max</sub>, VT<sub>2</sub>, HRVT<sub>2</sub>). **Results** Tr<sub>1</sub> was significantly related to HRVT<sub>2</sub> ( $r=0.48$ ,  $p<0.01$ ). Tr<sub>2</sub> was related to V<sub>max</sub> and VT<sub>2</sub> ( $r=0.40$  and  $0.45$ , respectively,  $p<0.05$ ) and HRVT<sub>2</sub> ( $r=0.61$ ,  $p<0.01$ ). Tr<sub>3</sub> was related to VT<sub>2</sub> and HRVT<sub>2</sub> ( $r=0.38$  and  $0.39$ ,  $p<0.05$ ). The direction of all correlations was positive, except for correlations between Tr<sub>1</sub> and VO<sub>2</sub>max, V<sub>max</sub> and VT<sub>2</sub>, which showed a negative trend. **Discussion** In all three intensity zones Tr was significantly positively related to some of the aerobic capacity indicators. The positive direction of correlations is congruent with previous findings of a greater activity-related Tr in highly fit than in moderately fit persons (Cheung & McLellan, 1998). The trend of negative correlations between Tr<sub>1</sub> and indicators of aerobic capacity suggests a possible fitness-related thermoregulatory differentiation across intensity zones. Aerobically fitter subjects show a slower Tr in the low intensity zone, and a higher one at intensities above VT<sub>1</sub>, as opposed to persons with lower aerobic capacity. Slower Tr<sub>1</sub> could result from a higher mechanical efficiency and/or lower

heat production in fitter subjects, or a local-core temperature discrepancy, at intensities below VT1. References Mora-Rodriguez et al. (2010). *Eur J Appl Physiol*;109:973-81. Cheung & McLellan (1998). *J Appl Physiol*;84:1731-9.

### THE LEVEL OF IMMUNOGLOBULIN AND BLOOD MORPHOLOGICAL INDICES AFTER SINGLE AND REPEATED WHOLE-BODY CRYOTHERAPY

Szygula, Z., Szpotowicz, B., Wiecek, M., Szymura, J., Maciejczyk, M.

*University School of Physical Education, Cracow, Poland*

**Introduction:** During the recent decade the interest in whole-body cryotherapy (WBC) has significantly increased. The application of it has become more common and the benefits of using cold as a treatment are observed not only in patients with different afflictions but also in athletes i.e. treatment of overuse and post traumatic injuries as well as for enhancing post effort recovery. **Objective:** To examine the influence of a single and repeated WBC on chosen immunoglobulin (IgG, IgM, IgA) and blood morphological indices (white blood cells, red blood cells, platelets, neutrophils, lymphocytes, monocytes, eosinophils, basophils, hemoglobin, hematocrit and reticulocytes). **Methods:** The study was carried out on ten athletes and ten non-athletes, young and healthy men (aged  $22 \pm 1.56$ , with a body mass index of  $21.71 \pm 2.44$  kg/m<sup>2</sup>). The participants were subjected to 12 whole-body cryostimulations (at temperatures of  $-130^\circ\text{C}$ ) in a special cryogenic chamber for 3 minutes, 3 times a week. Blood samples were collected four times - before cryostimulation and 30 minutes after the first and twelfth WBC. The subjects were asked to avoid physical exercise 48 hours before blood sampling. **Results:** Before the 1st WBC session, the level of hematocrit was significantly higher in the non-athletes group. As a result of a single exposure to cryogenic temperatures, a significant increase in the level of neutrophils was observed ( $p < 0.05$ ). Furthermore, a minor increase in the numbers of white blood cells, red blood cells and the percentage of reticulocytes was observed. However, as a result of repeating 12 WBC sessions, significant decreases in white blood cells, neutrophils, red blood cells, hemoglobin and hematocrit in athletes were noted. There was also a significant decrease in the levels of IgG and IgM after 11 treatments compared to the baseline value and before 12 treatment sessions compared to the first WBC ( $p < 0.05$ ) in athletes, but still within the normal range. RBC count was significantly lower in the non-athletes group after the 12 WBC sessions when compare to non-athletes, whereas platelets count, lymphocytes, monocytes, eosynophils, and basophils remained unchanged in this group. **Conclusion:** The observed changes could be a result of more sensitive immune systems in athletes. Therefore, it can be concluded that repeated whole-body cryostimulation could not be recommended to athletes. **Key words:** cryostimulation, athletes, non-athletes, immune system The study was financed by NCN; project No UMO-2011/01/N/NZ7/00652

### INFLUENCE OF TART CHERRY JUICE ON INDICES OF MUCOSAL IMMUNITY, SALIVARY CORTISOL, INFLAMMATION AND UPPER RESPIRATORY TRACT SYMPTOMS FOLLOWING MARATHON RUNNING

Dimitriou, L.1, Hill, J.2, Jehnali, A.3, Dunbar, J.3, Brouner, J.4, Howatson, G.5

*Middlesex University - 1:MU, UK, 2:SMUC, UK, 3:ipro Interactive Ltd, UK, 4:KU, UK, 5:NU, UK & NWU, SA*

**Introduction** This study's aim was to examine the effects of tart cherry juice on markers of stress, mucosal immunity, inflammation and respiratory tract symptoms following a marathon. **Methods** Twenty recreational Marathon runners assigned to either tart cherry juice (CJ) or placebo (PL) consumption for 5 days prior to, the day of, and for 48 h following a Marathon race. Markers of mucosal immunity (secretory immunoglobulin A (sIgA), immunoglobulin (IgG)), stress (salivary cortisol), inflammation (plasma interleukin-6 (IL-6) and C-reactive protein (CRP)) and self-reported incidence and severity of upper respiratory tract symptoms (URTS) were measured before and following the race. Data were analysed using a mixed model analyses of variance ANOVA with two between-participants factors (treatment: CJ versus PL) and four within participants factors (time: day before the race, immediately post-race, 24 h and 48 h post-race). **Results** All variables except mucosal immunity showed a significant time effect ( $P < 0.01$ ). Serum IL-6 showed a significant treatment effect ( $F(1,18)=12.920$ ,  $P=0.002$ ) and treatment by time interaction ( $F(3,54)=8.675$ ,  $P=0.009$ ) and was elevated immediately post-race, with a smaller elevation in the CJ group vs PL ( $38.98$  vs  $82.1$  pg/mL,  $P=0.009$ ). Serum CRP had a significant treatment effect ( $F(1,18)=12.920$ ,  $P=0.002$ ) and treatment by time ( $F(4,54)=10.667$ ,  $P=0.002$ ) and increased at 24 and 48 h post-Marathon with significantly smaller elevation in the CJ group vs PL ( $P=0.002$ ). The salivary cortisol and mucosal immune response (sIgA and IgG) to the Marathon revealed no significant differences between groups and no significant treatment by time interaction effect. The incidence and severity of URTS showed a significant treatment effect ( $F(1,18)=5.879$ ,  $P=0.026$ ) and treatment by time interaction effect ( $F(3,54)=5.242$ ,  $P=0.014$ ). URTS were higher at 24 h ( $P=0.022$ ) and 48 h post race ( $P>0.05$ ) in the PG compared to CG group. **Discussion** Cherry juice appears to provide a potential supplement to protect the upper respiratory tract from inflammatory symptoms caused by infectious and non-infectious agents (Spence et al., 2007, Robson-Ansley, et al, 2012), by potentially reducing exercise-induced pulmonary inflammation. Spence L, Brown WJ, Pyne DB, et al. (2007). *Med Sci Sports Exerc*, (39) 4, 577-86. Robson-Ansley P, Howatson G, Tallent J. et al. (2012). *Med Sci Sports Exerc*, 44 (6), 999-1004.

### NO CHANGE IN HEMOGLOBIN MASS AFTER 12 WEEKS OF INTENSIVE ENDURANCE TRAINING AT SEA LEVEL

Holden, G., Landgraff, H.W., Freuchen, F., Midttun, M., Raastad, T., Hallén, J., Paulsen, G.

*Norwegian School of Sport Sciences*

**Introduction** Hemoglobin mass (Hbmass) is associated with the maximal oxygen uptake (VO<sub>2</sub>max). A comprehensive review concluded that the variation in VO<sub>2</sub>max can be explained by Hbmass: an increased VO<sub>2</sub>max by  $4 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$  were correlated to an increase of 1g of hemoglobin (Schmidt & Prommer, 2010). Despite the relationship between VO<sub>2</sub>max and Hbmass a recent study found that increased VO<sub>2</sub>max was not accompanied by changes in Hbmass after 40 days of sea level endurance training (Eastwood et al., 2012). The aim of this study was to investigate the effects of a 12 week intensive endurance training regime at sea level on VO<sub>2</sub>max and Hbmass. **Methods** Thirty-one participants (19 females and 12 males; age:  $26 \pm 6$  yrs, VO<sub>2</sub>max  $53.5 \pm 7.6$  ( $\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ), Hbmass  $10.8 \pm 1.6$  (g/kg)) were recruited. The training protocol consisted of 3-4 endurance training sessions every week for 12 weeks, combining interval ( $4 \times 4$  min up to  $6 \times 6$  min;  $> 90\%$  HRmax) and continuous running sessions (30 and 60 min;  $\sim 85\%$  HRmax and  $\sim 75\%$  HRmax), respectively. VO<sub>2</sub>max was determined by an incremental running exercise until exhaustion on a treadmill. Hbmass was assessed by using a optimized version of the CO-rebreathing method (Schmidt & Prommer, 2005). All participants performed a familiarization test, and were tested before and after 5-6 and 12 weeks of training. **Results** After 12 weeks of intensive endurance training VO<sub>2</sub>max increased by  $10.1 \pm 5.2\%$  ( $p < 0.01$ ). However, no significant changes were observed for Hbmass. The non-significant change in Hbmass was  $-1.1 \pm 3.4\%$  (also no change after 5-6 weeks). The correlation between VO<sub>2</sub>max and Hbmass was at baseline  $r = 0.89$  ( $p < 0.0001$ ) in absolute values, and when adjusted for bodyweight  $r = 0.73$  ( $p < 0.0001$ ). The correlation between the percent change in VO<sub>2</sub>max and Hbmass was  $r = 0.34$  ( $p = 0.06$ )

in absolute values, but only  $r = 0.14$  ( $p=0.46$ ) when adjusted for bodyweight. Discussion Twelve weeks of endurance training increased  $VO_{2max}$ , while Hbmass did not change. This is in accordance with Eastwood et al (2012). The lack of change in Hbmass indicates that augmented  $VO_{2max}$  was due to other factors, such as improved cardiac output and improved oxygen extraction. References Eastwood, A., Bourdon, P. ### CHANGES IN THE WHOLE-BODY BIOELECTRICAL IMPEDANCE VECTOR INDUCED BY TRAINING IN AMATEUR FOOTBALL PLAYERS: PRELIMINARY RESULTS

Castizo, J.1, Roy, A.1, Vives, M.1,2, Paloma, V.1,2, Porta, A.3, Irujo, A.3

1: INEFC, UB (Barcelona, Spain); 2: Federació Catalana de Futbol (Barcelona, Spain); 3: GRCE, INEFC, UB (Barcelona, Spain);

**Introduction** Football is a team sport that incorporates frequent fluctuations between high and low exercise intensities. Rating of perceived exertion (RPE) is a valid, simple and cheap method for monitoring exercise intensity in football. Despite there is extensive information about physiological demands during a football match, less information is on the training sessions (Bangsbo et al., 2006) and in particular about the possible hydration changes generated. Bioelectrical impedance vector analysis (BIVA) is a non-invasive and safe technique for assessing hydration and body composition changes (Lukaski & Piccoli, 2012). This study applied BIVA to assess possible hydration changes evoked by one high intensity training session in a group of amateur football players (FP). Method 10 amateur FP completed anthropometric (ISAK) and bioelectrical assessments (BIVA) PRE and POST a high intensity training session ( $1.5 \pm 0.2$  h). Borg 15-point rating of perceived exertion scale was assessed to determinate the training session intensity. A tetra-polar phase-sensitive BIA (BIA-101; AKERN-Srl, Florence, ITALY) was used to measure resistance (R), reactance (Xc) and phase angle (PA). 50 kHz whole-body BIA vectors were analyzed by the R/Xc graphic method, and Z mean values plotted (Piccoli et al., 1994). Hotelling's T2 test determined differences in the complex localized vector through the 95% confidence and tolerance intervals. Results The FP registered the following anthropometric profile: age: 19,5 (1,3) years; height: 175,2 (5,4) cm; weight: 65,8 (6,8) kg; BMI: 21,4 (1,9) kg/m<sup>2</sup>; fat mass: 7,6 (1,6) %; muscle mass; 48,2 (2,6) %; bone mass: 16,5 (2,1) %; somatotype: 2,5-3,5-3,3. Borg's scale response following the training session was 14,5 (1,3) RPE. Significant changes were observed between PRE and POST training session in body mass: 65,8 (6,8) kg vs. 65,0 (6,7) kg ( $\Delta -1,23\%$ ,  $p=0,005$ ); R: 552,7 (59,3) ohms vs. 563,5 (65,5) ohms ( $\Delta 1,89\%$ ,  $p=0,037$ ); Xc: 67,9 (7,3) ohms vs. 69,8 (7,2) ohms ( $\Delta 2,89\%$ ,  $p=0,008$ ). BIVA showed no significant whole-body vector migration from PRE to POST training session ( $T2=0,33$ ;  $p>0,05$ ). Discussion Despite the significant differences in R and Xc, the BIA vector shows no significant displacement between PRE and POST conducted football training session. The sample characteristics, the workload type and the total time of the training session, could have influenced these results. However, the significance changes in body mass and bioelectrical variables, invite us to interpret these results with caution. Further research is needed in order to analyze the relationship between specific designs of football training sessions, and their effects in the hydration status of football players. ### ABDOMINAL TO LOWER BODY FAT MASS RATIO IMPACTS ON LIPOXMAX IN NORMAL WEIGHT WOMEN

Isacco, L.1, Thivel, D.1, Aucouturier, J.2, Duclos, M.3,4, Duche, P.1, Boisseau, N.1

Blaise Pascal

1: AME2P, CRNH Auvergne (Clermont-Ferrand, France), 2: EA4488, Univ. Lille Nord de France (Lille, France), 3: INRA, UMR 1019, UNH, CRNH Auvergne (Clermont-Ferrand, France) 4: CHU (Clermont-Ferrand, France) **Introduction** The exercise intensity that elicits the maximal lipid oxidation rate (MLOR), termed Lipoxmax (Perez-Martin et al., 2001), can be used to individualize training programs in healthy subjects or those with metabolic disorders willing to maximize lipid oxidation. Lipoxmax occurs at lower percentage  $VO_{2max}$  in obese than in normal weight (NW) subjects (Perez-Martin et al., 2001) but to our knowledge, little is known about the effect of preferential adipose tissue localization on Lipoxmax and MLOR in NW subjects. The aim of our study was therefore to investigate in NW women i) the impact of low (LA/LB) and high (HA/LB) abdominal to lower body fat mass ratio determined from DXA measurement on Lipoxmax and MLOR and ii) the relationship between MLOR and fasted hormonal (insulin, catecholamine, GH, IGF-1, ANP) and metabolic (glucose, FFA) plasma levels. **Methods** We investigated two groups of 11 LA/LB and 10 HA/LB NW women ( $22 \pm 0.6$  years old) matched for body mass ( $61.1 \pm 1.5$  vs  $63.6 \pm 2.2$  kg respectively), percentage body fat ( $25.6 \pm 1.3$  vs  $27.8 \pm 0.1$ ) and  $VO_{2max}$  ( $53.3 \pm 1.8$  vs  $49.8 \pm 2.4$  ml.kgFFM<sup>-1</sup>.min<sup>-1</sup>). Lipoxmax (% $VO_{2max}$ ) and MLOR (mg.min<sup>-1</sup>.kgFFM<sup>-1</sup>) were determined in fasted state from  $VCO_2$  and  $VO_2$  measurements (Péronnet & Massicotte 1991) during a 6min stages graded exercise starting at 20% predicted maximal aerobic power (MAP) with 10% MAP increment followed by a rapid incremental test until  $VO_{2max}$  (Brun et al. 2011). Resting blood samples were collected to determine plasma levels of hormones, glucose and FFA. Results Lipoxmax and MLOR were significantly higher in the LA/LB ( $54 \pm 4\%VO_{2max}$ ,  $8.4 \pm 0.9$  mg.min<sup>-1</sup>.kgFFM<sup>-1</sup> respectively) than in the HA/LB group ( $43 \pm 3\%VO_{2max}$ ,  $4.8 \pm 0.6$  mg.min<sup>-1</sup>.kgFFM<sup>-1</sup>) ( $p < 0.001$ ). GH plasma levels were positively associated with MLOR ( $r^2 = 0.21$ ,  $p < 0.05$ ). No differences between groups were observed for other hormones, glucose and FFA plasma levels. **Discussion** This study indicates an effect of adipose tissue localization on fat oxidation in NW women, with LA/LB women exhibited greater MLOR at a higher Lipoxmax compared with HA/LB women. Basal GH plasma level was the only hormonal or metabolic variable that could be partly linked to MLOR. Other studies are therefore needed to better understand the underlying mechanisms affecting this parameter. From a clinical perspective, adipose tissue localization is a factor to be considered in the prescription of exercise intensity for maximizing lipid oxidation. References Perez-Martin A et al. (2001). *Diabetes Metab*, 27, 466-474. Péronnet F, Massicotte D. (1991) *Can J Sport Sci*. 16:23-29 Brun et al. (2011). *Science & Sports*, 26, 57-71.

### GAIT SPEED AND HAND GRIP STRENGTH – MORE USEFUL THAN MUSCLE MASS TO ESTIMATE SARCOPENIA IN ELDERLY WOMEN?

Hofmann, M., Halper, B., Oesen, S., Bachl, N., Wagner, K.H., Wessner, B.

Centre of Sports Science and University Sports, University of Vienna

**Introduction** According to the European Working Group on Sarcopenia in Older People (EWGSOP) diagnosis of sarcopenia requires documentation of low muscle mass plus either low muscle strength or low physical performance [1]. The aim of the current study was to investigate (a) the prevalence of sarcopenia with or without obesity and (b) its association with frequently used sports motoric tests in elderly.

Methods Bioimpedance analysis was used to predict muscle mass of 102 institutionalized women aged  $82.6 \pm 5.9$  years. Skeletal muscle mass index (SMI) was calculated by body cell mass and height. Subjects having a SMI  $< 6.75$  kg/m<sup>2</sup> in addition to either showing a walking speed  $< 1$  m/s or a handgrip strength  $< 20$  kg were considered as sarcopenic [2]. Obesity was determined by a BMI  $\geq 30$  kg/m<sup>2</sup> [2]. In addition, participants completed functional tests to assess strength as well as aerobic capacity. These tests include isokinetic torque measurements of knee extensors - and flexors (Lido Loredan), 6-minute walking distance, functional reach, 30 second chair raise and arm lifting test. Results Out of 102 women 40 (39%) subjects were of normal weight without signs of sarcopenia, 35 (34%) were obese, 10 (10%) were sarcopenic and only 1 subject (1%) could be defined as having sarcopenic obesity. We did not detect any difference between these groups according to the measured functional tests (Kruskal Wallis test,  $p > 0.05$ ). Interestingly, a SMI  $< 6.75$  kg/m<sup>2</sup> did not describe differences in motor skills as compared by Mann-Whitney U test ( $p > 0.05$ ). This was in contrast to comparisons using gait speed. Differences between groups in the isokinetic peak torque of knee extension and flexion, chair raise test and 6-minute walking distance were detected (all  $p < 0.05$ ). The best discriminator was found to be hand grip test (76% of subjects below cut-off value). Women with reduced handgrip strength showed a significantly reduced outcome in all other functional tests (all  $p < 0.05$ ). Discussion The results of our study imply that only a small proportion of elderly institutionalized women are actually defined as being sarcopenic using the criteria of the EWGSOP. Especially, handgrip strength  $< 20$  kg resulted in weaker outcomes in all relevant functional tests. Handgrip strength was efficiently used to predict morbidity and mortality [3,4]. As this is a cheap test which can be used in a high number of subjects we suggest its broader use in studies for the screening of functional limitations. References [1] Cruz-Jentoft, A, et al. ### SPRINT INTERVAL TRAINING ON THE VERTICAL TREADMILL

Jordan, A., Fysh, M., Claxton, D., Purvis, A., Barnes, A.

*Sheffield Hallam University*

Introduction Over a third of injuries throughout the soccer season are related to repetitive impacts on joints during running (1). Recumbent exercise modes have been employed to reduce impact on joints during training (2). A vertical treadmill (VerT), which requires a running action in a recumbent posture on a vertically hung, non-motorised treadmill whilst the limbs are supported with overhanging resistance cables, was designed for the physical conditioning of athletes. It has not been established if there are any physiological adaptations or performance benefits of training using a VerT. The aim of this study was to determine the effects of sprint interval training (SIT) on the VerT compared with over ground sprint training on aerobic and anaerobic power. Methods With institutional ethics approval, twenty active males aged 23 (3) years, stature 1.79 (7.35) m, body mass 77.6 (12.6) kg volunteered for this study. Participants' aerobic and anaerobic running power were determined by incremental VO<sub>2</sub>max treadmill test and a maximum anaerobic running test (MART) respectively. Participants were pair matched, based upon their aerobic and anaerobic power, and assigned to VerT or 20 m shuttle sprint group (SG). SIT consisted of 4-6, 30 s all-out efforts with 4 minutes recovery between bouts, 3 days a week for 6 weeks. Results SIT increased VO<sub>2</sub>max from 46.8 (5.4) to 49.9 (4.9) ml/kg/min in the VerT ( $p = 0.00$ ) and from 46.1 (4.4) to 49.1 (5.2) ml/kg/min in the SG ( $p = 0.00$ ). MART score (O<sub>2</sub> equivalents) also increased from 105.2 (8.6) to 109.7 (8.7) ml/kg/min in the VerT ( $p = 0.00$ ) and from 104.8 (9.3) to 108.9 (9.2) ml/kg/min in the SG ( $p = 0.00$ ). There were no group x time interactions. Discussion The improvement in aerobic and anaerobic power for SG was similar to that reported previously (3). The findings of this study suggest that 6 weeks of SIT on the VerT results in similar improvements in aerobic and anaerobic running power to those from over ground sprint training. Therefore, the VerT could be used as a low-impact conditioning tool and might be a substitute for exercise involving prolonged over ground running. References 1. Engström, B. Forsblad, M. ### NONINVASIVE METHOD FOR EVALUATING SKELETAL MUSCLE OXIDATIVE CAPACITY WITH NEAR INFRARED SPECTROSCOPY IN VARIOUS SUBJECTS

Shinsuke, N., Yutaka, I., Yuko, K., Toshiyuki, K., Takeshi, S., Masako, F., Takafumi, H.

*Graduate School of Sport and Health Science*

Introduction Near infrared spectroscopy (NIRS) devices can noninvasively provide information about the changes in tissue oxygenation. Thus, it is expected for NIRS to be further used in clinical or field setup. Time constant for recovery of muscle oxygen consumption (TcVO<sub>2</sub>mus) after submaximal exercise is an index of muscle oxidative function (Motobe et al., 2003). However, only a few studies have investigated a usefulness of TcVO<sub>2</sub>mus. Therefore, the purpose of this study was to examine whether TcVO<sub>2</sub>mus was altered qualitatively in various subjects with differing conditioning. Methods Fourteen healthy men participated in this study. The subjects divided into two groups, a 21-d non-dominant arm immobilization group [19.5 $\pm$ 0.9 years, (mean $\pm$ SD) maximal voluntary contraction(MVC) for non-dominant arm 415.5 $\pm$ 72.4 N, dominant arm 413.3 $\pm$ 71.4 N] (n=8; IMM) (Kitahara et al., 2003) or training group (25.1 $\pm$ 0.9 years, MVC for non-dominant arm 409.3 $\pm$ 28.5 N, dominant arm 479.9 $\pm$ 54.7 N) (n=6; TRN). The TRN group conducted muscle endurance handgrip training (dynamic handgrip exercise at 30 % of MVC, 1 Hz until exhaustion) 5 times weekly and muscle strength handgrip training (70 % MVC for 2 seconds with 2 second rest interval, repeated 10 times) in the non-dominant arm 3 times weekly. We measured the following parameters for participant pre- and post- intervention on the non-dominant arm and dominant arm: MVC of the grip, forearm cross-sectional area (CSA), work capacity per CSA (dynamic handgrip exercise at 30 % of MVC, 1 Hz until exhaustion). The oxidative capacity was evaluated by the TcVO<sub>2</sub>mus using NIRS. Results There was no change for all parameters in the dominant arm. In the non-dominant arm there is no significant change in CSA in the IMM (pre 3604 $\pm$ 662 mm<sup>2</sup>, post 3568 $\pm$ 607 mm<sup>2</sup>) and TRN (pre 4015 $\pm$ 526 mm<sup>2</sup>, post 3988 $\pm$ 511 mm<sup>2</sup>), respectively. The MVC significantly decreased in the IMM (20.2%) and tended to improve in the TRN (4.5%) ( $p = 0.08$ ). The work capacity per CSA in the IMM significantly decreased (22.2%) and improved in the TRN (90.7%). The TcVO<sub>2</sub>mus significantly prolonged in the IMM (pre 46.0 $\pm$ 6.9 s, post 62.1 $\pm$ 17.3 s), and improved in the TRN (pre 65.7 $\pm$ 6.4 s, post 51.7 $\pm$ 3.67 s). Discussion The TcVO<sub>2</sub>mus decreased in the IMM (25.9 %) and improved in the TRN (20.9 %). These values are in accordance with the data reported in previous studies (Motobe et al., 2003, Hamaoka et al., 1998). The TcVO<sub>2</sub>mus is reported to be altered by the changes in the muscle oxidative capacity, such as the changes in mitochondrial volume and numbers, and oxidative enzyme activity (Motobe et al., 2003). Conclusion The TcVO<sub>2</sub>mus was altered with differing muscle conditioning. This result provides a qualitative, but reasonable evidence indicating that the TcVO<sub>2</sub>mus is useful index for evaluating muscle oxidative capacity. References Motobe M, et al., (2004). ## EFFECT OF HYPEROXIC RECOVERY ON OXIDATIVE STRESS DURING A SIMULATED CROSS-COUNTRY SKIING TEAM SPRINT

Hauser, A.1, Zinner, C.2, Wehrlich, J.P.1, Sperlich, B.3

1.Swiss Federal Institute of Sport Magglingen (Switzerland), 2.German Research Centre of Elite Sport Cologne (Germany), 3.University of Wuppertal (Germany)

**Introduction:** As the use of breathing oxygen-enriched air (hyperoxia) is no longer prohibited by the World Anti-Doping Agency, the question for elite athletes arises, whether the use of hyperoxia could be beneficial for improving competition performance. In competitive events its application is only practical during the recovery periods due to technical and heavy assemblies. There is evidence that hyperoxic recovery between bouts of high-intensity exercise has positive influence on key physiological variables of endurance performance (Nummela et al., 2002; Sperlich et al., 2011). However, it is still unclear whether acute exposure to hyperoxic air may produce additional reactive oxygen species (ROS). Therefore, the aim of the study was to evaluate the acute effects of hyperoxic recovery on oxidative stress during a simulated cross-country skiing team sprint competition. **Methods:** Seven well-trained male endurance athletes performed two 3 x 3-min all-out sprint intervals on a double-poling ergometer at simulated moderate altitude (~1800 m). During the 3-min recovery periods between the 3 x 3-min sprints, all athletes inhaled either hyperoxic (FIO<sub>2</sub> = 1.00) or hypoxic (FIO<sub>2</sub> ~0.165) air in a randomized and single-blind order. The level of ROS was measured prior the warm-up and directly after the exercise protocol, using the free oxygen radical test (FORT) (Callegari, Parma, Italy). The results are expressed as FORT units (FORT U), where one FORT U corresponds to 0.26 mg/L of H<sub>2</sub>O<sub>2</sub>. Oxidative stress is defined as values > 310 FORT U. **Results:** No differences between post-exercise level of ROS for hyperoxic (259.7 ± 29.8 FORT U) and hypoxic (283.6 ± 56.5 FORT U) trial were obtained (P = 0.28; effect size = 0.53). Pre- to post-exercise FORT values were the same with hyperoxic (262.3 ± 32.2 to 259.7 ± 29.8 FORT U; P = 0.69) and with hypoxic (268.4 ± 48.4 to 283.6 ± 56.5 FORT U; P = 0.21) recovery. **Discussion:** Hyperoxic recovery appeared to have no additional oxidative risk for athletes performing 3 x 3-min maximal interval workouts at moderate altitude compared to hypoxic recovery. Furthermore, with hyperoxic recovery FORT levels were for all athletes at all time-points below the normal range for healthy individuals (< 310 FORT U). However, it remains unclear whether a longer period of exposure to hyperoxic air during exercise may enhance ROS production and could lead to oxidative damage. **References:** Nummela A, Hamalainen I, Rusko H. ## HEART RATE HYSTERESIS IN TRIATHLETES DURING CYCLING AND RUNNING

Vázquez, P.1, Galán, J.1, Hristovski, R.2, Balagué, N.1

1. INEFC Barcelona (Spain), 2. Ss. Cyril and Methodius University, Skopje (Rep. of Macedonia)

**Introduction** In complex biological systems the hysteresis phenomenon explains the co-existence of different states for the same parameter value and informs about the nonlinearity of the phenomena under consideration. Heart rate (HR) features are especially important because the parameter is widely used in exercise monitoring and assessment. The purpose of this study was to reveal the existence of the hysteresis phenomenon in the evolution of HR during progressive loading/unloading cycling and running tests. **Methods** Twenty trained triathletes, M=24,17; SD=9,31 years old, previously familiarized with the experimental procedures performed 2 progressive loading/unloading tests (cycling and running, respectively) in two different days. HR and rate of perceived exertion (Borg's RPE 6-20 scale) were recorded and reported during the trials. In the loading phase triathletes started pedaling (70 rpm) at 100W (with increments of 30W .min<sup>-1</sup>) and running at 10km .h<sup>-1</sup> (with increments of 1km.h<sup>-1</sup> per minute), until they reached a RPE ≥ 18. The load was then progressively decreased (30W.min<sup>-1</sup> and 1km.h<sup>-1</sup>, respectively) like a mirror. The differences of HR median values for the same load intensities in the loading and unloading phases, respectively, were compared using non-parametric Wilcoxon matched pairs test. **Results** Results showed a clear HR hysteresis phenomenon between the loading and unloading phases of both tests. In the cycling test significant differences (p < 0.001) were found for all pair of loads (n= 6, loading/unloading, respectively). In the running task, the differences were higher for the 3 loads close to the maximum (p<0.001) and lower for the 3 loads close to the minimum (p<0.002; p<0.005; p<0.016, respectively). HR Median values of unloading phases were always larger than HR median values of loading phases in all participants. **Discussion** HR followed a different path during the loading and unloading phases although the external loads were the same. The HR hysteresis effect seems to be more pronounced in cycling than in running. Further research should investigate if this is related to the different demands of both types of exercise or the different training status of participants in both disciplines. The results point to the existence of hysteresis HR effects in trained triathletes during both cycling and running exercises. This feature should be taken into account for an accurate monitoring and training assessment.

## EFFECT OF THE EXERCISE MODE ORDER ON ARTERIAL STIFFNESS IN NORMOTENSIVE MEN

Domingues, W., Cavalcante, B.R., Silva, R.R.M., Soares, A.H.G., Alves, A.J.C., Oliveira, J., Oliveira, N.L.

Faculty of Sport University of Porto

**Introduction** Increased arterial stiffness (AS) of elastic vessels is considered an important cardiovascular risk factor and is associated with cardiovascular morbidity and mortality. Studies have showed that a single session of aerobic or resistance exercise promotes important hemodynamic changes. However, less is known about the acute effect of a single session combining resistance and aerobic exercise, and their order within the session on AS. **Methods** Six young healthy male participants (24.5±2.7 yrs) were submitted to two exercise sessions in which the exercise order was randomized to start with aerobic followed by resistance exercises (AR) or the reverse (RA). Each exercise session last approximately 1h. Aerobic exercise performed at 75-80% VO<sub>2</sub>peak for 35 min. Resistance exercises encompassed 3 sets of 8-10 RM for upper and lower body segments. Carotid-femoral pulse wave velocity (cf-PWV) was assessed through applanation tonometry by a single investigator at rest and after exercise session (2, 10, 20 and 30 min). **Results** For the AR session the cf-PWV (m/s) were: rest (5.8±1.1) and after exercise (2 min 5.9±0.7; 10 min 5.7±1.1; 20 min 5.9±1.4; and 30 min 5.5±0.8). For the RA session the cf-PWV (m/s) were: rest (5.6±1.0) and after exercise (2 min 5.8±0.9; 10 min 5.6±0.7; 20 min 5.8±0.9; and 30 min 5.3±0.5). There was no significant main effect of time or session x time interaction. **Discussion** The results of the present study indicate that exercise mode order within exercise sessions do not acutely influence the cf-PWV. Moreover, we did not found a main effect of time on cf-PWV, which is in disagreement with previous published data (Naka et al., 2003; DeVan et al., 2005) even though those studies did not use the combination of exercise modes on the same session. It is possible that the reduced sample size of this pilot study preclude the achievement of any significant main effect of the exercise order in the main outcome. Therefore, further studies with a large sample size are needed to ascertain if the exercise mode order within the exercise session is an explanatory factor of acute variation of AS. **References** DeVan, A. E.,

### **NUMBER OF MICTURITIONS AS A HYDRATION MARKER FOR KIDS**

Kavouras, S.A.1,2, Bougatsas, D.2, Arnaoutis, G.2, Tspouridi, S.2, Panagiotakos, D.B.2, Armstrong, L.E.3, Perrier, E.4, Klein, A.4

1: University of Arkansas (Arkansas, USA), 2: Harokopio University (Athens, Greece), 3: University of Connecticut (Connecticut, USA), 4: Danone Research (Palaiseau, France)

Hydration status, due to the dynamic nature and the constant turnover of body water, is not easily assessed. A valid estimation can be achieved with the use of various indices in the laboratory. Nonetheless methods that can be used easily in the field could be valuable tools for hydration assessment. Study Objective: To examine whether the number of bathroom visits could predict hypohydration in kids aged 8-14 years. Methods: 128 Greek healthy boys (n=75) and girls (n=53) aged 8-14 years (Height: 1.47±0.13 m, Weight: 42±12 kg, Fat: 25.1±7.7%, Total Body Water (TBW): 25.5±6.5 L) were asked to collect their urine for 24 hours while conducting normal daily activities. They were also instructed to record the times they visited the bathroom and to mark the volume and the time of each void on the urine container. 24h urine was analyzed for osmolality (Uosm) via freezing point depression osmometry. Results: Sensitivity analysis showed that the overall accuracy of the number of micturitions as compared with Uosm was 64.8±4.9%. Specifically, the sensitivity of a positive number of micturitions test (i.e., ≤5) was 54.8% and the specificity was 68.2% for detecting hypohydrated persons (i.e., Uosm>700). The threshold used (i.e., 5) was also the optimal cut-off point for number of micturitions according to the performed ROC (Receiver Operating Curve) analysis. Conclusions: According to our data less than or equal to 5 visits in the bathroom could lead to 24h urine Osmolality of >700mOsm/kg. These data suggest that the number of micturitions might provide an indication about hydration status of children aged 8-14 years.

### **BEHAVIOR OF HYPERTENSIVE BLOOD PRESSURE DURING RECOVERY IN INTERVAL TEST 10 RM**

Domingues, W.J.R.1, Moraes, M., de Oliveira, R.T.2, Neves, A.F.2, de Almeida, J.S.2, de Oliveira, S.N.2, Rossato, M.2, de Bezerra, E.S.2, Simão, R.3

1:FADEUP (Porto, Portugal), 2:UFAM (Manaus - AM, Brazil), 3:UFRJ (Rio de Janeiro - RJ, Brazil).

Introduction Application protocol testing with hypertensive people are not fully elucidated and specific yet, following the principles to people who aren't suffering HAS, scientific investigations are presented scarce in relation to appropriate recovery interval between attempts at strength test for hypertensive patients. Therefore, the aim of this study was to evaluate the behavior of the hypotensive effect in components of blood pressure in two different post-test of 10 maximum repetitions (10 RM). Methods 20 hypertensive on medication, 18 women and 2 men, with no experience on strength training, were subject an adaptation of 6 sessions and remained without training at the 72 hours before evaluation. A test of 10RM evaluated the strength of the arms (MS) in bench press and legs (MI) in leg extension. The interval between each set was 5 minutes. Trying to find the average of arterial pressure (MAP) before each attempt of 10RM (PRÉ), at intervals of 2 (2PÓS) and 4 (4PÓS) minutes, was measured systolic and diastolic pressures by auscultation. Data were expressed with values of central tendency (mean) and dispersion (standard deviation). Results The MAP not presented significant differences between periods analyzed when done for MI test, PRE (97,1±5,04); 2PÓS (97,7±6,57) and 4POS (95,8±5,48), p=0,56, like for MS, PRE (94,9±6,28); 2PÓS (96,8±7,17) and 4POS (95,1±6,33), p=0,62. Discussion The results of the present study identified no significant differences in the periods analyzed (POS2) and (POS4) in MAP. Whereas the 10RM test requires the subject intensities increasing as we approach the end of the test, and that the SBP and DBP rise progressively reaching the highest values in the last repetitions (MACDOUGALL et al., 1985), the ranges proposed in this study were insufficient to promote significant reduction in the values of MAP. Regarding the acute effects of resistance exercise highlights the post-exercise hypotension after exercise (BRUM et al., 2004), which was most evident in the hypertensive than normotensive (FORJAZ et al., 2000). ### **THE POWER DOPPLER ANALYSIS OF VASTUS LATERALIS MUSCLE VASCULARITY IN EXERCISE**

Martins, R., Armada, P.

*ESTESC-IPC; FMH-UNL*

INTRODUCTION Muscle structure and morphology can change with workout or physical exercise (1). During the exercise metabolic changes occur and blood flow within the muscle changes (2). Ultrasonography is an imaging technique useful to study the muscle morphology in physiological and pathological conditions (3). Power Doppler (PD) is a relatively new technique that significantly improves the sensitivity of ultrasound B-mode and reflects the blood flow in the tissues (4). PD provides a sensitive indication of muscle activity even with low contraction levels (5). The main goal of this study is to analyze if there is any flow blood alteration within the vastus lateralis muscle. METHODS Forty two healthy males volunteers (mean age 21±3 years) performed isometric and isokinetic contractions in different angles, with an isokinetic dynamometer. Ultrasound images in transverse plane of vastus lateralis muscle were acquired, before and after exercise, using PD to evaluate blood flow and quantified using MATLAB software. RESULTS With exercise, all 42 vastus lateralis muscles showed a significant subjective increase in apparent vascularity (p < .005). CONCLUSION Some studies showed changes in gastrocnemius muscle vascularity with Exercise-induced (2;6). This study, also, presents that PDS revealed marked increases in vascularity intramuscular after exercise. References 1. ## MYOCELLULAR ADAPTATIONS TO STRENGTH TRAINING IN POSTMENOPAUSAL OSTEOPOROTIC WOMEN

Raastad, T., Wiig, H., Kvernevik, K.J., Gautvik, K.

*Norwegian School of Sport Sciences*

**Introduction** Osteoporosis is associated with reduced muscle strength and muscle mass, and genetically predispositions may be involved in the accelerated decline in bone mass and muscle strength in some women (1). Nevertheless, we have earlier reported that postmenopausal osteoporotic women respond normally to heavy load strength training with increases in muscle strength of 30-40% and increased cross sectional area of thigh muscles of 7-8% after 15 weeks of training (2). However, the muscle cellular adaptation to strength training is so far not investigated in this patient population. Consequently, the aim of this study was to investigate changes in muscle fiber area, fiber distribution and the satellite cell response to 15 weeks of heavy load strength training in postmenopausal women. **Methods** A total of 22 osteoporotic women between 56 and 80 years of age were recruited from an earlier cross sectional study (1). The strength training was conducted three times per week for 15 weeks. After an initial familiarization to training over 2 weeks, strength training was performed with one to three 4-12 RM sets in squats, standing calf rise, leg press, rowing, chest press and shoulder press. Biopsies were collected from m. vastus lateralis before and after the training period. Muscle cross sections were analyzed for fiber types, fiber area and number of satellite cells and myonuclei using standard immunohistological techniques. **Results** There were no significant changes in muscle fiber area from pre to post training for neither type I fibers ( $4175 \pm 947$  vs.  $3942 \pm 1133 \mu\text{m}^2$ ) nor type II fibers ( $2829 \pm 847$  vs.  $2966 \pm 1105 \mu\text{m}^2$ ). Furthermore, there was no change in fiber type distribution from pre to post training (52% type I fibers and 48% type II fibers). The number of satellite cells and myonuclei is currently under investigation. **Discussion** Surprisingly, we did not observe any increase in fiber area despite a significant increase in m. quadriceps cross sectional area of 7-8% as previously reported (2). Interestingly, the frequency distribution of fiber areas shifted towards a higher number of fibers with small to moderate areas. Further analysis will show whether there were any changes in the number of satellite cells or myonuclei. **References** 1. Reppe et al. Bone 2010 Mar;46(3):604-12. 2. Raastad et al. ## EFFECT OF CAFFEINE INGESTION ON PERCEPTUAL AND PHYSIOLOGICAL RESPONSES TO PROLONGED MODERATE-INTENSITY ARM CRANKING

Alsoulfi, F.R.1, Baxendale, R.H.1, Al-Hazzaa, H.M.3, Mohammad, A., Alahmadi, M.A.4

*1: King Fahad Security College, Riyadh, Saudi Arabia, 2: School of Life Science, The University, Glasgow, Scotland, UK, 3: Pediatric Exercise Physiology Research Laboratory, King Saud University,*

**Introduction** Caffeine's metabolic and performance effects have been widely reported. However, caffeine's effects on affective states during exercise are unknown. Therefore, the aim of this study is to investigate the effects of caffeine on the perception of effort and fatigue during prolonged upper limb exercise. **Methods** A randomised double blind placebo controlled crossover design was used to compare the effects of caffeine at 7.5 mg/kg and a placebo of starch at the same dose. The caffeine was consumed in gelatine capsules 45 minutes before the start of the exercise test. Fifteen Healthy young males performed 20 min of arm exercise at an intensity equivalent to 90% of individual lactate threshold, determined from a standard ramp-incremental exercise protocol. Physiological as well as rates of perceived exertion using Borg (0-10) RPE scale and Visual Analogue Scales (VAS) were assessed during the last 20 seconds of each 5 minutes of the test and during three stages of post exercise. A 2-way repeated measures ANOVA was used to test the differences between the caffeine and the placebo responses. **Results** Caffeine ingestion produced no significant effect on RPE, (VAS), blood lactate concentration, peak oxygen uptake or peak minute ventilation. However, heart rate (HR) levels (mean +/- SD) were significantly higher after caffeine consumption than after placebo use at 15 min:  $144 \pm 4 \text{ b} \cdot \text{min}^{-1}$  vs  $134 \pm 4 \text{ b} \cdot \text{min}^{-1}$ , at 20 min:  $149 \pm 4 \text{ b} \cdot \text{min}^{-1}$  vs  $136 \pm 4 \text{ b} \cdot \text{min}^{-1}$ , at 2 min post exercise:  $116 \pm 4 \text{ b} \cdot \text{min}^{-1}$  vs  $106 \pm 3 \text{ b} \cdot \text{min}^{-1}$ , at 4 min post exercise:  $110 \pm 3 \text{ b} \cdot \text{min}^{-1}$  vs  $102 \pm 3 \text{ b} \cdot \text{min}^{-1}$ , and at 6 min post exercise  $106 \pm 3 \text{ b} \cdot \text{min}^{-1}$  vs  $100 \pm 3 \text{ b} \cdot \text{min}^{-1}$ . **Conclusion** Our findings indicated that except for the significant differences in HR responses, no noticeable variations were found in gas exchange, blood lactate or RPE responses between caffeine and placebo arm exercise trials.

## ACUTE EFFECT OF PELVIC PROPRIOCEPTIVE NEUROMUSCULAR FACILITATION TECHNIQUES IN CHRONIC LOW BACK PAIN

Comuk Balci, N.1, Gulsen, M.2, Zeybek, A.1

*1: Baskent University, (Ankara, Turkey) 2: Baskent University Ankara Hospital (Ankara, Turkey)*

**Introduction** Chronic low back pain (CLBP) constitutes a major proportion of disabling musculoskeletal conditions. Exercise is one of the most frequently used modalities in the rehabilitation of subjects with low back pain (Kofotolis et al., 2005; Malkia E et al., 1996). Proprioceptive neuromuscular facilitation (PNF) exercises are designed to enhance the response of neuromuscular mechanisms by stimulating proprioceptors (Voss et al, 1985). The aim of this study is to examine the acute effect of pelvic PNF exercises on pain, functional mobility, lumbar mobility, sacroiliac joint mobility in patients with CLBP. **Methods** Eleven participants with CLBP were participated (age= $58.36 \pm 13.07$  years). Pain intensity was evaluated with Visual Analog Scale (VAS) (Dickson et al., 1981). Functional mobility was assessed with Timed up Go Test (Podsiadlo et al., 1991) and Step-Up Tests (Jacobson et al., 2011). Lumbar mobility was assessed with trunk forward flexion, trunk lateral flexion, trunk rotation and trunk hyperextension tests (Mitchell et al., 1979). Sacroiliac joint mobility was evaluated with Gillet Test (Potter et al., 1985). All evaluations were performed before and after treatment. Treatment program including conventional physiotherapy consist of hotpack, ultrasound and TENS and pelvic PNF exercises. **Results** Significant differences were found in Timed Up and Go Test, Gillet Test on right side, Gillet Test on left side, trunk forward flexion, trunk right lateral flexion, trunk left lateral flexion, trunk hyperextension tests, step-up test with left leg, VAS ( $p < 0.05$ ). No significant difference was found in trunk rotation and step-up test with right leg ( $p > 0.05$ ) before and after treatment. **Discussion** According to our results pelvic PNF exercises enhance functional mobility, lumbar and sacroiliac joint mobility and decrease pain. Pelvic PNF exercises should be used in CLBP in physiotherapy programmes. Further studies are needed to conduct with larger sample size and investigate long-term effects of PNF exercises in CLBP. **References** Jacobson BH, Thompson B, Wallace I, Braun L, Rial C. (2011). ### **ACUTE EFFECTS OF SCAPULAR PROPRIOCEPTIVE NEUROMUSCULAR FACILITATION TECHNIQUES IN FROZEN SHOULDER**

Comuk Balci, N.1, Zeybek, A.1, Gulsen, M.2

1:Baskent University (Ankara, Turkey), 2:Baskent University Ankara Hospital, (Ankara, Turkey)

**Introduction:** Frozen shoulder is a common problem in general practice (Hand et al., 2008; Hannafi et al., 2000). The scapula plays several roles in facilitating optimal shoulder function (Paine et al., 1993). Use of the scapular component of the traditional proprioceptive neuromuscular facilitation (PNF) provides useful information on the kinaesthetic awareness of the scapula (Magarey et al., 2003). The aim of our study is to analyse acute effects of scapular PNF techniques on pain, shoulder functionality, scapular dyskinesia and shoulder range of motion in patients with frozen shoulder. **Methods:** Twenty patients with frozen shoulder were randomly assigned in PNF group (PG) (n=10, age=58.10±8.03 years) and to normal physiotherapy group (NG) (n=10, age=60.00±5.81 years). Visual Analog Scale (VAS) was used to assess pain intensity (Dixon et al., 1981). Shoulder flexion and abduction were assessed with Universal goniometer (Boone et al., 1978). Simple Shoulder Test (SST) was used to measure functional limitations (Ayhan et al., 2010). Scapular dyskinesia was evaluated with Lateral Scapular Slide Test (LSST) (Kibler et al., 1998). All evaluations were done before and after interventions in two groups. NG were received wand exercises and passive stretching exercises besides conventional physiotherapy including hotpack, ultrasound and TENS. PG were performed scapular PNF exercises addition to conventional physiotherapy. **Results:** Significant differences were found in LSST (1st test position) and in active range of motion of shoulder abduction after treatment between PG and NG. (p<0.05) NG gave better results than PG in LSST (1st test position) and active range of motion of shoulder abduction. No significant difference was found in LSST (2nd and 3rd test positions), VAS, SST and active range of motion of shoulder flexion after treatment between PG and NG (p>0.05). **Discussion:** According to our results; not only scapular PNF exercises but also other physiotherapy exercise approaches besides conventional therapy can be more effective on shoulder functions. Further studies are needed to conduct with larger sample size, perform with upper extremity PNF techniques and investigate long-term effects of PNF exercises. **Reference:** Ayhan C, Unal E, Yakut Y. ### **EFFECTS OF A PREVENTIVE PROGRAM ON OPTIMUM ANGLE OF KNEE FLEXORS IN SOCCER PLAYERS**

Martínez-Ruiz, E.1, Rubio-Arias, J.A.2, Esparza-Ros, F.1, Alcaraz, P.E.2, Mendiguchia, J.3

Catholic University of San Antonio

**Introduction** The incidence of hamstring injuries is high in soccer. A strategy commonly used to their prevention is eccentric strengthening of hamstring muscles. This exercise type has shown to increase the optimum angle of peak torque, which may result in greater structural stability at longer muscle lengths 1. Thus, the objective of this study was to assess the effects of a preventive eccentric and plyometric program on optimum angle of the knee flexors in soccer players. **Methods** Fifty male players were assigned to an intervention group (EG, n=27) or a control group (CG, n=23) in according to position and starting or substitute condition. Over the seven-week period of preventive training, two players from the EG suffered an anterior cruciate ligament and ankle sprain injury and two athletes from the CG suffered a low back and shoulder injury. Others were excluded by leaving their club or personal reasons. After these exclusions, 25 (22.8 ± 5.0 years, 174.8 ± 5.5 cm and 70.6 ± 8.3 kg) and 19 (22.1 ± 2.7 years, 176.8 ± 6.3 cm and 70.7 ± 6.8 kg) players constituted the EG and CG, respectively. Both groups performed regular soccer training during the seven-week period. The hamstring strength was assessed through an isokinetic concentric test in sitting position at velocity of 60°/s, 6 maximal contractions were measured. The second, third, fourth and fifth contractions were averaged for the determination of the optimum angle by fitting a 4th order polynomial curve 2. These measurements were repeated before and after of the intervention period for both groups. Data was analyzed with general linear model of repeated-measures, the priori level of statistical significance was set at p≤0.05. **Results** Significant different were observed in the optimum angles of knee flexors of the non-dominant leg of the EG (EG: 41.46 ± 2.2° pre-test and vs 36.13±2.4° post-test; p=0.030). Secondly, also were found significant different for non-dominant leg between both groups (EG: 36.13 ± 2.4° vs CG: 42.7 ± 2.4°; p=0.40). **Discussion** As claimed other authors 2, a preventive program of eccentric strengthening increases the optimum angles of the knee flexors. However, in our study such differences only were observed in the non-dominant leg of the EG, due to a difference in the optimum angle of knee flexors of each leg in pre-test. **References** 1. ## **Psychology**

### **INFLUENCE OF PSYCHOLOGICAL FACTORS ON FOOTBALL INJURIES**

Vago, P.1, Senesi, A.1, Frattini, G.1, Casolo, F.1, Gatti, M.2

Università Cattolica del Sacro Cuore - Milano (Italy)

**INTRODUCTION:** Current literature demonstrates that injury may have important psychological implications for competitive athletes including disruptions in mood state, a loss of positive social identity and uncertainties regarding the prospects of a return to pre-injury competitive levels. However, there is limited knowledge on the influence of psychological factors on football injuries. The aim of this study was to examine how much an injury-prone personality profile and symptoms of generalized anxiety disorder can influence the risk of injury in adult football players. A self-administered questionnaire inquired about the anxiety disorders as well as personality traits. **METHOD:** a population of 100 football players was divided into 3 groups: 52 players aged 18-25 yrs, 32 players aged 26-35 yrs, 16 players aged 36-45 yrs. Data gathering was based on an epidemiological questionnaire, the Big Five Questionnaire (Caprara, et al, 1993) and the Stai - Trait Anxiety Inventory with subscales Y-1 and Y-2 (Spielberger, et al, 1968). The participants were asked to rate questions using test-specific scales. Factor analysis of the data was performed and the matrices of correlation were tested with Principal Components (Oblimin Rotation) using SPSS software (Statistical Package for Social Sciences). Factor analysis simplified the variables, and the most

significant ones were interpreted. The Big Five broad factors (dimensions) of personality traits are: Extraversion -Agreeableness - Conscientiousness – Neuroticism-Openness to Experience The STAI Form Y measures anxiety and clearly differentiates between the temporary condition of “state anxiety” and the more general and long-standing quality of “trait anxiety”. RESULTS: Our football players were mainly midfielders (39) and defenders (31), with most active for > 10 yrs. Clinical examination revealed that most prevalent injuries were muscle and ankle strains (68%) and most injured anatomical structures were ligaments followed by tendons. Big Five factors and Stai were significantly correlated ( $R = 0.58, P < 0.01$ ) and also muscle-tendon strains with Stai Trait Inventory. DISCUSSION: There is a growing realisation that psychological factors, such as stress and anxiety, may also play a role in the frequency and extent of injury. The findings support suggestions that psychological measures have utility in predicting football injuries, as confirmed also for their validity in predicting injuries in elite athletes (Ivarsson et al. 2010). ### **THE EFFECT OF MENTAL TRAINING IN COLLEGIATE WOMEN'S FOOTBALL PLAYERS. : AN EXAMINATION OF PSYCHOLOGICAL COMPETITIVE ABILITY.**

Hasagawa, N., Koakutsu, A., Yao, N.

*AICHI TOHO UNIVERSITY., NATIONAL DEFENSE ACADEMY., TOKAI UNIVERSITY*

Introduction Psychological skills are very important factor in football games. And Psychological competitive ability is one of important factors in perform peak performance in football games, too. The purpose of this study was to examine the effect of mental training in collegiate women's football players. Methods Twenty-one female players (age:  $19.4 \pm 0.9$  years, 5 forwards, 6 midfielders, 8 defenders, 2 goalkeepers), who belong to the Aichi women's football division I league, participated in this study. They provided mental training program at 20 weeks. The effects of mental training were investigated using DIPCA 3. Results 8 factors of Psychological competitive abilities were increased after mental training program. Especially, they are significant increased Patience and Volition for self-realization ability. Discussion This mental training program was effectiveness for Collegiate Women's Football players. But all factors weren't increased after mental training program. Furthermore, it is necessary to improve this mental training program. ### **DECISION MAKING AND PERFORMANCE IN VOLLEYBALL. A STUDY IN TRAINING STAGES.**

Claver Rabaz, F., Carrasco, F., Gil, A., Moreno, A., Moreno, M.P.

*Faculty of Sport Science. University of Extremadura*

Introduction In the study of the decisional process in sport there are variables that interact to result in a specific decision in a game situation (Garcia et al., 2011). In this sense, the relationship between performance and cognitive variables was studied in various sports, such that players who showed a higher success in the decision reached a higher level of performance (Nielsen & McPherson, 2001). The goal of the study was to analyze decision-making and performance, depending on the role of game play volleyball players in action defense. Methods The sample was composed of 10 Under-16 players. The independent variable was game function, differentiating between defense specialists and non-specialists. The dependent variables were decision making, evaluated by the GPAI of Oslin et al. (1998) adapted for defense in volleyball, and performance in the defense action, measured by the statistical system FIVB (Coleman, 1975). Results No significant differences were found, based on the function involved nor in decision-making ( $F_{1,8} = 2.02, p = .193; \eta^2 = .202$ ), or performance in the defense action ( $F_{1,8} = .39, p = .548; \eta^2 = .047$ ). Discussion The results show that in formative stages, specializing in defense is not a determinant factor for sports performance in this action game. Thus, players who are at the beginning of sports training should conduct a comprehensive training in the different roles involved in volleyball. Subsequently, in a progressive manner, functional specialization will be structured, first defining the setter, and finally, the defense specialists, such as the libero (Mesquita et al., 2001). ### **TRACING THE PERSONOLOGICAL PROFILE OF INJURY-PRONE SOCCER PLAYERS**

Vago, P.1, Casolo, F.1, Cereda, F.1, Colombo, L.2, Gatti, M.2

*Catholic University of Milan, Italy*

INTRODUCTION In recent years a new line of research studies confirmed the relationship between the main personality traits and the injury risk, especially among soccer players (Johnson and Ivarsson, 2013). In addition, findings from other studies, including soccer players as participant, suggest that psychological factors such as competitive stress, anxiety and daily hassles are associated with increase injury risk (Adie, Duda et al., 2010). The aim of this study was to trace an early personological profile of the male soccer players who are prone to injuries. METHOD: The participants of the study were 100 soccer male players (aged 18 to 45 years), 37 defenders, 39 midfielders, 24 strikers. Each player filled in a qualitative questionnaire about his personal characteristics and sport practice (trainings, matches, etc.) and any previous injury. The participants also completed the Big Five Questionnaire (Caprara et al, 1993), that studies the big personality traits (open-mindedness, conscientiousness, energy, agreeableness, neuroticism/emotional stability). RESULTS: The data were tested for correlations between personality traits and number of injuries (divided in specific types). Meniscal injuries were positively correlated with conscientiousness ( $\rho = 0.209, p < 0.05$ ); tendinopathies were negatively correlated with agreeableness ( $\rho = -0.223, p < 0.05$ ), emotional stability ( $\rho = -0.280, p < 0.05$ ) and open-mindedness ( $\rho = -0.200, p < 0.05$ ). Fractures were also negatively related with agreeableness ( $\rho = -0.255, p < 0.05$ ) and emotional stability ( $\rho = -0.376, p < 0.01$ ). Personality differences between subjects who reported injuries and those that did not were also explored. Players with past meniscal injuries were found to be also more conscientious (Mann-Whitney's Test,  $p < 0.05$ ); players with past tendinopathies had lower values of agreeableness (T test,  $p < 0.05$ ), emotional stability and open-mindedness (T test,  $p < 0.05$ ); finally players with past microfractures (tiny breaks) had lower values of agreeableness and emotional stability (Mann-Whitney's Test,  $p < 0.05$ ). DISCUSSION: Soccer players with past injuries tend to show a more neurotic profile (less emotionally stable), but also other personality traits tied to specific types of accidents which warrant further investigation. ### **SOCIAL ENVIRONMENT, NEED SATISFACTION AND WELL-BEING IN HIGH-PERFORMANCE ATHLETES**

Castillo, I., Galilea, B., Alvarez, O., Balaguer, I.

*University of Valencia*

**Introduction** The Basic Need Theory, a sub-theory in the self-determination theory framework (SDT; Deci & Ryan, 2000) has postulated that an autonomy supportive environment should promote athletes' well-being and these associations will be mediated by the satisfaction of the three psychological needs (autonomy, competence and relatedness). In this study a model was proposed testing the hypothesized associations between athletes' perceptions of coach autonomy support, need satisfaction, and three indicators of well-being. It was hypothesized that as more autonomy support the athletes perceive more needs satisfaction will be informed and in turn more well-being will be perceived. **Methods** A total of 137 athletes (male = 51 and female = 86) from different sports training at the Centre de Tecnificació Esportiva de Esplugues de Llobregat (Barcelona, Spain), ranging in age from 14 to 18 years ( $M = 15.6$ ;  $SD = 1.02$ ), participated in this study. All participants had been practicing sport 4 days per week ( $M = 4.36$ ;  $SD = 0.65$ ), for over 4 hours per day ( $M = 3.80$ ;  $SD = 1.04$ ) and had worked with their coach for 2 years ( $M = 2.26$ ;  $SD = 1.12$ ). Participants completed a multi-section inventory including the Spanish adaptations of: Sport Climate Questionnaire (SDTwebsite; Balaguer et al., 2009; Subscale of Perceived competence from the Intrinsic Motivation Questionnaire (McAuley et al., 1989; Balaguer et al., 2008); The scale of the need for autonomy (Reinboth and Duda, 2006; Balaguer et al., 2008); The acceptance subscale of the need for relatedness scale (Richer and Vallerand, 1998; Balaguer et al., 2008). The subjective vitality scale (Ryan and Frederick, 1997; Balaguer et al., 2005) Subscale of Self-esteem of Self-Description Questionnaire III (SDQ-III, Marsh et al., 1994; Balaguer, Castillo, & Duda, 2008); and Satisfaction with life scale (Diener et al., 1985; Aienza et al., 2000). **Results** Structural Equation Modeling analyses showed athletes' perceptions of coaches' autonomy support positively predicted their psychological need satisfaction ( $B=0.40$ ). Finally, subjective vitality ( $B=0.58$ ), life satisfaction ( $B=0.41$ ) and self-esteem ( $B=0.49$ ) were positively predicted by the psychological needs satisfaction. **Discussion** Overall, findings support the importance of social psychological atmosphere in order to predict well-being via psychological need satisfaction. **References** Deci, E. L., & Ryan, R. M. (2000). The "what" and "why" of goal pursuits: human needs and the self-determination of behavior. *Psychological Inquiry*, 11(4), 227-268.

### **TESTING THE MULTI-ACTION PLAN INTERVENTION MODEL: A MULTI-METHOD ASSESSMENT WITH ELITE SHOOTERS**

Di Fronso, S., Robazza, C., Bortoli, L., Filho, E., Ripari, P., Bertollo, M.

*D'Annunzio University*

**Do not insert authors here** **Introduction** The multi-action plan (MAP) model reflects the notion that different psycho-bio-social states underlie distinct performance-related experiences. Previous empirical evidence suggests that attentional focus, affective states, and psychophysiological patterns differ among optimal-automatic (type 1), optimal-controlled (type 2), suboptimal-controlled (type 3), and suboptimal-automatic (type 4) performance experiences (Bortoli et al., 2012; Bertollo et al., in press). The aim of this study was to test the cortical pattern underpinning the performance categories conceptualized in the MAP model. **Methods** Five elite pistol shooters, members of the Italian Shooting Team, participated in the study. They ranged in age from 16 to 30 years and had extensive international experience. Participants performed 120 air-pistol shots at 10 meters from an official target. Following each shot, they reported perceived control and accuracy levels on a 0-11 scale. Objective performance scores were also gathered. Electroencephalogram (EEG) activity was recorded through a 32 channel system Advanced Neuro Technology (ANT). Alpha ERD/ERS analysis was performed. **Results** MANOVA analysis (2 performance  $\times$  2 control level) was conducted on the amplitude of alpha ERD/ERS assessed during the second preceding each shot. Findings revealed differences in cortical activity as related to performance categories ( $p < .001$ ). Specifically, type 1 performance (optimal-automatic) was characterized by clear ERS in the bilateral centro-parieto-occipital areas. The opposite effect was observed for type 3 performance, with clear ERD in the occipital area. Variations of this pattern were noticed for type 2 (optimal-controlled) and type 4 performance experiences. **Discussion** Overall, findings showed that lower cortical activation was associated with type 1 performance (optimal-automatic), thereby lending support to the well-established "neural efficiency hypothesis". Additionally, results confirmed that athletes may attain a good level of performance, even in conditions of low level of cortical arousal, when exerting control of idiosyncratic core components of action. These findings are congruent with the MAP framework, in which unique psycho-bio-social states underlie distinct performance-related experiences. **References** Bertollo, M., Bortoli, L., Gramaccioni, G., Hanin, Y., Comani, S., and Robazza, C. ### **EFFECTS OF SPORTS CLUB MEMBERSHIP, SEX, AND AGE ON PHYSICAL SELF-CONCEPT AND GOAL ORIENTATION IN GERMAN PRIMARY SCHOOL CHILDREN**

Lohbeck, A., Tietjens, M., Bund, A.

*University of Bremen, University of Muenster, University of Luxembourg*

**Introduction** The development of both a positive self-concept and an adequate goal-orientation is generally seen as a crucial factor in childhood and adolescence (e.g., Harter, 2007). Due to its social and performance-orientated structure, sport acts a socializing agent and plays an important role for the setting of these individual attributes (e.g., Conzelmann et al., 2011). However, little is known about the status quo of physical self-concept and goal-orientation in children of primary school age and in which extent it is affected by sports club membership, sex, and age. The aim of the present study was to analyze these relationships. **Methods** A sample of 365 primary school children of second ( $n = 176$ ,  $Age = 7.5$ ) and fourth grade ( $n = 189$ ,  $Age = 9.5$ ) completed questionnaires of physical self-concept and goal-orientation (see Lohbeck et al., under review). Items were reduced and linguistical simplified to be suitable for primary school children; in case of lack of understanding they were explained by the first author. Overall, the validation of modified questionnaires led to satisfying results (see Lohbeck et al., under review). **Results** Data were analyzed in separate  $2 \times 2 \times 2$ -ANOVAs with physical self-concept and goal-orientation as dependent variables. With regard to the physical self-concept, children belonging to a sports club reported significantly higher values than non-involved children,  $F(1,357) = 54.51$ ,  $p < .001$ ,  $\eta^2 = .13$ , as well as boys than girls,  $F(1,357) = 9.93$ ,  $54.51$ ,  $p < .01$ ,  $\eta^2 = .03$ . Age had no effect,  $F(1,357) = 1.56$ ,  $p > .2$ . Relating to goal-orientation, sports club membership and sex had

effects only on some subscales, however, second graders generally scored higher values than fourth graders, e.g.,  $F(1,357) = 22.64, p < .001, \eta^2 = .06$ . Discussion Findings show that yet in primary school age being in a sports club has a positive effect on the physical self-concept. The difference between boys and girls was found in prior studies too and has to be considered as a gender effect. Surprisingly, 7-year-old children demonstrated stronger achievement goals and motivation than 9-year-old children. Further studies should include motor performance tests to assess not only the level of physical self-concept but also its veridicality. References Conzelmann, A., Schmidt, A. & Valkanover, S. ## OPTIMIZING SELF-EFFICACY AND ANXIETY THROUGH COMPREHENSIVE COMPETITION PLANS IN CYCLING

Geisler, G.1, Linton-Boyce, B.2

1. *University of Tsukuba*, 2. *University of Edinburgh*

**Introduction** A common issue for athletes is the effect of pre-competitive anxiety on performance. This includes both the intensity and direction (interpretation) of anxiety. Self-efficacy is thought to be an important antecedent and mediator of anxiety (Hall et al., 1998) in that high efficacy individuals may view anxiety as a sign of psychological readiness whereas low efficacy competitors are more likely to perceive it as a sign of stress. To address athletes' psychological preparation, Arruza et al. (2009) noted that pre-competition plans can have a positive effect on perceived performance and anxiety, and that more emphasis should be placed on the development of such plans. Therefore, the aim of this study was to examine the effect of comprehensive competition plans on anxiety and self-efficacy among competitive cyclists in Barbados. **Methods** Eight competitive cyclists (aged 15-28 years) took part in a four-week program in which they learned to formulate and follow several pre-race plans during training. The plans were broken down into race segments and included imagery as well as mood-related cue words. At the end of this education period, the athletes developed similar plans for a competitive event. Data on four anxiety measures (cognitive and somatic anxiety intensity and direction) and self-efficacy were collected before and after the program via the CSAI-2 (Martens et al., 1990) and a two-item self-efficacy measure, respectively. Changes in the dependent variables were assessed through paired samples t tests while regression analyses were used to test whether self-efficacy could predict participants' scores on the four anxiety measures. **Results** After the program, there were significant decreases in cognitive and somatic anxiety intensity as well as more positive interpretations of somatic anxiety. However, there were no significant differences in self-efficacy. Of the eight regression analyses conducted, self-efficacy emerged as a predictor of cognitive anxiety intensity and somatic anxiety direction. **Discussion** The findings suggest that competition plans can decrease cyclists' anxiety intensity, likely through the knowledge of what needs to be done and what their abilities will allow them to do at different stages of a race. It is also possible that reductions in somatic (or bodily) anxiety intensity can lead to more facilitative somatic interpretations through a sense that physical symptoms are indicative of an excitement and confidence about taking on the various race segments as practised in the competition plans. Current evidence suggests that to reduce or optimize anxiety, competition plans should be developed for specific phases of races and sports competitions. **References** Arruza JA, Tellechea S, Gil de Montes L, Arribas S (2009). *Per & Mot Skills*, 109, 304-314. ## CORRELATION BETWEEN BMI AND COGNITIVE FUNCTIONING IN SCHOOL PUPILS IN TIRANA ALBANIA

Canaj, F.1, Qeleshi, A.1, Nurja, F.2, Canaj, K.1

1: *SPORTS UNIVERSITY OF TIRANA*, 2: *UNIVERSITY OF SHKODRA*,

**CORRELATION BETWEEN BMI AND COGNITIVE FUNCTIONING IN SCHOOL PUPILS IN TIRANA ALBANIA** **Introduction** The study tested the effect of physical development on executive functions in (7 to 14 years age) children. Pupils in this age represent a wide diversity of their development profile which differs in the terms of physical and cognitive parameters. Pupils have a great need for physical activity that comes out through the leisure time games they play or improvise. **Cog. funct. & executive funct.** in pupils may be particularly sensitive under the influence of increased physical activity, related to BMI changes. But how is the correlation between the physical development (BMI) and executive functions in inactive and active pupils, or in those who become active by increasing physical activity. **Methods** In this study participated 187 children (91 m. & 96 f.) from 1st to 7th grade. Conducted tests were: 1) RT to simple acoustic stimuli 9.86ms ( $\pm 1.92$ ), RT to simple visual stimuli 326.8 ( $\pm 1.11$ ), Attention control test 0.60 ( $\pm 1.18$ ). **Correl. analysis** was applied using P. **Correl.** if there is any correlation between the test scores and the child ability to these cognitive redevelopment parameters. **The Results of P. correlation coeff. and p-values (2-tailed) between BMI and cogn. tests revealed:** a) a significant positive correlation between scores of RT to simple visual and acoustic stimuli. ( $p=.78$ ). b) a significant positive correl. between BMI and balance test ( $p=0.21$ ). **One-way ANOVA** was used to evaluate diff. based on gender and age, **And pointed out:** a) no significant differences between males and females. b) **Signif.diff.** between grades. **Results** The results of Pearson correlation coeff. and p-values (2-tail.) between BMI and the cognitive tests revealed: a) there was a significant positive correlation between scores of RT to simple visual and acoustic stimuli  $p=.78$  related to BMI. b) There was a significant positive correlation between BMI and balance test  $p=0.21$  related to BMI. **One-way ANOVA** was used to evaluate diff. based on gender and age. **ANOVA results pointed out:** a) there were no significant diff. between m&f. b) There was significant diff. between grades (from 1 to 7). **References** Bouchard, C. 1994. ## STRUCTURAL EQUATION MODELING OF THE EFFECT OF COACH LEADERSHIP STYLE ON TEAM COHESION OF HIGH PERFORMANCE INDOOR SOCCER TEAMS

Nascimento Junior, J.R.A., Vissoci, J.R.N., Serpa, S., Pietrobon, R., Vieira, L.F.

*Maringá State University*

**Introduction** The development of sports group is characterized by being a dynamic process with constant changes in the processes of interaction and comprises a system of mutual connections of roles and relationships among group members (TRNINIC et al., 2008). In

this context, leadership style is considered a crucial factor for the development of group cohesion, cohesion being a psychological variable critical to the performance and success of a sports team (CARRON; HAUSENBLASS; EYS, 2005). Therefore, this study aimed to validate a predictive model concerning Coach Leadership and Group Cohesion in indoor soccer teams. Methods Participants included 120 male adult indoor soccer athletes from eight teams competing in the Brazilian Professional League, Brazil. Instruments for data collection were the Leadership in Sport Scale (LSS) and the Group Environment Questionnaire (GEQ). Data analysis was conducted through Structural Equation Modeling ( $p < 0.05$ ). Results Results evidenced a good model fit indicators for the proposed model (effect of coach leadership in social and task cohesion) and significant trajectories between all the variables ( $CF > 0.50$ ); the coach leadership style characterized as democratic and based on social support, reinforcement and training-instruction influenced positively task cohesion ( $CF = 0.70$ ) and moderately social cohesion ( $CF = 0.37$ ). Discussion For the indoor soccer from the state of Parana, the coach's leadership style based on democratic, reinforcement, social support and training-instruction behaviors is determinant to the development of task cohesion; however, it doesn't have the same importance for social cohesion. Carron, Eys and Hausenblass (2005) suggest that the higher the competitive level of the team is the smallest is the influence of the coach in social aspects of cohesion. Jowett and Chaundy (2004) emphasize that the leadership behaviors of training, education, democratic leader, support and feedback predict more task than social cohesion. Moreover, this study allows us to have a better understanding about the relationship between the variables and the importance of the coach to the development of team cohesion. References Carron AV, Hausenblass AA, Eys MA. (2005). *Group Dynamics in Sport*. Morgantown, WV: Fitness Information Technology. Jowett S, Chaundy V. (2004). An investigation into the impact of coach leadership and coach-athlete relationship on group cohesion. *Group Dynamics: theory, research and practice*, 8(4), 302-311. Trninic V, Papic V, Dimec T. (2008). Concepts of developing groups in sports games. *Acta Kines*, 2(2), 85-92.

### **LEADERSHIP STYLE OF COACHES OF HIGH PERFORMANCE BRAZILIAN INDOOR SOCCER TEAMS**

Nascimento Junior, J.R.A., Vieira, L.F., Nascimento, J.V.

*Maringá State University*

Introduction The literature has pointed out that a great sports coach is one that offers good support to the athletes, providing strategies and resources for developing athletes' performance and achieving the goals of the team. Thus, he may be considered a key factor for the athlete's performance in games and competitions (CHELLADURAI, 2007). Therefore, the goal of this study was to analyze the leadership style of coaches of high performance Brazilian indoor soccer teams. Methods The study included 122 athletes - members of eight indoor soccer teams participating in a Brazilian Professional League and their respective coaches, totaling 130 subjects. The instruments used were the Leadership Scale for Sports and a semi structured interview. For data analysis, it was applied the Kolmogorov-Smirnov, the Mann-Whitney ( $p < 0.05$ ) and Content Analysis. Results Athletes perceived that their coaches behavior is based mainly on training-instruction ( $Md = 4.2$ ), reinforcement ( $Md = 4.1$ ) and social support ( $Md = 3.7$ ); by comparing the coaches' self-perception, the perception and preference of athletes, it was found significant difference between athletes perception and preference in "training-instruction" "reinforcement" and "autocratic" dimensions. This finding shows that athletes would like their coaches provide further instruction and reinforcement during training and more autocratic in their decisions; in the analysis of the interviews it was found that athletes realize that their coaches are participatory during training and games, however, that such participation could be more intense, with more demonstration of authority. Discussion Our results indicate that there is a strong tendency for coaches to value more the behavior of training-instruction, reinforcement and social support, and the preference of athletes by autocratic style, which is confirmed by the literature (Chelladurai, 1990; Vincer and Loughhead, 2010). Thus, for the sporting context of high performance Brazilian indoor soccer, the leadership style is more oriented to optimize the athletes performance, emphasizing the instructions about the skills, techniques and strategies, which enables a positive feedback (reinforcement) regarding performance. ### **MOTIVATIONAL CLIMATE GENERATED BY SIGNIFICANT OTHERS AND LIFE SKILLS IN YOUTHS**

Bufo, A., Marchetti, R., Pesce, C.

*University of Rome Foro Italico*

Introduction The situational differences created by significant others, such as teachers, parents, coaches are reflected in the motivational climate perceived by youths and affecting their individual characteristics, such as achievement goals, self-determination, self-efficacy, skills and adaptive/maladaptive behaviors. However, there still is scarce evidence on the potential associations between a mastery vs. performance oriented climate generated by PE teachers, parents, and coaches and youths' self-perceptions in life skills which are considered protecting factors against maladaptive behaviours (WHO, 2003). Thus, this study examines if the motivational climate created by significant others (parents, coaches and teachers) and the individual motivational orientation in sports are associated with youths' self-awareness in setting goals and self-efficacy in intra- and interpersonal life skills. Methods Hundred and seventy-three junior-high school students were administered questionnaires evaluating their: (1) achievement goal orientation in sport and PE (Duda & Nicholls, 1992); (2) teacher-, parents-, and coach-initiated motivational climate (White et al., 1996; Whitehead et al., 2004; Papaioannou et al., 2007); (3) Self-efficacy in and knowledge of life skills (Caprara, 2001; Danish, 2000). Total scores for task vs. ego, mastery vs. performance, learning/enjoyment vs. worry conducive/success-without-effort scales were computed and submitted to bivariate correlation analyses. Results Pupils' task orientation and perception of mastery and learning/enjoyment climate were positively correlated with their perception of self-efficacy in positive emotion, school achievement, and social relations. Conversely, the latter except for the emotional skill were negatively correlated with a worry conducive climate generated by parents. Also, a positive correlation emerged between parents-initiated learning/enjoyment climate and pupils' self-efficacy in self-regulation and between mastery oriented climate in PE/sport and pupils' goal setting knowledge. In contrast, the latter was negatively correlated with a performance oriented, worry conducive and success-without-effort climate. Discussion Results, even though correlational in nature, highlight the role played by significant others in the development of youths' life skills, suggesting that a mastery, learning and enjoyment climate may positively contribute to it, while a climate that is performance oriented, worry conducive and reinforces success without effort may be detrimental. ## DOES FITNESS LEVEL MODULATE VIGILANCE OF YOUTH PEOPLE?

Bermejo, J.1, Ballester, R.1, Yuste, F.1, Llorens, F.1, Sanabria, D.2, Huertas, F.1

1: *Universidad Católica de Valencia*, 2: *Universidad de Granada*

**Introduction:** The study of the effects of physical exercise on cognitive processing is increasing in recent years. Many studies show how physical exercise modulates cognitive processes in different population groups (see review of Hillman, Erickson, & Kramer, 2008). Vigilance is very important in sport since it regulates the ability of the athlete to maintain the attention that allows him to capture and interpret information about the context. Previous studies carried out by our research group with children from 10 to 12 years found that those who practiced a sport (football) systematically (more than 5 h/week) had better attentional performance than those who are not practicing exercise in a systematic way (less than 2 h/week). However, the design employed in the experiment refused to clarify if this effect was due to the regular practice of a sport with high cognitive load or the level of fitness of the participants. **Method:** The objective of this study was to examine whether there is any relation between the systematic practice of a sport predominantly perceptual (football), the fitness level (VO<sub>2</sub> max through the Test Course Navette and recovery of the heart rate) and the vigilance (reaction time in psychomotor vigilance task) in children aged 12-13 years (children with a level of less than 2 hrs/week practice vs footballers from lower levels of a 1st division team). **Results:** Our study has found positive relationships between fitness level and vigilance measured by a psychomotor vigilance task. **Discussion:** Our results indicate that, at least in the early ages, attentional performance seems to be more modulated by variables associated with the physical condition of the participants than the experience which could result of the systematic practice of a particular sport predominantly perceptual. **References:** Hillman CH, Erickson KI, Kramer AF: Be smart, exercise your heart: exercise effects on brain and cognition. *Nature*. 2008; 9:58-65. ## PSYCHOMETRIC PROPERTIES OF THE BASIC PSYCHOLOGICAL NEED SATISFACTION SCALE IN SPANISH YOUNG FOOTBALL PLAYERS

González, L.1, Castillo, I.1, Torregrosa, M.2, Mercé, J.1, Soriano, G.2, Cruz, J.2, Balaguer, I.1

1: *Universitat de València (Spain)*, 2: *Universitat Autònoma de Barcelona (Spain)*

Self-determination theory (SDT; Deci & Ryan, 2002) suggests that the satisfaction of the basic psychological needs for autonomy, competence and relatedness are important predictors of optimal functioning in different contexts including sport. The purpose of this study was to analyze the psychometric properties of the Spanish version of the Basic Psychological Need Satisfaction Scale in sport. The participants in the study were 2245 grassroots football players (2041 males, 201 females, and 3 did not report gender) between the ages of 9 to 16 years old ( $M = 11.49$ ;  $SD = 1.19$ ) from 188 youth football teams corresponding to 39 football clubs in four regions in Spain (Barcelona, Castellón, Lleida and Valencia) pertaining to the European Project PAPA (Promoting Adolescent Physical Activity). On average, participants had played competitively for 3 years or more and they train with their respective teams 4.66 hours per week ( $SD = 1.19$ ). The participants completed a questionnaire package which included Basic Psychological Need Satisfaction Scale in football (i.e., autonomy, competence and relatedness), and Subjective Vitality Scale. Exploratory factor analysis, Cronbach's alphas and Pearson's correlations were employed to examine scale validity and reliability. The exploratory factor analysis showed a three-factor solution: competence (6 items), relatedness (4 items) and autonomy (4 items) accounting for 52.6% of the variance, with eigenvalues after rotation of 4.7, 1.5 and 1.1 respectively. Factor correlations ranged from .30 to .56. The reliability analysis showed good internal consistency (competence  $\alpha = .79$ , relatedness  $\alpha = .76$ , autonomy  $\alpha = .60$ ). Satisfaction of the basic psychological needs in young football players maintained a significant relationship in expected accordance with subjective vitality (competence and vitality = .46; relatedness and vitality = .50; autonomy and vitality = .22), which showed evidence of the construct validity and was consistent with the theoretical predictions. In sum, the results provided evidence of construct validity of the Basic Psychological Need Satisfaction Scale in Spanish young football players. This research was funded by the European Commission under the Seventh Framework Program - Health - 223600 - as part of the Project PAPA ([www.projectpapa.org](http://www.projectpapa.org)).

## Rehabilitation

### THE USE OF OBSERVATION IN REHABILITATION SETTINGS: APPLICATION OF AN APPLIED MODEL

McCullagh, P.1, Ste-Marie, D.M.2, Rymal, A.M.1, Hall, C.3, Law, B.4, O, J.1

1: *California State University East Bay (Hayward, USA)*, 2: *University of Ottawa (Ottawa, Canada)*, 3: *Western University (London, Canada)*, 4: *Nipissing University (North Bay, Canada)*

**Introduction** Over the last one hundred years there have been a variety of theoretical explanations to explain how one learns or changes behavior as a result of watching others. These theoretical orientations tended to parallel paradigms of the era and ranged from instinctual (Tarde, 1903), associative (Allport, 1924), reinforcement (Miller & Dollard, 1941), social-cognitive (Bandura, 1965-1997, Zimmerman, 2000), direct perception (Scully & Newell, 1985), and recently neurophysiological explanations (diPellegrino, Fadiga, Fogassi, Gallese, & Rizzolatti, 1992). Despite the varied theoretical orientations, little attention has been paid to how demonstrations can be used in practical settings. **Method/Results** This presentation will focus on the where, what, who, when, where, why, and how of using demonstration as suggested in a recent review that developed a model to be used by practitioners when using demonstrations (Ste-Marie, Law, Rymal, O, Hall, & McCullagh, 2012). Ninety one research papers were reviewed in developing the model. In addition observer characteristics as well as task characteristics were examined to determine the influence of all these variables on motor, cognitive, and affective outcomes. **Discussion** The model will be used as the basis for suggesting how to use demonstrations in rehabilitation settings. For example, when individuals are progressing through the rehabilitation process would it be better to show them a mastery model (someone who have already overcome the injury and is performing optimally) or a coping model (someone who is progressing through the rehabilitation process similar to your client). Other examples will be provided. **Selected References:** Ste-Marie, D.M., Law, B., Rymal, A.M., O. J., Hall, C., McCullagh, P. (2012). **Introduction** Participation in exercise program after breast cancer treatment has been significantly associated with a reduction in the risk of death and an improvement in quality of life (Holmes et al., 2005, Schneider et al., 2007). The aim of this study was to investigate the training and detraining effects of a combined resistance and aerobic training program in muscular strength and quality of life in women who have completed breast cancer treatment. **Methods** Ten women (age: 44.0±5.2 yrs) participated in a combined aerobic and resistance exercise program for 16 weeks. Training was supervised and lasted 16 weeks with a weekly frequency of 3 days per week. Muscular strength of lower limbs (10 RM) was measured at baseline, after 5 and 16 weeks of training as well as after 8 weeks of detraining. Finally quality of life was assessed with the Eortc QLQ-C30 questionnaire (ver. 3.0) at the beginning, at 16 and 24 weeks (Cull et al., 1998). **Results** The exercise training programme resulted in a significant strength improvement (leg extension: +53.1%, p<0.05, leg press: +59.9%, p<0.05) after 16 weeks. However 8 weeks of detraining, resulted in a significant reduction of muscular strength (leg extension: -20.4%, leg press: -15.3%, p<0.05). In quality of life feelings of weakness and tiredness significantly decreased by 45% and by 39% respectively while the feelings of sadness and easily anger decreased 33% (p<0.05). Finally the overall health and quality of life score was statistically improved at the end of the intervention period. **Discussion** Results of the present study indicate that combined exercise is an effective way to increase muscular strength and promote quality of life in women after breast cancer, highlighting the need for uninterrupted exercise throughout life. **References** Holmes M, Chen W, Feskanich D, Kroenke C., Colditz G. (2005). *JAMA*, 293:2479–86 Schneider C., Hsieh C., Sprod L., Carter S., Hayward R. (2007). *Annals of Oncology* 18: 1957. Cull A., Sprangers M., Bjordal K., Aaronson N. (1998). ISBN: 2-930064-15-3.

## **AQUATIC PULMONARY REHABILITATION: A PROPOSAL FOR THE PROMOTION OF HEALTH AND QUALITY OF LIFE IN PATIENTS WITH COPD.**

Neiva, C.M.1,2,3, Carvalho, A.S.1,4, Ferreira, M.G.A.M.1,5, Pessoa-Filho, D.M.2, Verardi, C.E.L.2, Ciolac, E.G.2, Quemelo, P.R.1, Souza, D.G.1

*1-UNIFRAN (Brazil); 2-UNESP (Brazil); 3-UNAERP (Brazil); 4-UNIARAXÁ (Brazil); 5-FACULDADES ATHENAS (Brazil)*

**Introduction** COPD is a disease that causes changes in lung function, dyspnea and peripheral skeletal muscle dysfunction. These factors lead to exercise intolerance and progressive worsening of fitness, with the consequence of social isolation, anxiety and addiction. Hydrotherapy can be used as a treatment for being a physiotherapy technique that provides an effective systemic improvements to these individuals, improving their quality of life. The objective of present study was to evaluate the impact and effectiveness of an aquatic therapy program in patients with COPD on improving the quality of life and evaluate this process in the context of health promotion. **Methods** The methods used were the following tools for data collection, evaluation form containing patient's medical history; manometer test, peak flow test; six-minute walk, quality of life questionnaire (SGRQ). We performed an initial assessment, the volunteers were treated from the intervention of an aquatic exercise program for 12 weeks and then reassessed. **Results** According to the results we are seeing an improvement in the PI Max. and PE.Max in 75% of the participants. Yet they're significant differences between the mean values of the phases before and after 12 weeks of hydrotherapy. We can also observe that the results related to PEAK FLOW for PFE pointed out an improvement until 61% for patients after 8 weeks of training, but there were no differences between 8th and 12th weeks. For the TC6 test we can identify a little but significant improvement after 12 weeks in 75% of the subjects. Finally, from the results obtained, we observed that the study participants had an improvement in physical functional capacity, ventilatory muscle strength and the degree of airway obstruction, having a positive effect on quality of life of these people, as observed data in the questionnaire SGRQ. **Discussion** Considering that this is a cases study due to the low number of subjects studied, we believe that the hydrotherapy to patients suffering from COPD was effective in promoting improvement over expiratory muscle strength as well as functional capabilities and also in general health and quality of life assessed by SGRQ. This, together with issues of low cost, easy applicability and good acceptance of the Protocol, allows us to suggest that the adoption of hydrotherapy as a alternative practice in processes and public policies aimed at promoting the health of the population, should be strongly encouraged. **THE AUTHORS THANKS TO** Mr. JOSÉ ROBERTO JARDIM, Ph.D. ASSOCIATED PROFESSOR OF UNIFESP (BRAZIL) BY CEDING THE CEDING THE RIGHTS TO USE THE SGRQ FOR RESEARCHS IN BRAZIL. **References** CASANOVA, C, COTE, C.G; MARIN, J.M; DE TORRES, J.P; AGUIRRE-JAIME, A; MENDEZ, R. et al. ## **THE EFFECT OF ENDURANCE AND STRENGTH TRAINING ON CHRONIC FATIGUE SYNDROME FOR WOMEN WHO HAVE COMPLETED TREATMENT FOR GYNAECOLOGICAL CANCER - A RANDOMIZED CONTROLLED TRIAL.**

Hausmann, F.1, Iversen, V.V.1, Kristoffersen, M.1, Vika, M.2

*1.Bergen University College, Bergen; Norway, 2.Haukeland University Hospital, Bergen / University of Bergen; Norway*

**Introduction:** Previous studies have shown that participation in physical training and educational and counselling groups may have positive effects on fatigue syndrome in the rehabilitation of cancer patients (1, 3). However, more research is demanded regarding the effects of physical training on chronic fatigue syndrome focusing on women treated for gynaecological cancer (2). The purpose of this study is to evaluate the effect of endurance and strength training on chronic fatigue syndrome for women treated for gynaecological cancer. **Methods:** Subjects: Approximately 600 women who completed curative treatment for gynaecological cancer at Haukeland University Hospital Bergen, Stavanger University Hospital and Sørlandet Hospital Kristiansand, Norway, between January 2007 and December 2011 received a request to participate, 120 accepted. A randomized controlled design was applied in this study: 1) Physical training in group, 2) Education and counselling groups, 3) Control group. The physical training group participated in two sessions per week (90 min) in a total of 16 weeks. The group training was carried out in a gym as follows; warm-up (15 min), endurance training (25 min) moderate to hard intensity, strength training (25 min), stretching and relaxation with focus on body awareness (25 min). The strength training part was performed using simple tools such as elastic bands and weights. All participants performed the same tests pre- and post-intervention and after 1 year. **Tests;** VO<sub>2</sub>peak was measured as a graded exercise test on a treadmill (Woodway, Germany) and maximal strength was measured in leg press, leg extension and chest press. Oxygen consumption was measured using a Jaeger Oxycon Pro in mixing chamber mode (Jaeger, Germany). Strength tests were performed in apparatus (Cybex International UK Ltd). The

---

women were also measured for chronic fatigue syndrome. The Fatigue Questionnaire (FQ) measures the presence and intensity of fatigue symptoms and contains 11 questions where 3 items are used in this context. The total fatigue score is the sum of physical and mental fatigue. Results: Collecting data will be accomplished April 2013 and the results will be fully analysed May 2013. Discussion: The study will indicate if physical exercise, here presented as endurance training and strength training in group sessions, will have significant effects on fatigue syndrome for women treated for gynaecological cancer. ### **OWNERSHIP AND GOVERNANCE OF SPANISH FOOTBALL CLUBS FROM THE FANS' PERSPECTIVE: AN EMPIRICAL EXAMINATION OF THE CONSEQUENCES OF THE COMMODIFICATION PROCESSES**

Llopis-Goig, R.

*University of Valencia*

**Introduction** During the past twenty years, Spanish football has witnessed an intense change process that has transformed some of its main structural characteristics in an extraordinary way. This process has been directly related to the commodification tendencies that have also affected other aspects of social and economic life, and it has had a strong influence on the recent evolution of football, determining aspects as varied as the greater professionalization of players, the corporatization of clubs, the proliferation of merchandising, rule-changes to draw in new customers, and a general redefinition of the competitive structures and ethos of the sport (Walsh and Giulianotti, 2001: 53). This study has set out to examine, from an empirical perspective, the social consequences of the commodification processes of football in the discourse of the sport's fans. **Methods** The analysis was based on interviews with 19 fans, 6 sport journalists and 3 professional sport managers. The fans were supporters of Valencia CF and Levante UD, two clubs with very different characteristics whose fans can be considered to represent the most frequent experiences, opinions and attitudes in Spanish football. **Results** The study has shown, in the first place, that the process of commodification has not affected the fans' feelings of identification with their clubs, although it has affected their repertoire of behaviours. A situation of hyper-consumption has been produced, which explains the growing personalization of football consumption and an intensification of the entertainment-festive dimension of attending matches at the stadiums. Secondly, the study has shown the existence of a sense of symbolic ownership of the club among Spanish fans that explains why the majority of them continue to consider themselves 'members', even though the transformation of the clubs into Limited Liability Sports Companies has turned these fans into shareholders or season ticket holders. **Discussion** This study has proposed the existence of a paradox of football, where fans' fascination with football co-exists with the feeling that the clubs are poorly managed and economically unsustainable. The tension created by these two extremes is resolved by fans distancing themselves from the club in anything not related to strictly sports-related aspects. A transformation occurs, then, of fans into hyper-spectators: consumers of the football show who voluntarily remove from the social dimension of the club. They go to the stadium looking for a psychologically pleasurable experience and only react in a critical way when their team accumulates periods of bad sports results, especially when, in addition, the playing style is not aesthetically pleasing to them. **References** Walsh, A. & Giulianotti, R.: (2001): 'This sporting mammon: a normative analysis of the commodification of sport'. *Journal of the Philosophy of Sport*, 28, 53-77

### **EVALUATION OF BODY MOVEMENTS PRESENT IN TRADITIONAL CHILDREN'S GAMES FROM THE PERSPECTIVE OF THE SOCIOLOGY OF CHILDHOOD**

Mello, A.M.

*UFRJ - Universidade Federal do Rio de Janeiro*

**Introduction** The field of the Sociology of Childhood changed the theoretical and methodological referential in the research on aspects of child culture (Corsaro, 2005). Part of the children's culture, the game is the child social activity and must be learned in the children's sociality context (Brougère, 1995). The traditional games occur in the interaction among peers and are practiced freely by children in different countries in accordance with rules accepted by the groups they belong to. They provide moments of physical activity, discoveries and social interaction. They stimulate basic motor skills like walking, running, throwing, jumping, swinging and such. These skills are formed by the coordinated action of moves that will serve as a basis for more complex learning. They also stimulate psychomotor functions like body scheme, tonus, coordination, spatial and temporal organization, rhythm, fine motor skills, laterality and balance (Mello, 2006). The objective of this study was to conduct a survey of children's traditional games in Brazil to investigate their characteristics as an integral social practice of child culture and to evaluate the bodily movements present in their practice. **Methods** We adopted the qualitative approach (Graton and Jones, 2010) and the methodological referential of the sociology of childhood (Corsaro, 2005; Sirota, 2006) that proposes children should be investigated as actors and subjects of their practices. In different regions of Brazil, 54 teachers, participants in the research as collaborators, observed games, heard the children's reports, developed a dialogue and recorded data on specific sheets. **Results and Discussion** The research recorded 72 traditional children's games in Brazil. Depending on the geographical area, they had different designations and suffered variations on the ways they were performed (examples: hide and seek, kite, goat-blind, marbles, jump rope, hopscotch). They were practiced in squares, streets, backyards and schools courtyards (outside the curriculum). During the games, intense social interaction occurred; 57% were practiced by boys and girls together; the ages ranged from 6 to 12; the predominant age range was 9 to 10 years (89%); on average, the groups had 6 to 10 participants simultaneously (43%). The research confirmed the presence of basic motor skills and psychomotor functions in different body movements recorded during the traditional games. **References** Brougère G (1995). *Jeu et éducation*. ## **AN INVESTIGATION OF LIFESTYLE AND PERCEIVED WELLNESS LEVEL IN JAPANESE COLLEGE FRESHMAN**

Mizumura, S., Tanaka, N.

*Meiji University*

Introduction "Wellness" is "an active process of becoming aware of and making choices toward a more successful existence" by National Wellness Institute (1). It is apparent that the concept of wellness is not widely spread throughout Japan. The authors believe that college students should be familiar with the concept before they graduate (2). Therefore, it is very important to research on parameters of wellness for college students. In the present study, we investigated the scores of the "wellness check test" which can evaluate the degree of lifestyle for wellness, the degree of perceived wellness and relationships between them. Materials & Methods A total of 767 Japanese college freshmen (360 female and 407 male) were surveyed in the present study. They answered the Wellness Check Test that consists of thirty questions divided by six factors as follows: 1) enjoying fitness, 2) eating well, 3) taking care of ourselves, 4) enjoying life, 5) relating to others and 6) being part of the world according to the six-grade system in each question. They also evaluated the degree of their perceived wellness according to the five-grade system. Results & Discussion Our main findings were that 1) the score of "enjoying fitness" of the wellness check test in male students was significantly higher than that in female students while female students scored significantly higher in the other 4 factors, 2) the degree of perceived wellness did not show significant difference between male and female, and 3) the students with higher degrees of perceived wellness showed higher scores of almost all the factors in the Wellness Check Test. Conclusion Our findings suggest that when we lecture on wellness to college freshmen, we should take into account both sexual differences in the scores of the wellness check test and differences of degree in perceived wellness. ## **ANALYSIS OF A PHYSICAL ACTIVITY IN A SPANISH PRISON**

García-Tardón, B.1, Pardo, R.2, Ruiz-Vicente, D.1, García-Pastor, T.1, Theirs, C.I.1, Pérez-Brunicardi, D.1

*1: Camilo José Cela University (Madrid, Spain), 2: Politécnica University (Madrid, Spain)*

INTRODUCTION Sport in prisons in Spain is part of the activities that the current legislation provides. There are several investigations which conclude that sport can contribute to increase the socialization (Castillo, 2004), the compensation of the subculture in prison (Arribas et al., 2001; Castillo, 2004; Chamarro, 1997; Ríos, 1986) or to improve the physical and psychological well-being (Ríos, 1986). The main objective of this study is to determine whether a particular sport physical activity has an effect on the participants and to evaluate the attendance to the activity, in order to determine the convenience of programming these activities. METHODS The study was performed in a football school located in a prison. An adapted questionnaire from Castillo (2004) was provided at the beginning and at the end of the investigation, and an attendance record was used and filled in every session. RESULTS The average of students who attended at the sessions was 24, which makes an average in percentage (over total enrollment) of 83%. The largest reason for not attending at the activity was injury or illness (50%), followed by permits (17%) or performing other activities (17%). In the provided questionnaires, the satisfaction with the coach was good evaluated and most of them asked for an increase in the frequency of the activity. DISCUSSION The high turnover of participants in the activity (because of dropouts) has been a major factor in the study. The main dropouts were due to transfer or release, as Chamarro said (1997). Control of any of these factors would help to this data to be different. Regarding the socialization factor, satisfaction with the coach or with the frequency of the activity, similar data have been obtained to Castillo in 2004, and it can be concluded that physical activity is clearly attractive in a prison environment. ### **EVIDENCE-BASED POLICY-MAKING: IMPLEMENTING EU SPORT POLICY IN HUNGARY**

Baráth, K., Farkas, J.

*Semmelweis University*

In 2007 the Hungarian Parliament unanimously passed the bill on the Sport Strategy of Hungary. It was progressive, but was not followed by the Action Plan including identifying the financial resources. Not surprisingly, the Strategy has not referred to the White Paper on Sport document of the European Union, which was accepted by the European Commission in 2007 as well. Since that time two other EU-level key policy documents have been issued (Communication on the European Dimensions of Sport in January 2011 and the Work Plan on Sport for 2011-2014 in June 2011) and Hungary, as one of the 27 members States actively participates in the implementation of the EU Work Plan on Sport via the active members of the Expert Groups. Nevertheless, still, national level implementation activities were not initiated via sustainable, purposely funded cross-sectoral cooperations and projects. There is a major development takes place in these weeks when a 18-month long national project begins with the financial support of the European Union's Social Fund, Social Renewal Operative Programme. The objective is to prepare a first ever white paper on sport in Hungary, which serves as one of the most significant inputs for a new policy paper and strategy for sport for the Hungarian member state. The call for proposal followed the structure of the White Paper on Sport and requested the applicant organisations to structure their research activities in the tender document along that structure. The authors aim to analyse the objectives and process of this important element of evidence-based policy-making in the field of sport, as one of the possible methods to successfully implement the community-level policy in one of the member states.

## PROBLEMS OF PROFESSIONAL BASKETBALL IN RUSSIA

Likhachev, O., Likhachev, O.E.1, Korshkov, V.A.2, Mazurina, A.V.1, Goryachev, V.A.1

1.Smolensk State academy of physical culture 2: Professional basketball club "Lokomotiv-Kuban", Russia

**Introduction.** Recently Russia started to build modern marketing relations in almost all including sports. All regions of Russia are facing absolutely new problems, highly connected with creation of stable middle and long-term financial systems of professional sport clubs. **Methods.** Initial information as social survey has been gathered during the Russian national championship in 2012/2013. The survey was direct and individual, with the questionnaire of 19 questions with the range of 4-8 possible answers. 36 coaches of professional basketball clubs have taken part in the research. **Results.** The table of problems has been formed and rated due to the remarks of coaches. To their point the solution of the problems mentioned should influence deeply the development of Russian basketball. First problem is the lack of financing of professional clubs. Second problem is the lack of legislative basis regulating the commercial activity in sports. The third place was occupied by the infrastructural problem – the absence of necessary sport halls with enough places and conveniences. The 4th problem lies in the level of basketball mastery of Russian basketball players which is in many cases lower than the skill level of European players. And the 5th problem found is the absence of professional sport managers with the work experience in basketball. **Discussion.** All problems mentioned had the highest priority for all the coaches interviewed. It has to be mentioned that almost none of them mentioned the problem of state financing – which could be easily explained by their professional orientation. It is more important for the coach or the athlete to receive money than to think where to get it. It makes no difference for them if financing comes from the state, sponsor or the ticket program. But this remains the major problem for Russia which could influence the future development of Russian basketball.

## Sport Statistics and Analyses

### OXYGEN UPTAKE RESPONSES DURING CYCLING AT MAXIMAL LACTATE STEADY-STATE AND CRITICAL POWER

Caritá, R.A.C.1, Pessôa Filho, D.2, Greco, C.C.1, Denadai, B.S.1

1. São Paulo State University (Rio Claro, SP), 2. São Paulo State University (Bauru, SP)

**Introduction** Comparisons between the CP and power associated to MLSS suggest that both are different and should not be used interchangeably (Jones et al., 2010). However, a complete physiological steady-state has been recognized up to the boundary circumvented by PC (Jones et al, 2008), which has been either considered to MLSS (Baron et al., 2003). This study aimed to analyze the profile of VO<sub>2</sub> response at CP and MLSS, during cycling exercise. **Methods** Eight active male cyclists (28.1 (3.6) years, 78.5 (12.5) kg, 176.0 (0.09) cm, and 2934.1 (587.3) mlO<sub>2</sub>.min<sup>-1</sup> VO<sub>2</sub>max) did perform, the following tests on different days: incremental exercise until exhaustion to determine peak oxygen consumption (VO<sub>2</sub>peak); 2-4 tests to determine the MLSS; 3 predictive tests (95, 100 and 110% IVO<sub>2</sub>max) for PC estimative; and one to test exhaustion at 100% of CP. The breath-by-breath VO<sub>2</sub> data was used to analyze the VO<sub>2</sub> responses during all tests performed. The VO<sub>2</sub> responses were time aligned, outlier were excluded, and interpolated second-a-second to be analyzed from punctual method. The analyzed parameters were: VO<sub>2</sub> end (mean 30s VO<sub>2</sub> at the end of exercise), and slow component (SC, the difference between mean 20s VO<sub>2</sub> around the 120s and 600s of VO<sub>2</sub> response). Differences between the parameters of VO<sub>2</sub> response were analyzed by independent T-test, with significance level set at 0.05. **Results** The VO<sub>2</sub> end (30th minute) value at MLSS (2420.6 (533.7) ml O<sub>2</sub>.min<sup>-1</sup>) did elicit 82.6 (7.6) %VO<sub>2</sub>peak, whereas VO<sub>2</sub> end values at PC (2898.6 (576.6) mlO<sub>2</sub>.min<sup>-1</sup>) did reach VO<sub>2</sub> peak value (99.3 (9.6) %VO<sub>2</sub>peak). Both responses (absolute and relative values of VO<sub>2</sub>end) were different between MLSS and PC. The SC was observed while cycling at MLSS (339.5 (238.7) ml.minO<sub>2</sub>-1) and PC (566.5 (287.9) ml.minO<sub>2</sub>-1), but they did not differ from each other, neither when expressed relative to VO<sub>2</sub> increment during exercise (16.6 (10.6)% and 23.0 (10.0)%, respectively). **Discussion** While delayed VO<sub>2</sub> steady-state was observed during cycling at MLSS and PC, it was truncated at VO<sub>2</sub>peak at PC for seven of eight subjects analyzed. On this base, PC differs substantially from MLSS. Despite the lack of metabolic correspondence has been extensively discussed (Jones et al., 2010), the noticeable difference in VO<sub>2</sub> response between both would probably reflect on the events leading to exhaustion (Baron et al, 2003), and must be carefully weighted when evaluate endurance capacity and plan training. **References** Baron, B., Dekkerle, J., Robin, S., Neviere, R., Dupont, L., Matran, R., y col. ### USING SPATIAL METRICS TO CHARACTERIZE TACTICAL BEHAVIOUR IN A BASKETBALL GAME

Lopes, A.1,2, Fonseca, S.1, Paulo, A.1, Leser, R.3, Baca, A.3

Universidade Lusófona de Humanidades e Tecnologias

Lopes, A.1,2, Fonseca, S.1, Paulo, A.1, Leser, R.3, Baca, A.3 1: FEFD-Universidade Lusófona (Lisboa, Portugal), 2: CIDESD (Portugal), 3: Centre for Sport Science and University Sports, University of Vienna, (Vienna, Austria) **Introduction:** Tactical behaviour usually refers to the players' actions, meaning that the position of every player is influenced by the tactical concepts (Jäger, Perl, & Schöhlhorn, 2007). A method for assessing tactical team performance is the observation of spatial patterns. Various spatial constructions have been used: convex hull (CH), bounding rectangle (BR), voronoi diagrams (VD) (Bourbosson, Sève, & McGarry, 2010; Fonseca, et al., 2012a). The purpose of this work is to identify the best candidate to describe team tactical behaviour. **Methods:** A training match of the talent Austrian's basketball team played in a 28x15m field was considered. Positional data of all players was collected using Ubisense Location System (Leser, Baca, & Ogris, 2011). The area of each spatial metric defined above was calculated for each team, using routines implemented in Matlab R2008a software. To quantify the teams' regularity of the spatial behaviour, the normalised measure of approximate entropy (Fonseca, et al., 2012b) was calculated for each metrics' time series. The Pearson correlation coefficient was used to evaluate the inter-team spatial relationship. **Discussion:** The used spatial metrics provided similar, but different, information about how teams used space by means of tactics. The analysis of this measures showed that the dispersion of the teams in the field tend to follow a dynamical teams' counter-phase (Yue et al., 2008), the area or dominant region of a team tends to contract when the opposite team area expands (Frencken, et al., 2011), and this was best reported by the VD. These kind of patterns' behaviour seem to be associated with the ball possession changes and/or disputes, following the results of Bourbosson et al. (2010), when they used similar spatial metrics (stretch index). VDs seem to overcome some limitations of other spatial metrics (Fonseca et al., 2012a). **References** Bourbosson, J., Sève, C. and McGarry, T. (2010). ### **ANXIETY, DECISION-MAKING AND PERFORMANCE IN VOLLEYBALL TRAINING STAGES. DIFFERENCES BETWEEN WINNER AND LOSER TEAMS**

Claver Rabaz, F.1, Del Villar, F.1, García-González, L.2, Jiménez, R.1, Moreno, M.P.1

1.UNIVERSIDAD DE EXTREMADURA; 2.UNIVERSIDAD DE ZARAGOZA

Introduction Volleyball is a sport with high technical, tactical, physical and psychological demands. In recent years, researchers had tried to discover the key factors related to the victory. (Kugler et al., 1996). The main objective of this study was to identify differences in cognitive (decision-making), emotional (anxiety) and performance variables between winning and loser teams in a sample of young volleyball players. Methods The study sample was composed of the 173 participants (74 males, 99 females) who belong to all the Under-16 teams (M: 14.63, SD: 1.05) which compete in the 'Extremadura Volleyball League'. The research followed the standards of the research ethics committee of the University of Extremadura (2010). The dependent variable was the match outcome. The independent variables were state anxiety (CSAI-2R), decision-making (GPAI) and performance (FIVB observation system). Results A T-test for independent samples was performed to check the differences between winner and loser teams in the studied variables. Results showed statistically significant differences in decision making, self-confidence and performance between players from winner and loser teams. Discussion With regard to decision-making, players of winner teams showed significant higher values than players from loser teams. In this regard, some studies have shown that experts take better decisions than novice players (Moreno et al., 2008). As for the anxiety variable, we found significant differences in self-confidence (the positive factor of anxiety), with values consistently higher in winners than in losers. Our results coincide with previous studies that found higher self-confidence scores in winner teams and no differences in cognitive and somatic anxiety (Tsopani et al., 2011). As for performance (in game actions), players from winner teams showed higher performance scores than losers. Our results coincide with previous studies that emphasize the importance of game actions in volleyball (Asterios et al., 2009). ### **HOW DOES MODIFYING COMPETITIVE OPPORTUNITIES AFFECT THE EXPERIENCES OF CHILDREN PLAYING RUGBY LEAGUE?**

Morley, D., Ogilvie, P., Rothwell, M.

*Leeds Metropolitan University*

HOW DOES MODIFYING COMPETITIVE OPPORTUNITIES AFFECT THE EXPERIENCES OF CHILDREN PLAYING RUGBY LEAGUE? Morley, D. 1, Ogilvie, P.1 & Rothwell, M.2 1 Institute of Sport, Physical Activity and Leisure, Leeds Metropolitan University, Leeds, UK; 2 Rugby Football League, Leeds, UK Introduction The Rugby Football League (RFL) in England has embarked on a review of their game as played by children. The 'traditional' game established for children was introduced some 20 years ago (Rothwell, 2012) and was designed to provide an 'enjoyable fun activity and a marked all round improvement in the technical abilities and awareness of those playing the game' (RFL, 2012, p.4). The RFL were keen to explore a 'modified' game that would encourage a higher frequency of skills being used as a result of changing the number of players, size of the pitch and rules. The aim of this study was to assess the attitudes of players and parents towards this 'modified' game and to understand the impact of these modifications on the frequency of skills being used. Methods An average of 60 players per week, aged 6-10, and 40 parents attended a 'competition festival' on four consecutive Saturdays, where they played both the traditional and modified versions of the game appropriate to their age. We employed a number of research techniques within a 'mosaic' approach (Clark & Moss, 2001). The techniques used within this approach consisted of 'tagging' the frequency of skills, surveys, graffiti boards, focus group interviews, role-play and video footage to stimulate discussion. Results Some modifications to the rules in the modified game had negligible impact on increasing participation through a higher frequency of skills in the game, particularly in terms of tackling and the fluency of passing. However, the modified game provided some positive outcomes, particularly in terms of the increase in scoring and passing, although the exact nature of these incidents within the game requires further exploration. The majority of parents refused to accept that the modification of the traditional game is necessary for their child's development, although the majority of children eventually preferred the modified game to the traditional one and recognised the benefits this could bring. Discussion With an increase in skill development opportunities, some children began to explore new roles within the game that they enjoyed. The lack of impact on skill frequency in some areas could be explained by the lack of time for the new rules to be interpreted by the players. If the game is to be modified it is vital that an effective communication strategy is employed to impart the rationale for this approach to the parents of all players. References Clark, A. & Moss, P. (2001). *Listening to young children: The Mosaic approach*. London: National Children's Bureau. Rothwell, M. (2012) *Primary Rugby League Review*. Leeds:RFL. ### **EVOLUTION OF THE EFFICACY OF GAME PHASES IN U-14, U-16, U-19, NATIONAL LEVEL, AND INTERNATIONAL MEN'S VOLLEYBALL TEAMS**

García de Alcaraz, A., Palao, J.M., Ortega, E.

*University of Murcia*

INTRODUCTION In volleyball, teams can play in two different phases: a) side-out or complex 1 (receiving team), or b) complex 2 (serving team). The efficacy of these phases depends on the players and teams ability to execute the actions that involve the game phases. No studies have been found in the reviewed done about the level of efficacy of the games phases in the different age groups. Performance of these phases may vary depending on training years and/or players maturity (Malina & Bouchard, 1991). The aim of this study was to analyse the efficacy of game phases in U-14, U-16, U-19, national level, and international men's volleyball teams METHOD A stratified random sample of 300 sets (60 sets per category) was selected according to performance level. The sample was taken from teams

playing Spanish National Men's Volleyball championships (2009) in under-14, under-16, and under-19 categories, senior national (A1-league 2008-09-10 sessions), and senior international categories (Olympic Games 2008). A correlational intergroup design was used. The variables of this study were: a) competition category, and b) efficacy game phases (percentage of points obtained being in reception and in serving). Match observation was carried out by an experienced observer, using Data Volley® software. Reliability was .93 with Cohen Kappa test. Kruskal-Wallis test ( $p < .05$ ) and Bonferroni Procedure for post hoc analysis were calculated using statistical package SPSS 15.0. RESULTS In the formation categories (U-14 to U-19), the efficacy of the receiving team improved from 48.37% to 55.20%. Teams from national and international level had an efficacy in reception phase close to 70% and a Kill efficacy of 30% approximately. The efficacy of the receiving team improved statistically significant through the different age groups ( $p = .000$ ) and decrease the efficacy of serving team ( $p = .000$ ). The most remarkable change of the efficacy was observed between the under-19 and national category. DISCUSSION AND CONCLUSIONS The efficacy of reception phase increase and the serving phase decreased through the competition groups studied. These results highlight the need to establish specific normative profile for the different level of performance (category groups of competition) and to adapt the training methodology to the peculiarities of each level of competition. ### T-PATTERN ANALYSIS IN SOCCER: DETECTING REGULARITIES IN ATTACK PLAYS

Anguera, M.T.1, Zurloni, V.2, Jonsson, G.K.3, Diana, B.2, Elia, M.2

1: University of Barcelona (Barcelona, Spain), 2: University of Milano-Bicocca (Milano, Italy), 3: University of Iceland (Reykjavik, Iceland)

**Introduction** The dynamics of play during a match between opposing teams are clearly complex phenomena that traditional approaches to the quantification of team sports are not able to identify. The aim of this study was to describe a method for detecting the dynamics of play in professional soccer through an analysis of temporal patterns (Camerino et al., 2011; Fernández et al., 2009). In particular, the objective was to reveal the hidden yet stable structures which underlie the interactive situations that determine the attack actions of play in soccer. **Method** The methodological approach is based on observational design, supported by digital recordings and computer analysis. The observational design (Anguera et al., 2011) was nomothetic, point and multidimensional. **Participants** The study is part of a broader research project involving the analysis of all games played by AC Milan (Italy) during the 2012-2013 national League Championship; the matches here considered are those played during the first leg. **Instruments** The matches were recorded with LINCE software (Gabin et al., 2012). The variables considered in this study, that fulfill the conditions of exhaustiveness and mutual exclusivity, are: lateral position, zone, lateral passing, zone passing, ball recovery and loss, ball out of play. Data were analyzed with Theme 6 beta. This software detects the temporal and sequential structure of data sets, revealing repeated patterns that may regularly or irregularly occur within a period of observation (T-patterns). A T-pattern is essentially a combination of events where the events occur in the same order with the consecutive time distances between consecutive pattern components remaining relatively invariant (Magnusson, 2005). **Data analysis** Ongoing work **References** Anguera, M.T., Blanco-Villaseñor, A., Hernández-Mendo, A., Losada, J.L. ### DOES OUTPERFORMING AN OPPONENT ON SELECTED ACTION VARIABLES LEAD TO WINNING THE MATCH IN ENGLISH CHAMPIONSHIP SOCCER?

James, N., Rees, G., Taylor, J., Vučković, G.

Middlesex University

**Introduction** Contemporary empirical research has attempted to describe differences between soccer teams that are deemed as successful and unsuccessful using frequencies of action variables, frequently labelled performance indicators (e.g. Lago-Ballesteros and Lago-Penas 2010; Lago-Penas et al., 2010). It is suggested that coaches could design training practices to control such variables in future competition (Lago-Penas et al., 2010). This current investigation attempts to identify whether outperforming the opposition on an action variable relates to winning matches in the English Championship. **Methods** Nineteen action variables were collected from 277 English Championship matches (2010-11 season) using the Amisco Pro analysis system (Amisco Pro, Sport-Universal, Nice, France). Chi-square analyses were used to discriminate match outcomes using the IBM SPSS statistics package (v19, SPSS Inc., 2010). Results When the home team scored first they won 70.6% of matches compared to 67.8% for the away team (Chi-square= 119.86,  $df = 2$ ,  $p < 0.05$ ,  $\Phi = 0.68$ ). The only other variables that resulted in a greater than 50% chance of winning the match were receiving less red cards (home 57.1%; away 62.5%) and having more shots on target (home 54.0%; away 54.0%). All other variables (in order of magnitude for the home team: greater percentage of first time passes, less time in possession (2nd half), more shots, less yellow cards, more time in possession (1st half), more forward pass completions, more offside decisions, more pass completions, more time in opposition territory, more final third entries, less fouls, more corners, greater average number of touches per possession, more individual ball possessions, more passes, more forward passes) produced greater likelihoods of winning for the home team compared to the away team. These ranged between 34.8% and 48.4% (home team) and 22.0% and 40.2% (away team). **Discussion** Performing better on the action variables used in this study; and routinely collected by professional soccer teams; did not in the majority of instances, predict match outcomes particularly well. This suggests that their value as performance indicators is dubious. However a lack of sophistication in the analysis techniques may have contributed to this finding. For example, soccer is a multi-faceted sport whereby unsuccessful performance on one action variable may be counteracted by successful performance on another variable. Hence some teams may perform well on one combination of variables whereas another on an entirely different set of variables. It is therefore suggested that more complex analysis procedures e.g. logistic regression or multilevel linear models should be used to determine the extent to which these action variables counteract each other for individual teams. **References** Lago-Ballesteros, J. & Lago-Penas, C. (2010). J Hum Kinet, 25, 85-91. Lago-Penas, C., Lago-Ballesteros, J., Dellal, A. & Gomez, M. (2010). J Sports Sci and Med, 9, 288-293.

## RELATIONSHIP AMONG THROWING VELOCITY, GRIP STRENGTH, AND ANTHROPOMETRIC PARAMETERS IN TOP CLASS FEMALE WATER POLO PLAYERS

Manchado, C., Ferragut, C., Abrales, J.A., Vila, M.H.

1: University of Alicante, Alicante, Spain ; 2: University of Alcalá, Madrid, Spain; 3: University of Murcia, Murcia, Spain; 4: University of Vigo, Pontevedra, Spain

**Introduction** Throwing velocity of the ball is an important skill in water polo and a very important aspect for success (Bloomfield et al, 1990). The velocity of a water polo throw is not only dependent on the muscular strength, but others aspects like body segments coordination, technical skills and anthropometric characteristics (Van der Wende, 2005). The aim of this work is to establish the importance of the anthropometric factors in the throwing velocity. **Methods** Twelve elite trained female water polo players participated in this study. International Society for the Advancement of Kinanthropometry (ISAK) protocol was used to determine the anthropometric profile of the water polo players. In order to assess their specific explosive strength production, a radar gun (StalkerPro Inc., Plano), with 100 Hz frequency of record and with sensibility 0,045 m•s<sup>-1</sup> was used. The radar was placed behind the goal post and in a perpendicular direction to the player. The players were instructed to perform 6 maximal throws under 3 different conditions from the 5 m penalty line (1.- no defender or goalkeeper; 2.- goalkeeper only; 3.- with goalkeeper and previous displacement). Additionally, Maximal isometric hand-grip force was recorded using a handheld hand-grip dynamometry (T.K.K. 5401, Japan), with a sensitivity of 1 N. The players performed 2 repetitions at maximum intensity with the dominant hand. **Results** Only the condition 2 shows a significant correlation with grip strength ( $r = 0.607$ ;  $p = 0.036$ ), biacromial breadth ( $r = 0.714$ ;  $p = 0.0089$ ) and muscle mass (by Lee) ( $r = 0.579$ ;  $p = 0.048$ ). **Discussion** The positive correlations of throwing velocity (in the throwing with goalkeeper condition) with the breadths and maximal grip, show that the muscle mass and the strength levels are another component that influences decisively the ability to throw fast, in line with those reported by Van der Wende (2005). The grasp of the ball is essential in water polo. A good grasp is related to the ball's velocity when throwing (Visnapuu and Jurimae, 2007). The dependence of the throwing velocity of the biacromial breadth is confirmed in the present study, with particular relevance to the wings; the importance of this parameter, particularly in the rotation of the trunk and shoulders during the throw, was highlighted before (Elliott and Armour, 1988; Van der Wende, 2005). The different lengths studied were not correlated with the throwing velocity, as suggested before (Bloomfield et al. 1990; Van der Wende, 2005). **References** Bloomfield J., Blanksby BA, Ackland TR, Allison GT. ## EVOLUTION OF INJURY INCIDENCE DURING A SEASON IN SPANISH SOCCER FIRST-DIVISION

Gracia-Marco, L., Moliner-Urdiales, D., Noya Salces, J., Gomez-Carmona, P.M., Sillero-Quintana, M.

UNIVERSITY OF EXETER

**Introduction** There is a lack of epidemiological data on injuries in Spanish male professional soccer Leagues. The purpose of this study was to examine the evolution of injury incidence throughout a season of the Spanish soccer First-Division and to analyse differences between competition and training. **Methods** During the season 2008/2009, 16 out of 20 clubs competing in Spanish Soccer First-Division were involved in the study. Competition and training exposure were weekly estimated in a team basis. Injuries during training and competition were prospectively collected using a specific web survey based on the Fédération Internationale de Football Association (FIFA) Consensus Statement (Fuller et al. 2006). Injury incidence during training and competition was calculated per 1000 hours of exposure. Chi-square tests were used to analyse differences in injury incidences between training and competition and also to analyse differences in injury incidence according to the periods of the season. **Results** A total of 1293 injuries were identified among the 427 analysed players (524 competition injuries vs. 769 training injuries). The total exposure was 228,742.7 h (12,038h of competition exposure vs. 216,704.7h of training exposure). The injury incidence was higher in competition than training (43.5 vs. 3.5;  $p < 0.001$ ). The training injury incidence in the pre-season (July and August) was higher than the incidence in the rest of the season (all  $p < 0.001$ ). In addition, competitive period I (from September 2008 to January 2009) was more injurious than competitive period II (from February to June 2009;  $p < 0.001$ ). The injury incidence during training tended to decrease throughout the season, especially since November. The competition injury incidence in competitive period II was higher than the incidence in competitive period I ( $p < 0.001$ ). Injury incidence peaks in May after a progressive increase from the beginning of the season. **Discussion** The results showed a high injury incidence in Spanish Soccer First-Division, indicating that competition was much more injurious than training. Training injury incidence was higher during the pre-season and tended to decrease throughout the season, while competition injury incidence increased progressively throughout the season. These differences between injury incidences in competition and training according to the period of the season suggest the need of specific injury prevention protocols in the Spanish soccer First-Division. **References** Fuller CW, Ekstrand J, Junge A, Andersen TE, Bahr R, Dvorak J, Hagglund M, McCrory P, Meeuwisse WH. ## ANALYSIS OF RECURRENCE INJURIES IN SPANISH SOCCER FIRST-DIVISION

Gracia-Marco, L., Moliner-Urdiales, D., Noya Salces, J., Gomez-Carmona, P.M., Sillero-Quintana, M.

UNIVERSITY OF EXETER

**Introduction** There is a lack of epidemiological data on injuries in Spanish male professional soccer Leagues. The purpose of this study was to examine the incidence of recurrence injuries throughout a season of the Spanish soccer First-Division and to analyse differences between competition and training. **Methods** During the season 2008/2009, 16 out of 20 clubs competing in Spanish Soccer First-Division were involved in the study (427 players). Incidence on recurrence injuries and injury severity during training and competition were prospectively collected using a specific web survey based on the Fédération Internationale de Football Association (FIFA) Consensus Statement (Fuller et al. 2006). Competition and training exposure were weekly estimated in a team basis. Recurrence injuries were defined as injuries of the same type and location occurred after the player's recovery and return to full participation. The severity of recurrence injuries was based on the following scale: minor, equal or major; in comparison with the prior injury severity. Injury incidence during training and competition was calculated per 1000 hours of exposure. Chi-square tests were used to analyse differences in injury incidences between training and competition. **Results** A total of 145 out of 1293 injuries (57 competition injuries vs. 88 training injuries) were considered as recurrence injuries during 228,742.7 hours of exposure (12,038h of competition vs. 216,704.7h of training). Incidence of recurrence injuries was 0.63 per 1000h of exposure (4.73 during competition vs. 0.41 during training;  $P < 0.001$ ). The 72.4% of recurrence injuries were of equal or major severity than the original injury. In addition, equal and major recurrence injuries (2.2 and 1.6) showed higher incidence than minor injuries (0.8). **Discussion** Our results agree with previous studies in European teams and competitions, (Walden,

---

Hagglund et al. 2005; Ekstrand, Hagglund et al. 2011) showing that the 11% of the injuries were recurrence injuries, and the 30% of these injuries cause longer absences than do non-recurrence injuries. These results suggest that additional efforts improving rehabilitation processes in Spanish Soccer First-Division are needed in order to reduce the risk of recurrence injuries. ## **BALL PASSING FLOW PATTERNS IN BASKETBALL REVEAL DIFFERENT SETS OF CONSTRAINTS**

Daskalovski, B., Naumovski, M., Hristovski, R., Zivkovic, V.

*Ss Cyril and Methodius University*

Introduction Team invasion games are characterized by emerging patterns of ball passes as a result of confluence of two major classes of constraints: Task instructional constraints and immediate informational constraints occurring in local interactions between players of both teams. The aim of this investigation was to analyze the ball passing patterns during attack of the two high performance basketball teams: Igokea and Olympia competing in the Adriatic League. Methods The observational data collection was conducted by the Tacto software (Duarte et al. 2010). 325 attacking passes performed during the whole match were analyzed. The attacked area was divided in 9 quadrants of equal size. The absolute probabilities of ball allocation within the quadrants were calculated as relative frequencies. Conditional probabilities of passes among quadrants were also calculated. Then the most probable sequences of passes among quadrants were estimated to detect the characteristic channels of ball flow during the attack of both teams. Results The stochastic process analysis showed different ball passing flow patterns. The preferred ball flow of Igokea was located in the left side of the attacked area with only one high probability flow loop to and from the outer zone. It was also characterized with directed flows toward the central zone of the attacked area. On the contrary, Olympia's emergent actions preferably were dispersed at the right hand side of the attacked area with 3 flow loops to and from the outer zones. Discussion The spatial patterns of passing revealed in this study show different structure of play that emerged as a consequence of the confluence of tactical task and immediate informational constraints impinging on the attacking team. Whereas attacking patterns of Igokea as a host team were characterized by more direct flows into the defense area of the opposing team with only one loop circulating toward the outer area, the team of the guest team Olympia showed several looping flows of passes mainly located in the outer areas. This loop patterning was mainly a consequence of the task instructional constraints where patiently conducted attack i.e. 'laying on the ball' was an imperative. The team of Igokea also possessed more concentrated ball positions in contrast to Olympia who manifested more dispersed ball allocation as a consequence of the previously mentioned task constraints. ### **PHYSICAL ACTIVITY AND BODY MASS INDEX IN A SAMPLE OF ELDERLY PEOPLE**

Kortajarena, M., Hoyos, I., Irazusta, A., Fraile, A.B., Ruiz, F., Irazusta, J., Gil, J.

*Univeristy of the Basque Country*

INTRODUCTION The benefits of physical activity (PA) on the prevention of obesity are well known (Warburton et al. 2006). However, there are few studies analyzing the relation between objectively measured PA in elderly people and health parameters. Therefore, this study aimed to examine the association between objectively measured PA and obesity related parameters by gender. MATERIAL AND METHODS Participants were 100 elderly people aged  $\geq 60$  years old who were all capable of performing basic daily activities by themselves and who lived on their own. PA was assessed by Actigraph GT3X accelerometer. Examined variables were: counts per minute (CPM), steps per day (SPD), minutes of sedentary (0-99 CPM), light (100-1951 CPM,  $< 3$  METs) or moderate-to-vigorous PA (MVPA) ( $\geq 1952$  CPM,  $> 3$  METs) (Freedson, 1998). Body Mass Index (BMI) was calculated and classified as normal weight, overweight, and obese (NHLBI 1998). Waist (WC) and hip circumferences were measured and waist-to-hip ratio calculated (WHR). Data were analyzed by: t-test, ANOVA (post-hoc Scheffe test) and Pearson's correlation coefficients. RESULTS Participants were 65% women (70.1  $\pm$  6.60 yrs; BMI 27.3  $\pm$  3.72 kg·m<sup>-2</sup>; WC 87.7  $\pm$  9.14 cm; WHR 0.83  $\pm$  0.05) and 35% men (70.6  $\pm$  7.37 yrs; BMI 27.5  $\pm$  2.76 kg·m<sup>-2</sup>; WC 98.1  $\pm$  9.11 cm; WHR 0.94  $\pm$  0.05). Daily CPM were 262 for both genders and the SPD were 11,742 and 11,849 in male and female respectively. Mean values of PA in the normal weight group were 312 CPM and 13,522 SPD; in the overweight group 259 CPM and 11,784 SPD; in the obese group 208 CPM and 9,793 SPD. Differences between the values of the normoweight and the obese group were significant; both in CPM and in the SPD ( $P < 0.05$ ). PA measurements, both CPM and SPD, correlated inversely with BMI ( $P < 0.01$ ), WC ( $P < 0.01$ ) and WHR ( $P < 0.05$ ). MVPA also correlated inversely with BMI ( $P < 0.001$ ), WC ( $P < 0.001$ ) and WHR ( $P < 0.05$ ). DISCUSSION The finding that men and women are similar regarding average CPM and SPD sheds new light on earlier findings. This finding does not meet with those of other studies, where men achieve more steps per day (Colley et al. 2011). In this study the more active participants were associated with healthier BMI values, as described previously by others (Davis et al., 2011). Moderate-to vigorous PA is more closely related with lower BMI values than less intense PA. REFERENCES Colley, R.C. et al. (2011). ### **INJURIES IN GERMAN PROFESSIONAL MEN'S ICE HOCKEY - VIDEO ANALYSIS OF MATCH INJURIES**

Luig, P., Klein, C., Henke, T.

*Ruhr-Universität Bochum*

Introduction: Because of its speed, equipment and body contact ice hockey is probably more dynamic and physical than most other team sports. This is certainly one main reason why ice hockey is so popular in Germany. But what is attractive to the audience might also bear a certain injury risk. With 40.1 time-loss injuries per 1000 match hours ice hockey has indeed the highest match injury incidences among German professional team sports. This fact is endangering game operations of the clubs through steadily increasing insurance rates. Methodology: Two consecutive first and second league seasons (2010-2012) were analyzed with regard to registered injuries, resulting costs and disabilities. National ice hockey journals were consulted to describe the sample of all professional hockey players that played at least once in a competitive match. Injury data including information about nature and severity of the injury were provided by the Ger-

man accident insurance of the athletes (VBG). Moreover, identifiable match injuries were assessed through video analysis to objectify the circumstances and situations that frequently lead to injuries. The gathered information was used to reveal key areas for prevention and to tailor targeted counter-strategies for elite clubs, coaches, athletes and referees. Results: During the two seasons 2,594 injuries were registered causing direct medical costs of 4.4 million and 31,000 days of disability. 60 % of injuries needed medical treatment only, 40 % caused time-loss (disability). Each player sustained 1.9 injuries per season (0.8 time-loss injuries/season). Head injuries (20.9 %), knee injuries (12.4 %) and shoulder injuries (11.1 %) were observed most often. Beside the aforementioned three body regions, ankle injuries, with regard to their severity, also appeared as another key region. In case of head injuries direct checks to the head as well as contact with sticks and boards were monitored as most frequent injury situations. Immediate contact with boards was also the predominant trigger for shoulder injuries. Concerning knee injuries pivoting or coordination deficits in non-contact skating situations were quite frequent, followed by knee-on-knee hits by opposing players. Most ankle injuries result from direct contact with the puck or from canting of the skate on the icy surface. Discussion: Fair-play and respect among ice hockey players is still of prime interest when it comes to decreasing the number of injuries, particularly as severe head injuries commonly result from irregular checking. Additionally, referees should receive more support in identifying and penalizing gross unsportsmanlike conduct. Furthermore, improving checking and skating technique, already in young ages, will help athletes to withstand crucial game situations that frequently lead to injuries.

### **EFFECTS OF RAPID WEIGHT LOSS AND RECOVERY ON MUSCLE SIZE, FORCE AND POWER GENERATION CAPACITY IN JAPANESE WRESTLERS**

Kumagawa, D.1, Arakawa, H.1, Saito, Y.1, Suzuki, N.1, Motonaga, K.1, Kondo, E.1, Kamei, A.1, Asakura, T.2, Wada, T.2, Kawahara, T.1

1: *Japan Institute of Sports Sciences (Tokyo, Japan)*, 2: *Kokushikan University (Tokyo, Japan)*

**Introduction** It is well known that wrestlers undergo rapid weight loss and recovery before competitions. Such rapid changes in the weight of wrestlers are likely to have a negative effect on the recovery of their physical fitness for competition. However, it is not been sufficiently studied whether the effects of rapid weight loss and recovery entail differences in muscle size and function. Therefore, this study investigated the effects of rapid weight loss and recovery on the muscle size, force and power generation capacity in Japanese wrestlers. **Methods** The participants were male wrestlers aged 19 to 21. All participants belonged to university wrestling teams and underwent wrestling training throughout the year. The participants lost 6% of their body weight in 56 h, and recovered in 15 h. The cross-sectional area (CSA) of the thigh and trunk muscles was determined using magnetic resonance imaging (MRI). Isometric maximal voluntary contraction during knee extension and flexion was measured using an isokinetic dynamometer. In addition, the power generation capacity of muscles was determined by 30-s maximal pedaling using a bicycle ergometer. Measurements were performed 1 week prior to weight loss (pre-WL), after the weight loss (WL), and after recovery of the body weight (post-WL). **Results** The body weight decreased significantly between the pre-WL and WL periods, and increased significantly between the WL and post-WL periods. Significant differences at all CSA measurement sites were observed for both the thigh and trunk muscles in the two periods. However, the CSA change ratio was almost the same for each site. The isometric knee extension and flexion torques also remained unchanged between the pre-WL and post-WL periods. However, the peak and mean power during the 30-s maximal pedaling decreased significantly between the pre-WL and post-WL periods. **Discussion** These results suggest that the CSA of trunk and thigh muscles are strongly affected by rapid weight loss and recovery, although differences in muscle size due to rapid weight change are not observed across CSA measurement sites. Isometric maximal voluntary contraction during knee extension and flexion remains unchanged, however, power generation capacity is markedly lower after weight recovery as compared with that prior to weight loss. The effects of rapid weight loss and recovery may differ between muscle force and power generation capacity. **References** Fogelholm GM, Koskinen R, Laakso J, Rankinen T, Ruokonen I. ### **THE INDUCED MUSCLES ACTIVATION IN WHOLE BODY VIBRATION TRAINING AT DIFFERENT VIBRATION EXPOSURE TIME**

Wu, Y.C., Shen, F.Y., Tsai, Y.P., Lin, H.T., Hu, C.Y.

*Kaohsiung Medical University*

**Introduction** The effect of Whole body vibration (WBV) in neuromuscular system is through stimulates the receptors in muscles and tendons, and causes muscle stretch reflex (Cardinale, 2003). It has been broadly applied in the muscle strengthening (Adams, 2009). How much the muscles activation induced from the mechanical vibration and whether they are affected by the vibration exposure time are still rare discussed. The purpose of this study is to investigate the muscles activation differences and muscles activation change at different vibration exposure time during WBV training. **Methods** Five university students (20.2±0.5 years old) without any lower extremity musculo-skeletal injuries history and cardiovascular disease at least one year were participated in this study. The vertical vibration training was set at 2 mm amplitude and 35 Hz vibration frequency. The subject kept knee flexion at 145 degrees during WBV training. The electromyography was used to detect the muscles activation and the rectus and biceps femories were investigated. Five different training exposure time were tested in this study. They are continuous four minutes WBV without rest, one minute WBV with one minute rest for four, six, eight, and ten repetitions. The root mean squared of electrical potential of each muscle at every minute during the WBV were calculated. One sample t-test was used for test the statistical difference of muscle activation at different exposure vibration time in five training programs. **Results** The results found that during the WBV, the rectus femoris showed significant larger activation than the biceps femoris (30.45 •V vs. 11.35 •V). However, there was no significant difference in the muscle activation in between every minute in five training programs. **Discussion** The WBV induced different muscles activation for different muscles. In the knee flexion postures, WBV induce larger extensor (rectus femoris) contraction than in flexor (biceps femoris). With one minute vibration and one minute rest WBV training protocol, the induced muscle activation kept at the same level at least ten repetitions that represented muscles vibrated at this intensity were without any fatigue tendency. **References** Adams JB, Edwards D, Serravite DH, Bedient AM, Huntsman E, Jacobs KA, Del Rossi G, Roos BA, Signorile JF (2009). *J Strength Cond Res* 23, 237-245. ## EFFECTS OF LOW-VOLUME EXERCISE TRAINING AND VITAMIN E SUPPLEMENTATION ON OXIDATIVE STRESS IN OLDER ADULTS

Takahashi, M.<sup>1,2</sup>, Miyashita, M.<sup>3</sup>, Park, J.H.<sup>1</sup>, Kawanishi, N.<sup>1,2</sup>, Bae, S.R.<sup>1</sup>, Nakamura, Y.<sup>4</sup>, Sakamoto, S.<sup>4</sup>, Suzuki, K.<sup>4</sup>

1: Waseda University, 2: Research Fellow of the Japan Society for the Promotion of Science, 3: Tokyo Gakugei University, 4: Waseda University

**Introduction** Elevated oxidative stress leads to the development of cardiovascular diseases and atherosclerosis (Bjelakovic et al., 2007). On the other hand, many studies have shown that resting oxidative stress markers decrease after endurance exercise and vitamin E supplementation (Peternelj et al., 2012). However, the least amount of physical activity and the combined effects of antioxidant required to alter the levels of oxidative stress markers are unclear. Thus, the purpose of this study was to investigate the effects of a 12-week low-volume walking program below the current recommended amount of exercise (< 150 min/week) and vitamin E supplementation on oxidative stress markers in older adults. **Methods** The participants were non-randomly assigned to the following four groups: control (C, n=14), vitamin E (S, n=10), exercise (Ex, n=7), or vitamin E and exercise (S + Ex, n=7). The S and S + Ex groups were instructed to take vitamin E ( $\alpha$ -tocopherol, 300 mg/day) capsules for 12 weeks. The exercise program of Ex and S + Ex groups consisted of walking for 30-60 min/session 2 days per week for 12 weeks. Blood samples were taken at baseline and immediately after 12 weeks. **Results** The serum derivatives of reactive oxygen metabolites were significantly decreased in the S, Ex, and S + Ex groups after 12 weeks compared with the baseline values (three-factor ANOVA, main effects of exercise and time, and an interaction between exercise and time,  $P < 0.01$ ). Conversely, serum biological antioxidant potential concentrations in the S and Ex groups were significantly higher at 12 weeks than at the baseline (three-factor ANOVA, main effects of supplementation and time,  $P < 0.05$ ). Plasma thioredoxin concentrations in the S, Ex, and S + Ex groups were significantly higher at 12 weeks than at the baseline values (three-factor ANOVA, a main effect of time, and interactions between supplementation and time, and between exercise and time,  $P < 0.05$ ). **Discussion** Our findings will be of interests to sedentary older adults that even a low-volume exercise training (90 min/week) was effective in reducing resting oxidative stress in older adults. These findings might encourage more people to incorporate a small amount of physical activity into their lives. Moreover, our findings suggest that the daily recommended doses of vitamin E supplementation (300 mg/day) would be effective for improving oxidative stress status in elderly individuals. Thus, our findings may indicate that the benefits of the least amount of physical activity and vitamin E supplementation translate to reduced risks of cardiovascular disease and atherosclerosis related to oxidative stress in the long-term. **References** Bjelakovic G. et al. (2007). *JAMA*, 297, 842-857. Peternelj TT and Coombes JS. (2012). *Sports Med*, 41, 1043-1069

## INTRATENDINOUS INJECTIONS OF HYPEROSMOLAR DEXTROSE UNDER SONOGRAPHIC GUIDANCE IN THE TREATMENT OF LATERAL EPICONDYLITIS

Algergawy, S.

benha university faculty of medicine

**Abstract** **OBJECTIVE:** Hyperosmolar dextrose is one of the most commonly used proliferants. When injected, it causes inflammation with the intent to induce a healing response. We aimed to study intratendinous injections of hyperosmolar dextrose by ultrasound guidance. **PATIENTS AND METHODS:** Thirty patients, 20 men and 10 women with clinically determined chronic (lasting 3 months or longer) lateral epicondylitis were recruited. All patients noted pain intensity levels significant enough to prevent the participation in activities, such as playing tennis sports or lifting heavy objects. All patients underwent sonography-guided intratendinous injection of 25% hyperosmolar dextrose every 4 weeks. At baseline and before each injection, clinical assessment was performed using a visual analogue scale (VAS) for pain at rest (VAS1), pain during normal daily activity (VAS2), and pain during or after sporting or other physical activity (VAS3). Sonographic parameters including tendon thickness, echogenicity, and neovascularity were also recorded. **RESULTS:** The mean percentage of reduction for VAS1 was 80.5% ( $p < 0.001$ ), for VAS2 of 81.0% ( $p < 0.0001$ ), and for VAS3 of 69.1% ( $p < 0.0001$ ). The mean tendon thickness decreased by 13%. The number of tendons with anechoic clefts or foci was reduced by 71%. Echogenicity improved in 40% but was unchanged in 30%. Neovascularity was decreased in (60%) but no neovascularity was present before or after treatment in (10%). **Conclusion:** Intratendinous injections of hyperosmolar dextrose by ultrasound guidance was effectively decreased elbow pain, and improved strength in subjects with chronic lateral epicondylitis.

## RESEARCH ON CONDITIONING AND MANAGEMENT FOR MENSTRUATION IN JAPANESE ELITE ATHLETES

Honda, A., Suzuki, N., Nakamura, M., Takahashi, H.

Chukyo University

**Introduction** Many female athletes have suffered from menstrual problems, or have problems of conditioning concerned with menstrual cycle. However, in Japan, there were few data on menstrual status, management of menses and condition throughout menstrual cycle, especially at the national top level. Therefore, to assess exactly current status for these data, we conducted survey in the form of questionnaire targeting national elite athletes. **Methods** Subjects were 242 Japanese female athletes aged  $22.4 \pm 4.7$  yrs (from 14 to 42). They were certified reinforcement athletes from 24 sports, and had participated in international competitions such as the Olympic Games or world championships. They answered self-written questionnaire including menstrual status, subjective condition and symptoms throughout menstrual cycle, management of menses and so on. **Results** Ninety-six percent of subjects had undergone menstruation. Mean age at menarche was  $13.1 \pm 1.9$  yrs (from 9 to 20). Although many athletes had regularly menstruation (69%) judged from menstrual cycle, some athletes had problems with menstrual irregularities (14%), epimenorrhoea (6%) and amenorrhoea (3%). During menstruating and luteal phase, many athletes had menstrual pain, premenstrual syndrome such as lower abdomen, breast and back pain, weight gain and mental problems. Especially, for 40% of them, menstrual pain interfered with their daily life. Thus more than 30% of athletes answered that the condition during these phases was bad or worse, though they did not appeal bad condition during other phases. On the other hand, most athletes did not change their training menu, intensity and amount throughout cycle, and did not control the course of the menstrual cycle (not taking oral contraceptive pill), despite having various symptoms. In addition, whereas 40% of total athletes had anxieties about menses, consultation rate of gynecology and rate of recording basal body temperature (BBT) was low (respectively 30% and 24%). **Discussion** These results indicated that not so many Japanese top athletes took special cares for management of menses or conditioning throughout cycle, despite having various symptoms, anxieties and so on. Therefore, we needed to recommend BBT measurement for assessing menstrual status and conditioning, and to provide information on exercise and menses.

## ASSESSMENT OF ENERGY EXPENDITURE IN PREGNANT WOMEN

Silva, F.1,4, Silva, I.2, Bezerra, S.3, Aragão, T.4

1: University Center of Estácio-Ceará - Brazil, 2: University of Porto – Faculty of Sport – Portugal, 3: University Center of Estácio-Ceará - Brazil, 4: Origo treinamento individualizado - Brazil

**Introduction** There is a relationship between physical activity and health, and is evidenced in many studies; During gestation, a woman's natural phase, since it shows no pathology, may adopt an active style of life. Energy expenditure in physical activity is directly related to the frequency, duration and intensity of human movement developed in various tasks. The rating level of physical activity of the population has been the target of many studies worldwide as a way to identify the impact of sedentary lifestyle of the human being. With the aim to measure energy expenditure in pregnant women. **Methods** This study was quantitative character, cross-sectional, based on the study of (Chasan-Taber, 2004) being used after Transcultural Adaptation Process, resulting in the Physical Activity Questionnaire for Pregnant Women - QAFG (in Portuguese) (SILVA, 2007). The questionnaire captures energy expenditure in METs for both the intensity is classified as in 'light' (1.5 to <3.0 METs), 'sedentary' (<1.5 METs), 'moderate' (3.0 to 6.0 METs) and 'strong' (> 6.0 METs). The study was conducted in the city of Fortaleza, Ceara, Brazil, the sample consisted of 30 pregnant women with Social Class A and B. Seen in medical clinics private network, which had between 16 to 40 years. **Discussion** In the validation study conducted in Massachusetts the Pregnancy Physical Activity Questionnaire - PPAQ - shows that the first choice for pregnant women in activity energy expenditure was watching TV and video, followed by walking slowly, thus presenting level between 'light' to 'moderate' intensity (CHASAN-TABER 2004). Corroborating these data, a study performed by Silva et al. (2007) in Fortaleza, assessed 305 pregnant women, also noted a marked reduction in physical activity patterns in the evolution of pregnancy. **Conclusion** In the sample 36.6% of women were classified as 'moderate'. The study also showed a reduction in physical activity during the three trimesters of pregnancy. The socioeconomic characteristics, with high purchasing power, may indicate percentage of pregnant women with moderate physical activity considered since the first trimester, and was decreasing with the outcome of pregnancy. Another factor that deserves mention was the absence of practicing sports among these women. Therefore, activities that require greater energy expenditure were not practically performed by pregnant women. **References** CHASAN-TABER, L. et.al. Development and Validation of a Pregnancy Physical Activity Questionnaire – PPAQ *Medicine & Science in Sports & Exercise*. Vol. 36 N. 10, pp. 1750-1760, 2004. SILVA, F.T. Avaliação do nível de atividade física durante a gestação. *Rev. Bras. Ginecol. Obstet.* 2007; 29: 490-500.

## RESPIRATORY ADAPTATIONS AFTER COMPLETING THE SÃO PAULO INTERNATIONAL MARATHON 2012

Santos, J.M.B., Luna Jr, L.A., Sierra, A.P.R., Benetti, M., Bachi, A.L.L., Tubaldini, M., Rodrigues, B., Kiss, M.A.P.D., Gabriel, E.A., Vaisberg, M.

UNIFESP, USP, UniNOVE

**Introduction** Many physiological aspects should be considered in exercise training prescription, including musculoskeletal, cardiovascular and respiratory limitations related to overload imposed by the training itself. Many investigators have focused the cardiovascular and musculoskeletal systems, while respiratory responses remain unclear. The aim of this work was to investigate the respiratory responses presented by recreational runners after high intensity endurance exercise. **Methods** Twelve male subjects (age 34.5±8.12 years, height 176.46±5.21 cm, weight 73.3±8.47 kg, %fat 16.6±5.90) participating in the São Paulo International Marathon 2012 performed a pulmonary function test before and 0/5/10/15/20 minutes after a maximal progressive cardiopulmonary exercise test. Two different situations were compared: a week before the marathon and between 3rd and 15th day after the challenge. Additionally, blood samples were collected immediately and 72 hs after the marathon to analyse biochemical markers of stress and inflammation. Data are presented as difference mean±standard deviation and difference media and were compared with Wilcoxon test (p <0,05). **Results**

	Basal	After	p	Difference	Difference	Marathon	Mean	Media							
Pre	5.06	4.93	0.21	0.11	± 0.64	0.28	FVC T0	5.09	4.75	0.05*	0.32	± 0.50	0.40		
T5	5.13	5.08	0.14	0.16	± 0.60	0.32	FVC T10	5.16	4.95	0.02*	0.45	± 0.50	0.55		
T15	5.20	4.79	0.05*	0.38	± 0.63	0.52	FVC T20	5.11	4.74	0.09	0.27	± 0.53	0.43		
Pre	622.10	623.91	0.81	-27.19	± 144.59	25.62	PEFr T0	642.90	626.94	0.05*	39.73	± 57.36	59.25		
T5	629.90	606.48	0.02*	51.19	± 56.99	54.91	PEFr T10	640.70	569.19	0.00*	63.45	± 51.19	53.61		
T15	622.35	576.42	0.01*	38.63	± 45.98	27.54	PEFr T20	651.50	584.88	0.01*	72.73	± 49.95	62.73		
	Basal	Immediately after	72 hs after	Lactate	1.78 ± 0.52	4.98 ± 0.99#	2.37 ± 0.95#	hs-CRP	0.16 ± 0.19	0.18 ± 0.23	1.13 ± 0.53#	CPK	245.5 ± 150.67	558.75 ± 349.56#	1690.19 ± 2547.61#

Leuko-cytes 4.97 ± 1.09 12.52 ± 3.58# 4.86 ± 1.35 # different from basal (p<0.05) No correlations were found between ventilatory parameters and biochemical markers. **Conclusions** These results suggest that high intensity prolonged endurance exercise can elicit some pulmonary adaptations with respiratory limitations that increased during the first 10 minutes after maximal exercise. The biochemical markers confirmed the physiological stress and inflammatory responses presented after completing a marathon, but are not directed related to the observed pulmonary adaptations.

## BIOELECTRICAL IMPEDANCE VECTOR POSITION OF ITALIAN DIVISIONS SOCCER PLAYERS: REFERENCE VALUES FOR THE SOCCER POPULATION

Gatterer, H.1, Pagani, L.2, Marella, M.3, Gulisano, M.4, Piccoli, A.5, Angelini, F.6, Burtcher, M.1, Levi Micheli, M.3

University Innsbruck

1: University Innsbruck, Department of Sport Science (Innsbruck, Austria), 2: Malta Football Association, Technical Centre (Malta, Malta), 3: University of Florence, Physical Education, Sport & Health (Florence, Italy), 4: University of Florence, Department of Anatomy, Histology and Forensic Medicine (Florence, Italy), 5: University of Padova, Department of Medicine (Padova, Italy), 6: University of Pavia, Italian Society of Sport Nutrition and Wellness (Pavia, Italy) **Introduction** Bioelectrical impedance values (resistance, reactance and phase-angle) are well established for the normal population or within the clinical setting and are considered indicators for hydration status and cell function (Lukaski and Piccoli, 2012; Norman et al., 2012). However, such reference values do not exist for the soccer population. Therefore, the goal of present investigation was to provide a set of bioelectrical impedance data of a large sample of soccer players. **Methods** In total 893 players who were registered within the 10 categories of the Italian Football Federation participated in the study. Players were classified into 5 groups according to their skill level. Whole-body impedance measurements were performed at the training centres of the teams during the first half of the competitive period. Besides estimation of fat free mass (FFM), fat mass (FM) and body cell mass (BCM), the

bioelectrical impedance vector analysis (BIVA) was performed. BIVA in contrast to the estimated masses does not depend on equations and displays differences in hydration, BCM and phase-angle. Furthermore BIVA allows establishing population specific 50%, 75% and 95% tolerance ellipses. Results In comparison to the other divisions and to the normal population, the vector and the tolerance ellipse of the elite-level showed a shift to the left ( $p < 0.001$ ). When compared to the elite-level, lower skilled players had lower phase-angles ( $7.7^\circ$  vs.  $7.2^\circ$ ), BCMs (40.5 kg vs. 37.2 kg) and fat-free masses (66.3 kg vs. 63.0 kg) ( $p < 0.05$ ). Discussion In conclusion, soccer players differ from the normal population in regard to BIVA. Muscle mass and function, as indicated by BCM and phase-angle, increase with increasing skill-level. The soccer specific tolerance ellipses might be used for classifying individual vectors and to define target regions for low level players. References Lukaski HC, Piccoli A (2012). ### SENSORIMOTOR CONTROL OF THE LUMBAR SPINE IN MALE COMPETITIVE WEIGHT-LIFTERS, SWIMMERS, SOCCER AND HOCKEY PLAYERS

Dalichau, S.1,2, Moeller, T.1, Scheele, K.2

*BG Unfallambulanz u. Rehasentrum*

1: BG Rehabilitation Centre (Bremen, Germany), 2: Institute of Sports Science, University of Bremen (Germany) Introduction The efficiency of the proprioception of the joints determines the quality of co-ordinative control of the postural and motor apparatus and, hence, the physical performance in everyday life and sport. In addition, the kinaesthetic, articular receptors in muscle-tendon tissue, capsule and ligaments serve as prophylaxis against injury and premature degeneration (Richardson 1996). Most previous studies have been devoted to the joints of the extremities (Barrett 1991). Only a few investigations have been devoted to the proprioception of the spine or of the lumbar spine (Gill and Callaghan 1998; Packhurst and Burnett, 1994). So it was the aim of this study to quantify objectively spinal position sense and to evaluate the influence of sports and low back pain on the proprioception of the male lumbar spine. Methods In a controlled cross-sectional study 34 hockey players, 31 gymnasts, 38 swimmers and 54 non-athletes aged 16 to 33 years had to reproduce different defined joint positions in extension (10 degrees) and flexion (15, 30, 45 degrees) of the lumbar spine by means of an ultrasonic measuring system (20 Hz) as well in four-point kneeling as in standing when blindfolded. Results In general the accuracy of position sense was significantly greater in standing than in four-point kneeling ( $p = 0,002$ ), what indicated an intensified use of further mechanisms of control for protecting the erect position. Furthermore there was a tendency for extreme joint positions to be reproduced more exactly as compared with the medium positions ( $p = 0,034$ ). As a result of an increased nociception in subjects with low back pain the reproduction angles in the extreme positions were significantly less than intended ( $p = 0,004$ ). In comparison to the control group competitive weight-lifting did not influence the proprioception of the lumbar spine. However, there were appreciable different deviations from the defined joint positions in swimmers and gymnasts as well as in hockey players ( $p = 0,006$ ). Discussion Both perceived pain and especially the specific requirement profiles of gymnastics, hockey and swimming seemed to be responsible for the modification of the depth sensitivity of the lumbar spine (Byl and Sinnott 1991). ### TRICHOPHYTON INFECTION IN JAPANESE FEMALE ATHLETIC STUDENTS

Aya, M.

*Mukogawa Women's University*

TRICHOPHYTON INFECTION IN JAPANESE FEMALE ATHLETIC STUDENTS Maruo, A.1, Yamamoto, S.2, Tanaka, S.3 1Graduate School of Health and Sports Sciences, Mukogawa Women's University 2Institute for Health and Exercise Science, Mukogawa Women's University 3Department of Health and Sports Sciences, Mukogawa Women's University 【Introduction】 Tinea is a superficial type of dermatomycosis caused by trichophyton fungus present on dead layers of the skin, nails, and hair. Although it is the most common type of human mycosis, few reports have been presented. Since 2001, tinea capitis has become widespread among martial arts participants and the number of people with trichophyton fungus has increased, while infected judo wrestlers in high schools and universities in Japan have also been reported. It is considered important to investigate this disease, as it is increasing in young individuals. Here, we investigated the relationship between various types of trichophyton infection and sports participation. 【Methods】 A survey that included questions about club activities, acquaintances, and medical history of trichophyton infection was distributed to female university students. A total of 506 students with a mean age of 19.6 years completed the questionnaire, for a response rate of 100%. We compared athletic with non-athletic students using a chi-square test for statistical analysis. P values  $< 0.05$  were considered to be significant. 【Results】 There were 136 students (36.7%) with knowledge of trichophyton in the athletes group and 66 (43.7%) in the non-athletes group, which was not a significant difference. In the athletes group, 22 (6.0%) had a history of trichophyton, while 11 (7.3%) of the non-athletes noted such a history, which was not a significant difference. In addition, medical history of trichophyton among contact sports (3.4%,  $n=5$ ), ball sports (5.0%,  $n=14$ ) and barefoot sports (7.9%,  $n=5$ ) did not significantly differ. 【Discussion】 Recognition of and anamnesis for trichophyton infection vary, as the proportion of individuals who recognize athlete's foot is much higher than that of those who recognize tinea corporis. Reports have shown that athlete's foot is the most common type of dermatosis, thus it is reasonable that the proportion of individuals who recognize it is higher than that of those who recognize tinea of the head and body. In the present study, there were scant differences between athletes and non-athletes in regard to recognition of and anamnesis for each type of trichophyton infection. 【References】 Tatuya.U, Kazumi.T : supports and athlete's foot 『Clinical sports medicine』 1998;15-6 : 681,682 Nobuo.H : The history with athlete's foot and human 2010 ; 54-2 : 174

### THE USE OF TRANSCRANIAL ELECTRICAL STIMULATION TO RECOVERY ATHLETES

Roguleva, L., Koryagina, U., Zamchy, T.

*Siberian state university of physical education and sport*

INTRODUCTION Great psycho-emotional and physical stress that accompanies the participation of athletes in competition, raises the problem of finding the means and methods to improve the processes of recovery of physiological functions. Transcranial electrical stimulation of the brain (TES) is a non-invasive and drug-free methods, and is a weak current through electrodes placed on the scalp. This effect selectively activates defense mechanisms of the brain and causes increased release of endorphins and serotonin (Petersen N. T. et al., 2001; Markina L.D., 2004). METHODS The study involved 10 powerlifters aged from 18 to 24, high qualification. To study of mechanism

autonomic regulation analysis of heart rate variability (HRV) was used. Athletes were tested for a week before the competition (background), before and after the event and after the TES - an experimental group and the control group - 20 minutes after the competition. In the experimental group a session of TES, duration 20 min, pulse bipolar current, the maximum value of 3 mA was held. RESULTS HRV analysis has shown that the most significant changes occurred after the competition in terms of reflecting the voltage of the central mechanisms of heart rate regulation. After the competition, the athletes there is a decrease of the current functional status and the prevalence of sympathetic activity level to reduce the activity of background parasympathetic autonomic regulation. After the competition following indicators changed: Mo decreases to  $525 \pm 21$  ms, variation range (VR) decreases to  $112 \pm 20$  ms, increases the strain index (SI) to  $658 \pm 158$  and the index of vegetative balance (IVB)  $654 \pm 154$ . After TES session the following indicators changed: increased Mo on 13%, VR increased by 2 times, SI, heart vegetative indicator and the IVB decreased by 3 times. In the control group, HRV was not significantly changed. DISCUSSION Thus, transcranial electrical stimulation, based on the selective activation of endorphins and serotonin mechanisms of the brain, can accelerate recovery processes autonomic regulation of physiological functions powerlifters after load. ### **ANKLE JOINT KINEMATICS IN SUBJECTS WITH MEDIAL TIBIAL STRESS SYNDROME DURING SIMULATED RUNNING.**

Akiyama, K., Noh, B., Fukano, M., Fukubayashi, T.

*Waseda*

**Introduction** The ankle joint motion of subjects with medial tibial stress syndrome (MTSS) during sports performance is not understood. The purpose of this study was to investigate the in vivo kinematics of the ankle joints in subjects with MTSS during simulated running. **Methods** Five young volunteers with MTSS in their lower legs provided written informed consent to participate in the present study. Each running trial was recorded using cineradiography. Images were obtained cineradiography sampling at a 60 Hz. Geometric bone models of the tibia and talus/calcaneus were created from computed tomography scans of the distal part of one lower limb. Following a combination of approaches, anatomical coordinate systems were embedded in each bone model (Yamaguchi S, et al., 2009). After modelling of the tibia and talus/calcaneus, these models were matched with the orthogonal images. The in vivo ankle positions were then reproduced using the three-dimensional ankle model. The following two types of ankle joint motion were examined: talocrural joint motion (relative motion of the talus with respect to the tibia) and subtalar joint motion (relative motion of the calcaneus with respect to the talus). The ankle positions at different time intervals from heel strike to heel off during running were then reproduced from a series of three-dimensional ankle models. **Results** During simulated running, from heel strike to heel off, a significantly larger range of plantar flexion motion was observed in the talocrural joint than in the subtalar joint. During the stance phase, a larger range of the internal/external rotation and inversion/eversion angles were observed in the subtalar joint than in the talocrural joint, respectively. The contribution of the subtalar joint towards active supination/pronation motion was greater than that of the talocrural joint. **Discussion** The kinematic data obtained in this study may have important clinical implications. Knowledge of ankle joint kinematics in subjects with MTSS during normal closed kinematic chain motion (stance phase of running) is important. These results add quantitative data to an in vivo database of subjects with MTSS. **References** [1]. Yamaguchi S, et al., *Foot Ankle Int.* 30(4):361-366, 2009.

### **EVALUATION OF THE TRUNK AND LOWER-LIMB MUSCLE ACTIVITIES DURING LUMBAR STABILIZATION EXERCISES AFTER ELECTROACUPUNCTURE**

Izumi, S., Kondo, H., Sakuraba, H., Miyamoto, T., Miyakawa, S.

*Hosei University*

**Introduction** Application of acupuncture results in a temporary decrease in muscle activity. The effect on the muscle that has not received the acupuncture is unclear. The present study investigated the immediate efficacy of electroacupuncture compared to no acupuncture on the muscles activities of the trunk and lower limb during lumbar stabilization exercises. **Methods** Eight healthy male subjects ( $19.5 \pm 0.7$  years) were randomized to receive either electroacupuncture or no acupuncture (remaining lying down) in a crossover fashion with 1 week between trials. Two exercises were performed on the floor: elbow-toe and back bridge. Electroacupuncture or no acupuncture was conducted for 10 min before the exercises. Electroacupuncture was applied at dachangshu (BL25; the muscles of the low back). Pairs of surface electrodes were used to record the electromyographic signal amplitude of the rectus abdominis, external oblique, internal oblique, erector spinae, lumbar multifidus, rectus femoris, gluteus medius, and biceps femoris muscles. The EMG data were normalized as the percentage of maximum voluntary contraction, and data between doing each exercise with or without electroacupuncture were compared using the Wilcoxon signed-rank test. **Results** With the elbow-toe exercise, the activity level of the rectus abdominis muscle was decreased with electroacupuncture ( $p = 0.08$ ). When performing the back bridge exercise, the activity level of the external oblique muscle was enhanced with electroacupuncture ( $p = 0.02$ ). **Discussion** This study indicates that the activity of the muscle that did not receive acupuncture is influenced by the activity of the opposing muscle that did receive the acupuncture. **References** Hübscher M, Vogt L, Ziebart, T, Banzer, W. (2010). *Euro J Appl Phys*, 110, 353. Imai A, Kaneoka K, Okubo Y, Shiina I, Tatsumura M, Izumi S, Shiraki H. (2010) *J Orthop Sports Phys Ther*, 40, 369-375.

### **AGEING COMPARATIVE STUDY BETWEEN DIFERENT CITIES IN BRAZIL AND PORTUGAL: A HEALTH ANALYSES, AGEING AND QUALITY OF LIFE**

Veran, P.

*UNIVERSITY OF ÉVORA*

**Introduction** The population estimates in the studied countries show that Portugal is nowadays in the list of the oldest countries in the world and in Brazil the "ageing of the top" will occur up to 2025 occupying the 6th elderly population of the world, in absolute terms. **Methods** The aim of this study was to analyze comparatively Life Quality between the senior citizens who participate in the Public Physical Activity Programs at Nisa, Portugal (Program Activ Sénior) and Florianópolis, Brazil (Programa Floripa Ativa). A transversal descriptive study was carried out including 258 senior citizens, both genders, using the Brazilian and Portuguese versions of the Short Form 36 questionnaire. **Results** The global Cronbach's alpha was 0.72 for the Physical and 0.73 for the Mental Component. Descriptive analysis showed that the subjects' average age was 69,56 years old (PD: +/- 5,74 years) and that most of them were women (84,8%). The best scores for both cities/countries were obtained for the Mental Component. There were statistically significant differences for the following dimensions: Physical Pain, General Health and Vitality. **Discussion** Therefore, it was possible to conclude that the most significant percentage

belongs to the women. The feminization of ageing, estimates for average age and participation of women in studies related to ageing are always in greater numbers (Matsudo et al., 2011). The results of this study suggest that the collective health strategies that have been adopted in Nisa/Portugal and Florianópolis/Brazil through their Programs were able to establish social bonds and provide health gains, bringing benefits for active ageing. References Matsudo, SM, et al. (2001). *Braz. J Sport Med*, 7, 2-13.

### **SWEAT LOSS AND FLUID INTAKE DURING SWIMMING TRAINING IN SPRING AND SUMMER AT AN OUTDOOR SWIMMING POOL: A FIELD STUDY**

Taimura, A.1, Matsunami, M.2, Sugawara, M.1

1:Nagasaki University (Nagasaki, Japan), 2:Nishi-Nippon Junior College (Fukuoka, Japan)

**Introduction** Several papers have reported on sweat loss and fluid intake during swimming training at indoor pools (Taimura et al., 1997, 2006, 2008). The water temperature of indoor swimming pools is managed constantly, but, in the case of outdoor swimming pools, the water temperature depends on the temperature outside. This study clarified sweat loss and fluid intake during swimming training in spring and summer at an outdoor swimming pool. **Methods** The subjects were 18 male college swimmers. They were informed of the aims, risks, and benefits of this investigation both verbally and in writing prior to signing an informed consent document. The body weight before and after training, the volume and the frequency of fluid intake and urination during training were measured. The subjects were allowed to take fluid ad libitum during training. The sweat loss during exercise was calculated from the weight loss, the fluid intake and the volume of urination [(body weight before training - body weight after training) + fluid intake during exercise - the volume of urination]. **Results** The mean outdoor and water temperature during swimming training was  $25.0 \pm 0.9^\circ\text{C}$  and  $33.2 \pm 1.2^\circ\text{C}$ ,  $23.7 \pm 0.1^\circ\text{C}$  and  $32.0 \pm 0.3^\circ\text{C}$  in winter and summer, respectively. Sweat loss, fluid intake and fluid intake ratio (fluid intake / sweat loss  $\times$  100) were  $280.6 \pm 181.6$  g,  $153.4 \pm 122.9$  g,  $37.3 \pm 29.3\%$  in spring and  $610.5 \pm 281.7$  g,  $302.3 \pm 197.0$  g,  $33.1 \pm 21.8\%$  in summer, respectively. The sweat loss and fluid intake in summer were significantly greater than those in spring ( $P < 0.05$ ). The fluid intake ratio in spring was significantly greater than that in summer ( $P < 0.05$ ). **Discussion** Sweat loss and fluid intake during swimming training was related to pool conditions. However, there was no difference in the fluid intake ratio between summer and winter. Swimmers should have more fluid intake before/during swimming training to prevent dehydration, especially in summer. ### **ETUDE DES EFFETS DE LA RÉADAPTATION CARDIAQUE PAR L'EXERCICE PHYSIQUE CHEZ LES CORONARIENS**

Saidaissa, K., Saidaissa, S.

IEPS, Mostaganem University

**Résumé** La réadaptation cardiaque prend une part grandissante dans la prise en charge des coronariens. Il y a cependant une grande discordance entre son apport bénéfique certain chez ces patients, démontré par toutes les études et le peu de centres existants principalement dans les pays en voie de développement ; d'autant plus que ces effets sont obtenus avec un excellent rapport coût-bénéfice. Cette étude qui devait traiter, en principe, toutes les phases classiques de la réadaptation cardiaque, ne s'est intéressée qu'à la phase qui met en évidence les aspects du réentraînement à l'effort... A cet effet, nous considérons que l'entraînement physique est une partie clé de la réadaptation cardiaque. Les effets physiologiques obtenus par cet entraînement influencent la morbidité et la mortalité des patients de manière significative. Ces effets physiologiques sont accompagnés d'effets psychologiques favorables. A souligner que pour obtenir ces résultats, l'entraînement doit répondre à un certain nombre de critères : • être fondé sur l'entraînement dynamique, • être régulier, • calibré par une épreuve d'effort, • représenter un volume et une intensité de travail suffisants. Cette approche complète bien évidemment l'éducation à la prévention des différents facteurs de risque : • sevrage tabagique, • diététique, • lutte contre la sédentarité, • meilleure connaissance de la maladie, etc. Nous avons donc collaboré avec le service de médecine du sport qui a lancé cette discipline et nous rapportons notre première expérience en réadaptation cardiaque avec l'étude de 158 patients pris en ambulatoire. Les résultats ont montré l'amélioration fonctionnelle chez tous les patients avec une qualité de vie jugée meilleure par tous sur un questionnaire remis en fin de programme.

### **FUNCTIONAL INTEGRATED TRAINING: THE CONCEPTUAL FRAMEWORK APPLIED IN SPORTS CONDITION TRAINING, HEALTH-RELATED EXERCISE AND INJURIES PREVENTION**

Furtado, G., Letieri, R., Colado, J.P., Mané, P.I., Dantas, E.M.

Faculty of Sports Sciences and Physical Education

1: FCDEF-UC (Coimbra, Portugal), 2: FPE-URC (Iguatú, Brazil); 3: DPES-UV (Valencia, Spain); UNI-RIO (Rio de Janeiro, Brasil) **Introduction:** Several strategies for prescription physical exercise have emerged in recent years. For this reason, the term Functional Training (FT) is usually used to refer to a 'new' system of training that seeks to develop the physical fitness qualities (PFQ) of a more integrated one (King et al. 2000). Therefore, the aim of this study was to suggest a conceptual framework (CF) for the FT and to identify the main areas of application. **Procedure:** For this purpose was performed systematic review of the scientific literature. Our objective is to present a CF for FT as a complex and multidimensional system, emphasizing more specific approaches of the sciences of human movement to understand the real practical application of the FT in health-related exercise, sports condition training and injuries prevention. **Evidences:** Applied to the sport condition training, the goals are causing the individual to increase their performance and to prevent injuries. In the health-related exercise the applications of FT are to promote the improvement of PFQ, and create new practices in response to a low physical fitness of the population. **Discussion:** The development of a CF can provide a basic and standardized foundation, which definitions support a theoretical model and to assist in the practical application of scientific evidence support (Garber et al., 2011). In this proposal, was possible to develop a model to identify some specific approaches within each area of knowledge of the science of human movement applied to the FT. Therefore, what is proposed from the CF presented here is the understanding that FT consist as the improve PFQ (e.g. coordination, balance and strength) combining the core training and training in all plane of motion as well as development of energetic systems. (Clark et al, 2009). The strength workout is extensively revised in the literature it is associated with the increase of other indicators of PFQ and injuries prevention (Brent et al. 2009; Behm and Colado, 2012; Colado and García-Massó, 2009). The sport and exercise sciences have discovered new ways to enhance the performance of human and this has reflected in new forms of practical application in sport, health-related exercise and rehabilitation sciences as well. ## **ASSOCIATION OF THIGH, CALF, AND ABDOMEN CIRCUMFERENCES AND ARTERIAL STIFFNESS IN MIDDLE-AGED MALES WITH METABOLIC SYNDROME**

Jee, H., Kim, Y., Jin, Y.

*Namseoul University*

**Background and purpose:** Association of body circumference (CC) and atherosclerosis has been observed in recent studies. However, studies in such area are rarely conducted and poorly understood. Furthermore, mixed results have been reported. We aimed to test the cross-sectional association of arterial stiffness with calf, abdomen, and thigh circumferences (CC) to elucidate the association of CC to arterial stiffness in middle-aged males with metabolic syndrome. **Methods:** The study was performed on 143 males participants aged between 45 to 60 years who have visited A general hospital in Seoul, Korea for annual health examination. The participants were screened for metabolic syndrome with health questionnaire, 8 hr fasting blood tests, anthropometric measurements, and PWV. Blood tests included TC (total cholesterol), TG (triglyceride), HDL-C, LDL-C, glucose, insulin, and HbA1c. Subjects with metabolic syndrome were selected based on guidelines of NCEP-ATP III and WHO: TG > 150 mg/dl, HDL-C > 40 mg/dl, SBP > 130 mmHg, DBP > 85 mmHg, fasting glucose > 110 mg/dl, WC > 90 cm. Subjects with 3 or more were categorized as metabolic syndrome. **Results:** The present study showed that calf, abdomen, and thigh circumferences (CC) were significantly greater in those with metabolic syndrome (MS) than those without metabolic syndrome (NMS). However, when MS was divided in groups in quartile by circumferences, those with greater thigh and calf circumferences had significantly less baPWV. When odd ratios were calculated through logistic regression analysis based on 1400 cm/sec as atherosclerosis, those with less thigh and calf circumferences had greater risk for atherosclerosis in relationship to abdomen. **Conclusions:** The present study shows an inverse relationship between baPWV and thigh and calf circumferences in those with metabolic syndrome. Lower body musculature and sarcopenia may be related to risk for baPWV.

## **AN OXYGEN INHALATION TO IMPROVE FUNCTIONALITY AND RECOVERY OF SKIERS**

Koryagina, U., Mihalev, V., Reutskya, E.

*Siberian state university of physical education and sport*

**INTRODUCTION** In sports practice, there aids and methods increasing adaptive capacity of an athlete. Such means may be a breathing air mixtures (BAM) with high oxygen content (Han, Kim, Lim, & Kim, 2011). The aims of this study was to determine the effect of BAM containing 93% oxygen on the functional status and recovery skiers. **METHODS** The experiment was attended by 26 elite male skiers. The average age of athletes was  $20 \pm 1.79$  years old, the experience of sports activities is  $6.4 \pm 1.5$  years. To evaluate the performance of athletes the incremental exercise test on a treadmill was used. The test used a standard protocol (Power, Handrigan & Basset, 2011). In the process of the step test with the help of Polar heart rate monitor at each stage was recorded heart rate, defined anaerobic threshold (AT), was calculated power of the work performed (W), oxygen uptake (VO<sub>2</sub>). The research program included a two-fold tests with a break of at least 3 days. Before the second test athletes for 10 minutes BAM containing 93% oxygen with a portable oxygen concentrator Air Sep Life Style, performance 5 l/min. Before and after BAM with a high content of oxygen functional status was evaluated respiratory and cardiovascular systems of athletes. **RESULTS** Analysis of respiratory system parameters shows that breathing concentrated oxygen leads to an increase in vital capacity due to an increase in respiration volume ( $p < 0.001$ ). Analysis of the aerobic performance of athletes has shown that BAM containing 93% oxygen to the maximum load leads to an increase in VO<sub>2</sub> max, AT ( $p < 0.001$ ), oxygen uptake at AT ( $p < 0.001$ ), while the increase in the aerobic zone ( $p < 0.001$ ), aerobic threshold power ( $p < 0.001$ ), decrease value of time in the anaerobic zone and increase in total power test ( $p < 0.001$ ) compared to the level registered after the first load testing, in which athletes did not use BAM. Analysis of heart rate variability and circulation shows increasing efficiency of functioning cardiovascular system of an athlete. There are decrease heart rate, increase systolic volume, also by athletes with moderate prevalence of autonomous regulation circuit increase heart rate variability indicators: SDNN, CV, Mo, pNN50, RMSDD ( $p < 0.001$ ). Also, using this mixture during 20 min after the maximum load is faster recovery of the cardiovascular and respiratory systems of elite skiers. **DISCUSSION** The use of BAM containing 93% oxygen has a positive effect on the functional state of athletes and is also a specific factor that increases the reserve capacity of respiratory and non-specific stimulus, mobilizing the adaptation body's structures athletes. The use of oxygen support before maximum load capacity increases athletes aerobic capacity, anaerobic power and efficiency performance. **REFERENCES** Han, S-W., Kim, H-R., Lim, S-G. & Kim, C-S. ## **EFFECT OF ACUTE MOUNTAIN SICKNESS ON POSTURAL FLEXIBILITY**

Werner, I., Wille, M., Weisleitner, A.

*Institute of Sport Science*

**Introduction** Fast ascents to high altitude regions may provoke head ache, acute mountain sickness (AMS) or even high altitude cerebral or pulmonary edema (HACE, HAPE). Hypoxia is supposed to affect the basal ganglia and cerebellar pathways which are important for postural adjustments. Hiking on mountain trails often demands well controlled posture to avoid stumbling and slipping. Deterioration of postural control is linked to HACE, but no relationship between postural control and AMS has been observed (Bird et al., 2011). Short term learning effects to map postural flexibility have not yet been taken into account. **Methods** Seventy healthy subjects (mean age 26, SD 5 y) were exposed for 7h to normobaric hypoxia at a simulated altitude of 4500m (12.6% FIO<sub>2</sub>). The Lake Louise Score (LLS) was used to diagnose AMS after 0.5h and 6h followed by balance testing (S3-check, Raschner et al., 2008) which was also performed 10 min before entering the hypoxic chamber. Half of the subjects balanced on a platform with anterior-posterior tilt and medio-lateral tilt respectively. Three trials of 30 s each were registered and resulted in a stability score. 15 s of warming up were permitted before each trial. Subjects showing a LLS > 3 were rated as having AMS. ANOVA with repeated measures (3 trials, 3 time points: before, 50min and 6h:50min in hypoxia, 2 groups: AMS yes or no) was conducted for each balance task separately to reveal differences in short term learning effects according to AMS status. Significance level was fixed at  $p < 0.05$ . Results Twenty-four participants suffered from AMS. An overall learning effect was seen in the ante-posterior task without any interactions. In the medio-lateral task a significant main effect of trials (Greenhouse-Geisser corrected  $F(1.6,56) = 5.3$ ,  $p = 0.014$ ,  $\eta^2 = 0.16$ ) and an interaction of trials and time points ( $F(4,112) = 3.67$ ,  $p = 0.008$ ,  $\eta^2 = 0.12$ ) showed that hypoxia affects adaptation strategies within trials. Interestingly the AMS group tended to adapt differently

( $F(4,112)=1.96$ ,  $p=0.106$ ,  $\eta^2=0.07$ ) and showed significantly less improvement within trials in hypoxic conditions compared to the non-AMS group (contrasts:  $F(1,28)=4.39$ ,  $p=0.045$ ,  $\eta^2=0.14$ ). Discussion Whereas non-AMS participants showed a similar progression of trials at different time points, AMS patients seemed to deteriorate in the ability to select relevant information for improving performance in consecutive trials. The general effect of hypoxia on postural flexibility should be investigated with a control group design. Differences in adaptation of AMS patients could be sharpened by executing more test trials. ## GROWTH AND BODY COMPOSITION OF RHYTHMIC GYMNASTICS ATHLETES OF ON THE SOMATIC MATURATION

Camargo, C.T.A., Gomez-Campos, R.A., Cossio-Bolaños, M.A., Barbeta, V.J.O., Arruda, M., Guerra-Junior, G.

*Universidade Estadual de Campinas UNICAMP*

**Introduction** The effect of sports training on normal growth and sexual maturation of rhythmic gymnastics athletes is still a matter of debate. Studies report that the intense training at an early age can adversely affect physical growth, maturation and body composition in young female athletes (Daly et al., 2005). Therefore, the aim of the study was to analyze the growth and body composition of athletes in rhythmic gymnastics in relation to somatic maturation. **Methods** A descriptive cross sectional study with a sample of 136 athletes from 23 Rhythmic Gymnastics teams in 10 states of Brazil. We evaluated anthropometric measurements of weight, sitting height. We calculated the lean and fat mass, fat percentage and peak height velocity (PHV). The weight and height were transformed into z scores compared with the average of the reference for age and sex (WHO, 2007). **Results** The z scores for weight and height were negative in all ages, and the average weight ranged from -0.3 to -0.8 and from -0.2 to height of -0.8. The maximum PHV appeared to  $12.1 \pm 0.8$  years and up to four years after it was observed a significant increase in weight, height, sitting height, body fat percentage, fat mass and lean. The average age of menarche was  $13.2 \pm 1.3$  years. **Discussion** The rhythmic gymnasts in this study had weight and height below the reference for age, peak growth rate and age at menarche within the normal and delayed recovery of weight and height during puberty. There was an increase in the percentage of fat and the fat and lean mass after 2 years of PHV and the occurrence of menarche, which can be explained by the fact that female puberty be modulated by estrogen which promotes fat accumulation (Georgopoulos et al., 2010). Thus, periodic controls of growth in children and adolescents during the sports training are needed. References Daly RM, Caine D, Bass S, Pieter W, Broekhoff J (2005). Growth of highly versus moderately trained competitive female artistic gymnasts. *Med Sci Sports Exerc* 37:1053-60. ## THE EFFECT OF "FUNCTIONAL SOCKS" FOR FOOT ARCH AND EMG OF THE LOWER LEG MUSCLES DURING TREADMILL WALKING AND RUNNING

Kudo, H.I, Takizawa, Y.I, Kurata, T.2

*1:Mejiro University 2:Oyama Sports Medicine Clinic*

**Introduction** In recent years, socks for the purpose of the support of the foot arch named 'functional socks' are spread out. The functional socks is not the pressure to calf muscles, but it support a heel and foot arch by original knit, and an aim of the socks fatigue reduction. However, there is not the report that examined the effect of these socks. Therefore, the purpose of this study was elucidate the effect of "functional socks" during treadmill walking and running. **Methods** This study comprised 20 healthy college student volunteers. In all volunteer, EMG of the calf muscle using PowerLab (AD Instrument) and the foot pressure mapping using F-scan system (Nitta). %MVC (normalized by maximum voluntary contraction) during treadmill walking and running were calculated from surface EMG. The foot pressure evaluated the load ratio of the middle foot part for the whole foot part except the toe (Modified Arch Index : MAI). **Results** MAI of 'functional socks' group showed a high value from the normal socks group, but the significant difference was not seen. In 'functional socks' group, the %MVC of the flexor hallucis longus muscle showed lower value than normal socks group during walking and running. The %MVC of the soleus muscle and the medial gastrocnemius muscle also showed low value in 'functional socks' group. **Discussion** These results suggest that the 'functional socks' did not have significant effect to structural support for the foot arch. However the 'functional socks' may be able to reduce muscle fatigue.

## TEAM DOCTOR IN FORMULA ONE: EPIDEMIOLOGY

Zaccaria, D.

*University of Pavia*

**INTRODUCTION** The physician for a sports team is the physician who is in charge of coordinating the medical staff and medical services for the team. A Formula One (F1) team consists of 75 people of which only 2 or 3 are athletes, with the balance comprising of mechanics, engineers, technicians and managers. The FIA regulations do not require the presence of a doctor for each team. **METHODS** This paper refers to three F1 world championships (2009-2010-2012 seasons respectively of 17 Grand Prix (8 non-European), 19 (10) and 19 (10). Data has been collected on the types of medical intervention required, and has been classified by medical specialty, by the time of the week / day and by the patient who underwent the treatment. The average duration of a GP in Europe was  $6.5 \pm 1.1$  days, and  $13.7 \pm 1.2$  days for travel since many of the non-European GPs are back to back. **RESULTS** Only 1% of the recipients of the medical service were the drivers. Most of the work performed was on the team crew (76%). 13% was carried out on other teams, while the remaining 10% on other individuals (journalists, photographers, members of the catering crew, guests). The average of interventions was  $54.3 \pm 2.7$  per day in overseas GPs while  $41.7 \pm 1.9$  per day in Europe. With reference to the type of interventions, 27% were related to orthopaedic problems, 17% pulmonology and ENT, 15% gastrointestinal problems, 7% urogynaecological disorders, 13% surgical issues and the remaining to others (emergencies, insect bites, dehydration, dental, etc...). The most of the events occurred during overnight or during the hours of qualifications or GP. The events were concentrated in the first and last days of the event. **DISCUSSION** In conclusion, it is clear that the doctor meets more illnesses than injuries, many of which are seen in the family doctor medicine. The timing of events can be related to hazardous and strenuous activities when assembling and setting down the garage, sometimes associated with jet lag as well as the moments that require greater speed and accuracy as qualifying sessions and GP. According to the number and types of cases, the presence of a doctor within each team has to be strongly recommended. The F1 team doctor must be a good general practitioner and must have an excellent knowledge of anti-doping regulations and BLS procedures as dangerous and life-threatening injuries may always occur in Motorsports. **REFERENCES** -Hunter HC: Medical team coverage of motor sports events. *J Am Osteopath Assoc*. 1996;96(3):179-180 -

### **HAEMODYNAMIC RESPONSES DURING GRADED PLANTAR FLEXION EXERCISE IN MIDDLE-AGED MEN AND WOMEN WITH TYPE 2 DIABETES**

Egaña, M., O'Connor, E., Kiely, C., Green, S., O'Shea, D.

*Trinity College Dublin*

In this study we tested the hypothesis that type 2 diabetes (T2D) impairs the haemodynamic responses to a maximal incremental plantar-flexion exercise but that these impairments are not sex-specific. Forty-four middle-aged individuals with T2D (30 male, 14 female), and 34 age- and BMI-matched healthy individuals (16 male, 18 female) were tested. After establishing each participant's maximal voluntary contractions (MVC), participants performed an intermittent incremental plantar-flexion exercise (6s duty cycle: 2 s contraction, 4 s relaxation) until failure in the supine posture. The test began with a force production of 100N for 2 min, and thereafter the required force was increased every two minutes by 200N (men) or 150N (women). Calf blood flow (BF) was measured contraction by contraction using venous occlusion plethysmography. Ethical approval was obtained from the Trinity College Dublin Faculty Research Ethics Committee. Peak force expressed as a percentage of the MVC (% MVC) was significantly reduced in men and women with T2D compared with their respective non-diabetic counterparts (men,  $60.4 \pm 11.1$  vs.  $68.0 \pm 10.8$ ; women,  $63.3 \pm 11.2$  vs.  $74 \pm 21.4$ ). Peak BF (ml/min) and hyperaemic (slope of BF vs the percentage of peak force; ml/min/%peak F) responses were also reduced in women with T2D compared with healthy women (Peak BF,  $460.6 \pm 126.8$  vs.  $628.3 \pm 347.7$ ; slope,  $3.78 \pm 1.74$  vs.  $5.85 \pm 3.14$ ) and in men with T2D compared with non-diabetic men (Peak BF,  $621.7 \pm 241.3$  vs.  $721.2 \pm 359.7$ ; slope,  $5.75 \pm 2.66$  vs.  $6.33 \pm 3.63$ ). The magnitude of these impairments was not different between males and females. The results suggest that the type 2 diabetes-induced impairments in calf incremental plantar-flexion exercise are related to reductions in blood flow but that they are not affected by sex in middle aged participants.

### **CHANGES IN STRENGTH OF KNEE EXTENSORS AND FLEXORS FOLLOWING REPEATED FOOTBALL MATCHES DURING A WEEKLY MICROCYCLE**

Ermidis, G., Chatzinikolaou, A., Draganidis, D., Barbero, J.C., Mohr, M., Tsoukas, D., Mandalidis, D., Athanasopoulos, S., Douroudos, I.I., Jamurtas, A., Fatouros, I.G.

*Democritus University of Thrace*

High intensity, accumulated fatigue and muscular strain induced by a football match as well the dynamic match/training scheduling predisposes football players to injury during subsequent training or competition. Among football injuries, muscle strains of hamstring origin are considered to be the most prevalent. The aim of the present study was to determine the effects of consecutive football matches on knee extensor and flexor muscle strength and damage. Forty elite football players were randomly assigned to either an experimental group that participated in three football matches (EG, N=20) or a control group that participated only in training (C, N=20). Three days after an initial 8-day preparatory period consisting of daily practices, EG played three matches within a 7-day microcycle (Sunday-Wednesday-Sunday matches). Participants in both groups trained daily according to an in-season training model. Blood samples were collected, muscle damage was determined (DOMS, delayed onset of muscle soreness; KJRM, knee joint range of motion) and muscle strength (at 0 deg/sec as well as concentric and eccentric strength at 60 and 180 deg/sec on an isokinetic dynamometer) of knee flexors and extensors was measured before and after the preparatory period, before and after each match and daily in between matches (and for 3 days after the last one). Blood was analyzed for inflammatory markers (creatine kinase activity, c-reactive protein, leukocyte counts). Data analysis revealed that isometric, concentric, and eccentric strength of knee flexors and extensors was considerably reduced after each match. This reduction was more prolonged after the first two matches and it was accompanied by marked alterations of the flexor to extensor strength ratios (both concentric/concentric and eccentric/concentric). This reduction was correlated to CK elevation. Muscle damage and strength reduction was more evident and prolonged for knee flexors than extensors. These results suggest that consecutive football matches may result in a reduction of athlete's potential for knee stabilization.

### **INVESTIGATION OF THE FIRST AID KNOWLEDGE LEVELS OF UNIVERSITY STUDENTS WHO ACTIVELY DO SPORTS**

Gumus, M., Akalin, T.C., Kudak, H.H., Ciplak, M.E., Gelen, M., Yamaner, F.

*Bülent Ecevit University*

Introduction Death rates caused by the accidents and natural disasters are high both in our country and in the world. Among the 21 objectives of the "Health for Everyone in 21st Century" issued by World Health Organization which aims to protect and improve human health in a life-long period, the ninth aim is "Reducing Accidental Injuries" The skill and knowledge levels of the society and individuals in the field of first aid is unknown. In this context, training and informing the society about first aid is gaining high importance. For this reason, this article can be considered as a descriptive study conducted on 1386 students which aims to evaluate the level of knowledge of university students who are actively involved in sports and who are not. Methods 1386 students, having an average age of 21.46, 660 of which are females and 726 of which are males, who are engaged in team or individual sports or none voluntarily participated the study. A survey form composed of 16 questions and demographic inquiry was used as the data collection instrument. Statistical analysis of the data was carried out using SPSS 16.0 program, the results were presented as "mean and  $\pm$  standard deviation" and t-test was performed in order to find out whether there is a statistically significant difference between the mean scores of the study groups. The results of the analyses were evaluated within 95% confidence interval ( $p < 0.05$ ). Results A statistically significant difference of  $0.039 \pm 0.14$  was detected between the first aid knowledge levels of male and female students ( $p < 0.05$ ). No statistically significant  $0.92 \pm 0.14$  difference was detected between the first aid knowledge levels of the students who actively do sports and who do not ( $p > 0.05$ ). It was discovered that, out of the 318 students who actively do sports, 37.1% encountered an incident which required first aid once, 27% twice, 21.4 three times, 8.8% four times, 5.1% five times and 0.6% six times. In the study, it was found out that a large number of students (18.6%) had not received first aid related training. There is a  $0.001 \pm 0.18$  statically significant difference between the participants who received first aid training and those who did not ( $p < 0.005$ ). It was also discovered that 15 of the participants had first aid certificates, 1373 of the participants did not have any such certificates and a statistically significant difference of  $0.002 \pm 0.16$  was detected between the participants who have first aid certificates and those who do not ( $p < 0.005$ ). Discussion According to the findings of this study which aims to determine the university students' level of knowledge regarding first aid, it was found out that the students did not possess sufficient knowledge about first aid,

and that, being aware of their lack of knowledge, they confessed their need for first aid education. References Health 21 for European Region, WHO

### **MEDICAL DISQUALIFICATIONS FROM COMPETITIVE SPORT: TRENDS DETECTED IN COURSE OF THE PRE-PARTICIPATION SCREENING AT THE SPORTS MEDICINE SERVICE OF BOLZANO/BOZEN FROM 1983 UNTIL 2010**

Schenk, K., Ferrari, M., Frizzera, S.

*Regional Hospital of Bolzano/Bozen*

**Introduction** In contrast to many other countries, the Italian sports medical pre-participation screening program is not limited to elite athletes, but everyone participating in organized training and competition is required by law to undergo a periodical preventive medical evaluation consisting in personal and family history, 12-lead electrocardiograms at rest and after exercise, spirometric test and physical examination. If irregularities are detected, further medical diagnostics are requested to evaluate the eligibility for competitive sports. **Methods** All cases of medical disqualification, from the implementation of the regional Sports Medicine service in 1983 until 2010, were reviewed, annual prevalence and sorts of cardiovascular causes were analyzed. Data of the period before and after 1997 were statistically compared. Results Overall, in the course of 28 years at the Sports Medicine service of Bolzano/Bozen 189,830 pre-participation screening tests were performed and 762 times the detection of a severe pathology motivated the medical disqualification (558 cases before and 204 cases since 1997). The annual prevalence was on average 0.44±0.30%, but was significantly higher during the first period (0.69±0.20% vs 0.19±0.07%). The annual percentages of cardiovascular motivated disqualifications increased in time (66.2±11.8% vs 77.9±9.6%). While the annual proportion of arrhythmias, conduction anomalies and cardiomyopathies within cardiovascular causes were not significantly different before and after 1997, valvulopathies (13.2±5.3% vs 19.6±6.5%) and congenital heart diseases (2.0±2.0% vs 7.8±5.3%) have become proportionally more frequent. Ischemic heart disease became more prevalent as cardiac reason for disqualification (9.1±5.6% vs 14.1±7.7%;  $p=0.058$ ). **Discussion** The benefit of the Italian pre-participation screening system is impressively demonstrated by the decline of sudden cardiac death among athletes since its implementation in 1982 in Veneto region (1). Our data document a decreasing annual prevalence of disqualifications as a result of the continuous progress in differential diagnostics and therapies. Cardiovascular pathologies are by far the most frequent motivation for medical disqualification from participation in sports and have proportionally further increased in the recent years. Concepts to further improve effectiveness and cost-value ratio of the medical pre-participation screening are discussed. References 1 Corrado D, Basso C, et al. (2006). JAMA, 296, 1593-1601.

### **THE EFFECT OF X-CUPWARE IN SOCCER TRAINING IN YOUTH.**

Concepcion, J., Gomez, G., Alonzo, J., Raya, D., Medina, M., Puello, M.

*AMEXA-XEMIDE-CENETED*

Soccer players who become professional drag injuries due to bad training during youth. We watch 476 patients from different categories of soccer from youth teams and professional trying to figure out how to prevent those injuries, and prevent that some of the player who won't become professionals could continue practicing the sports without health issues. We developed special software (X-cupware) to upload the data we collected (anthropometrics, dynamics, imagenology, surgery reports). And we gave the trainers web access, to our artificial intelligence method, the software automatically makes a suggestion in where the player should be more effective. But our software not only give suggestion to the coach but also to medical boards of the teams in how to resolve in time the injuries so they could be back in the team in healthy conditions. There is a big underreporting about injuries in base soccer in Spain, the main cause is due to what we call sports momentum timing, a big factor it's also players don't know the basics about athletism and the coaches refer they don't have time to teach that. With our software and direct intervention we reduced indirect injuries over 40% and the rehabilitation period reduced by 60% on direct injuries. Also the software was used by parents and coaches to learn about the status and correct procedures during the injury. With our system what we are trying to do is to create a milestone in youth soccer teams in Spain, we all know this follow up system is well known by the big teams (Real Madrid-Barcelona), but most of the worst injuries happens in early steps. By using mibox software technology, combined with footplus IBP system, and adidas dynamic recording system, we bring up a tool wich is in used by CENETED soccer school professionals to prevent these injuries from happening at the palm of their hand using a x-cupware terminal phone at very low cost. ### **RELIABILITY OF GLUTEUS MAXIMUS MUSCLE THICKNESS MEASUREMENTS WITH ULTRASOUND**

Seiya, S.I, Takuya, S.I, Rieko, K.I

*I:Chukyo Univ (Aichi, Japan)*

**Introduction** Gluteus maximus muscle (GM) is a large muscle that engages the movement of the hip joint. This muscle connects to trunk and lower limbs, and plays a big role in various movements. But it is difficult to evaluate the form of this muscle exactly by using ultrasound. Although MRI is utilized by medical professionals for its high accuracy, it is not readily available in many settings and considered inconvenient due to its expensive cost and lack of portability. On the other hand, ultrasound is more suitable for collect much data. In assessing GM by using ultrasound, it must be noted that gaining the reliability of the use of ultrasound as an imaging tool is crucial since its accuracy is influenced by the positioning of the ultrasound probe. Little study has been done to measure the thickness of GM using ultrasound in Japan. The aim of this study was to measure the thickness of GM by using ultrasound to examine its intra-rater reliability. **Methods** Japanese male rugby football players were recruited in this study (n=6). The thickness of GM was measured twice on different days using ultrasound. Landmarks were marked at proximal 1/4, middle, and distal 1/4 of the straight line from posterior superior iliac spine to greater trochanter. Interclass Correlation Coefficient (ICC) was used to examine the intra-rater reliability of two testing data taken on two different days. ICC=0.81~1.00 was considered high (Landis et al., 1977). Results The differences between the two testing data were the proximal 1/4; 0.24cm (ICC=0.97), the middle; 0.40cm (ICC=0.85), the distal 1/4; 0.32cm (ICC=0.88). The maximum difference between the two testing date was ICC>0.85 (0.77cm). The averages of the thickness (±SD) were proximal 1/4; 5.74cm (±1.20), middle; 5.98cm (±0.86), distal 1/4; 5.19cm (±0.73). **Discussion** All data showed high reliability (ICC >0.80) in this study. Our result showed that an ultrasound is suitable to measure the thickness of GM. The proximal 1/4 had the highest reliability (ICC=0.97). However it was the middle point that reported the largest thickness. Therefore, further study must be done to decide the best landmark of these three points when measuring GM. More study is needed to decide the best landmark to measure GM by comparing and considering the data taken by using MRI. Further study in this area using ultrasound will be useful to establish a portable and cost efficient method to evaluate the thickness of

GM that can be use in on-site sports settings. References Landis JR, Koch GG: The measurement of observer agreement for categorical data: *Biometrics*, 33: 159-174, 1997

### **INFLUENCE OF POST-EXERCISE LIMB BLOOD FLOW STIMULATION ON PERFORMANCE RECOVERY**

Bieuzen, F., Borne, R., Hausswirth, C.

*Institut National du Sport, de l'Expertise et de la Performance*

Introduction Elite sport requires athletes to complete multiple bouts of high-intensity exercise with limited rest periods that are not sufficient for full recovery. To facilitate the performance recovery, recovery therapies like active,1 immersion2 or neuroelectromyostimulation3 (NEMS) have achieved very good results. It has been hypothesized that the increase of blood flow with these strategies could accelerate the supply of oxygen rich blood, increase the flush of waste products and help reduce H+ levels associated with lactic acid build-up. Consequently, the assumption of a strong relationship between blood flow and high intensity performance recovery is often cited although never tested. Therefore, the aim of this study was to test this hypothesis by stimulating the blood flow at three different levels during a 30-min recovery intervention period between two sessions of multiple sprint interval (three 30-s WanT) exercise. Methods Thirty-seven trained athletes participated in a randomized controlled trial. Each session consisted of performing 3 x 30 WanT (bouts 1-3) followed by a randomly assigned 30-min recovery intervention of either: high blood flow (Veinoplus Sport®)(HBF), low blood flow (Cefar-Compex Theta 500®)(LBF); sham NEMS device (SHAM; that does not stimulate the blood flow) and passive recovery (PAS). A 30-s WanT was then repeated (bouts 4) and compared to bout 1 for peak power and mean power. Measures of blood flow, blood lactate and heart rate were recorded every 3 min throughout the recovery intervention period to monitor physiological responses. Results Blood flow was significantly higher in HBF group compared to PAS, SHAM and LBF groups. Examination of heart rate and blood lactate revealed no recovery effect. The recovery of mean power was likely beneficial in the HBF group compared with the SHAM group and very likely beneficial compared with the PAS group and the LBF group. The recovery of peak power in the HBF group was likely beneficial and very likely beneficial compared with the LBF group and the PAS group, respectively. Conclusion Stimulate total blood flow at a high velocity is a mean of preserving performance when repeating acute exhausting exercise interspersed by short recovery period. However this positive effect is not accompanied by a greater lactate removal. References 1. Heyman E, et al. ### **CELLULAR AND BIOCHEMICAL PARAMETERS OF EXERCISE-INDUCED OXIDATIVE STRESS: EFFECTS OF EXPLOSIVE-TYPE MODERATE INTENSITY TRAINING IN THE ELDERLY**

Sabatini, S.1, Beltran Valls, M.R.1, Ceci, R.1, Dimauro, I.1, Brunelli, A.1, Ciminelli, E.2, Tranchita, E.2, Duranti, G.1, Parisi, P.1, Parisi, A.2, Pittaluga, M.1, Caporossi, D.1

*University of Rome FORO ITALICO*

BACKGROUND: Reactive oxygen species (ROS) production increases during aging. This could be due, almost in part, to a decrease of antioxidant capacity and other protective mechanisms such as heat shock proteins (HSPs), thus making elderly subjects susceptible to oxidative stress. Regular physical activity has been hypothesized to provide protection against oxidative damage at all ages. Several studies have incorporated, as an attractive exercise modality for older adults, a low frequency explosive-type moderate resistance training (EMRT). It is highly effective in eliciting a significant enhancement in muscular strength without stress-related negative effects. The purpose of this work was to investigate the effect of EMRT on both biochemical and cellular biomarkers of oxidative stress evaluated in trained elderly subjects in response to a maximal exercise stress test. METHODS: Sixteen elderly persons (aged 72.5 years), were randomly assigned to two different groups: a training group (explosive-type resistance training for 12 weeks) and a control group (that not participate to training protocol). Plasma redox homeostasis (total antioxidant status, (TAS) and glutathione (GSH)), oxidative damage (malondialdehyde (MDA) and protein carbonylation levels), and repair system (Hsp70 and Hsp27 expression in leukocytes) were evaluated before and after the maximal exercise stress test. RESULTS: No differences were found comparing biological and biochemical parameters between two groups before the training protocol. The maximal exercise stress test lead to an increase of all the parameters related to oxidative stress. However, after the EMRT, the training group showed a less pronounced increase in oxidative stress parameters following the maximal exercise stress test compared to control group. A 25% reduction ( $p < 0.05$ ) were found in GSSG levels and GSH/GSSG ratio was increased by 20% ( $p < 0.05$ ) compared to control group. MDA and protein carbonylation levels were 25 % reduced respect those found in control group. Hsp70 and Hsp27 expression showed a lower protein basal levels in the trained group, with a higher protective response after 24 hrs from the test ( $p < 0.05$ ). CONCLUSIONS: Our data show that, in trained elderly subjects, the EMRT protocol is able to induce a cellular adaptation, through influencing glutathione homeostasis and heat shock proteins levels after a maximal exercise stress test.

### **FACTORS INFLUENCING THE APPLICATION OF INFRARED THERMOGRAPHY IN ATHLETES: A CLASSIFICATION PROPOSAL**

Fernández-Cuevas, I.1, Marins, J.2, Arnaiz Lastras, J.1, Gómez Carmona, P.1, Sillero-Quintana, M.1

*1 INEF-UPM (Madrid, Spain) 2 LAPEH (Viçosa, Brazil)*

Introduction Infrared Thermography (IRT) is a technique with a rising number of new and interesting applications on physical activity and sport field, as for example the prevention and monitoring of injuries (Hildebrandt et al., 2010). However, working with IRT requires taking into account many factors, which could influence either the evaluation or the interpretation of the thermal images (Zaproudina et al., 2008). The primary objective of this work is to propose a classification of the factors that influence IRT applications in athletes. Methods We performed a systematic review using 9 search engines to identify studies that are related to IRT and its influencing factors. Search queries included IRT synonyms and keywords related with the influencing factors. The inclusion criteria were: (1) the literature was written in English, (2) the participants were humans, and (3) the skin temperature was assessed using non-contact IRT. Potentially relevant studies that may have been missed in the original search were also included by reviewing the bibliography of the identified articles. The original studies that were published in the previous 20 years were preferentially considered. Results: 378 articles were selected from database. Based on these articles, we propose a classification of factors into three primary groups: • Environmental factors: Related to

the place where the evaluation is made. • Individual factors: Those factors that are related to the subject being assessed and his/her personal characteristics, which could influence skin temperature (Tsk). These factors will be divided into intrinsic and extrinsic factors. • Technical factors: Factors that are linked to the equipment that is used during the IRT evaluation. Conclusion: IRT has suffered periods of lost of credibility due to a lack of standardization and under-estimation of its limits (Head et al., 2002). Nowadays, the increase of knowledge, the technological advances and the new human IRT applications draw an optimal scenario to start a new period based on a more standardised and reliable research field. This proposed classification is a first step in order to build a common framework for future research. Nonetheless, further investigation is needed to increase the knowledge about the degree of influence of the most factors listed in this work. References • Head, J. F., & Elliott, R. L. (2002). ## THE ROLE OF PHYSICAL ACTIVITY ON WOMEN ANTIOXIDANT CAPACITY

Adriana Santos, Z.

*University of Trás-os-Montes e Alto Douro, Portugal*

**Introduction** Regular physical activity induces several health benefits reducing several risk factors action that enhance the development of hypokinetic diseases. The relevance of the relation between physical activity and health increases when the age related loss of functionality is considered. Particularly in women, the study of age related changes functionality are frequently confounded due to hormonal changes. Considering, oxidative stress importance in many pathophysiological conditions, and the hormonal and exercise influence in antioxidant capacity, the aim of this study was to analyze the association between daily physical activity in women over 40 years of age antioxidant capacity. **Methods** Thirty seven women over 40 years of age (from 41 to 82 yrs), not suffering from any motor incapacity, participated in this study. Daily physical activity was quantified by IPAQ, Antioxidant capacity (Catalase activity) was analyzed in plasma with the subjects in fasting conditions. Descriptive data analysis and Pearson correlation between variables was done in SPSS. Significant level was set at  $p < 0.05$ . **Results** Our results revealed that no association between age and daily physical activity exist with serum Catalase activity. **Discussion** Considering the multiple and complex reactive oxidant species (ROS) scavenges systems, our results suggest that other antioxidants systems should be more prone to changes induced by age and daily physical activity. It is possible that other antioxidants systems have changed or that ROS production has not increased significantly with age. Moreover, it is possible that an exercise program may produce different results due to the control of training workload. **References** Valletta EA, Berton G. ## Training and Testing

### EFFECTS OF SHORT-TERM HIGH-INTENSITY INTERVAL TRAINING ON OXIDATIVE STRESS RESPONSES AND ANTIOXIDANT STATUS IN HEALTHY HUMANS

Bogdanis, G.C.1, Stavrinou, P.1, Fatouros, I.G.2, Philippou, A.1, Draganidis, D.2, Chatzinikolaou, A.2, Ermidis, G.2, Maridakis, M.1

*1: University of Athens (Greece), 2: Democritus University of Thrace (Komotini, Greece)*

**Introduction** High-intensity interval training (HIT) has been characterized as an effective method for improving both aerobic and anaerobic fitness and promoting health (Gibala et al., 2012). Although high-intensity exercise elevates oxidative stress markers, limited information exists regarding the effects of short-term HIT on the antioxidant mechanism. It was hypothesized that nine sessions of HIT would reduce oxidative stress and improve antioxidant status responses to high-intensity exercise. **Methods** Eight physically active males performed nine HIT sessions over 3 weeks. Each session included four to six 30-s bouts of high-intensity cycling separated by 4 minutes of rest. Blood samples, collected before and after (30 min, 24 h, 48 h) the first and last training session, were analyzed for creatine kinase (CK) activity, protein carbonyls (PC), thiobarbituric acid reactive substances (TBARS), total antioxidant capacity (TAC), glutathione peroxidase (GPX) and catalase activity (CAT). **Results** Before training, acute exercise elevated PC, TBARS, GPX, TAC and CK, which peaked 24 h post-exercise ( $252 \pm 30\%$ ,  $135 \pm 17\%$ ,  $10 \pm 2\%$ ,  $85 \pm 14\%$  and  $36 \pm 13\%$ , above baseline, respectively;  $p < 0.01$ ), while CAT peaked 30 min post-exercise ( $56 \pm 18\%$  above baseline;  $p < 0.01$ ). Training resulted in a reduction of oxidative stress markers (PC by  $13.3 \pm 3.7\%$ ; TBARS by  $7.2 \pm 2.7\%$ ,  $p < 0.01$ ) and CK activity, despite the fact that total work done was  $10.9 \pm 3.6\%$  greater in the post- compared with the pre-training exercise test. Training also induced a marked elevation of antioxidant status indices (TAC by  $38.4 \pm 7.2\%$ ; CAT by  $26.2 \pm 10.1\%$ ; GPX by  $3.0 \pm 0.6\%$ ,  $p < 0.01$ ). **Discussion** Short-term HIT attenuated oxidative stress and up-regulated antioxidant activity after only nine training sessions totaling 22 min of high intensity exercise. Antioxidant enzyme up-regulation in muscle may be related to the increased maximal oxygen uptake after training (Jenkins et al., 1984, Burgomaster et al., 2005) since a relationship between antioxidant enzyme activity and succinate dehydrogenase activity as well as with fiber type composition in muscle has been reported (Laughlin et al., 1990). These results led further support to the effectiveness of HIT not only for physical conditioning but also for promoting health. **References** Burgomaster KA, Hughes SC, Heigenhauser GJ, Bradwell SN, Gibala MJ. ### THE INFLUENCE OF MOTOR ABILITY AND PHYSICAL CAPACITY ON TEAM SELECTION AND PHYSICAL MATCH PERFORMANCE IN YOUTH SOCCER PLAYERS

Lovell, T.W.1,2, Bocking, C.J.2, Fransen, J.3, Coutts, A.J.2

*1) University of Technology, Sydney, 2) Knox Grammar School, Sydney, 3) Gent University, Belgium*

**Introduction** When identifying talent for team selection, many confounding factors may influence a coach's perception. The dynamic nature of sport talent therefore requires a multidimensional approach so that potentially gifted players are not overlooked (Vaeyens et al. 2008). The aims of this study were to examine 1) how a multitude of physical- and coordination-related characteristics related to team selection and 2) the effect of these characteristics on the match physical activity profile of different playing levels in youth soccer players. **Methods** 170 adolescent soccer players (aged 10-16 y), ranging from sub-elite to recreational, participated in the study. Players had previ-

ously been graded by soccer coaches into the A, B or C team for each of the five age-groups. Maturity was estimated using anthropometrical measures of stature, body mass and leg length. Physical characteristics of endurance, leg power, flexibility, strength, speed, repeat-sprint ability and agility were assessed. Motor coordination (KTK) and soccer-specific coordination (UGent Dribble) were also measured. Physical activity profile data was collected during soccer matches using 15Hz GPS devices. Results Regression analysis revealed that 42% of the adjusted variance in distance/min during matches could be explained by measures of endurance, motor coordination and dribbling ability ( $Y = 83.515 - 0.18 \text{ moving sideways} + 0.235 \text{ jumping sideways} - 0.2 \text{ soccer dribble} + 0.473 \text{ YoYo IR1 distance}$ ). Physical fitness, motor coordination, dribbling ability and physical match performance significantly influenced team selection ( $p \leq 0.001$ ). Multivariate analysis showed "A" players to cover more total distance/min, low-intensity running/min, high-intensity running/min and very high-intensity activity than their counterparts during matches (all  $p \leq 0.05$ ). No difference in chronological age or maturity was observed between playing levels. Discussion The present results highlight the multitude of physical- and coordination-related factors that influence team selection in youth soccer. In agreement with previous research (Vaeyens et al. 2006), these results show that selected youth soccer players possess superior physical quality and skilled performance. Physical match performance was also shown to influence playing level, with "A" team players producing superior total distance/min and distance/min in all intensity categories. These findings show physical capacity and motor coordination to be associated with physical match performance, and the important implications this may have for talent selection in youth soccer. References Vaeyens, R. et al. (2008). *Sports Med*, 38(9), 703-14. Vaeyens, R. et al. (2006). *Br J Sports Med*, 40(11), 928-34.

## **EFFECTS OF PARKOUR TRAINING ON STRENGTH AND BODY COMPOSITION IN ADOLESCENTS**

Dvořák, M., Baláš, J., Bunc, V.

*Charles University in Prague*

Introduction The aim of the study was to describe effects of Parkour training on strength characteristics and body composition in adolescents. Materials and Methods Six participants (age =  $16 \pm 2$  years) took part in a controlled indoor Parkour intervention - ten week training with the frequency one hour per unit two times a week. Training units were prepared in accordance with the Parkour Generations teaching materials (Parkour Generations, 2013). Standing broad jump was used to measure explosive strength, hand grip test to evaluate the grip strength, sixty second sit-up test and bent-arm hang test were used to measure muscle endurance. BIA 2000 M (Data Input, Germany) was used to quantify the changes in fat, fat free mass (FFM), and the ratio of extracellular and body cell mass (ECM/BCM). Paired t-test ( $p = 0.05$ ) and omega squared were calculated to assess the differences between pretest and posttest. Results We found a significant increase in standing broad jump ( $p = 0.01$ ),  $\uparrow 17$  cm; sit-up test ( $p = 0.05$ ),  $\uparrow 4$ . (Tab. 1) There were no significant differences in hand grip ( $p = 0.48$ ),  $\downarrow 1$  kg; bent-arm hang ( $p = 0.13$ ),  $\uparrow 0.9$  s; fat ( $p = 0.12$ ),  $\downarrow 1.4\%$ ; FFM ( $p = 0.16$ ),  $\uparrow 1$  kg; ECM/BCM ( $p = 0.52$ ),  $\downarrow 0.01$ . (Tab. 1; Tab. 2) Discussion We agree with Leite et al. (2011) who stated that Parkour training has positive effect on explosive strength of lower extremities. We stated higher explosive strength and abdominal muscle endurance after the Parkour training. We have not found a significant effect on the muscle endurance of upper-body, the grip strength and the body composition. The main limitation of the study is the small sample size and the absence of control group. Conclusion In conclusion, the Parkour training increased explosive strength of lower extremities and abdominal muscle endurance. There were no changes in upper-body endurance, grip strength and body composition. References 1. PARKOUR GENERATIONS. (2013). [www.parkourgenerations.com](http://www.parkourgenerations.com) 2. LEITE, N. et al. (2011). *Rev Bras Med Esporte*, 17(3), p. 198-201.

## **EFFECT OF RECOVERY ON PACING STRATEGY IN THE HEAT**

Roelands, B., De Pauw, K., Vanparijs, J., Meeusen, R.

*Vrije Universiteit Brussel; Fund for Scientific Research Flanders (FWO)*

Introduction Recovery from exercise is an integral component of training and performance. Although recovery modalities are gaining wide acceptance among elite athletes, little information is available with regard to the effects of recovery interventions on performance and pacing strategy during a subsequent exercise trial the same day in the heat ( $30^{\circ}\text{C}$ ). The purpose of the present study was to determine the effect of active recovery (AR), passive rest (PR) and cold water immersion (CWI) after 90min intensive cycling on pacing strategy and performance on a subsequent short time-trial (TT2;  $\pm 12$ min). Methods Nine trained male subjects (age:  $22 \pm 3$  years;  $\text{O}_2\text{max}$ :  $62.1 \pm 5.3 \text{ ml} \cdot \text{min}^{-1} \cdot \text{kg}^{-1}$ ) completed a maximal cycle test, familiarization trial and 3 experimental trials. All experimental trials were performed in  $30^{\circ}\text{C}$  (RH 50%) and included a one hour constant load trial at 55% of the maximal power output ( $\text{W}_{\text{max}}$ ), followed by a TT in which subjects had to complete a predetermined amount of work as fast as possible (calculated duration: 30min @75%  $\text{W}_{\text{max}}$ , subjects were free to change the resistance), a 15min recovery intervention, a 45min rest period and TT2 (calculated duration: 12min @85%  $\text{W}_{\text{max}}$ ). During CWI subjects were seated in  $15^{\circ}\text{C}$  water until sternum level. AR consisted of cycling at 80W. Friedman tests ( $p < 0.05$ ) were performed. Post-hoc analysis with Wilcoxon Signed-rank tests was conducted with a Bonferroni correction applied. A one sample t-test (within each condition) was used to reveal changes in pacing strategy. Results A significantly different pacing strategy emerged during TT2 after CWI compared to AR and PR. CWI resulted in an even pacing strategy, while AR and PR resulted in a gradual decline of power output after the onset of TT2 ( $p \leq 0.046$ ). This consequently led to 4.2% and 4.7% slower TT2 finishing times in PR and AR compared to CWI. However, these differences were not statistically significant. Discussion A 4% faster TT performance is consistent with the findings of Vaile (2011), who found an ergogenic effect of CWI on a subsequent 30-35min performance, and Peiffer (2010), who showed CWI between two cycle bouts improved the second performance in the heat (no rest between recovery and second bout). Furthermore, the pacing strategy during TT2 differed. CWI resulted in an even pacing strategy, whereas after AR and PR subjects immediately decreased the power output. The difference in pacing strategies between the recovery conditions is likely due to decreased thermal strain after CWI. References Vaile J et al. *Br J Sport Med* 2011;45(10):825-9; Peiffer J et al. *Br J Sport Med* 2010;44:461-465

## **HEAVY STRENGTH TRAINING IMPROVES BOTH SPRINT AND TIME TRIAL PERFORMANCE IN HIGH-LEVEL CYCLISTS**

Rønnestad, B.R.1, Hollan, I.2, Hansen, J.1

*(1) Lillehammer University College, Lillehammer, Norway, (2) Hospital for Rheumatic Diseases, Lillehammer, Norway*

INTRODUCTION During the last decade, there has been an increased research focus on the effect of strength training on cycling performance (1,3,4). Most of the studies indicating a performance enhancing effect of strength training have been performed on cyclists with maximal oxygen uptake ( $\text{VO}_2\text{max}$ )  $< 65 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ , and there is still lack of knowledge of the effects of heavy strength training in very skilled cyclists. The aim of the present study was therefore to test the hypothesis that heavy strength training improves classical indicators

of endurance cycling performance in high-level cyclists. METHODS Twenty cyclists, which were close to the criteria suggested by Jeukendrup et al. (2) that describes elite cyclists, were assigned to either usual endurance training combined with heavy strength training [E+S; n=12 (♂=10, ♀=2), mean age (year±SD)=19±2 years, body mass=67±8 kg, height=178±9 cm, VO<sub>2</sub>max=77±7 ml·kg<sup>-1</sup>·min<sup>-1</sup>] or to usual endurance training only [E; n=8 (♂=6, ♀=2), age=20±2 years, body mass=72±9 kg, VO<sub>2</sub>max=72±6 ml·kg<sup>-1</sup>·min<sup>-1</sup>]. The strength training was performed twice a week and consisted of four lower body exercises (3x4-10RM) for 10 weeks. Pre-tests were performed 12-15 days after the end of the competition season and consisted of maximal voluntary contraction force (MVC) in isometric half squat, peak- and mean power output during 30 s Wingate test, power output at 4 mmol blood lactate concentration during an incremental cycling test, VO<sub>2</sub>max, mean power output during 40-min all out cycling, and lower body lean body mass (LBMLB). RESULTS At the pre-test, there were no differences between the groups in any of the measurements. After the intervention period, E+S increased LBMLB (2.3±1.8%), MVC (21±13%), peak- and mean power output in the 30 s Wingate test (6±5% and 3±3%, respectively), mean power output during 40-min all out cycling (5±6%), and had a tendency of 3±5% improvement in power output at 4 mmol blood lactate concentration (p=0.06). These variables were not changed in E. There was a significant difference between groups in relative improvement in MVC half squat, mean power output during Wingate test, mean power output during 40-min all out cycling. CONCLUSION Adding heavy strength training to usual endurance cycling training results in favourable adaptations in classical performance indicators without compromising the development of VO<sub>2</sub>max in high-level cyclists. This finding is in agreement with previous observation in less trained cyclists (e.g. 2,4). REFERENCES 1. Bastiaans et. al., EJAP, 2001;86:79-84 2. Jeukendrup et al. JSMS, 2000;3:414-33 3. ### EFFECT OF BALLISTIC ISOMETRIC CONTRACTION PROTOCOL IN THE STABILIZATION OF NEUROMUSCULAR VARIABLE IN ELDERLY

Souza, T.M.F., Libardi, C.A., Conceição, M.S., Bonganha, V., Fazolin, M.A.F.G., Chacon-Mikahil, M.P.T., Cavaglieri, C.R., Moraes, A.C., Ugrinowitsch, C.

*University of Campinas*

Introduction: To accurately determine of results in a strength evaluation is indicated the perform of familiarization process to achieve the stabilization of measure (WALLERSTEIN et al., 2010). About this process, Bazzuchi et al. (2004) suggest that the measure variation should be lesser than 5% among tests, indicating that only one familiarization session would not be sufficient to achieve the stabilization of measure. Aim: To verify the stabilization of Peak of Torque (PT) in a ballistic isometric test in elderly. Methods: Participated of this study 10 individuals (67 + 8.52 years, 68.49 + 6.60 kg and 1.64 + 0.07 m). The participants performed a maximum ballistic isometric contraction (MBIC) protocol on isokinetic dynamometer (Biodex System 4, Biodex Medical Systems, USA) composed by ten 2-s submaximal isometric contraction separated by 20-seg intervals as warm-up and four 2-s MBIC separated by a 3-min interval. Were measured the knee extensor muscle Peak of Torque (PT) that was provided in real time on the dynamometer screen during the trials. To comparison among the trials was used ANOVA for repeated measures. Results: No difference in PT (Nm) among the trials of individuals was found (set 1 = 134.3 + 39.13, set 2 = 139.8 + 41.23, set 3 = 139.6 + 42.88, set 4 = 146.1 + 42.76), where the percentage of variation was in mean of 3%. Discussion: Ordway et al. (2006) related a variation of almost 8% in values of PT in second session of isometric tests. In the same way, Wallerstein et al. (2010) reported that the elderly needed of three familiarization sessions to stabilize PT values during MBIC, while the present study found the stabilization of PT in only one session. Conclusion: Using a specific protocol of MBIC, we found the stabilization of PT in first familiarization session. References: Bazzuchi, I. Felici, F. ### OXIDATIVE STRESS MARKERS IN DIFFERENT ALTITUDE TRAINING STRATEGIES IN ELITE ATHLETES

Rodríguez, F., León-López, J., Calderón, C., Feriche, B., Pérez-Sánchez, M., Iglesias, X.

*Institut Nacional d'Educació Física de Catalunya, University of Barcelona*

Introduction Hypoxia is known to induce oxidative stress in animal models and humans due to increased oxygen uptake and electron drain at the mitochondrial respiratory chain, resulting in increased biological tissue oxidation (Guzy & Schumacker 2006). During altitude training exposure two independent stimuli (intense exercise and hypoxia) may have a cumulative effect on oxidative stress (Pialoux et al., 2006). We aimed to analyse the prooxidant-antioxidant balance during different strategies of moderate altitude training in elite athletes. Methods 57 elite swimmers took part in four training camps at moderate altitude (CAR Sierra Nevada, 2320 m), living and training at "high" (H) or "low" (L) level, using different strategies during a period of four (LL-TL, LH-TH, LH-TL) or three weeks (LH-TH3). Prooxidant-antioxidant balance was evaluated before (W0) and once a week during the camp (W1 to W3 or W4) in peripheral blood samples by measuring plasma free radical NO (nitrites), lipid (LPO) and protein (carbonyls) oxidation, and the erythrocyte antioxidants glutathione (GSH), glutathione disulphide (GSSG), glutathione peroxidase (GPx) and glutathione reductase (GRd), with different commercially available kits. Two-way RM ANOVA was used for group comparisons. P<0.05 was considered significant. Results Compared to baseline values (W0), nitrites increased in W2 in the LH-TH group, reaching greater levels than LH-TL and LH-TH3 groups, but returned to baseline at W4. LPO increased more than two-fold in LH-TH and LH-TL at W4. Carbonyls increased in all groups from W3 onwards (from W2 in LH-TL). The erythrocyte activity of GPx did not change in any of the groups. GRd activity was higher in LH-TH at W3 and W4 as compared to LH-TL only. GSH did not change in any of the groups, while GSSG increased in LL-TL but decreased in LH-TL at W4. The GSSG/GSH ratio did not change in any of the groups. Discussion Four weeks of AT resulted in an increase of oxidative damage markers in moderate altitude compared to training at sea level. The free radical NO increased in LH-TH as compared to LH-TL, indicating a higher risk of health disturbances when living and training at altitude for more than three weeks. However, a seemingly adequate antioxidative defence was maintained, since intracellular GSH, the ratio GSSG/GSH, and the activity of GPx and GRd remained stable. ## EFFECTS OF A SIX-WEEK PLYOMETRIC AND BALLISTIC RESISTANCE TRAINING ON VERTICAL JUMPING PERFORMANCE

Selima, E., Bogdanis, G., Veligeas, P., Terzis, G.

*National and Kapodistrian University of Athens*

**Introduction** Muscle power is a prerequisite for success in many sports and thus several studies have aimed to determine the most effective training programs that maximize adaptations. Previous studies have shown that a combination of power training (i.e. vertical jumps without an external load) and high load strength training (i.e. 90% of maximal strength) for 12 weeks, improves jump height and power across a wide range of external loads (Cormie et al., 2007). The purpose of the present study was to examine the effect of a combination method of training with eccentric and ballistic exercises for six weeks, in vertical jump height and power. **Methods** Eight physically active male students (age:  $21.2 \pm 1.8$  years, body mass:  $78.6 \pm 7.7$  kg, height:  $1.78 \pm 0.05$  m) were trained for six weeks (3 sessions per week). During session 1 and 3 of each week, participants performed six sets of two eccentric squat movements with a load of 65% of maximum half squat strength (1 repetition maximum-1RM), separated by a four-minute recovery. In the second training session of each week, participants performed six sets of four maximal-effort jump squats with a load of 30% of 1RM separated by a four-minute recovery. In the first, second and third minute of recovery after each set in all training sessions, participants performed a maximal-effort counter-movement jump. Loaded (15%, 30%, 45% and 65% of 1RM) and unloaded vertical jump performance was measured before and after training. A two-way ANOVA followed by Tukey post-hoc test was used to examine the influence of training on vertical jump performance. **Results** After 6 weeks of training, half squat strength was increased from ( $146 \pm 25$  kg to  $166 \pm 7$  kg,  $p < 0.01$ ). Jump height was increased for loaded and unloaded trials (0% =  $35.9 \pm 5.4$  vs.  $42.3 \pm 6.8$  cm; 15% =  $24.2 \pm 3.4$  vs.  $30.6 \pm 3.7$  cm; 30% =  $18.3 \pm 2.8$  vs.  $23.1 \pm 3.1$  cm; 45% =  $12.7 \pm 2.7$  vs.  $17 \pm 3.2$  cm; 65% =  $6.05 \pm 1.6$  vs.  $10.3 \pm 3.4$  cm; before vs. after training,  $p < 0.01$ ). Relative peak power (W/kg body mass) was also increased across all loads (0% =  $47.1 \pm 4.2$  vs.  $51.8 \pm 5.2$  W/kg; 15% =  $38.0 \pm 2.4$  vs.  $42.9 \pm 2.8$  W/kg; 30% =  $33.3 \pm 2.2$  vs.  $37.0 \pm 1.9$  W/kg; 45% =  $29.0 \pm 1.7$  vs.  $32.2 \pm 2.1$  W/kg; 65% =  $23.7 \pm 2.3$  vs.  $26.9 \pm 2.0$  W/kg; before vs. after training,  $p < 0.01$ ). **Discussion** The combined training program with eccentric and ballistic exercises resulted in a relatively large improvement of jump height (16.8% in the unloaded jump) and peak power (about 11.7% across all loads), in only 6 weeks. The results of this study may have practical applications in training for sports that require high leg muscle power. **References** Cormie P, McCaulley GO, McBride JM. ## COMPARISON OF TWO INCREMENTAL FIELD TESTS TO DETERMINE MAXIMAL AEROBIC VELOCITY IN ASIAN PROFESSIONAL FOOTBALL PLAYERS

Brocherie, F.1, Girard, O.2, Yasumatsu, M.3, Hayakawa, N.3, Millet, G.1

*1 ISSUL, Department of Physiology, Faculty of Biology and Medicine, University of Lausanne, Switzerland; 2 Research and Education Centre, Aspetar, Qatar; 3 Japan Football Association, Japan*

**Introduction** The aim of this study was to determine whether the maximal aerobic running velocity (MAV) determined from an incremental intermittent (45-s run/15-s rest) field test (45-15FIT) and the peak velocity (VYo-Yo) achieved during the Yo-Yo Intermittent Recovery Test level 2 (YYIR2) could be used interchangeably. **Methods** Thirty-three international football players (age:  $23.2 \pm 2.8$  years), members of two Asian Football Confederation national teams, randomly performed two intermittent field-tests: the 45-15FIT (Assadi and Lepers 2012) and YYIR2 (Krustrup et al. 2006). The velocity reached during the last stage of the 45-15FIT was considered as the MAV, while the VYo-Yo achieved during the YYIR2 was calculated according to Kuipers et al. (Kuipers et al. 1985). During both tests, heart rate was continuously recorded at 5-s intervals and peak values (HRmax) were determined. **Results** The MAV achieved during the 45-15FIT was higher ( $18.8 \pm 0.9$  vs.  $18.3 \pm 0.4$  km.h<sup>-1</sup>;  $p < 0.01$ ) than VYo-Yo measured during the YYIR2 (distance covered =  $913 \pm 209$  m). Similarly, HRmax values were higher ( $195 \pm 5$  vs.  $188 \pm 6$  bpm;  $p < 0.05$ ) at the end of the 45-15FIT compared to the YYIR2. Those HRmax values were significantly correlated ( $r = 0.60$ ,  $p < 0.001$ ). Moreover, MAV was correlated with both VYo-Yo ( $r = 0.56$ ,  $p < 0.001$ ) and the distance reached during the YYIR2 ( $r = 0.52$ ,  $p < 0.01$ ). However, the error of the estimate ( $0.77$  km.h<sup>-1</sup>) was not constant: above  $18.1$  km.h<sup>-1</sup>, (i.e. the velocity where MAV and VYo-Yo are equal) MAV values tended to be higher than the VYo-Yo, whereas MAV values tended to be lower than VYo-Yo below  $18.1$  km.h<sup>-1</sup>. **Discussion** Despite a significant relationship between MAV and VYo-Yo, it is probably not appropriate to estimate MAV from the VYo-Yo, due to the exaggerated standard errors observed here. Moreover, higher HRmax values reached during the 45-15FIT when compared to the YYIR2 may indicate that peak velocities reached during those field tests should not be used interchangeably to individualise high-intensity intermittent training intensities in football players. **References** Assadi H, Lepers R (2012) Comparison of the 45-second/15-second intermittent running field test and the continuous treadmill test. *Int J Sports Physiol Perform* 7: 277-284 Krustrup P, Mohr M, Nybo L, Jensen JM, Nielsen JJ, Bangsbo J (2006) The Yo-Yo IR2 test: physiological response, reliability, and application to elite soccer. *Med Sci Sports Exerc* 38: 1666-1673 Kuipers H, Verstappen FT, Keizer HA, Geurtens P, van Kranenburg G (1985) Variability of aerobic performance in the laboratory and its physiologic correlates. *Int J Sports Med* 6: 197-201

## THE IMPORTANCE OF SCALING VO2MAX TO PREDICT CROSS-COUNTRY SKIING PERFORMANCE

Carlsson, T.1,2,3, Carlsson, M.1,2,3, Rønnestad, B.4, Hammarström, D.2,3, Malm, C.1,5, Tonkonogi, M.2

*1: Umeå University (Umeå, Sweden), 2: Dalarna University (Falun, Sweden), 3: Dala Sports Academy (Falun, Sweden), 4: Lillehammer University College (Lillehammer, Norway), 5: Winternet (Boden, Sweden)*

**Introduction** A high maximal oxygen uptake (VO2max) is of importance for success in elite male competitive distance cross-country skiing (Carlsson et al. 2012). However, it is still debatable how VO2max should be expressed to best indicate skiing performance. Therefore, the purpose of this study was to establish the optimal body mass exponent for VO2max to indicate performance in elite-standard male cross-country skiers. **Methods** Twenty-four elite-standard male cross-country skiers completed an incremental treadmill roller skiing test in diagonal stride technique determining VO2max. Performance data was compiled from a 15-km classic technique race. To predict performance a log-transformation of power-function model:  $\text{Race speed} = \beta_0 \cdot \text{VO2max}^{\beta_1} \cdot m^{\beta_2}$  was used, where  $\beta_0$  to  $\beta_2$  are constants, and  $m$  is body mass. Statistical analyses used R version 2.13.2 (R Development Core Team, New Zealand) and alpha was 0.05. **Results** Participants' VO2max was  $5.39 \pm 0.57$  l/min (mean  $\pm$  s) and  $m$  was  $75.5 \pm 6.3$  kg. Mean race speed was  $5.83 \pm 0.41$  m/s. The model that best predicted performance was:  $\text{Race speed} = 8.829 \cdot \text{VO2max}^{0.663} \cdot m^{-0.355} = 8.829 \cdot (\text{VO2max} \cdot m^{-0.535})^{0.663}$ , that explains 69.2% of the variance in race speed for the 15-km classic technique race ( $P < 0.001$ ). For the VO2max-to-mass ratio within the model, the 95% confidence interval (CI) for the body-mass exponent ranged from -0.947 to -0.122. **Discussion** The optimal body mass exponent for VO2max to indicate performance in elite-standard male cross-country skiers was -0.535. Moreover, the CI for the body-mass exponent does not support the use of simple ratio-standard scaling and absolute expression of VO2max as indicators of 15

km classic ski racing performance in elite-standard men skiers. References Carlsson M, Carlsson T, Hammarström D, Tiivel T, Malm C, Tonkonogi M. (2012). *J Strength Cond Res.* 26(6), 1496-504.

### HEREDITY: A STUDY OF FLEXIBILITY IN PAIRS OF MONOZYGOTIC AND DIZYGOTIC TWINS

Sousa, E., Oliveira, M.V., Alonso, L., Rego, J.T.P., Dantas, P.M.S.

*Universidade Federal do Rio Grande do Norte*

Introduction: The understanding of the influence of hereditary and environmental can build an important criterion to guide the practice of physical activity appropriate to the characteristics of individual and collective. The aim of the study was analyzing the heredity of flexibility using dizygotic (DZ) and monozygotic (MZ) twin pairs, in Brazilian northeast. Methods: Was analyzed 36 twin pairs of 08-36 years old in Natal/Brazil, 20 MZ and 16 DZ individuals respectively. For determining zygosity, besides family information, was applied questionnaire (PEETERS et al., 1998) and anamnesis. Flexibility was evaluated with the subjects in supine position, they perform three times the movement of hip flexion, with one minute interval between each movement. The angular positions were recorded by an electronic goniometer (Miotec Ltda, Brazil), the highest value being adopted as reference. The statistical analyses were made of the variance in pairs of twins and sequence determination of the medians of these variances. Intervening variables such as gender, age, and sexual maturation were controlled. It was calculated the index of heritability for the variable of the study demonstrating how much has genotypic and phenotypic character. Was used the Clark (1956) equation: Heritability ( $h^2$ ) =  $(S^2_{DZ} - S^2_{MZ}) / S^2_{DZ}$ . Results: The median of in pairs variances were of 15.53 to MZ and 44.66 to DZ. It was observed that the heritability for flexibility presented moderate (59%). Discussion: Findings of this study agree with literature (BOUCHARD, 1997; BOUCHARD et al., 1989), where the estimate of heritability of hip flexibility of 70% was also classified as moderate heritability, while the age used was limited to 10 to 17 years old, we understand that even increasing age, as the case in this study, there was no change in percentile ranking. Suggesting that the level of flexibility tends to decrease individually and over time due to various factors as demonstrated in the literature. It was concluded, therefore, that the environment influences in part in trainability this motor capacity, which is an indicator of physical fitness. References BOUCHARD, C. ### ASSESSMENT WITH TENSIOMYOGRAPHY OF FATIGUE-INDUCED CHANGES IN THIGH MUSCLES DURING 1-DAY BASKETBALL TOURNAMENT

Harley, S.

*TMG-BMC Ltd.*

Background: Several studies have used tensiomyography (TMG) to detect mainly acute fatigue-induced changes in muscle contraction properties; these changes are exercise-type specific. Aim: We aimed to investigate acute and delayed fatigue-induced changes in the tensiomyographic twitch response in the biceps femoris (BF) and vastus lateralis (VL) in amateur basketball players, during a 1-day basketball tournament. Materials and methods: Six healthy, amateur basketball players (mean age  $35 \pm 3$ , BMI  $26 \pm 3$ ) participated in the study. TMG was used on the dominant BF and VL, to measure muscle contraction time (Tc), reaction time (Td), relaxation time (Tr), maximum radial displacement (Dm) and sustain time (Ts). Contraction velocity (Vc) and ratios of parameters between VL and BF were calculated. Subjects played in the same team and tournament rules ensured each player played approximately the same amount of time. TMG measurements were conducted before and after the first and second games, with a 4-hour rest period between games. Paired t-test was used to evaluate statistical significance between results. Results: VL Tc was significantly lower prior to the first game than before ( $p=0.020$ ) and after the second game ( $p=0.042$ ). VL Td before the first game was significantly lower than before ( $p=0.046$ ) and after ( $p=0.025$ ) the second game. VL Dm, Vc, Tr and Ts did not differ significantly throughout the measurements. BF Dm and Vc were significantly higher (respectively  $p=0.009$  and  $p=0.003$ ) before the first game compared to after the second game. There were no other significant changes in muscle contraction properties for the BF. The ratios of Tc and Dm between VL and BF were significantly lower prior to the first game than at the end of the second game. No other significant differences in ratios between VL and BF were found. Discussion: Contraction time is a parameter that readily distinguishes slow and fast motor units; studies have shown that Tc is a good predictor of %MHC in the estimation of fiber type muscle composition. The increase in VL Tc after the second game may indicate the muscle's inability to recruit type II fibers due to fatigue. The increased VL Td, indicating an increased electromechanical delay, further supports our findings. In the BF these increases were not apparent suggesting that the BF was not as fatigued as the VL. Furthermore, increases in BF Dm and Vc suggest the muscle was potentiated. A 4-hour rest period did not affect the muscle contraction properties between games. TMG presents a sensitive method to study fatigue-induced changes in muscle contraction properties in individual muscles in order to assess individual athlete and whole team preparedness. Similar study designs in larger study samples should provide more consistent results.

### RELATIVE AGE EFFECTS IN AUSTRALIAN FOOTBALL LEAGUE DRAFTEES

Coutts, A.J., Vaeyens, R., Kempton, T.

*University of Technology, Sydney (UTS)*

Introduction: It is well known that the relative age effect (i.e. having a birth date earlier within an age grouping) provides a selection advantage in competitive sport. This advantage persists into adulthood and has been demonstrated through bias in seasonal patterns in the dates of birth in many professional sports. The relative age effect is underpinned by a number of physical, social and psychological advantages provided to relatively older players within an age group, but these advantages may not persist into adulthood. In Australian Football (AF), both adolescent (i.e.  $<20$  y) and mature-age (i.e.  $>20$  y) athletes are recruited to the professional league via a player draft, but the relative age effects in this group have not been examined. Therefore, this study examined the birth distribution for adolescent and mature age players selected in the Australian Football League (AFL) National Draft between 2001 and 2011. Methods: Birth-date information was accessed for all first time draftees selected in the AFL National Draft between 2001 and 2011 ( $N=737$ ). Players were classified as either adolescent (i.e.  $<20$  y the draft year,  $N=694$ ) or mature (i.e.  $>20$  y in the draft year,  $N=43$ ) draftees. Results: Chi squared analysis showed clear bias in the birth distribution of adolescent draftees towards players born in the first part of the classification period for both quartile ( $p<0.001$ ) and half-year ( $p<0.001$ ) compared to the Australian national population. There was a reverse relative age effect for

mature age draftees, with a significant bias towards players born in the latter part of the selection period for both quartile ( $p=0.034$ ) and half-year ( $p=0.003$ ) compared to the Australian national population. Discussion: The selection bias towards relatively older adolescents in adolescent AFL draftees may be related to advanced physical and psychological maturity, and exposure to higher level coaching compared to their younger counterparts. The new finding of a reverse RAE in mature age draftees supports the need for strategies to encourage continued participation pathways for talented AF players born later in the selection year.

### CHANGES IN HIGH-INTENSITY RUNNING CHARACTERISTICS OF ELITE YOUTH RUGBY LEAGUE PLAYERS DURING MATCHES

Twist, C.1, Doncaster, G.2, Sykes, D.3, Highton, J.1

1: University of Chester, UK, 2: University of Staffordshire, UK, 3: Heriot-Watt University, UK.

**Introduction** Elite senior rugby league players show a reduction in high intensity running activity towards the end of a match (Sykes et al., 2011). These players are also susceptible to temporary reductions in high intensity running capacity after intense periods of activity during a game (Waldron et al., 2012). Changes in high intensity running towards the end of a match and after the most intense periods of play have yet to be elucidated in elite youth rugby league players. Therefore, the purpose of this study was to describe the changes in high intensity running of elite youth rugby league players during competitive matches. **Method** Twenty-six elite youth rugby league players ( $18.9 \pm 1.2$  y,  $1.83 \pm 0.05$  m,  $95.9 \pm 9.7$  kg) were classified into positional groups of outside backs ( $n = 10$ ), pivots ( $n = 4$ ), props ( $n = 7$ ) and back row ( $n = 5$ ). Data were collected from five different games (81 performances;  $3 \pm 1$  matches per player) during the 2011 competitive season. Using 5 Hz GPS the overall locomotive rate (m/min) and high intensity locomotive rate ( $>14.4$  km/h) were recorded. The high intensity locomotive rate for each 5 min period of the match was also calculated, with the highest value being taken as the peak 5 min period. **Results** Overall relative distance covered during a match was  $92.7 \pm 6.2$ ,  $98.4 \pm 6.0$ ,  $95.3 \pm 6.7$  and  $95.0 \pm 5.8$  m/min for outside backs, pivots, props and back row, respectively ( $P > 0.05$ ). In all positions, high intensity locomotive rate was lower in the first half ( $13.6 \pm 5.2$  m/min) compared to the second half ( $15.6 \pm 4.8$  m/min;  $P < 0.05$ ). The peak high intensity locomotive rate was only different between outside backs ( $29.2 \pm 7.1$  m/min) and props ( $22.4 \pm 2.9$  m/min;  $P < 0.05$ ), as values for pivots ( $26.2 \pm 6.1$  m/min) and back row players ( $24.9 \pm 3.7$  m/min) were not different ( $P > 0.05$ ). High intensity locomotive rates in the 5 min after the peak period were lower for all positional groups, with values of  $13.2 \pm 7.9$ ,  $13.8 \pm 6.5$ ,  $9.3 \pm 3.3$  and  $13.1 \pm 5.0$  m/min (all  $P < 0.05$ ) for outside backs, pivots, props and back row players, respectively. However, the reduction in high intensity locomotive rate in the subsequent 5 min period was only lower than the overall mean high intensity rate for props ( $P < 0.05$ ). **Discussion** Increases in high intensity running from the first to the second half suggest that elite youth rugby league players do not fatigue towards the end of a match. However, reductions in high intensity locomotive rates after the most intense period of exercise indicate that temporary fatigue does occur during a match. As well as enlightening conditioning practices, these data are useful for informing the coach's tactical decisions and interchange strategies. **References** Sykes D, Twist C, Nicholas C, Lamb K. ### EFFECT OF INTERVAL TRAINING AND SMALL-SIDED GAMES ON SPECIFIC RESISTANCE ON AMATEUR SOCCER PLAYERS

Marreco-Gouveia, V.1, Alves, F.2

1Faculty of Human Kinetics- Technical University of Lisbon; 2 CIPER-Technical University of Lisbon

Seven university soccer players (age= $20.0 \pm 1.6$  years; height= $175.6 \pm 7.6$  cm; weight= $73.3 \pm 8.5$  kg; experience= $2.1 \pm 1.5$  years) participated in this study to determine the effect of two training protocols in soccer specific resistance. They executed YYIRT1 before a 4 weeks period of the interval running training (IRT) (4x3 minutes running at 90-95% HRmax with 3 minutes of active recovery at 60% HRmax). They executed the YYIRT1 again and started a new period of 4 weeks with resort to small-sided games (SSG) with the same load of IRT (4x4, area of 20x20 meters, limit of 2 consecutive touches for player). Repeated the YYIRT1. We used Friedman test and in the cases with significant statistical differences we have used the non parametric multiple comparison test. No statistically significant differences in VO2peak (50.30, 51.65 and 52.90 ml.kg<sup>-1</sup>.min<sup>-1</sup>). In the distance covered in YYIRT1 we observed significant statistical differences ( $P < 0.05$ ), between the first and third (1062m and 1320m) evaluation and between the second and the third (1191m and 1320m). In future studies will be important no determine VO2max in laboratory, use 2 different groups and to submit the training methods for 8-12 weeks, at least 2 times a week.

### NORMALIZED HEART RATE: A NEW CONCEPT TO BETTER SUMMARIZE EXERCISE INTENSITY AFTER TRAINING SESSIONS

Zabala, M., Morente-Sánchez, J., Mateo-March, M.

Faculty of Sport Sciences - University of Granada

**NORMALIZED HEART RATE: A NEW CONCEPT TO BETTER SUMMARIZE EXERCISE INTENSITY AFTER TRAINING SESSIONS** Zabala, M.1,2 Morente-Sánchez, J.1& Mateo-March, M.2,3 1 Faculty of Sport Sciences, University of Granada (Spain) 2 Spanish Cycling Federation, Madrid (Spain) 3 University Miguel Hernández, Elche (Spain) **Introduction** Heart Rate is a one of the most common used variables to describe exercise intensity, while some other variables have been used as e.g. time/distance, watts, etc. Some years ago a new concept was developed to better describe what happened after a cycling workout: the so-called Normalized Power [1], which pretends to better describe the variation in wattage during a workout to get a more representative value of the session rather than the average value that can not reflect any variation itself. So, e.g. the same value of 150 ppm does not mean the same objective or work developed, because it could be reached after continuous constant intensity (low variation), or after interval-series training (high variation). So, the aim of the study was to propose the use of normalized Heart Rate (HRn) instead of the average HR (HRavg) to better describe exercise intensity as a summary of a training session. **Methods** Twelve under-23 elite road cyclists (mean age:  $19.67 \pm 1.12$  years) participated in the study. Training was monitored during  $20 \pm 2$  training sessions measuring HR (Polar RS800). Then HRn was calculated following 4 steps: 1) to get an average mobile value of 30 seconds from the original HR data in a new column, 2) to raise to the power of four of the previous column in a new one, 3) to get the average value of the previous column, and 4) to get the fourth root of the previous value. Descriptive and correlation statistics was carried out. **Results** Values of HRavg and HRn were calculated for each session that were divided into a) Continuous, and b) interval-series sessions. The respective values for HRavg and HRn were  $138.4 \pm 10.8$  vs.  $143 \pm 10.2$  ppm for a), and  $139.5 \pm 33.3$  vs.  $150 \pm 11.3$  ppm for b). The correlations between HRavg and HRn were  $r=0.89$  in a), and  $r=0.50$  for b), but there was no correlation when relating HRavg and HRn of all the sessions -a) and b)-. **Discussion** HRavg does not discriminate how we have reached this value after a training session, so if we cannot see all the HR data we cannot know accurately which kind of exercise intensity has been developed. The

same value of HRavg can be reached by means of completely different training stimulus. On the other hand, HRn shows another aspect that represents much better the type of exercise developed. This is why in a) the differences between HRavg and HRn are small and there is a significant correlation, while in b) the difference between HRavg and HRn is important and the correlation is low. So, we suggest the use of HRn as a better summary of training intensity and, more important, to use this value instead of HRavg to get the training load using TRIMP. References 1. Allen H & Coggan A. 2006 Velopress.

### **INFLUENCE OF THE PLAYING SURFACE ON PHYSIOLOGICAL, PHYSICAL AND PERCEPTUAL RESPONSES DURING A SMALL-SIDED-GAME ON HIGH-LEVEL FEMALE SOCCER PLAYERS**

Baron, R.1, Dal, L.1, Le Moal, E.1, Owen, A.L.2, Prioux, J.1, Zouhal, H.1

*1 M2S Laboratory (Rennes, France), 2 Rangers Football Club, Sports Science Department, Glasgow, Scotland, UK.*

**Introduction** It is well known that playing surfaces in soccer influenced physical performances, physiological responses and recovery from fatigue induced by the game in male soccer players (Andersson et al 2008). However, little is known in female soccer players. Consequently, the aim of this study was to analyze the influence of three playing surfaces (wet turf (WT), dry turf (DT) and artificial turf (AT)) on women physical, physiological and perceptual responses during a small-sided game (SSG). **Methods** Eight soccer women players (national level) ( $21.25 \pm 1.5$  yr.) participated in three games, separated by at least 48h: (3 x 4 min, 4 vs. 4 players on a pitch of 20 x 30 m, with 2 minutes of passive recovery between each 4 min). Three surfaces were tested on randomized order: WT, DT and AT. Different variables were measured: physical performances using GPS, heart rate during exercise (HR<sub>ex</sub>), blood lactate (La) and rate of perceived exertion (RPE). Each player performed a Counter Movement Jump (CMJ) before and after each game in order to analyze the strength and power recovery of lower limbs. **Results** The results show that HR<sub>ex</sub> was significantly higher ( $p < 0.05$ ) during WT ( $171.0 \pm 6.8$  bpm) than during AT ( $163.8 \pm 8.6$  bpm) and DT ( $162.3 \pm 2.2$  bpm). Hence, blood La was significantly higher ( $p < 0.05$ ) during WT ( $3.0 \pm 0.4$  mmol.L<sup>-1</sup>) than during AT ( $2.2 \pm 0.5$  mmol.L<sup>-1</sup>) and DT ( $p < 0.001$ ) ( $1.7 \pm 0.6$  mmol.L<sup>-1</sup>). In addition, significant decrease of CMJ performances was observed after WT comparing to AT and DT ( $p < 0.05$ ). However, no significant differences were noted concerning the RPE between the three surfaces ( $10.7 \pm 0.7$ ;  $10.5 \pm 0.9$  and  $9.8 \pm 0.6$  respectively for WT, AT and DT). **Conclusion** In conclusion, our results suggest that playing surface has an influence on physical and physiological responses during small-sided games in high level women soccer players. However, players perceived no differences between the three surfaces concerning the hardship of playing surface. References Andersson H, Ekblom B, Krstrup P. (2008) J Sports Sci. 26 : 113-122.

### **EFFECT OF HEAVY STRENGTH TRAINING ON PERFORMANCE DETERMINANTS AND PERFORMANCE IN TRAINED FEMALE CYCLISTS**

Vikmoen, O.1, Rønnestad, B.R.1, Ellefsen, S.1, Raastad, T.2

*(1) Lillehammer University College (2) Norwegian School of Sports Sciences*

**Introduction** Equivocal findings exist on the effect of adding heavy strength training (HST) to the normal endurance training on cycling performance in trained cyclists (1,3,4,5). Most previous research in this area is performed with male subjects. The only study focusing on female cyclists did not find any effect of adding HST to the normal endurance training on cycling performance (2). However, the strength training volume in that study was low including only one strength exercise (squat). Therefore, the purpose of this study was to investigate the effects of HST on determinants of cycling performance and cycling performance in trained female cyclists. **Methods** Nineteen trained female cyclist ( $33 \pm 8$  years,  $64 \pm 7$  kg,  $VO_{2max}$ :  $54 \pm 3$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) were randomly assigned to either usual endurance training combined with HST (E+S, n=11) or to usual endurance training only (E, n=8). The strength training consisted of four lower body exercises (3 x 4-10 repetition maximum (RM)), which were performed twice a week for 12 weeks. 1 RM in one-legged leg press,  $VO_{2max}$ , power output at 3.5 mmol.L<sup>-1</sup> blood lactate concentration ([La-]), oxygen consumption at 150 W and mean power output during a 40 min all-out time trial were measured before and after the intervention. **Results** There were no differences between the groups in any of the measurements at the pre-test. E+S increased 1RM in one-legged leg press more than E (39% vs. 6%,  $p < 0.05$ ). Body mass was slightly reduced in E (1.4%,  $p < 0.05$ ), while there were no change in E+S. E+S improved body weight adjusted (BWA) power output at 3.5 mmol.L<sup>-1</sup> blood [La-] and mean BWA power output in the 40 min all-out trial with 8% and 6% respectively ( $p < 0.05$ ). None of these changes occurred in the E group. BWA oxygen consumption at 150 W was reduced by 4% in the S+E group ( $p < 0.05$ ) with no change in the E group and the changes were different between the groups. BWA  $VO_{2max}$  did not change in any group. **Discussion** The main finding of this study was that adding HST to usual endurance training in female cyclists increased mean power output during a 40 min all-out time trial and power output at 3.5 mmol.L<sup>-1</sup> blood [La-]. This seems in part to be caused by a better cycling economy because there was no increase in  $VO_{2max}$ . These improvements could not be seen in a group only performing their usual endurance training. These findings are in agreement with recent findings in male competitive senior and junior cyclist (1,3,4), but contradicts a study on female cyclist (2). References 1. ### **THE RELATIONSHIP BETWEEN PHYSICAL ABILITIES AND BOTH BALL-CARRYING AND TACKLING AMONG UNDER-15 TO -17 ELITE, YOUTH RUGBY LEAGUE PLAYERS**

Waldron, M., Twist, C., Worsfold, P., Lamb, K.

*University of New England\**

**Introduction:** In rugby league, physical collisions, such as tackling and ball-carries, are some of the most demanding aspects of match performance. Video analysis techniques can reliably identify tackles, carries and their outcomes during rugby league competition. Among adolescent players, there has been no investigation of such skills during match play or an attempt to identify the physical qualities that contribute to their successful execution. Accordingly, it was the aim of this study to investigate the relationships between the physical abilities of adolescent rugby league players and their tackling and ball-carrying skills performed during competitive matches. **Methods:** Ethical approval was given to undertake a three-season (under-15, -16 & -17) study with a total of 28 elite youth rugby league players. Participants were annually assessed for predicted aerobic power (multi-stage fitness test), vertical jump height, sprinting performance (10-30 m) (velocity, acceleration & force) and anthropometric variables. Players' average frequency of successful and unsuccessful tackling and ball-carrying skills during match time were also assessed across the season. **Results:** Relationships (R) were found between successful ball-carrying and 10 m sprinting force among under-15 ( $R = 0.702$ ,  $P < 0.001$ ), -16 ( $R = 0.607$ ,  $P < 0.001$ ) and -17 players ( $R = 0.671$ ,  $P < 0.006$ ). There were no relationships ( $P > 0.05$ ) found between tackling during matches and any measured physical ability.

Discussion: Consistent with the general match demands of rugby league, the results show the importance of force generation (mass x acceleration) in performing successful ball-carries at all adolescent age groups. Such findings further support the previous assertion that horizontal motion can facilitate success in contact situations during rugby league match play (Baker & Newton, 2008). That none of the measured physical abilities explained tackling performance perhaps highlights the greater importance of technique (which was not assessed) in executing tackles during matches. Rugby league practitioners should prioritize the development of 10 m acceleration, alongside gains in 'propulsive' body mass, in order to optimize ball-carrying, but not tackling, performance during competition. Baker DG., Newton, RU. (2008). *J Strength Cond Res*, 22(1), 153–158.

### SYNCHRONIZED SWIMMING SHUTTLE TEST: A PHYSICAL FITNESS TEST FOR SYNCHRONIZED SWIMMERS

Rodrigues, L., Garrido, N.D., Alentejano, T., Vigarrio, P.S., Hercowitz, S., Assis, C.A., Almeida, J.R.

*UNIVERSIDADE DE TRÁS OS MONTES E ALTO DOURO- PORTUGAL, UNIVERSITY OF ALBERTA - CANADA, UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - BRASIL*

This study developed a physical fitness test for synchronized swimmers: The Synchronized Swimming Shuttle Test (SSST). Phase one of the study tested the reliability of the test. Forty eight female volunteer athletes were tested twice with an interval of 48 hs. Results showed a good reliability (correlation coefficient of 0.80 ( $p \leq 0.01$ )). Phase two of the study tested the sensitivity of the SSST. Eight athletes from the Brazilian national team were tested twice with 3 month interval in between tests. Results showed an improvement of 26.3% (Wilcoxon,  $p=0.011$ ,  $p < 0.05$ ). The proposed test is sensitive to differences in levels of categories. So the average results of the test and retest for the SSST senior categories (test = 112.5 m; retest = 125m), junior (test = 87.5 m; retest = 112.5 m) and juvenile (test = 87.5 m; retest = 93.8 m) showed that the performance SSST increases with age. The SSST results were correlated against the existing national team selection physical fitness tests (TAFT) and the results of a routine. Results showed no correlation (Spearman,  $r = -0.006$ ,  $p = 0.99$ ). between the TAFT and the SSST and there was no strong correlation between the SSST and the routine (Spearman,  $r = -0.006$ ;  $p = 0.99$ ). The results of the present study suggests the test can be applied to measure progress from one phase to the other of training but is not ideal to predict routine results in team trials. Future research should focus on the correlation between the SSST and physiological golden standards such as oxygen consumption and lactate to determine if the test is a good indicator of the level of fitness of synchronized swimmers. ### POSITIONAL DIFFERENCES IN MATCH RUNNING PERFORMANCE IN MEN RUGBY SEVENS

Suarez-Arrones, L.1,2, Urbano, R.1,2, Suarez, G.1,2, Saez de Villareal, E.1

*1Pablo de Olavide University, Seville; 2QDIEZ, Seville*

Introduction Recent investigations have shown that rugby sevens is characterized by relatively high running demands and short recovery periods between running bouts (Higham, Pyne, Anson, & Eddy, 2012; Suarez-Arrones, Nunez, Portillo, & Mendez-Villanueva, 2012). These running demands appear to be higher than those encountered in both rugby union and rugby league, but the impact of playing position associated with rugby sevens match play are presently unknown. The aim of this study was, therefore, to describe the running match demands relative to positional groups in male rugby sevens. Methods Time-motion analysis of running activity was collected in 10 highly-trained men rugby sevens players during 23 matches. GPS technology was used to assess match running demands. Results The average total distance ( $\pm$ SD) covered by the players throughout the match was  $102.3 \pm 9.8$  m $\cdot$ min $^{-1}$  with a range of 85.9 to 127.4 m $\cdot$ min $^{-1}$ . As a percentage of total distance, 35.8% ( $36.6 \pm 5.9$  m $\cdot$ min $^{-1}$ ) was covered walking, 26.0% ( $26.6 \pm 5.5$  m $\cdot$ min $^{-1}$ ) jogging, 10.0% ( $10.2 \pm 2.4$  m $\cdot$ min $^{-1}$ ) running at low intensity, 14.2% ( $14.5 \pm 4.0$  m $\cdot$ min $^{-1}$ ) at medium intensity, 4.6% ( $4.7 \pm 1.6$  m $\cdot$ min $^{-1}$ ) at high intensity, and 9.5% ( $9.7 \pm 3.7$  m $\cdot$ min $^{-1}$ ) sprinting. Over the whole match, backs covered substantially more total distance ( $+10.0 \pm 0.96\%$ ; moderate ES), distance at speeds  $>14.0$  km $\cdot$ h $^{-1}$  ( $+26.4 \pm 6.2\%$ ; moderate ES) and  $>20.0$  km $\cdot$ h $^{-1}$  ( $+35.0 \pm 10.8\%$ ; moderate ES) than forwards. Discussion For the first time, we report positional differences in match running demands in rugby sevens. Overall, backs presented augmented running demands in comparison with the forwards. As expected, both playing positions, backs (107 m $\cdot$ min $^{-1}$ ) and forwards (98 m $\cdot$ min $^{-1}$ ) covered greater distance per minute than the same positions in other rugby codes. ### ENERGY CONTRIBUTIONS OF 200M SPRINT-CANOEING ON WATER

Li, Y., Niessen, M., Hartmann, U.

*University of Leipzig*

Introduction 200m sprint-canoeing had its debut in 2012 London Olympic Games. There is a lack of investigation on energy contributions of this sport event, especially when paddlers performing on water. The aim of this study was to investigate the energy contributions of 200m sprint-canoeing on water. Methods Eight male national successful sprint-canoeists ( $21 \pm 3$  yrs,  $180 \pm 2$  cm,  $79 \pm 4$  kg) participated in a 40s all-out paddling on water to simulate the 200m race. Oxygen uptake and blood lactate were measured with MetaMax 3B (MetaMax 3B, Cortex Biophysic GmbH, Leipzig, Germany) and Biosen S-line (BIOSEN S line, EKF Diagnostic, Barleben, Germany) during the tests. The calculation of energy contributions was based on fast component of oxygen debt (anaerobic alactic, AnAl), maximum net blood lactate after 40s (anaerobic lactic, AnLa), and accumulated oxygen uptake above resting level during 40s (aerobic, Aer) (Beneke et al. 2004). Results The energy contributions during the 40s all-out sprint-canoeing from AnAl, AnLa, and Aer were  $46.8 \pm 22.6$  kJ,  $33.3 \pm 6.4$  kJ, and  $34.5 \pm 4.5$  kJ, with relative contributions of  $38.4 \pm 12.6\%$ ,  $30.3 \pm 8.8\%$ , as well as  $31.3 \pm 5.4\%$  from AnAl, AnLa, and Aer, respectively. Discussion The relative aerobic contribution in this study was similar to that in sprint-kayaking on ergometer with Japanese university males (29.4%; Nakagaki et al. 2008), but much lower than those in sprint-kayaking and canoeing on ergometer with US national team members (35-40%; Byrnes and Kearney 1997), which might result from possible different factors (e.g. method in calculating energy, testing protocol, level of exhaustion, individual physiological character, etc.). As the first approach to analyze the energy contributions in 200m sprint-canoeing on water with the measurement of oxygen uptake and blood lactate, this study displayed an energetic profile for this sport event, which should be considered when establishing the training philosophy of this discipline. ## CHRONIC EFFECTS OF A COMPLEX TRAINING PROGRAM ON SPRINT AND MUSCLE ARCHITECTURE OF PROFESSIONAL SOCCER PLAYERS

Gomes, P., Silva, W.A.B.

*Universidade Gama Filho*

Do not insert authors here! Introduction In a recent meta-analysis (Gouvea et al., 2012), complex training has been shown to acutely improve performance in sport activities that require muscle power. Only two studies have looked at the chronic effects, particularly in sprint activities (Alves et al., 2010; Kotzamanidis et al., 2005), but none have looked at the possible mechanisms that would explain performance improvement. The study aimed to observe the effects of four weeks of a conditioning activity (AC) on the 30 meter sprint run (T30) and see whether these changes were accompanied by modifications in the vastus lateralis (VL) muscle architecture – fascicle pennation angle, fascicle length and muscle thickness. AC is defined as a heavy strength stimulus prior to a main activity, such as sprint. Methods: Eighteen players (age:  $21 \pm 1.5$  years; mass:  $69.7 \pm 7.24$ kg), randomly separated in two groups, were submitted to three sets of a 30 m sprint with one min rest between runs (CON= control) or one set of three repetition maximum on a smith machine, nine min prior to the same runs (EXP= experimental), for four weeks, twice a week. All runs were monitored by an electronic system (Proteksen 1.0, Proteksen, RJ, Brasil). All subjects went through an extended field of view ultrasonography scan of the muscle vastus lateralis using dedicated software (GE Logic E & LogicView, GE Healthcare, EUA) with the images assessed by a public domain software (ImageJ, NIH, EUA, Ver.1.45s). All procedures were repeated at the end of the training period. Results Repeated measures Anova (group x time) showed significant main (group) effect ( $P < .001$ ). The EXP showed significant decreases ( $P < .001$ ) in time at the end of the study, while no differences were observed for the CON. A 2x2 anova showed significant increases in fascicle length, ( $P < .001$ ) but no changes in pennation angle or muscle thickness in the EXP as a result of training. No changes were observed in CON group. Discussion The present study not only confirmed that sprint time can be improved (Kotzamanidis et al. (2005) with complex training, but also that this can be accomplished with shorter periods of time (4 weeks). Muscle architecture changes were only observed for fascicle length, possibly explained by the addition of sarcomeres in series in the muscle that could hypothetically increase muscle-shortening velocity. ## CONTINUITY OF YOUNG SOCCER PLAYERS IN A PROFESSIONAL CLUB

Bidaurrazaga-Letona, I., Lekue, J.A., Amado, M., Granados, C., Santos-Concejero, J., Gil, S.M.

*University of the Basque Country (UPV/EHU), Athletic Club of Bilbao, UCT/MRC, ESSM, University of Cape Town*

Acknowledgements This study was partially supported by a grant from the Basque Government (UE09+/07) IBL is supported by a predoctoral fellowship from the Basque Government (BFI2010-35) Introduction In elite soccer, clubs have the interest to identify the most talented players. Therefore, the aim of this study was to analyze the differences between players who were successful or unsuccessful in progressing to the next category in a professional club. Methods 37 soccer players of the Athletic Club of Bilbao participated in this study (mean age  $12.83 \pm 0.62$ ). The following measurements were taken during season 2010-2011: -Anthropometry: height, sitting height, weight, six skinfolds, diameters and perimeters. Body composition was calculated. -Performance tests: velocity (15m), agility (Barrow's test), Yo-yo IT level 1, CMJ and hand dynamometry. The results of each test were transformed into z-scores and summed up to make a total score of performance (SCORE). -Age at peak height velocity (APHV) was calculated to divide players into 3 maturity groups: early (EM), average (AM) and late (LM) (Sherar et al., 2005). Mean  $\pm$  standard deviations were calculated and to show differences among groups Student t-test or U-Mann-Whitney test and Cohen's d were used. Results In season 2011-2012, 20 players (51.3%) continued in the club (C) whereas 17 players (43.6%) dropped-out (D). Players who continued were taller and heavier ( $p > 0.05$ , but  $d = 0.417$  and  $0.519$ , respectively). There were significant differences ( $p < 0.05$ ) in: sum of skinfolds (mm) [47.23(C) - 52.04 (D)], Yo-yo IT level 1 (m) [1378(C) - 1131.76(D)] and SCORE [0.97(C) - -1.14(D)]. APHV was 13.3 to 15.4 years. 15AM and 5LM players continued while 16AM and 1LM players dropout. There were not EM players. There was a trend for AM players having larger body-size and more fat ( $d = 0.567$  to  $0.954$ ). We found significant differences ( $p < 0.05$  to  $0.01$ ) between maturity groups in: velocity (m/s) [6.27(AM) - 6.54(LM)], agility (s) [11.24(AM) - 10.76(LM)], CMJ (cm) [34.32(AM) - 37.77(LM)], Yo-yo IT level 1 (m) [1190.96(AM) - 1646.66(LM)] and SCORE [-0.69(AM) - 3.59(LM)]. Discussion Players that continued were larger in body-size, had less fat and performed better in performance tests. The two groups did not differ significantly in maturity status. However, most LM players continued in the club: they had less body-size, less fat and significant better results in performance than their older peers. This is in agreement with Deprez et al. (2012) that suggest that LM players remain in their sport by outperforming their more mature counterparts. References Sherar LB et al. (2005) *J Pediatr* 147, 508-14 Deprez D et al. (2012) *Int J Sports Med* 33, 987-93

## RELIABILITY OF RPE DURING FUNCTIONAL FITNESS TESTS IN FEMALE FIBROMYALGIA PATIENTS

Soriano-Maldonado, A.1, Segura-Jiménez, V.1, Aparicio, V.A.2,1, Álvarez-Gallardo, I.C.1, Estévez-López, F.1, Camiletti-Moirón, D.2,1, Ruiz, J.R.1,3, Ortega, F.B.1,4,3, Delgado-Fernández, M.1

*1: University of Granada, Spain; 2: University of Granada, Spain; 3: Karolinska Institutet, Huddinge, Sweden; 4: University of Granada, Spain; 5: University of Cadiz, Spain*

Introduction: The functional capacity fitness tests are commonly used for monitoring health status in fibromyalgia patients. Frequently, the rating of perceived exertion (RPE) is used to assess perceived effort during and after testing. Several psychological factors are often altered in fibromyalgia patients. Therefore, it is unknown how accurate RPE is on this specific population. Consequently, it is of interest to analyze the reliability of the RPE while performing the tests in this population. The aim of the present study was to assess the reliability of the RPE for estimating perceived effort after performing each of the functional capacity tests in female fibromyalgia patients. Methods: Sixty eight female fibromyalgia patients (age: 51.5y; SD: 8.8y) performed the following functional capacity fitness tests in two different occasions separated by 7 days: chair sit and reach, back scratch, hand grip strength, chair stand, 8 feet up & go, and 6-minute walk. Patients were asked to perform the tests at their maximum level. The RPE was assessed after completing each test. The test-retest differences in the functional capacity tests and RPE were analyzed by paired samples Student's t-test for normally distributed variables and Wilcoxon for non-normally distributed variables. The test-retest reliability of the RPE was analyzed by means of the intraclass correlation coefficient (ICC) and standard error of the measurement (SEM). Results: Significant test-retest differences were found in chair stand and arm curl test scores (both,  $P < 0.001$ ). No test-retest differences were observed in RPE ( $P > 0.05$  for all tests). The ICC (95% confidence inter-

val) and SEM observed for the RPE were: 0.72 (0.54-0.83) and 1.8 points for chair sit and reach; 0.72 (0.55-0.83) and 1.8 points for back scratch; 0.71 (0.54-0.82) and 1.7 points for hand grip strength; 0.75 (0.60-0.85) and 1.6 points for chair stand; 0.76 (0.61-0.85) and 1.7 points for 8 feet up & go; 0.69 (0.50-0.81) and 1.6 for arm curl test; 0.65 (0.39-0.80) and 1.9 points for 6-minute walk. Discussion: The ICC showed values ranging from moderate to good, indicating a fair reliability of the RPE for assessing perceived effort after the functional capacity tests in female fibromyalgia patients. These results were also supported by the SEM. Therefore, the results of the present study suggest that the RPE might be used for monitoring perceived effort in female fibromyalgia patients.

### **EFFECTS OF DIFFERENT PACESETTERS ON THE ENERGY EXPENDITURE DURING ARM CRANK ERGOMETER EXERCISE**

Lecce, D.1, Cortis, C.1, Sanuheza Alfaro, S.P.1, Fattorini, L.2, Rodio, A.1

*1 University of Cassino and Southern Lazio –Italy; 2 Sapienza University of Rome – Italy*

**Introduction** Although training synchronized with music has been recognized to have a positive effect on physical activity (1), there is a lack of knowledge concerning the use of others pacesetters on performance. Therefore, the aim of this study was to verify the effects of visual and acoustic pacesetters on oxygen consumption (VO<sub>2</sub>) and heart rate (HR) during exercise performed on an arm crank ergometer. **Methods** Six physically active male subjects (age: 27.0±5.5 yrs; height: 177.5±2.5 cm; weight: 75.5±6.8 kg) participated in this pilot study. Participants were underwent to a 20 minutes exercise at an individualized load corresponding to the 80% of the ventilatory threshold, performed on arm cranking ergometer (Monark 881E, Stockholm, Sweden). Three randomized experimental sessions were performed by each subject: training with music (TM), training with a video representing an exercise performed by another subject with no audio (VS) and training with a video including a series of rhythmic images with no audio (VRI). HR and VO<sub>2</sub> were continuously (K4 b2, Cosmed, Rome, Italy) measured during the three sessions. Level of significance was set at p<0.05. **Results** VO<sub>2</sub> (1.8±0.4 l.min<sup>-1</sup>) and HR (135.1±9.5 b.min<sup>-1</sup>) were lower (p<0.05) in the VRI with respect to TM (VO<sub>2</sub>: 2.4±0.1 l.min<sup>-1</sup>; HR: 163.6±19.5 b.min<sup>-1</sup>), while no differences emerged with respect to VS (VO<sub>2</sub>: 2.03±0.23 l.min<sup>-1</sup>; HR: 142.6±11.7 b.min<sup>-1</sup>). **Discussion** Findings from this preliminary study showed lower energy expenditure when exercising watching an image sequence than observing an athlete performing the same technical movements. The lower metabolic and cardiac response observed could be explained by the theory of mirror neurons (2). In fact, watching another person performing a motor task could activate neurons coding the same specific motor task while reducing the neuronal activity linked to intermediate cognitive mediation. Comparing the two visual sessions, differences in VO<sub>2</sub> and HR could be due to the fact that in the VRI the rhythm is better time locked while in the VS the recurring motion of athlete's gesture makes the rhythm less obvious. Moreover, a tempting hypothesis could be that visual pacesetters may increase the arousal state and reduce noises (i.e. other than the motor task). **Results** from this investigation could be used for the development of new training strategies, in which images projected at various frequencies can be showed to the athletes to indicate the correct rhythm of the technical movement. **References** 1. Karageorghis et al. *Res Q Exerc Sport* 2006 2. Rizzolatti et al. *Nat Clin Pract Neurol* 2009

### **TIME-MOTION ANALYSIS IN KICKBOXING COMPETITIONS**

Sanuheza Alfaro, S.P.1, Rodio, A.1, Fattorini, L.2, Lecce, D.1, Cortis, C.1

*1 University of Cassino and Lazio Meridionale (Italy); 2 Sapienza University of Rome (Italy)*

**Introduction** Kickboxing is as a combination of martial arts including Karate, Muay Thai and Western boxing. It is a high-intensity sport activity, based on kicking and punching techniques (Arseneau et al. 2011). Although successful performance is determined by a combination of both complex technical and tactical skills within an unpredictable situation (El Ashker 2012; Buse et al. 2008), scant information is available regarding time-motion aspects of actual competition. Thus, the aim of this study was to analyze the time-motion structure of Kickboxing competitions. **Methods** A time-motion analysis was performed (Dartfish TeamPro, Lausanne, Switzerland) from 6 video recordings of 12 elite Italian Kickboxing athletes (weight categories: -57kg; -67kg; -71kg; -75kg; +91kg) during the 2012 National Tournament organized as a selection for the upcoming European Championship. Duration (s) of fighting and nonfighting phases was recorded during full-contact (athletes can throw punches and kicks with full power at legal targets above the waist) matches (three 2-minute rounds, with 1-minute rest in between). Differences (p<0.05) in relation to rounds (round1 vs round2 vs round3) were analyzed. **Results** No differences emerged for combat phases duration (fighting: 2.3±2.3s; nonfighting: 2.1±1.9s). Fighting showed a difference (p<0.05) between rounds with longer actions during round2 (2.4±2.7s) and round3 (2.4±2.1s) with respect to round1 (1.8±1.8s). On the other hand, nonfighting phases did not show any difference with respect to rounds (round1: 1.9±1.9s; round2: 2.4±2.2s; round3: 2.0±1.8s). **Discussion** Findings indicate that no differences emerge in fighting and nonfighting duration during elite kickboxing competitions and that fighting actions are shorter during round1 with respect to the last ones. This was probably due to the presence of a greater number of explosive actions (shorter in duration) during round1 with respect to the last part of the match, probably due to fatigue and/or to a tactical strategy. Since it is often difficult to plan an appropriate training program that reflects the real match conditions, this study could provide useful indications to coaches and staff. In particular, our findings underline the importance of high-intensity activities in kickboxing, suggesting an intermittent training regimen with an effort to rest ratio of 1:1 (2s effort: 2s rest). **References** Arsenau et al. ### **TIME COURSE OF STRENGTH GAIN IN ELBOW FLEXOR MUSCLE INDUCED BY DYNAMIC RESISTANCE TRAINING**

Hatanaka, S., Fukusaki, C., Ishii, N.

*The University of Tokyo*

**Introduction** It becomes possible to predict the effects of varied regimens of resistance training on muscular strength gain by analyzing the results of a number of previously reported studies with different regimens (Wernbom et al., 2007). However, comparing the results of studies with different training period is difficult, and the use of simple "gain rate", i.e., dividing total strength gain by training period, would be insufficient. This problem arises from the non-linear characteristics of the time course of strength change induced by strength training. To solve this problem, this study investigated the time course of strength gain in elbow flexor muscle induced by unilateral arm curl training, and tried to fit the results to several functions. **Methods** Fourteen untrained male subjects (age, 22-26 yr) performed three sets of dynamic elbow flexion exercise three days per week for fifteen weeks. Intensity was 80%1RM (1RM, one-repetition maximum), and subjects performed repetitions until failure. Elbow flexion strengths (isometric torque and 1RM) were measured prior to every training session, and the exercise load was adjusted to 80%1RM. Before the experiment, the subjects were asked about their experiences of training or regular sport activities. The muscle thickness of Biceps brachii was measured with B-mode ultrasound imaging before and after the

period of training. Results Muscle thickness, isometric torque and 1RM showed significant increases after the period of training ( $P < 0.05$ ). The changes in 1RM strength during the period of training showed two different characteristics depending on the subjects: exponential with time for major group ( $n=9$ ) and quasi-linear with time for minor group ( $n=5$ ). All of the subjects in major group had some previous experiences of sport activities, whereas four out of five subjects in minor group had not the exponential time course was not described with single rate constant, and could be divided into an initial rapid phase and a late slow phase around 3 wk after the beginning of training. Discussion The present results suggest that, in most cases, an exponential function with two rate constants or a combination of exponential and linear functions can adequately predict the strength gain during the period of training. The initial rapid increase would be mainly caused by neural adaptation, whereas the later slow phase would be limited by the increase in muscle mass. References Wernbom M, Augustsson J, Thomee R. ### CAFFEINE-CONTAINING ENERGY DRINK IMPROVES PHYSICAL PERFORMANCE OF FEMALE FOOTBALL PLAYERS DURING A SIMULATED MATCH

González-Millán, C., Salinero, J.J., Abián-Vicén, J., Areces, F., Lara, B., Muñoz, V., Portillo, J., González-Ravé, J.M., Barbero-Álvarez, J.C., Del Coso, J.

*University Camilo José Cela*

Introduction The effects of caffeine ingestion on male team-sports players have been recently established (Del Coso et al, 2012). However, there is little information about the effects of caffeine intake on female team-sports (Astorino et al, 2012). Since the ability to perform repeated sprints with minimal recovery is one of the most important capacities on team sport, the aim of this study was to investigate the effects of a caffeine-containing energy drink on the capacity of female football players to repeat sprints. Methods A double-blind placebo controlled and randomized experimental design was used in this study. On two different days separated by a week sixteen semiprofessional female football players ( $161.2 \pm 5.9$  cm and  $57.8 \pm 7.69$  kg) ingested 3 mg of caffeine per kg of body mass in the form of an energy drink (Fure@ProEnergetics) or the same drink without caffeine (placebo). After sixty minutes for caffeine absorption they performed a counter-movement jump (CMJ) and a 7x30m sprint test. Later, a simulated football match was played (2x40min, with 15min half time). Distance and speed were measured using global positioning satellite devices (GPS, 5Hz) and heart rate was recorded during the game. Results In comparison to the placebo drink the ingestion of the caffeinated energy drink increased the mean CMJ height ( $27.3 \pm 3.8$  vs  $26.2 \pm 3.8$  cm;  $P < 0.05$ ), the average ( $24.2 \pm 1.6$  vs  $24.5 \pm 1.7$  km/h;  $P < 0.05$ ) and the maximal running speed during the sprint test ( $25.0 \pm 1.4$  vs  $25.6 \pm 1.4$  km/h;  $P < 0.05$ ). During the simulated match, the energy drink increased the total running distance ( $6631 \pm 1618$  vs  $7087 \pm 1501$  m;  $P < 0.05$ ), the number of sprints bouts ( $16.3 \pm 9.2$  v  $21.4 \pm 13.3$ ;  $P < 0.05$ ) and the running distance covered at  $> 18$  km/h ( $161 \pm 99$  vs  $216 \pm 103$  m;  $P < 0.05$ ). No significant differences were found for the heart rate ( $P > 0.05$ ). Discussion An energy drink with a dose equivalent to 3 mg of caffeine/kg increased the ability to repeatedly sprint and the jump height during football specific tests. In addition, increased the total running distance covered during a simulated game, the number of sprints bouts and the running distance covered at high-intensity. These results suggest that energy drinks might be an effective ergogenic aid to improve physical performance of female football players. ### EFFECTS OF FATIGUE ON POWER AND COORDINATIVE PERFORMANCES

Cortis, C.I, Sanhueza Alfaro, S.P.1, Capranica, L.2

1: *University of Cassino and Lazio Meridionale (Italy)*; 2: *University of Rome Foro Italico (Italy)*

Introduction Fatigue during exercise is a complex phenomenon with a number of contributing factors (3). Literature suggests an exercise-related arousing effect after team sport competitions addressing the central nervous system ability to cope with the control of complex tasks in trained subjects (1,2). Because no study investigated the effect of local fatigue on fine neuromuscular activation patterns, the purpose of this study was to establish the acute effects of a fatigue protocol (FP) on jump and inter-limb coordinative performances in field settings. Methods Sixteen (Male=11, Female=5) young adults (age range: 20-24 yrs) answered the International Physical Activity Questionnaire (IPAQ) to ascertain quantity and quality of their weekly physical activity (PA). The load imposed by FP (squatting activity at a frequency of 60bpm to exhaustion) was ascertained by ratings of perceived exertion (RPE) and muscle pain (RMP). Before and after FP, countermovement jump (CMJ), in-phase (IP) and anti-phase (AP) inter-limb coordination (synchronized hand and foot flexions and extensions at 80, 120, 180bpm) were recorded. ANOVA for repeated measures was used to verify difference ( $p < 0.05$ ) between pre and post data. Results No gender differences emerged for the analyzed variables. IPAQ showed that subjects engaged in  $4 \pm 2$  sessions/weekly of vigorous and moderate PA. During FP, subjects performed  $233 \pm 116$  squats. Subjective ratings at the end of FP were significantly ( $p < 0.001$ ) higher (RPE:  $7.2 \pm 1.2$ pt; RMP:  $6.1 \pm 2.1$ pt) with respect to basal values (RPE:  $1.5 \pm 2.3$ pt; RMP:  $0.6 \pm 1.4$ pt). Post-fatigue CMJ ( $41.7 \pm 6.7$ cm), IP (80bpm:  $55.1 \pm 13.4$ s; 120bpm:  $45.8 \pm 17.5$ s; 180bpm:  $23.0 \pm 17.2$ s), and AP (80bpm:  $40.3 \pm 19.4$ s; 120bpm:  $15.1 \pm 15.3$ s; 180bpm:  $6.9 \pm 5.3$ s) performances did not show any difference with respect to pre-fatigue (CMJ:  $42.5 \pm 8.0$ cm; IP: 80bpm= $57.0 \pm 10.3$ s; 120bpm= $47.7 \pm 17.4$ s; 180bpm= $22.8 \pm 16.4$ s; AP: 80bpm= $34.9 \pm 24.4$ s; 120bpm= $10.4 \pm 14.3$ s; 180bpm= $4.1 \pm 4.7$ s) values. Discussion The proposed FP posed a high load on subjects, who rated the exercise as "very hard". Although an arousing effect counteracting fatigue effects and facilitating performance of complex motor behaviors has been reported after high intensity activities (1,2), CMJ, IP and AP performances did not show any change at the end of FP. It could be speculated that the high PA level of participants might have helped them preserving their power and coordinative performances at the end of FP. However, the total duration (8-min) of FP might not represent an acute exercise bout of appropriate intensity and duration to find beneficial effects on performances. References 1. ### INCREASED TRAINING ADAPTATIONS WHEN TESTING ON OWN BIKE VS. LABORATORY ERGOMETER

Hansen, J., Rønnestad, B.R.

*Lillehammer University College*

Regular laboratory testing of lactate profile and maximal oxygen uptake ( $VO_{2max}$ ) on cycle ergometers is important to monitor training adaptations in competitive cyclists (1). Laboratory ergometers might be suitable for tracking small, but important changes in the competi-

five cyclists' performance (2). However, previous research indicates that peak power output achieved in the laboratory may be different compared to outdoor cycling (3). Cyclists spend a lot of time optimizing their seating position and the waste majority of training is done on their own bike (OB). We are not aware of any studies comparing training adaptations tested on a laboratory ergometer with adaptations tested on the cyclists OB. We hypothesized that after a training period there would be a larger improvement in power output at a blood lactate concentration ( $[La]$ ) of 1.5 mmol·l<sup>-1</sup> on the cyclists OB compared to laboratory ergometer. Thirteen trained cyclists (body mass 76±7 kg, height 181±5, VO<sub>2</sub>max 63±6 ml·kg<sup>-1</sup>·min<sup>-1</sup>) was assigned to performed a 12 week training program of 9.5 ± 3.8 h·week<sup>-1</sup>. Power output at  $[La]$  of 1.5mmol·l<sup>-1</sup> was determined during an incremental cycle test. Pre- and post-tests were performed both on Lode Excalibur Sport ergometer and on their OB in the laboratory, stationed on Tacx Flow with PowertapSL+ mounted on the rear wheel. The test order was randomized and cadence, length of the crank arm, time of day and preparation to the two tests were the same at pre and post-tests. Following the training period the power output at  $[La]$  of 1.5mmol·l<sup>-1</sup> increased significantly from 197±11 W to 227±11 W ( $p>0.05$ ) on OB, while there was a non-significant increase on the Lode ergometer from 196±10 W to 216±11 W. At a power output of 225 W a reduction in heart rate was observed on OB (from 149±4 beats·min<sup>-1</sup> to 142±5 beats·min<sup>-1</sup>;  $p<0.05$ ), while the reduction on the Lode ergometer was non-significant (from 147±5 beats·min<sup>-1</sup> to 144±5 beats·min<sup>-1</sup>). There was no significant change in VO<sub>2</sub> at 225W with either OB or the Lode ergometer. The overall finding was that using a cyclists' own bike to test power output at  $[La]$  of 1.5 mmol·l<sup>-1</sup> seems to be more sensitive towards adaptations that actually takes place during a training period. Although the Lode ergometer can be adapted to the individual cyclist in numerous ways, it appears that using a cyclists' OB to test power output at  $[La]$  of 1.5 mmol·l<sup>-1</sup> is more sensitive than the ergometer to measure training adaptations following a training period. Therefore, statistical significant improvements were detected when cyclists were tested on their own bike, while no statistical significant changes was detected by using the Lode ergometer. ### A CAUSAL-MORPHOLOGICAL EVALUATION OF SPRINT MOTIONS FOR ELEMENTARY SCHOOL CHILDREN

Kokudo, S.

Kobe University

**Introduction** The purpose of this study was to establish a preliminary causal-morphological model of the sprint skill in order to develop some effective methods for teaching the overhand throw in the physical education class of elementary school. **Methods** The causal-morphological model of the sprint skill was drawn on the cycle-causal model, which was applying cause and effect diagram or fishbone diagram, one of the quality control tools. The model covered the descriptive checkpoints of previous studies. It was composed 3 major motions; ground catching, driving, and swing action, which included 25 morphological observation points. Every morphological observation was categorized into 2-3 levels respectively. Intermediate sprint forms of 30 elementary school children; 18 boys and 12 girls, 8-10 years old, were shot by digital video cameras. Their forms were played in slow motion or frame-by-frame, and an investigator evaluated the checkpoints. Qualitative factor analysis was applied in order to identify uni dimensionality of sprint skill. Correlation coefficient was calculated between object scores and running time of 10-meter intermediate sprint. **Results and Discussions** Two factors were extracted from 21 variables; the eigenvalues were 5.969(28.4%) for first factor and 2.652(12.6%) for second factor, the Cronbach alphas were 0.874 and 0.654. Four variables were omitted because of low communality. In the first factor, "arm swing down motion" (factor loading was 0.770) and "elbow longitudinal direction motion"(0.703) showed the highest factor loading. Twelve of 21 variables showed the factor loadings of 0.6 or more, and every factor loadings were positive, though "foot over push"(0.209) showed lowest factor loadings in the first factor. In the second factor, although "highest knee position" (-0.657) showed highest factor loading, the value was negative. Only four variables showed factor loadings above 0.5, and the factor loadings of 11 variables were negative in the second factor. The correlation coefficient between the first factor and sprint time was -0.374( $p<0.05$ ), that of second factor and running was 0.067(Ins). Therefore it is suggested that the first factor reflect the sprint skill. However, the correlation coefficient is not so high, because viewpoints of the pitch and stride were not fully included in the evaluation criteria. In addition, we observed some children who waving their arms in the lateral direction in order to induce a twist action. Such aspects were not included in this study. **Conclusions** Sprint motion was able to evaluate with one-dimensional scale from 21 viewpoints. It explained sprint time significantly. We need to improve further aspect because the viewpoints did not reflect some of the observed motions. This work was supported by Grant-in-Aid for Scientific Research(C), (24500697) Japan.

### ESTIMATION OF LOAD MAXIMIZING MECHANICAL POWER OUTPUT USING THE BALLISTIC BENCH PRESS AND BENCH THROW TEST

Kobayashi, Y.1, Akagi, R.2, Hirayama, K.3, Nakagaki, K.1, Kawamori, N.1

1: Japan Institute of Sports Sciences (Tokyo, Japan), 2: Shibaura Institute of Technology (Saitama, Japan), 3: Waseda University (Saitama, Japan)

**Introduction:** Training at the load that maximizes peak mechanical power (P<sub>max</sub>) is considered superior for the development of power (Nibali et al., 2013). Ballistic bench press (BP) and bench throw (BT) are often used for the determination of P<sub>max</sub> load in the upper body. Because of the braking phase in BP that occurs when using a light or medium load (Sanchez-Medina et al., 2010), the load-power spectrum in BP is different from that found in BT. The result is that the P<sub>max</sub> load for BP is different from that of BT. The purpose of this study was to determine the relationship between BP and BT, with respect to P<sub>max</sub> and P<sub>max</sub> load. **Methods:** Thirteen male collegiate footballers participated in the study. Testing session one involved the determination of each subject's one-repetition maximum (1RM) bench press strength using a Smith machine. Testing session two involved the performance of ballistic BPs and BTs using the Smith machine set at several different loads ranging from 30.0 kg to 90% of 1RM. Barbell positions were measured using a linear position transducer, and barbell velocity, force and power output during ballistic BP and BT were calculated using a dynamic equation. P<sub>max</sub> and P<sub>max</sub> load were determined by fitting second-order polynomials to the data. **Results:** P<sub>max</sub> in BP was significantly smaller than in BT ( $P<0.05$ ). However, P<sub>max</sub> load in BP was significantly greater than in BT. P<sub>max</sub> in BT was significantly correlated with P<sub>max</sub> in BP ( $P<0.05$ ). P<sub>max</sub> load in BT was not significantly correlated with P<sub>max</sub> load in BP. **Discussion:** The results suggest that P<sub>max</sub> load is higher when using the BP test compared with BT and that it is difficult to predict P<sub>max</sub> load for BT using the P<sub>max</sub> load for BP. **References:** Nibali ML, Chapman DW, Robergs RA, Drinkwater EJ. ### MAXIMAL SWIMMING DISTANCE AT ANAEROBIC CRITICAL VELOCITY

Costa, A.M.1,2, Silva, P.3, Conceição, A.2,3, Neiva, H.1,2, Louro, H.2,3

1: University of Beira Interior (Covilhã, Portugal); 2: Research Center in Sports Science, Health and Human Development (Portugal); 3: Polytechnic Institute of Santarém (Rio Maior, Portugal)

**Introduction:** Recent studies showed strong relationships between anaerobic critical velocity (AnCV) and distances with high anaerobic demands (Fernandes et al., 2008; Neiva et al., 2011). As an inexpensive and non-invasive method it seems relevant to conduct further studies to verify the use of this recent functional parameter. Therefore, the aim of this study was to assess AnCV in swimming, its relationships with short distance performance and determine the maximal distance that can be performed at this assessed velocity. **Methods:** Nine male swimmers performed 15, 25 and 50 m maximal front-crawl swimming to calculate ACV. Each swimmer also performed 100 m front-crawl at maximal velocity. Additionally, it was aimed to assess the maximal distance that could be performed at the previously assessed individual AnCV (up to 150 m). Capillary blood lactate concentrations and biomechanical variables were assessed on both swimming tests. **Results:** Results show that AnCV and maximal 100 m front-crawl were highly correlated ( $r=0.88$ ,  $P<0.01$ ) and no differences ( $P>0.05$ ) were noted between them ( $1.61 \pm 0.07$  m.s<sup>-1</sup> and  $1.60 \pm 0.08$  m.s<sup>-1</sup>, respectively;  $P=0.34$ ). The swimmers were able to perform  $97.22 \pm 20.51$  m at AnCV. However, no relationship was found between the total distance achieved and AnCV ( $r=0.27$ ,  $P=0.49$ ) and 100m performance ( $r=0.49$ ,  $P=0.19$ ). Blood lactate concentration values were also different in the 3rd and 5th minutes of recovery between the two tests ( $P<0.05$ ). Likewise, variations of the biomechanical variables were noted between the tests. **Discussion:** Linear relationships and no differences were found between AnCV and 100m swimming velocity, corroborating data found in the literature. This result suggests that AnCV is an important indicator of performance in short events. However, swimmers were not capable to maintain the velocity correspondent to AnCV for more than  $97.22 \pm 20.51$  m as possible changes in technique due to fatigue could lead to an increase in body drag. Moreover, no consistent relationships were found between the total distance achieved at AnCV and AnCV, which highlights that higher assessed velocities are not necessarily correspondent to more swimming distances. More research is needed to understand the effects of training on anaerobic power and on anaerobic capacity and the relationship between these two components of swimmer's anaerobic fitness level. **References:** Fernandes, R., Aleixo, I., Soares, S., Vilas-Boas, J. ### RELATIONSHIP ON PARA-CYCLISTS CATEGORIES IN MAXIMAL AEROBIC POWER OUTPUT AND TIME TO EXHAUSTION DURING BICYCLE ERGOMETER EXERCISE

Weissland, T., Lepretre, P.M.

EA-3300, UFR-STAPS

**Introduction** The Para-Cycling Classification separates the blind and visually impaired (B on tandem with a valid pilot; P), impairments of leg muscle (divided into 5 classes; C1-5) and those with impaired coordination and balance (using tricycle; T1-2) [UCI Cycling Regulations]. The average speed of the winners of time-trial men event, measured during the last Olympic and Paralympic Games, shows a linear decrease in speeds in different classes of disability ( $y=-2.61x+53.73$ ;  $R^2=0.95$ ) and reflects the degree of muscle strength deficit in the production of mechanical power and pedalling efficiency. The aim of this study was to examine the relationship between the 9 classes of para-cyclists in the maximal power associated at VO<sub>2</sub>peak (pVO<sub>2</sub>peak) and the time to exhaustion at pVO<sub>2</sub>peak (tlim). **Methods** 23 men of the French team of Para-cycling (3P, 3B, 5C5, 2C4, 3C3, 3C2, 1C1, 2T2, 1T1) participated in a training session. With their bikes, they took a continuous incremental test based on their disability category (15, 20 or 25 Watt.min<sup>-1</sup>) with a Cyclus2 ergometer to determine VO<sub>2</sub>peak and pVO<sub>2</sub>peak. 48 hours later, following a standardized warm-up (30 min), they performed exhaustive (tlim) exercise at their MAPO. Cardiorespiratory parameters (VO<sub>2</sub>peak, VEpeak, HRpeak) were measured breath-by-breath with the Cosmed K4b2. In investigating the relationships between respective items of measurement, a Pearson's correlation coefficient was calculated. The level of significance was set at  $P<0.05$ . **Results** Means pVO<sub>2</sub>peak, VO<sub>2</sub>peak, VEpeak, HRpeak and tlim were respectively ( $313 \pm 74$ W;  $64.9 \pm 6.1$  mL.min.kg<sup>-1</sup>;  $158 \pm 17$  L.min<sup>-1</sup>;  $187 \pm 11$  b.min<sup>-1</sup>;  $242 \pm 57$ s). The degree of disability was linearly correlated with the inter-class changes in pVO<sub>2</sub>peak ( $R^2=0.92$ ) but not in VO<sub>2</sub>peak, VEpeak and HRpeak. No significant relationship was found between VO<sub>2</sub>peak and tlim ( $r=0.61$ ,  $p=NS$ ). tlim was inversely correlated with pVO<sub>2</sub>peak ( $r=-0.75$ ,  $P<0.05$ ). **Discussion** pVO<sub>2</sub>peak pilots are the highest and are similar to those recorded by Billat et al., 1996 and unlike the pVO<sub>2</sub>peak, B's tlim are superior. This result is different from that of Caputo et al. (2003) who showed that endurance training seems to influence tlim differently. We found a relationship between pVO<sub>2</sub>peak and tlim similar to what Renoux found in swimmers (2001). Billat et al., 1996 observed the tlim at vVO<sub>2</sub>peak higher among kayakers compared to runners and cyclists. Limitation caused by muscle disease requires improved endurance during an exhaustive exercise at pVO<sub>2</sub>peak. This result has an application in training. **References** UCI Cycling Regulations (2012), F0712, part 16. Billat A et al. (1996) Ergonomics, 39:2, 267-277. Renoux JC. (2001) Arch Physiol Biochem. 109 (5): 424-9. Caputo F, Mello MT, Denadai BS. (2003) Arch Physiol Biochem. 111(5): 461-6.

### THE INFLUENCE OF AUDITORY DISTURBANCE ON BALANCE ABILITY IN YOUNG PEOPLE: A PILOT STUDY

Lo, C.

Cheng Ching General Hospital

**Introduction** Balance plays an important role in sports related performance. Visual, vestibular, and proprioceptive feedbacks are key factors to maintain balance. Auditory stimulation or noise was considered as a proprioceptive disturbance in balance test. In previous studies, music has been shown to have a beneficial effect in sports related performance by increasing muscular coordination and oxygen saturation. However, no study demonstrates how auditory disturbances affect balance parameters, such as steadiness, symmetry, and dynamic balance. Therefore, the purpose of this study is to explore the influence of auditory disturbance on balance in young people. **Methods** Nineteen health young people (aged 19 to 25) without hearing deficit were included in this study. Each participant was tested in 4 different conditions randomly: quiet with eye open, white noise with eyes open, quiet with eyes close, and white noise with eyes close. The white noise that produced by Adobe Audition 2.0 was exported through earphone and the volume was set in 85 dB. Sway area, sway path length, forward/backward and lateral deviation of each participant's COG were measured by Zebris FDM platform during one leg standing balance test to quantify static standing balance. **Results** No statistically significant difference was found in eyes close conditions. However, in eyes open situation, there was a significant difference in the sway path length between quiet and white noise condition ( $p=0.019$ ). Regardless in white noise or quiet condition, better balance performances were noted in one leg standing

balance test. Conclusion The study indicated that 85dB white noise may disturb one leg static standing balance in eyes open condition in healthy young population. In other words, noise may have an adverse effect on balance related performance. But the influence of other of auditory characteristics in balance, such as frequency, volume and rhythm, are still unknown and will be discussed in further study. ## COMPARISONS OF MECHANICAL OUTPUTS, ELECTROMYOGRAMS, MUSCLE DAMAGES, AND PHYSIOLOGICAL RESPONSES BETWEEN MANUAL AND WEIGHT RESISTANCE TRAININGS

Arakawa, H.1, Higa, K.2, Tanimoto, M.3

1: *Japan Institute of Sports Sciences (Tokyo, Japan)*, 2: *The University of Tokyo (Tokyo, Japan)*, 3: *Kinki University (Wakayama, Japan)*

Introduction Manual resistance training (MRT) has many advantages over traditional weight resistance training (WRT), such as minimal requirements for equipment and potential for maintaining maximum muscular tension throughout the movement, including in the eccentric phase. Although MRT has been widely adopted in practice, there have been no studies examining the biomechanical and physiological characteristics of MRT. The purpose of the present study was to investigate the force generation, muscle activity, and physiological responses of MRT and to compare these data with those of WRT. Methods Unilateral elbow flexion was performed 10 repetitions by 8 healthy male adolescents. Flexion was performed with a repetition maximum (RM) of 10 using manual resistance for one arm and weight resistance for the other in randomized order. In both conditions, the joint moment, joint work, and muscle activity observed by electromyography (EMG) were evaluated. The muscular force in MRT was measured using a custom-made instrument. Muscle fatigue and damage were measured before, immediately after, 15 and 30 min after the exercises for fatigue markers, and 2 and 4 days after the exercises for damage markers. Results As compared with WRT, MRT showed significantly greater joint moments (35 Nm vs. 28 Nm within the concentric phase; 50 Nm vs. 28 Nm within the eccentric phase) as well as more negative joint work in the eccentric phase (-73 J vs. -45 J). Additionally, the markers of muscle damage were significantly greater in MRT than in WRT. There was no significant difference in the EMG and muscle fatigue markers. Discussion Results of the present study suggested that MRT can provide muscles with higher-intensity mechanical stimulation than traditional high-load WRT, while maintaining similar degrees of muscle activity and fatigue. Thus far, several studies have investigated the effects of MRT on physical fitness through practical approaches (Dorgo et al., 2009). The present study revealed the biomechanical and physiological basis for the effects of MRT. Theoretically, the greater overload achieved by MRT should result in more pronounced strength development (Andamovich et al., 1987). Note, however, that during the implementation of MRT, trainees are prone to submaximal performance because quantification of the resistance by a spotter is unavailable. Therefore, to take advantage of the greater mechanical loading in MRT, it is important to take into account both the trainee's effort and the spotter's instruction. ## ACUTE EFFECTS OF TWO DIFFERENT WARM-UP PROTOCOLS ON FLEXIBILITY AND LOWER LIMB EXPLOSIVE PERFORMANCE IN ELITE FEMALE ARTISTIC AND RHYTHMIC GYMNASTS

Dontj, O., Tsolakis, Ch., Katsikas, Ch., Bogdanis, G.C.

*NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS*

Introduction Little evidence exists on the effects of the combination of static stretching and sport specific exercises that induce post-activation potentiation (PAP) on subsequent muscle performance (Tsolakis, & Bogdanis, 2012). The aim of this study was to examine the combined effect of static stretching and tuck jumps on leg muscle power and flexibility of elite female gymnasts. Methods Twenty-four elite female gymnasts (14 artistic and 10 rhythmic), participated in this study. A repeated measures, within subject randomized design was used to compare the effects of the two different warm-up protocols on hip joint flexion range of motion (ROM) and counter-movement jump (CMJ) height. One warm-up included short (15 sec) static stretching followed by 5 tuck jumps (S-WU), while the other included longer static stretching (30 sec) followed by 3x5 tuck jumps (L-WU). ROM was measured before and after warm-up, after the stretching interventions and after the tuck jumps. CMJ was measured after warm-up, after stretching, immediately after and at 4, 8 and 12 min of recovery following interventions in order to examine possible interaction between fatigue and PAP. Results The 3-way ANOVA revealed significant main effects for sport, warm-up protocols and time for ROM ( $p < 0.01$ ). As expected, rhythmic gymnasts had greater ROM than artistic gymnasts. A warm-up protocol x time interaction was also found for ROM ( $p < 0.01$ ). L-WU increased ROM more than S-WU by 8.3% for both artistic and rhythmic gymnasts. This increase peaked immediately after stretching and remained unchanged after the tuck jumps. The 3-way ANOVA for CMJ performance showed only a sport and time main effect ( $p < 0.01$ ), with no main effect for condition. Artistic gymnasts had greater CMJ than rhythmic gymnasts. CMJ remained unchanged compared to the baseline value in the S-WU condition, but increased by 4.6%, 4 min into recovery in the L-WU condition. Discussion The L-WU protocol, that included a combination of 30 s static stretching and 3 sets of tuck jumps, resulted in a significant increase in flexibility and leg muscle power in both artistic and rhythmic gymnasts. Although ROM was higher in rhythmic gymnasts and CMJ was higher in artistic gymnasts, the effects of the two warm-up protocols were similar in the two groups of athletes, with L-WU giving better results for both ROM and CMJ. ## EFFECTS OF MUSCLE CONTRACTION TYPE ON POSTACTIVATION POTENTIATION

Tsoukas, A., Bogdanis, G.C., Veligeas, P., Tsolakis, C., Terzis, G.

*UNIVERSITY OF ATHENS*

Introduction Previous studies examined PAP and noted that the type of muscle contraction might have different effects on PAP (Rixon et al. 2007). In those studies the volumes of preload have not been equalized. The primary purpose of this study was to examine the effect of isometric, concentric and eccentric muscle contraction as a preload on vertical jumping performance with equated volumes. The secondary purpose was to determine the individual timing potentiation. Fourteen athletes that involved with athletic jumps participated in a control condition and three experimental conditions. Methods Fourteen track and field athletes (height:  $1.77 \pm 0.05$  m; body mass:  $79.0 \pm 7.1$  kg; body fat:  $9.1 \pm 6.8\%$ , maximal half squat strength, one repetition maximum-RM:  $173 \pm 29$  kg) took part in this study. Following familiarization and preliminary testing, participants visited the laboratory on four randomly assigned occasions, one week apart. On each occa-

sion, participants performed the conditioning exercise (isometric, eccentric, concentric and control) followed by performance testing (countermovement jump-CMJ), at 15 seconds, 2, 4, 6, 8, 10, 12, 15, 18 and 21 minutes. The load on all conditions was equated by measuring the impulse of the force on a force plate. Data were analyzed using a 2-way ANOVA with repeated measures on both factors (condition x time). Significance was accepted at  $p < 0.05$ . Results The 2-way ANOVA showed a condition x time interaction ( $p < 0.01$ ) as well as a time main effect ( $p < 0.01$ ). In all experimental conditions, CMJ performance was decreased immediately after the end of the conditioning muscle contractions and then recovered over time. When data were examined on an individual level, CMJ performance was increased ( $p < 0.01$ ) by  $0.6 \pm 1.0\%$ ,  $1.5 \pm 1.2\%$  and  $3.0 \pm 1.2\%$ , respectively, in the concentric, eccentric and isometric conditions. In the control condition, CMJ performance was progressively decreased over time reaching a low of  $-7.3 \pm 0.5\%$  after 21 min. Discussion Isometric conditioning exercise was found to give the greatest potentiation on subsequent explosive muscle performance. These results are in accordance with those reported by Rixon et al. (2007), who also found that an isometric protocol similar to that used in the present study resulted in a 2.9% increase in CMJ compared to a dynamic protocol (3 RM). These results have practical value for coaches and suggest that brief isometric contractions can be used to attain a postactivation potentiation effect on leg muscle power.

## EXECUTIVE FUNCTION IS IMPROVED FOLLOWING A MULTICOMPONENT MOTOR-CONTROL TRAINING IN OLDER PEOPLE

Martinez-Navarro, I., Blasco-Lafarga, C., Sanchis, G., Cordellat, A., Roldan, A., Gil, J., Valencia-Peris, A.

UNIVERSITY OF VALENCIA

**INTRODUCTION.** Although some studies have pointed to promising effects of physical training on cognition in older adults, a recent review has not found sufficient evidence and further trials are claimed (1). Therefore, our purpose was to evaluate whether a multicomponent motor-cognitive training was able to enhance executive control among older people. **METHODS.** 15 participants (13 women, 2 men;  $71.3 \pm 3.9$  yrs) were involved in this pilot study. They exercised for 1 hour, twice-weekly for 7 months. Training program consisted of mainly gait and strength exercises in which coordinative, cognitive and balance challenges were progressively added using a dual-task methodology. The Stroop Colour Word Test was employed to assess cognitive functioning. Performance was quantified by the time (in seconds) participants took to read the 100 items of each part. Following Colcombe et al. review (2), part A (SCWTA) and B (SCWTB) were considered controlled processes tasks and part C the executive task (SCWTC). Interference score (SCWTINT) served as the measure of executive function. Participants were tested one week before and after the intervention. Non-parametric Wilcoxon test was conducted to assess the effect of the exercise upon cognitive functioning (SCWTA, SCWTB and SCWTINT) and Cohen's *d* was used to evaluate the magnitude of the effect. **RESULTS.** A significant improvement following the training was observed both in a controlled process task and executive function. Time in SCWTA and SCWTINT score decrease 12% ( $d=0.63$ ;  $p < 0.05$ ) and 16% ( $d=0.46$ ;  $p < 0.05$ ) respectively. Improvement in SCWTA was also nearly significant ( $d=0.28$ ;  $p=0.064$ ). **CONCLUSIONS.** The outcomes of this pilot study, although preliminary, suggest that multicomponent approaches based on dual-task methodology and a progressive increase in coordinative, balance and cognitive demands hold a great potential for enhancing executive function in older adults. This is line with other recent studies (3, 4). However, our improvement in both controlled process task (i.e., SCWTA) and executive function differs from the selective improvement hypothesis proposed by Colcombe et al. (2), according to which only executive function tasks were enhanced following physical training. **REFERENCES.** 1. Snowden M, Steinman L, Mochan K, Grodstein F, Prohaska TR, Thurman DJ, et al. ## ARE GAINS IN PHYSICAL AND COGNITIVE EXECUTIVE PERFORMANCE FOLLOWING A FUNCTIONAL TRAINING IN OLDER ADULTS RELATED?

Martinez-Navarro, I., Blasco-Lafarga, C., Sanchis, G., Cordellat, A., Roldan, A., Gil, J., Valencia-Peris, A.

UNIVERSITY OF VALENCIA

**INTRODUCTION.** It has been found no associations between gains in VO<sub>2</sub>max and cognitive performance following physical training in older adults (1). Similarly, Karavirta et al. (2) reported no significant correlations between training responses in cardiovascular endurance (VO<sub>2</sub>max) and strength (maximal leg extension force) following a endurance-strength concurrent training. Hence, our target was to evaluate whether executive function (EF) and functional fitness (FF) responses following a multicomponent motor-cognitive training in older people were related to each other or not. **METHODS.** 15 participants (13 women, 2 men;  $71.3 \pm 3.9$  yrs) were involved in this pilot study. They exercised for 1 hour, twice-weekly for 7 months. Training program consisted of gait and strength exercises aimed at improving participants' functionality through progressively increasing coordinative, cognitive and balance demands. Stroop Colour Word Test interference score (SCWTINT) was used to evaluate EF. FF was assessed by means of chair-stand test (CST), 6-min walk test (6MWT) and timed Up&Go test (TUGT). Participants were tested one week before and after the intervention. Spearman rank-order correlation coefficient was used to study possible relationships between changes in studied variables from pre to post-test condition. **RESULTS.** No significant relationships were found among variables. However, a tendency towards significance was found between CST and TUGT ( $r=0.488$ ;  $p=0.065$ ). **CONCLUSIONS.** The nearly significant association between CST and TUGT is probably due to shared neuromuscular mechanisms involved in both tasks (3), whilst gains in 6MWT seem to be mediated by different pathways. Meanwhile, the absence of relationship between gains in physical and cognitive performance displayed in our pilot study coincides with previous investigations (1). Notwithstanding, further studies with larger samples but similar promising training approaches (4, 5) are needed to deepen into the mediators of cognitive enhancement following physical exercise. **REFERENCES.** 1. ### **THE IMPACT OF TRAINING SURFACE IN VO2MAX OF PREPUBESCENT VOLLEYBALL PLAYERS.**

Gortsila, E., Theos, A., Maridaki, M.

*University of Athens*

**INTRODUCTION** Volleyball and beach volleyball are characterized by rapid accelerations, decelerations and sudden changes of direction (Young et al., 2001, Bishop, 2003). Performance recovery and repeated maximal efforts ability are influenced by aerobic metabolism (Lidor and Ziv, 2010). The purpose of the present study was to examine the impact of training surface in VO2max of prepubescent volleyball players. **METHODS** Thirty female prepubescent volleyball players (age:  $11.2 \pm 0.6$  yrs) took part in this study and were randomly allocated in two groups. Group A (N=15) participated in a 10 week training programme on sand surface, while group B (N=15) participated in a same programme on land surface. 20m shuttle run tests were conducted on hard surface before (pre) and after (post) the training period. The equation of Leger et al. (1988) was used for the prediction of VO2max. Differences in VO2max pre - post training and between the groups were analysed using T-test. Results are presented as mean  $\pm$  SE. **RESULTS** VO2max did not differ between groups in the pre condition (Group A:  $44.4 \pm 0.1$  ml/kg/min vs. Group B:  $44.4 \pm 0.1$  ml/kg/min,  $p=0.09$ ) while it was significantly improved ( $p<0.001$ ) in both groups in the post condition (Group A:  $48.8 \pm 0.3$  ml/kg/min vs. Group B:  $45.9 \pm 0.2$  ml/kg/min). In the post condition VO2max differed significantly between groups Group A:  $48.8 \pm 0.3$  ml/kg/min vs. Group B:  $45.9 \pm 0.2$  ml/kg/min,  $p<0.001$ . **DISCUSSION** Despite the fact that VO2max was improved in both groups after the 10-week training program, the much greater improvement achieved in group A suggests that the training surface may play an important role. **REFERENCES** 1. ### **INFLUENCE OF A SOCCER-SPECIFIC TRAINING PROGRAM IN PHYSIOLOGICAL CHARACTERISTICS OF PRE-PUBERTAL BOYS**

Papanakos, C., Dellis, D., Theos, A.

*National & Kapodistrian University of Athens*

**Introduction** Participation in structured training programs seems to promote growth and maturation in children (Cunha et al., 2011, Moore et al., 2010). The purpose of the present study was to investigate the influence of a soccer-specific training program on physiological characteristics of prepubescent boys. **Methods** 24 prepubescent boys (age:  $10.6 \pm 0.4$  yrs) took part in this study and were randomly allocated in 2 groups. Exercise group (EG, n=12) participated in a soccer-specific training program (3 days/week) for three months, while control group (CG, n=12) did not participate in any structured training program. Body mass, body height, percent body fat, counter-movement jump (CMJ) and Illinois agility test were measured in both groups before (pre) and after (post) the completion of the 3-months training program. Differences between groups were analyzed using T-test and the results are presented as mean  $\pm$  SE. **Results** Body mass and body height did not differ between groups neither in the pre nor in the post condition (Pre:  $p=0.12$ , Post:  $p=0.19$ ), but were significantly increased in both groups after the 3-months period ( $p<0.01$ ). Changes in percent body fat did not differ between groups in the pre condition (EG:  $13.3 \pm 0.5\%$  vs. CG:  $13.6 \pm 0.4\%$ ,  $p=0.62$ ), while in the post condition percent body fat increased significantly only in the control group (CG:  $13.6 \pm 0.4\%$  vs.  $13.9 \pm 0.3\%$ ,  $p<0.01$ ). CMJ and Illinois agility test did not differ between groups in the pre condition. Performance in CMJ was significantly improved in both groups after the 3-months period, but the EG performed significantly better than the CG (EGpost:  $27.3 \pm 0.7$ cm vs. CGpost:  $23.5 \pm 1.4$ cm,  $p<0.05$ ). In the post condition Illinois agility test was significantly improved only in the EG and differed significantly from the CG (EGpost:  $19.4 \pm 0.3$ sec vs. CGpost:  $20.5 \pm 0.3$ sec,  $p<0.01$ ). **Discussion** The results of the present study suggest that a 3-months soccer-specific training program induces significant decreases in body fat and significant performance improvements in CMJ and Illinois agility test. **References** Cunha G., Lorenzi T., Sapata K., Lopes A.L., Gaya A.C., Oliveira A. ### **STRENGTH AND PSYCHO-BIOLOGICAL DECLINING IN ULTRA-CYCLIST: A DESCRIPTIVE CASE-STUDY**

Lopez-Grueso, R.1, Guerrero-Lopez, F.J.2,3, Sanchis-Chorda, J.4, Jimenez-Reyes, P.5, Ferrando, B.4

*1 Universidad Miguel Hernández de Elche. Spain 2 Instituto Nutrición Deportiva (IND) Valencia. 3 Universidad Politécnica Madrid. 4 University of Valencia. INCLIVA. Dpt. Physiology. 5 UCAM, Murcia*

**Introduction** The long duration sport events affect to endurance performance, physical and mental, conditioning the performance. However, the decrease in these physical-biological aspects in a long-distance cycling test (1000km non-stop) could be interesting to reach the highest level for the ultra-athletes. **Methods** A well-trained ultra-endurance sport man completed 1000km non-stop of cycling in a circuit (4.7km) with a maximum of 40 hours. During the entire test (before, during -6 occasions- and immediately at the end) we evaluated the decreasing of power output and the psycho-biological markers through strength levels (counter-movement jump, CMJ and squat jump, SJ), and psychobiological markers (rate of perceived exertion -RPE scale- and moods -POMS scale). All data were compared longitudinally. **Results** Strength or peak power output levels, expressed by SJ and CMJ, were diminished during the test, appearing in a progressive declining until the end (SJ= -14.9%; CMJ= -9.4%). These losses were accompanied of similar variations in POMS and RPE scales. Thus, the value of Fatigue was positively correlated with RPE scale and the Tension was inversely correlated with the RPE scores in the measures. **Discussion** To consider a psycho-biological approach between realized and perceived effort with the mood state is an interesting tool to assess the relation in power capacity and perceived exertion in these ultra-endurance events. **References** • Del Coso J, González-Millán C, Salinero JJ, Abián-Vicén J, Soriano L, Garde S, Pérez-González B. ## SESSION-RPE IN SOCCER: RESPONSE SHIFT AND RECALL BIAS

Fanchini, M., Ferraresi, I., Petruolo, A., Azzalin, A., Schena, F., Impellizzeri, F.M.

*FC Inter, Milan, Italy, University of Verona, Italy, FC Varese, Italy, FC Gozzano, Italy, AS Monaco, Pr Monaco, CeRISM, Rovereto, Italy, Schullthess Clinic, Zurich, Switzerland*

Introduction Session-RPE is frequently used to monitor the training process as a valid measure of internal training load in soccer [1]. Nevertheless some methodological aspects that may influence the session-RPE have been not studied yet. Is it possible to collect RPE after 48 hours particularly when players are not too collaborative as could happened after a match? To answer this question, it is needed to investigate two attributes: response shift and recall bias. Response shift concerns a change in perception due to reconceptualization, reprioritization, scale recalibration after a period of time [2]. Recall bias concern the ability to remember the RPE given and could have influenced the retrospective assessment of RPE. The aims of this study were to investigate response shift (RS) and recall bias (RB) in session-RPE. Methods Fifty-eight soccer players (age  $21.6 \pm 5.0$  yrs, height  $178 \pm 6.5$  cm, weight  $72.4 \pm 6.4$  kg) reported RPE (BorgCR100®) after a training/match and after 48 hours (RPE48). RS has been investigated with a retrospective assessment using the widespread used "Then-test" (during the first part of the season). In a second part of the season RB was investigated asking players whether they remembered exactly the RPE given. If RPE was not remembered, a new rating was requested and considered an addition evaluation of RS. RS and RB were assessed in training sessions (RST and RBT) and matches (RSM and RSM). Bland-Altman method was used to study the agreement between RPE and RPE48. Results Data are presented mean ( $\pm$ SD). The number of players analysed were 58, 22, 34, 51 for RSM, RST, RBM and RBT. The mean RPE and RPE48 in RSM was  $59.2 \pm 13.2$  and  $58.6 \pm 12.8$  au respectively with mean difference RPE48-RPE of  $-0.5$  au (95%LOA  $-6.0$  to  $5.06$  au). The mean RPE and RPE48 in RST was  $46.8 \pm 9.8$  and  $48.9 \pm 9.5$  au, respectively with mean difference RPE48-RPE of  $2.2$  au (95%LOA  $-11.7$  to  $16.1$ ). The mean RPE and RPE48 in RBM was  $55.7 \pm 17.7$  and  $57.1 \pm 18.5$  au, respectively with mean difference RPE48-RPE of  $1.4$  au (95%LOA  $-6.9$  to  $9.7$ ). The mean RPE and RPE48 in RBT was  $46 \pm 11.6$  and  $47.1 \pm 12.8$ , respectively with mean difference RPE48-RPE of  $1.1$  (95%LOA  $-4.4$  to  $6.6$ ). Discussion Response shift was not found after matches suggesting that the perception of the construct of interest (effort) was not changed after 48 hours. Despite the "then test" is frequently used to investigate RS in clinical assessment, we are not able to exclude players focused on the previous rating. The RST assessment showed that session-RPE can be collected even after two days without, influencing the rating and therefore the TL calculation. However, for both RSM and RST we cannot exclude an effect on RPE48 due to the rating already given (effect of recall); therefore these findings should be confirmed with other experimental approach other than the "then test" for investigating RS in RPE. 1. Impellizzeri. *Med Sci Sports Exerc*, 2004. 36(6): p. 1042-7. 2. Schwartz. *Quality of Life Research*, 2010. 19(4): p. 455-464.

## AGE-RELATED DIFFERENCE AND THE EFFECT OF BALL CARRYING TECHNIQUE ON ACCELERATION AND MAXIMUM RUNNING SPEED IN RUGBY PLAYERS

Urbano, R.1,2, Suarez, G.1,2, Nuñez, J.2, Gonzalo-Skok, O.3, Suarez-Arrones, L.1,2

*1 QDIEZ, Seville (Spain); 2 Pablo de Olavide University, Seville (Spain); 3 USJ, Zaragoza (Spain)*

Introduction In rugby, there are different ways to carry the ball while players are running. The most common ways are to carry the ball in both hands and to carry it under one arm (1). The aim of this study was compare the effect of ball carrying technique on acceleration and maximum running speed in rugby players and the age-related difference. Methods Sixteen high-level senior rugby players, thirteen U20 rugby players and twenty-two U16 rugby players participated in this study. The sprint performance of players was determined using a 40-m sprint effort with electronic timing gates with split time at 10-m. Some players also were asked to wear a GPS unit. Players performed 3 sprints: without ball, with the ball under one arm and with the ball in both arms. Results Senior rugby players were significantly faster than U16 in 10-m distance, although there were no differences between senior rugby players and U20 or between U20 rugby players and U16. Senior and U20 rugby players were significantly faster than U16 in 40-m, with no differences between two of them. The average sprint time showed that in 10-m there were no significant differences when players carried the ball with one or two hands or without ball. In 40-m, senior and U20 rugby players had the fastest sprint without ball and we only had significant differences when they carried the ball with both hands. U16 rugby players decreased significantly their speed when they carried the ball with one or two hands compared to running without the ball. The sprint distance to reach the peak of speed (GPS) was significantly higher in senior and U20 than in U16. Discussion According to prior studies (Walsh et al. 2007), our results showed that different ways to carry the ball have not a significant effect on sprint time in 10-m. Similar to Grant et al. 2003 (2), in 40-m sprint distance players reflected higher sprint times running with the ball in two hands than running with the ball in one arm or running without the ball. These differences increased in younger players who also worsened sprint time with the ball in one arm. References 1. Walsh, M, Young, B, Hill, B, Kittredge, K, and Horn, T. ## ISOKINETIC MUSCLE STRENGTH PROFILE OF ELITE MALE HANDBALL PLAYERS

Póvoas, S.1,2, Ascensão, A.3,5, Magalhães, J.3,5, Seabra, A.4,5, Oliveira, E.2, Soares, J.4,5, Rebelo, A.4,5

*1: CIDESD, 2: Maia Institute of Higher Education (Maia, Portugal), 3: CIAFEL, 4: CIFID, 5: Faculty of Sport, University of Porto (Porto, Portugal)*

Introduction Handball is a complex highly demanding intermittent sport where powerful high-speed actions of the upper- and lower-extremity muscles are repeatedly performed throughout the game (Póvoas et al., 2012). This may contribute to the high incidence of the knee and shoulder joint injuries (Langevoort, Myklebust, Dvorak, & Junge, 2007). Thus, we aimed to analyse shoulder internal/external rotators and knee extensor/flexor isokinetic muscle strength profile of elite male team handball players according to playing position. Methods Sixty-three elite players (18 wings, 26 backcourt players, 9 pivots and 10 goalkeepers) from six teams of the Portuguese Handball Professional Male League performed concentric strength tests of both dominant (D) and non-dominant (ND) upper and lower limbs at  $90^\circ$  s $\rightarrow$  1 (1.57 rad.s $\rightarrow$  1) on an isokinetic dynamometer (Biodex-System 2, New York, USA). Shoulder internal and external rotators and knee flexor and extensor muscles peak torque and bilateral muscle strength deficits and antagonist/agonist ratio were determined. Results Shoulder internal rotation and knee flexor/extensor strength of the D limb was higher than the ND limb. No significant differences were observed between D and ND shoulder in the external rotation muscle strength. Shoulder and knee bilateral deficit values were equal or less than 7%. Shoulder and knee antagonist/agonist balance ratio was 55 and 52% for the D side and 56% and 54% for the ND. No significant differences were observed between the two sides or playing positions. Discussion Lower limb bilateral deficit and antagonist/agonist balance ratio are within recommended values for low velocities (<10–15% and between 50 a 60%, respectively) (Aagaard,

Simonsen, Magnusson, Larsson, & Dyhre-Poulsen, 1998; Brown, 2000). The upper-limb values are lower than those suggested in the literature for asymmetric sports, although no handball players were included in the sample. These values appear to be specific to handball players. Playing position demands seem to have no effect on shoulder and knee isokinetic strength profile or to induce an "unbalance" (out of the recommended) pattern between agonist and antagonist or D and ND muscle strength. ## COMPARISON HIGH AND LOW FREQUENCIES WHITE NOISE IN BALANCE FUNCTION

Lo, T.

*Chung Shan Medical University*

**Introduction** The study aimed to discover if balance function would be affected by the low and high frequencies white noise stimuli. Noise and music composition can contain a variety of frequency. There are many kinds of noises existed in our environment in daily living. Most people like to listen music by wearing earphone when they are having exercises or outdoor activities. The acoustic signals were transferred into vibration form to inner ear. The characteristics of acoustic signal may affect the balance system. One of acoustic signal characteristics is frequency. **Methods** Nineteen participants were recruited in this study and had been tested their hearing with normal range. The one leg standing tests were performed and four parameters, sway area, sway path length, vertical and horizontal distances, were recorded. The white noise generated and divided into high and low frequency by Adobe Audition 2.0. The earphone had been calibrated the intensity of presented sound by artificial ear. The stimuli were separated into low and high frequencies white noise respectively at 85 dB. All participants were asked to wear on earphones during the test with eye opened condition. **Results** The results of low frequencies white noise indicated higher values of sway area, sway path length, vertical and horizontal distances in average when compared with the results of high frequencies. There were two significant differences in sway area and vertical distance when compare with high and low frequency noises ( $p < 0.05$ ). **Discussion** The inner ear consists of cochlear and vestibular. The membrane labyrinth connects these two parts. The low frequencies elements travel along from the basal to the apical of cochlear. The pattern of traveling wave is the high to low frequency. The results may suggest that low frequency white noise would cause more interference to the balance function. **References** Bassi Luciani L, Genovese V, Monaco V, Odetti L, Cattin E, Micera S., (2012). ## ROBUSTNESS OF THE LINEAR CRITICAL VELOCITY MODEL FOR SPRINT PERFORMANCES

Karsten, B., Arpinar-Avsar, P., Hazir, T., Kosar, S.N., Cinemre, A., Utku, B., Cass, G., Beedie, C.

*University of Greenwich*

**Introduction** In the linear models of Critical Power and Critical Velocity (CV), intensities or distances are chosen that lead to exhaustion within 2 to 15 min (1). Whipp et al. (2) state that intensities which result in less than 2 min exhaustion times are to be avoided. Regardless of intensity or duration, the two parameter model presupposes that a fixed percentage of  $VO_{2max}$  is instantly available, that it can be sustained throughout the test, and that the anaerobic work capacity is fully explored. According to Hill and Kennedy (3) these requirements do not fit test durations of less than 1 min. This study investigated if durations of less than 2 min fit the two parameter linear distance-time CV model. **Method** 16 active subjects (mean  $\pm$  SD: age  $22 \pm 3$  yr, body mass  $73 \pm 10$  kg,  $VO_{2max}$   $47.34 \pm 5.17$  ml $\cdot$ kg $\cdot$ min $^{-1}$ ) performed a test to exhaustion on a treadmill for  $VO_{2max}$  determination. Subjects run 3200m, 1600m and 800m and sprint distances over 400m, 200m and 100m in randomised order separated by 24 h. The linear distance-time model was used for CV and anaerobic running distance (ARD) estimations using the long distances (CVL) and the long and sprint distances (CVLS). CVL was used to examine the fit between the sprint performances over 400m, 200m & 100m and the distance-time model. A paired t-test was used to identify statistical differences. **Results** A significant difference between mean CVL and mean CVLS values ( $3.54$  m.sec $^{-1} \pm 0.35$  and  $3.79$  m.sec $^{-1} \pm 0.86$  respectively,  $t(15) = -17.72$ ,  $p \leq 0.01$ ,  $r = 0.99$ ) and between mean ARDL and ARDLS values ( $277$  m  $\pm 50.8$  and  $132$  m  $\pm 16.8$  respectively,  $t(15) = 16.42$ ,  $p \leq 0.01$ ,  $r = 0.94$ ) was observed. **Discussion** Even though fitting the regression line, there was a significant difference between measured variables. Whilst the measured values for CVL consistently underestimated values for CVLS, the opposite applied to ARD values. This is supported by data reported by Hill and Kennedy (3), who state that a certain portion of  $VO_{2max}$  in nature is not instantly available, and that the anaerobic work capacity is not fully expended in performances of less than 1 minute durations. Interestingly, when comparing CVL with CV values derived from the 3200m, 1600m, 800m and 400m performance times, a significant difference was not evident, whilst remaining for ARD values. It is not the mechanical constraints that appear to limit the linear critical velocity model as proposed by Whipp (2), but fundamental physiological processes as outlined by Hill and Kennedy (3). **References** 1. ## MEASUREMENT SYSTEMS OF WELLNESS AND SPORTS TECHNOLOGY

Hakkarainen, A.1, Heikkinen, T.1, Kaikkonen, V.2, Mäki, M.2, Ollikkala, A.2, Rätty, J.2, Hemming, B.3, Laurila, T.3, Ohtonen, O.1, Piirainen, J.1, Korhonen, T.4, Linnamo, V.1

*1 University of Jyväskylä, Finland, 2 University of Oulu, Finland, 3 Centre for Metrology and Accreditation, Finland, 4 Jyväskylä University of Applied Sciences, Finland*

**INTRODUCTION** The purpose of the Measurement Systems of Wellness and Sports Technology project is to develop measurement systems which can be utilized in individual sports and wellness applications as well as demanding industrial measurement technologies. Project is a part of Centre for Measurement and Information Systems (CEMIS) and it aims to develop research methods for elite cross-country skiing research, coaching and ski service as well as for snow properties. Demands for non-invasive and wireless measurements are present both in elite sport research and coaching and in individual wellness and healthcare applications. **METHODS** Project has been divided in five different method sections. I: Measuring optical properties of snow using holographic and diffuse reflectance imaging, II: Measuring of a ski profile with an optical non-contact chromatic confocal microscopy (2D and 3D), III: Non-invasive measurements for

sports and wellbeing applications - development of an immunosensor for the determination of salivary cortisol, IV: Versatile measurement system with wireless data transmission for skiing and V: Development of a dynamic balance measurement and training system. RESULTS I: Imaging method can be used to calculate the size of a snowflake or ice crystal, and applied to measure any similar size objects in free fall. II: Method was applied to analyze grinding profiles of 100 pairs of skis in co-operation with the Finnish Olympic Committee and University of Helsinki. III: Cortisol immunosensor based on the direct competitive enzyme linked immunosorbent assay (ELISA) method was used for determining cortisol concentrations in a buffer at physiological levels. IV: A prototype of a versatile skiing measurement system was developed. V: System was used in a research project in which the effects of proprioceptive and plyometric training on dynamic balance control in young and elderly women were studied. DISCUSSION This co-operation project has proven to be very fruitful and developed methods such as ski profile and dynamic balance system have already been utilized in data collection for scientific publications. Dynamic balance system appears to be useful also for training purposes. For some methods, however, the results are still preliminary and more research is needed to clarify the applicability of the method. Challenges exist e.g. in verifying the function of wireless measurements and synchronization of the data and on the matrix interferences caused by saliva enabling salivary cortisol measurements.

### **STUDY OF PHYSICAL, TECHNICAL AND ANTHROPOMETRIC FACTORS IN AN ELITE JUNIOR FOOTBALL TEAM ACCORDING TO THE AGE**

Soriano, M.L.L., Salinero, J.J., del Coso, J., Abián-Vicén, J., Burillo, P., Gutiérrez del Pozo, D., Gonzalez-Millan, C.

*Camilo José Cela University*

Introduction: At junior football levels it is necessary to evaluate physical, technical and anthropometric parameters, in order to undertake correct planning and control of the training. In this field, research with adult football players cannot be applied to junior categories. The aim of this study was to assess the physical and technical parameters and anthropometry of young players aged 13 to 19 through specific and nonspecific tests (Gorostiaga et al. 2004). Methods: 130 young footballers belonging to the junior teams of a professional football team ( $15.5 \pm 1.9$ ), performed a countermovement jump on a force plate, a repeated sprints test (RSA) with time measured by using photoelectric cells, a specific running test with a ball under control, while anthropometric parameters were measured by bioimpedance. Results: The age of the players was significantly correlated with all the variables studied. There was a significant correlation between age and the best sprint ( $r = -.73$ ) and the average of all sprints ( $r = -.71$ ) in the RSA test. Correlation between age and CMJ was significant ( $r = .64$ ). The CMJ height improved up to the age of 18 years and then the improvement plateaued. The relation with age in the dribbling test was lower ( $r = -.314$ ). Controlling body size, all the correlations remained significant ( $P < 0.05$ ). Discussion: The higher rate of development in the running sprint capacity is between 13 and 15.6 years. Jump capacity and dribbling ability improved from 13 to 17.5 years. From these ages on, the rate of improvements significantly dropped. The use of specific tests is a worthwhile instrument for gauging the development and maturation in young football players. This may help coaches to design appropriate training sessions, focusing on the development of different physical abilities. ### **THE INFLUENCES OF A PROGRAM CONTENT ON THE FUNCTIONAL ABILITIES AND PERFORMANCE VELOCITY IN TECHNICAL MOVEMENTS USED IN KARATE SPORT**

Kapo, S., Cutuk, H., Kafedzic, E., Kajmovic, H.

*Faculty of Sports and Physical Education, University of Sarajevo*

Introduction Researches of the influence of the program content on functional abilities and performance velocity are of particular importance, as the karate is a very complex sport, in which facts mentioned here are important for efficacy of the results achieved at the competition (Kapo, 1999). The aim of this work is to determine the influence of program content on the functional ability and velocity of execution of technical movements in karate sport. Method Research sample consisted of 15 male respondents, aged between 15 and 19 years, who attended the training process for three years at least. The program content activities have been conducted within a period of two months, in six microcycles. In order to assess the functional abilities, we have implemented the Konkoni test, and for evaluation of technical elements execution, we used the modified tests (Kuleš, 1998). To determine the relations between functional capabilities and specific variables, the Pearson's correlation coefficient has been used, as well as Kolmogorov-Smirnov's Z-value and multiple analysis of variance. Results and Discussion The values of Pearson's coefficients of correlation between various indices of movement velocity in situations before and after program activities, indicates that correlation, which is statistically important at the level less than 1%, visible between the variables Kiz - kizame tsuki and Bag before (0,94) and Kiz and Bag (0,97), Kiz and LM - left mawashi - (0,69), Kiz and RM - right mawashi (0,80), after program activities. The significance of Pearson's correlation coefficients does not have a level of 0.5% between indexes of muscle and fat mass, at one hand, and velocity of individual movements in karate at the other hand, before and after program activities indicates that the variable BFM significantly and negatively correlated with variables Bag and LM, that means that increasing of BFM values (fat mass) the values in Bag and LM are lower, and vice versa. Variable BFM significantly and negatively correlated only with variables LM and RM after the program activities. The analysis of variance with repeated measurements indicates that all F-ratios statistically significant at levels far lower than 1% and the possibility of their accidental occurrence is practically equal to 0. This mean that changes in average values of the dependent variables before and after program activities are significant. Conclusion Based on correlation coefficients of functional capabilities and situational-motor abilities it has been proved that program activities have an impact on the functional capacity and the velocity of execution of technical movements in karate sport, indicating their importance in the specification equation of karate sport, and are responsible for a quick recovery and high intensity during the combat. (1999): The influence basic-motor abilities on the efficiency of execution of competitive techniques and tactics in karate – Master Thesis, Sarajevo.

### **ANALYSIS OF FAST BREAK ACTIONS IN ELITE AND SUB-ELITE ITALIAN MALE BASKETBALL GAMES**

Conte, D.1, Lupo, C.2, Capranica, L.1, Favero, T.3, Tessitore, A.1

*1: University of Rome*

Introduction In basketball, fast-break actions (FB) are the best way to create easy scoring opportunities, however in literature few studies investigated these actions. Therefore, this study aimed to investigate a potential difference of performance in FBs, during elite (E) and sub-

elite (SE) basketball games. Methods Hence a notational analysis was carried out during 5 E (1st division) and 5 SE (3rd division) Italian male games. The FB were classified as primary and secondary, while the executions were categorized in 3 successive phases: initiating, advance, completion (Refoyo et al., 2009). In turn, for each phase the different type of actions (phases: initiating (rebound, steal, interception and throw in), advance (dribbling and passing) and completion (scored and not scored)) and playing zones (phases: initiating (lane, baseline-free throw line, free throw line-half court line; frontcourt, out of bound), advance (center or sideline) and completion (lane; intermediate; outside 3pt line)) were analyzed. Furthermore, FB actions were divided in those performed with an equal (attacking vs defending team) and with an unequal (superiority for the attacking team) number of players. The duration of FB was also calculated. Descriptive statistics (frequency and percentage) and Chi-square were applied to investigate the FB performance parameters, and to estimate differences between E and SE games. Results A significant difference was found between E and SE games for primary and secondary FB actions ( $p < 0.05$ ), while the Chi-square analysis showed no differences between E and SE games for number and execution of FBs, so data were pooled for descriptive analysis. Thus, rebound ( $43.5 \pm 19.1\%$ ) and lane ( $59.7 \pm 15.7\%$ ) during initiating phase, dribbling ( $75.7 \pm 11.8\%$ ) and center ( $60.2 \pm 15.4\%$ ) during advance phase and scored ( $48.5 \pm 22\%$ ) and lane ( $70 \pm 13.5\%$ ) during completion phase were registered as frequency of occurrence for type of actions and playing zones, respectively. Moreover, regarding the number of players involved, most of FB actions were performed with superiority ( $52.3 \pm 14.2\%$ ), while the mean duration of FB actions was  $4.92 \pm 1.22s$  and  $5.10 \pm 1.24s$  for E and SE games, respectively. Discussion This study showed no differences in terms of number and execution of FB in E and SE games. Furthermore, these results could give information to coaches about the planning and the organization of FB training, suggesting to set up drills by means of teams with both the same number and superiority of opponents. Besides, the duration of FB actions should be up to 5 seconds. Reference Refoyo I, Uxia Romaris I, Sampedro J. (2009) *Revista de Psicología del Deporte*, 18, 439-444.

### DIFFERENCES IN THE PERFORMANCE TESTS OF THE FAST AND SLOW SSC AMONG PROFESSIONAL AND ELITE YOUTH SOCCER PLAYERS

Sander, A.1, Keiner, M.2, Wirth, K.2, Schmidtleicher, D.2

1: Bobsled and Luge Association of Germany, 2: Institute of Sport Science Johann Wolfgang Goethe-University Frankfurt Germany

Introduction The requirement profile in team sports is very complex. In addition to technical and tactical requirements, there are conditional requirements. These conditional requirements are the basis for technical and tactical tasks (Verheijen 1998). Therefore, increasing the power performance of an athlete should facilitate entry into higher divisions, which should integrate elite junior players into the professional sport. The aim of this investigation was to evaluate a suspected difference in performance tests of the slow and fast SSC among professional, amateur and elite youth soccer players with and without strength training experience ( $n=86$ ). Methods A cross-sectional data were collected. The participants were divided into 3 groups. Group 1 consisted of professional players in the first and second division in Germany (PRO,  $n=26$ ). Group 2 contained youth elite soccer players in a U19 (under 19 years old) team at the youth training centre of a professional team (JUN,  $n=30$ ). Group 3 consisted of players in the U19 team that required a minimum of 2 years of strength training at the training centre of a professional team (KT,  $n=30$ ). All soccer players were tested in 10-, 20- and 30 meter sprint, change of direction sprint (COD), SJ, CMJ and DJ from four different heights. Results The results of the SJ showed a significant better performance ( $p < 0.01$ ) of the KT ( $41.1 \pm 4.9$  cm) compared to all groups. In the CMJ, the KT ( $42.4 \pm 5.0$  cm) was significant ( $p < 0.01$ ) better compared to JUN. There were found no significances between KT and PRO. In all DJ performances PRO was significantly ( $p < 0.01$ ) better compared to JUN. There were found no significances between KT and PRO. The JUN displayed a significant ( $p < 0.01$ ) poorer performance in straight sprint over 10-, 20- and 30m compared to PRO and KT. There were no significant differences between PRO and KT. In the COD, the KT displayed a significant ( $p < 0.01$ ) better performance compared to JUN and PRO. Discussion The data suggest that additional periodised strength training in youth soccer players has a positive effect on concentric force development and the fast and slow SSC (Rønnestad et al. 2008). In some cases, youth players who completed complementary strength training for at least two years attained better strength and power performance than the PRO players, and the youth players never performed worse than the PRO players. High performances in speed, changes of direction and high jumping ability determine the level of performance in soccer, and they can determine the success or failure of a player (Reilly 2007; Verheijen 1998). References Reilly, T. (2007). *Science of training – soccer*. London: Routledge. Rønnestad, B.R., Kvamme, N.H., Sunde, A. & Raastad, T. (2008). Short-term effects of strength and plyometric training on sprint and jump performance in professional soccer players. *J Strength Cond Res*, 22: 773-780. Verheijen, R. (1998). *Conditioning for soccer*. Spring City: Reedswain.

### EFFECTS OF LONG-TERM STRENGTH TRAINING ON SPRINT PERFORMANCE IN ELITE YOUTH SOCCER PLAYERS

Sander, A.1, Keiner, M.2, Wirth, K.2, Schmidtleicher, D.2

1: Bobsled and Luge Association of Germany, 2: Institute of Sport Science Johann Wolfgang Goethe-University Frankfurt Germany

Introduction In soccer, strength and power are important because of the large number of power actions performed during the game. Therefore, the aim of this study was to examine the influence of periodised strength training for power performance over two years. Methods In this study, 134 elite youth soccer players were recruited from two youth training centres. The cohorts were arranged as follows: A (under 19 years), B (under 17 years), and C (under 15 years). The participants in each cohort were divided into two groups. One group (STG) was subjected to regular soccer training in addition to strength training (hypertrophy- and IK-blocks) twice a week for two years. The other group (CG) completed only the regular soccer training. For strength training, both the front squat and the back squat were performed once a week. The subjects were tested on the one-repetition maximum of the front and back squat and a linear sprint over 30 metres. Results There was significantly better performance from the STG on 1RM ( $p < 0.001$ ) of up to 300%. The CG also showed significantly better performance on 1RM of up to 65%. In the sprint, the STG displayed significantly better improvements ( $p < 0.05$  to  $p < 0.001$ ) of up to 6%. The CG showed significantly better performance of up to 3%. Discussion This investigation illustrates the positive influence of strength training on maximum strength and sprinting performances in adolescent soccer players. Other studies have not shown such large percentage changes in maximum strength after strength training (Blimkie 1992; Chelly et al. 2009; Hartmann et al. 2012). In Sprint performance, Comfort, Haigh & Matthews (2012) demonstrated similar changes of 5.9% to 7.6% (5 m, 10 m and 20 m) of elite rugby players after an 8-week strength training programme. This finding is justified by the coordinative difficulty of the sprint movement. During the sprint, in addition to the power level, technical elements influence performance. The effects of strength training are reflected in the sprint performance. Therefore, it seems beneficial for youth to perform strength training to exploit the reserve capacity in sprint performances. References Blimkie, J.R. (1992). Resistance training during preadolescence. *Sports Medicine*, 15 (6), 389-407. Chelly, M.S., Fathloun, M., Cherif, N., Amar, M.B., Tabka, Z. & VanPraagh, E. (2009). Comfort, P., Haigh, A. & Matthews, M.J. (2012). Are changes in maximal squat strength during preseason training reflected in changes in sprint performance in

rugby league players. *Journal of Strength and Conditioning Research* 26, 772-776. Hartmann, H., Wirth, K., Klusemann, M., Dalic, J., Matuschek, C. & Schmidtleicher, D. (2012). Influence of squatting depth on jumping performance. *Journal of Strength and Conditioning Research*, 26 (12), 3243-3261.

### USE OF VIDEO ANALYSIS TO TRAIN SPIKE IN VOLLEYBALL

Parisi, F., Di Tore, A., Raiola, G.

*University of Salerno, Italy*

**Introduction** The video analysis is an effective tool in the Match and Performance Analysis (Raiola 2011). As volley is a quick and return sport, it helps to identify in the delayed time the single movement and evaluate the attacks assigning score. However, there is no study concerning the use of this video analysis in teaching and education of technical skills. The aim of this study is to verify whether the use of video analysis tool in the methodology of training is useful to get the skills of the attack. Another purpose is to verify if the visual feedback has a weight in learning and performance improvement (Raiola 2012). **Methods** The work involves the use of video analysis software Kinovea during training. The athletes involved are female, under 16, divided into two groups: control and experimental. Both groups are filmed for 30 workouts. They all follow the same path as specific training for the attack. At each meeting, is proposed the video of the previous training attack to every athlete belonging to 'experimental' group. The coach doesn't comment the video and doesn't give information about errors. At the end of the training the coach assesses the performance with indicators and defined descriptors. The data concerning the first and last video are compared for each individual athlete and for each groups. The parameters analyzed in the video are: preparation of the body to the gesture and body angle with the floor, sequence of steps, angle of the arms, attack's phase, position of the body relative to the ball, fall to the ground with both feet. The evaluation of the ability of the attack is carried out by a coach with a table which lists the parameter markers and quantitative descriptors. **Results** All athletes improve attack skills. The experimental group has an higher average, median and mode than the control group. The multiple and linear regression showed a constant increase trend of skills during the training of individual athletes. In the experimental group the maximum habilitation levels of the control group are attained before. **Discussion** The results show the usefulness of video analysis in the training. In all athletes of the experimental group are found improvements compared to the athletes of control group. This highlights the absolute utility of the tool. The difference between the experimental group and the control group is related to the visual feedback. It would be useful to do research on the development of others volley skills with the use of video analysis to include this assessment tool in the theory of volley training. **References** Raiola G. ### THE EFFECT OF DIFFERENT FORMS OF HIGH-INTENSITY INTERMITTENT RUNNING EXERCISES ON NEUROMUSCULAR FATIGUE

Feroli, D.1, Bosio, A.2, Connolly, D.2, Carlomagno, D.2, Romagnoli, M.3, Rampinini, E.1,2

*1 Faculty of Exercise Sciences-Università degli Studi di Milano(Milan, ITALY); 2 Human Performance Lab, MAPEI Sport(Olgiate Olona, Italy); 3 School of Medicine-Catholic University Valencia(Valencia, Spain)*

**Introduction** Intermittent exercise has been found to cause a greater degree of neuromuscular fatigue than constant load exercise on a cycle ergometer. In this study we compare central and peripheral components of neuromuscular fatigue on knee extensor (KE) muscles following different forms of high-intensity intermittent running exercises. **Methods** 8 male subjects (24±5 yrs) completed four 16 min running trials. The mean running speed was the same across all trials (8.9 km/h). Subjects performed 1 trial at constant speed (CON) and 3 trials with three different forms of intermittent running; comprising of the same total and high-intensity distance (1173 m at >15 km/h) but different number of accelerations (LOW, 55; MID, 80; HIGH, 190). Blood lactate concentration and RPE were recorded at the end of each trial. To assess KE muscle contractile properties, passive mechanical responses to electrical stimulations, maximal voluntary isometric contraction, and maximal muscle activation levels were measured before and after completion of the running exercise. Peripheral KE neuromuscular properties were determined using 3 paired stimuli at 10Hz (low frequency) and 100Hz (high frequency). Maximal activation levels were established using twitch interpolation technique. EMG signal was also recorded during the test. Differences between the conditions were analyzed using ANOVA's. **Results** RPE was higher after all intermittent trials compared to CON (p<0.05). Blood Lactate was significantly higher after LOW compared to all the other conditions, whereas CON was significantly lower than all intermittent trials (CON, 2.4±1.0; LOW, 8.1±3.2; MID, 5.8±2.7; HIGH, 4.7±2.4 mmol/L). No evidence of the presence of central fatigue was found, while peripheral fatigue was evident in all conditions. However, KE peak torque values obtained using 10Hz electrical stimuli decreased significantly more after HIGH compared to all other conditions, with the reduction being significantly lower after CON (CON, -31%, LOW, -35%, MID, -36%, HIGH, -39%). **Discussion** All trials induced peripheral fatigue, temporarily altering KE muscle contractile properties. HIGH increased the quantity of low-frequency fatigue compared to all other conditions; this might be explained by the greater number of accelerations. Differences in blood lactate concentrations suggest a dissimilar contribution of anaerobic glycolysis. In conclusion, different forms of high-intensity intermittent running exercise can significantly impact upon energetic system activation and the quantity of peripheral fatigue induced.

### IMPACT OF FIELD WORK ON MORPHOLOGICAL CHARACTERISTICS AND MOTOR EFFICIENCY

Zorec, B.1, Zorec, R.2, Jeler, M.2, Zorec, J.3

*1: FVV, (Maribor, Slovenia), 2: MF, (Ljubljana, Slovenia), 3: FGG, (Ljubljana, Slovenia)*

**Introduction** In our research we have decided to explain how field work influence on morphological characteristics and motor ability. Successful job performance of police officers and criminal investigators significantly depends on endurance, speed and strength. **Methods** The main aim of this research was to establish the correlations between field work and certain dimensions of the motor and morphological space between police officers and criminal investigators. With 12 morphological and 4 motor variables (run over 60 m, hang with elbows bent, long jump, run over 2400 m) we defined morphological status and motor efficiency. The significance of the difference between the arithmetic means has been evaluated by the t-test. The connection and dependence of individual subspaces of psychosomatic status has been determined by regression analysis. **Results** The results pointed out that police officers in their professional daily work are forced to greater use of different motor activities than criminal investigators. The basic statistic parameters showed that criminal investigators are on average four years older than police officers and they also have 17% more fat tissue. The larger quantity in fat tissue

could be explained by the theory on the increase accumulation of subcutaneous fat tissue on the upper body associated with age (McArdle et al., 1996) and the other reason for increased fat tissue could be motoric of the work performed. The results also showed a large influence of morphological characteristics (subcutaneous fat) on motor abilities. Police officer's work requires a well developed energy component of movement which reflects in the motor abilities associated with speed and strength endurance. Professional work of police officers require mastering complex motor programs (coercive means, overcoming the hurdles, etc.) which are characterized by variability and involvement of several different factors, are much greater in comparison with criminal investigators. Discussion By the research it has been established that field work is in a large extent an important factor for morphological and motoric status of police force. Test subjects significantly differ in the thickness of the subcutaneous fat (morphological status) and in repetitive, aerobic ability and explosive power (motor status). We are convinced their training program and psychosomatic tests in relation to the motor space should be monitored more regularly. References McArdle, W., Katch, F., Katch, V. (1996). ### **PHYSIOLOGICAL CHARACTERISTICS OF FEMALE GYMNASTS; A FOLLOW UP STUDY.**

Theos, A., Sawvadi, A., Moustogiannis, A., Dallas, G.

*University of Athens*

Introduction Maturation and growth influence physiological characteristics, especially flexibility and strength (Baxter et al. 2002). The purpose of the present study was to investigate differences in physiological characteristics of female gymnasts after a three-year training period. Methods Nine female recreational gymnasts participated in this study. Measurements of flexibility (sit and reach) and arm strength (handgrip) for both hands were conducted at first when children were  $10.8 \pm 1.1$  yrs (body weight:  $33.7 \pm 8.6$  kg, body height:  $138.1 \pm 11.1$  cm) and were repeated again when they were  $13.8 \pm 1.1$  yrs (body weight:  $42.4 \pm 10.3$  kg, body height:  $147.2 \pm 12.7$  cm). Differences between measurements were analyzed using T-test. Results are presented as mean  $\pm$  SD. Results BMI differed significantly between measurements ( $19.2 \pm 2.1$  vs.  $17.4 \pm 2.7$  kg/m<sup>2</sup>,  $p > 0.01$ ) since both body height and body weight were also significantly increased ( $p < 0.001$ ). Flexibility was significantly reduced ( $31.0 \pm 5.9$  vs.  $29.7 \pm 5.1$  cm respectively for the two measurements,  $p > 0.01$ ) while on the other hand arm strength was significantly increased in both hands ( $p < 0.001$ ). Percent improvement of arm strength was  $25.5 \pm 12.1\%$  and  $29.9 \pm 13.9\%$  for the right and left arm respectively and did not differ between arms ( $p = 0.49$ ). Discussion Results of the present study indicate that gymnastics training promotes flexibility, since it was not decreased despite the fact that body height was significantly increased. It also seems to promote symmetrical development of arm strength, since there are no differences between hands. References Baxter-Jones AD, Maffulli N. (2002). Br J Sports Med, 36(1): 13-15.

### **ASSESSMENT OF A COMPLEX DIVING TASK OF YOUTH SOCCER GOALKEEPERS – REPRODUCIBILITY OF TWO NEW TESTS**

Rebello-Gonçalves, R.1, Figueiredo, A.1, Coelho-e-Silva, M.J.1, Fernandes, R.1, Valente-dos-Santos, J.1, Duarte, J.1, Simões, F.1, Pereira, J.P.1, Severino, V.1, Tessitore, A.2

*1: University of Coimbra; 2: University of Rome, "Foro Italico", Rome, Italy*

Introduction: The present study examined the test proprieties of two goalkeeper-specific performance protocols developed to assess a complex diving task (with catch of the ball) in young soccer goalkeepers. Methods: Twenty-six volunteers ( $14.5 \pm 2.5$  years) carried out the Sprint & Dive (SpD) and Shuffle & Dive (ShD) tests in two main sessions, each separated by one week. The SpD requires goalkeepers to accelerate during 3-m and dive and catch a stationary ball after performing a change of direction in a total distance of 10-m. The ShD test involves a lateral shuffle in a total distance of 12.55-m. Participants performance was measured as total time for right (R) and left (L) sides. The paired samples t-test was used to compare the means of trial 1 and 2. Reproducibility was assessed using the technical error of measurement (TEM) and relative TEM. Reliability coefficient was also calculated (Mueller & Martorell, 1988). The Bland-Altman (1986) procedures were conducted to determine limits of agreement (LOA) between trial 1 and trial 2. Results: For both tests, performance significantly differed between trials 1 and 2 (SpD-R:  $t = 2.801$ ,  $p = 0.010$ ; ShD-R:  $t = 4.059$ ,  $p = 0.000$ ), except when performed to the left side (SpD-L:  $t = -1.152$ ,  $p = 0.260$ ; ShD-L:  $t = 1.313$ ,  $p = 0.201$ ). Test-retest analyses are quite similar for the protocols and side variation: SpD-R (TEM=0.09;  $r = 0.90$ ; LOA=-0.16 to 0.28), SpD-L (TEM=0.09;  $r = 0.89$ ; LOA=-0.29 to 0.23), ShD-R (TEM=0.19;  $r = 0.90$ ; LOA=-0.24 to 0.58) and ShD-L (TEM=0.20;  $r = 0.88$ ; LOA=-0.47 to 0.61). Data also indicated a within-subject variance of 4.18%, 4.37%, 3.97% and 4.16%, respectively for test protocol and side. Discussion: The present data demonstrate that the SpD and ShD are reproducible. However, future research is needed to examine the validity of the test to discriminate goalkeepers by competitive level. ### **THE INFLUENCE OF GAME ACTIONS ON THE RECOVERY KINETICS OF PHYSICAL PERFORMANCE AND SUBJECTIVE RATINGS IN SOCCER**

Nédélec, M.1,2, McCall, A.1,2, Carling, C.2, Le Gall, F.1,2, Berthoin, S.1, Dupont, G.1,2

*1: UDSL, EA 4488 (Lille, France), 2: LOSC (Camphin-en-Pévèle, France)*

Introduction Measures of overall distance covered and high-intensity running activity are commonly used to monitor players' physical exertion during a soccer match (Carling et al., 2008). However, game actions such as jumps, contacts and changes in direction can induce muscle damage affecting the magnitude of fatigue and time to recover fully after competition (Nédélec et al., 2012). This study aimed to examine the relationship between the frequency of such actions performed during a match and the recovery kinetics of physical performance and subjective ratings. Methods Time motion analyses were performed from video recordings on 10 outfield professional soccer players (age:  $21.8 \pm 3.2$ yr; height:  $178.1 \pm 5.4$ cm; body mass:  $76.5 \pm 7.6$ kg) over 4 competitive matches (14 observations in total). The frequency of 8 playing actions completed by players during the match was recorded by the same experienced observer: sprint <5m; sprint >5m; high-intensity running; change in direction; contact with opponent; jump to head ball; shot/long pass; tackle. Subjective ratings (sleep, fatigue, muscle soreness, stress) and physical tests were performed before and 24, 48 and 72h after the match. Physical tests included countermovement jump (CMJ) on a force platform (Kistler AG), 3-s isometric maximum voluntary contraction of the hamstrings (Schache et al., 2011) and a 6-s sprint on a non-motorised treadmill (Woodway Force 3.0). Results Significant correlations were found between muscle soreness and number of sprints <5m performed at 48h (Pearson  $r = 0.74$ , 95%CI: 0.35 to 0.91,  $p < 0.01$ ) and 72h

post-match (Pearson  $r=0.57$ , 95%CI:0.05 to 0.84,  $p<0.05$ ). A significant relationship (Pearson  $r=-0.55$ , 95%CI:-0.84 to -0.03,  $p<0.05$ ) was also established between CMJ performance decrement at 24h and the number of changes in direction performed during the game. Discussion Our results suggest that a higher frequency of short sprints and changes in direction performed during soccer match negatively impacts the recovery kinetics of CMJ performance and muscle soreness. These playing actions are associated with rapid accelerations/decelerations which are particularly damaging to muscles (Howatson and Milak, 2009; Magalhães et al., 2010) and should be taken into account when evaluating soccer match-induced fatigue. ## DEEP AND SUPERFICIAL ABDOMINAL MUSCLE ACTIVATION DURING TRUNK EXERCISE WITH BREATHING CONTROL

Shima, N.1, Kawabata, M.2, Kubota, T.3

1: Tokai Gakuen University (Aichi, Japan), 2:Sagamihara Kyodo Hospital (Kanagawa, Japan), 3:Juntendo University (Tokyo, Japan)

Introduction Intra-abdominal pressure (IAP) development is closely related to breathing behavior (Kawabata et al. 2010). The transversus abdominis (TrA) has been ascribed a specific role in spine stabilization, which has motivated core stability exercises (Bjerkedals et al. 2010). However, it is not well known that deep and superficial abdominal muscle activation during trunk exercise with breathing control. The purpose was to evaluate the levels of activation of the TrA and the superficial external oblique (EO) muscles during prone bridge exercise with and without breathing control. Methods Maximal IAP during the Valsalva maneuver (maxIAP) and maximal electromyographic activity (EMG) of TrA and EO during isometric trunk strength were measured in 8 trained men. They performed a prone bridge exercise with abdominal breathing, pilates breathing (thoracic breathing with pulling the lower part of the abdomen towards the spine), and long exhale breathing. Inspiratory and expiratory volumes were calculated from air-flow data. The data of IAP and EMG during prone bridge exercise were measured, and normalized by maxIAP and maximum EMG, respectively. Results In a prone bridge exercise, the IAP and TrA during inhale and exhale were greatest with pilates breathing. There are higher %maxIAP in abdominal, pilates, and long exhale breathings than normal breathing. TrA activity with abdominal, pilates, and long exhale breathings was greater than with normal breathing. However, EO was not different from each breathing control. Discussion Our finding of an increase in TrA activation independent of EO indicates that their deep abdominal muscle activate with breathing control. However, superficial abdominal muscle is not affected by breathing control. This increased TrA activation with breathing control is more variable during exhale breathing than inhale breathing. These results suggest that breathing control during core stabilization training affect their deep abdominal muscle activity. ## THE ANTHROPOMETRIC CHARACTERISTICS OF YOUNG PADDLERS AND ITS RELATIONSHIP WITH PERFORMANCE

Fernandes, R.A.1, Gomes, B.B.1, Rebelo-Gonçalves, R.1, Duarte, J.1, Pereira, J.R.1, Santos, A.C.1

University of Coimbra

Introduction The aim of this study was to describe the anthropometric characteristics of athletes competing in the level of 15 and 16 years old and its relationship with performance. Methods The sample included a total of 23 paddlers ( $15.39 \pm 0.46$  years) who participated in the national control, competing at 1000 meters and organized by the Portuguese Canoe Federation. The physical fitness of the athletes was assessed by performing a test of sit-ups, push-ups, pull-ups (Fitnessgram, 1999) and handgrip strength (Eurofit, 1988). Anthropometric assessment included body mass, stature, sitting height, lengths (arm span, arm, forearm and hand), circumferences (brachial, brachial in maximum contraction and chest) and biacromial diameter. Body composition (Slaughter et al., 1988) and upper limb volume in the dominant limb (Rogowski et al., 2008) were also assessed. Biological maturation was assessed by maturity offset (Mirwald et al., 2002) and percentage of predicted mature stature (Khamis & Roche, 1994-1995). Results An association was found between participants who performed better at 1000m and body mass ( $\rho \leq 0.05$ ), brachial circumference ( $\rho \leq 0.01$ ), brachial circumference in maximum contraction ( $\rho \leq 0.01$ ), chest circumference ( $\rho \leq 0.01$ ), upper limb volume ( $\rho \leq 0.05$ ), arm volume ( $\rho \leq 0.01$ ) and pull-ups ( $\rho \leq 0.01$ ). Maturity offset correlated with stature ( $\rho \leq 0.01$ ), sitting height ( $\rho \leq 0.01$ ), body mass ( $\rho \leq 0.01$ ), arm length ( $\rho \leq 0.05$ ), hand length ( $\rho \leq 0.05$ ), brachial circumference in maximum contraction ( $\rho \leq 0.05$ ), chest circumference ( $\rho \leq 0.01$ ) and the upper limb volume ( $\rho \leq 0.01$ ). Discussion This study offers the anthropometric profile of the young male paddler, and reveals that the athletes with slightly larger upper body dimensions and with better results in the pull-up test have better performance at 1000 meters, which may allow the use of this information as a guide in the process of talent identification in flatwater racing by the sports agents (federations, clubs and coaches). ## THE EFFECT OF STATIC STRETCHING DURATION ON SPEED AND AGILITY PERFORMANCE

Chatzinikolaou, A.1, Draganidis, D.1, Avloniti, Ch.1, Avloniti, A.1, Tsoukas, D.1, Ermidis, G.1, Protopapa, M.1, Smilios, I.1, Fatouros, I.1

Democritus University of Thrace

Introduction Stretching constitutes an integral part of the warm-up process for many sports (McHugh & Cosgrave, 2010). Although static stretching (SS) has been used from coaches for many years, recent studies indicate that SS may have a negative or no effect on athlete's anaerobic performance (McHugh & Cosgrave, 2010; Van Gelder & Bartz, 2011). However there is limited information regarding the optimal duration of SS in respect to speed and agility performance. Therefore, the aim of this study was to investigate seven SS durations on 10, 20 m. and T-test performance of various sports athletes. Methods Following a familiarization period, twenty healthy young athletes (age  $20.1 \pm 1.9$  yrs, height  $1.82 \pm 6.8$  m, weight  $76.3 \pm 4.4$  kg, % Body fat  $7.2 \pm 2.9$ ) participated in our stretching protocols and performance assessment in a counterbalanced fashion. SS (10, 15, 20, 30, 40, 60 seconds) and control (C, no stretch), were performed for gluteus,

quadriceps, hamstrings, adductors and calves, following eight minutes of aerobic exercise in a self-defined intensity. Two trials of 20 m. with a 10 m. split and two trials of T-test (New test, photocells system, Finland) separated by 3 minutes rest periods, were performed 3 minutes following the C or SS protocols. Differences were examined through an ANOVA repeated measures. Results SS protocols of 15 and 20 seconds induced a 1.6–2 % improvement on 10 and 20 m. speed ( $p < .05$ ). Performance on T-test remained unaffected by all SS protocols. Discussion These results indicate that SS of short duration may improve speed (10 m., 20 m.). Longer durations had no effect on speed. SS appears to leave agility unaffected. These results indicate that SS does not produce adverse effects on speed and agility performance. References Van Gelder LH and Bartz SD. (2011). *J Strength Cond Res*, 25(11), 3014–3021. McHugh MP, Cosgrave C H. (2010). *Scand J Med Sci Sports*, 20, 169–181.

### PHYSIOLOGICAL, BIOCHEMICAL AND AUTONOMIC RESPONSES TO THREE DIFFERENT TRAINING SESSIONS PERFORMED IN TETHERED SWIMMING

Loures, J., Zapatero, E.C., Silva, A.S.R., Silva, M.S., Kalva, C.A., Papoti, M.

*Unesp*

Introduction It is not well established if acute tethered swimming training sessions with same load, but with variations in volume and intensity will lead to similar responses of physiological, biochemical and autonomic parameters. Thus, we investigated the biochemical, physiological and autonomic responses after different training sessions in tethered swimming. Methods Trained swimmers ( $n=6$ ) performed an incremental tethered swimming test to determine the anaerobic threshold (AT) (Papoti et al., 2009) and performed training at Z1=below 75% of AT during 40min; Z2=100% of AT during 30min; Z3=above 150% of AT during 20min. Before and after these sessions, blood lactate concentrations ([Lac]), rating of perceived exertion (RPE) and heart rate variability (HRV) parameters (i.e. standard deviation of all beat to beat intervals – SDNN, square root of the mean square of the differences between interval consecutive heart beats – RMSSD, and low-frequency - LF) were determined. In addition, biochemical measurements (testosterone - T, cortisol - C, and creatine kinase - CK) were measured before, after and 24h after the training sessions. Loads were measured by training pulse (TRIMP), which was assumed as the final product of the intensity (%AT) by effort time. The all TRIMPs corresponded to 3000 u.a. Results [Lac] (mM) after Z3 was significantly higher ( $6.74\pm 3.38$ ) compared to Z2 ( $2.63\pm 2.24$ ) and Z1 ( $0.93\pm 0.19$ ). [Lac] after Z2 was significantly higher than Z1. RPE after Z3 ( $88.2\pm 17.2$ ) was significantly higher than Z2 ( $12.07\pm 2.27$ ) and Z1 ( $8.25\pm 0.88$ ). CK (U/L) after Z3 ( $45.8\pm 9.2$ ) was significantly different from Z2 ( $45.8\pm 9.2$ ) and Z3 ( $43.8\pm 10.6$ ) U/L, and C (mcg/dL) after Z3 ( $12.5\pm 6.5$ ) was significantly different than Z1 ( $6.4\pm 1.8$ ). The HRV (SDNN) after Z1 ( $108.48\pm 10.23$  ms) was different from Z2 ( $70.38\pm 16.39$  ms) and Z3 ( $48.78\pm 22.51$  ms). The RMSSD (ms) after Z1 ( $89.44\pm 24$ ) was different from Z2 ( $47.12\pm 19.48$ ) and Z3 ( $38.34\pm 27.52$ ) while, LF (ms<sup>2</sup>) after Z1 ( $4637.40\pm 2928.65$ ) was different from Z3 ( $774.00\pm 769.63$ ). Discussion The results about [Lac] and PSE corroborate with previous studies that showed that these markers are more sensitive to intensity than volume. The behavior of C and T was more influenced by intensity while, CK was more influenced by volume. The autonomic system was more stressed by intensity than volume. We can conclude that intensity seems to be the pivotal factor for the significant alterations of the physiological, biochemical (except CK) and autonomic parameters. References Papoti et al. (2009). *Int J Exerc Sci*, 2(4):269–79.

### A COMPARISON OF DEVELOPMENT IN STRENGTH, POWER, AND ENDURANCE IN FEMALE NATIONAL TEAM JUDOKAS, WRESTLERS, AND BOXERS OVER A 6-YEAR PERIOD

Sjökqvist, J.1,2, Nilsson, R.2, Holmberg, H.C.1,2

*(1)Swedish Winter Sports Centre, Östersund, (2) Swedish Olympic Committee, Stockholm*

Introduction: Female wrestling, boxing and judo are relatively new sports in the summer Olympic Games, and physiological profiles in these athletes are limited. The purpose of this study was to describe and compare the development of strength, power, strength endurance and endurance in female national team wrestlers, judokas, and boxers from 2006–2011. Methods: Between the years 2006–2011, national team female judokas, wrestlers, and boxers were assessed twice/year. Upper and lower body maximal strength was analyzed using a 1-repetition maximum (1-RM) bench press and parallel back squat while strength endurance was assessed using maximum repetition chin ups, dips, and the “brutal bench”. Relative strength in bench press and back squat was calculated as weight lifted divided by body weight. Power was analyzed using a hop mat and timing gates performing a squat jump (SQJ), a countermovement jump (CMJ), a countermovement with arms (CMJa), and a 10m sprint run (Maulder & Cronin, 2005). Endurance was measured manually with a 3000 meter Cooper run test. Repeated measures ANOVA was used to detect any significant differences in the aforementioned physical qualities from 2006–2011 within the sport while an independent T-test was used to detect differences in physical qualities between sports. Results: Boxers were significantly weaker both maximally and relatively than judokas and wrestlers (both  $P<0.05$ ). As for strength endurance, boxers performed less repetitions in all three exercises ( $P<0.05$ ). Moreover, wrestlers jumped significantly higher in the SQJ than judokas and boxers. In the CMJ, both boxers and judokas jumped higher than boxers while in the CMJa only wrestlers’ jumped higher than boxers ( $P<0.05$ ). Wrestlers ran faster over 10 m than both judokas and boxers ( $P<0.05$ ). Judokas ran significantly slower than wrestler and boxers in the 3000 meter Cooper test ( $P<0.05$ ). No significant changes in strength, strength endurance, power, and endurance occurred from 2006–2011 in respective sports ( $P>0.05$ ). Conclusion The sport of judo and wrestling produce a stronger and more powerful female athlete than boxing. This would be expected as both these sports require more strength and power to perform point-scoring techniques. However, no significant development in strength, strength endurance, power and endurance has occurred over a 6-year period in female judokas, wrestlers and boxers. References Maulder, P. & Cronin, J. (2005) “Horizontal and vertical jump assessment: reliability, symmetry, discriminative and predictive ability” *Physical Therapy in Sports*, 6: 74–82

### VALIDITY OF COD5X5M TEST IN SOCCER PLAYERS

Urbano, R.1,3, Gonzalo-Skok, O.2, Arjol-Serrano, J.L.2, Suárez, G.1,3, Suárez-Arrones, L.1,3

*1: UPO (Seville, Spain), 2: USJ (Zaragoza, Spain), 3: QDIEZ (Seville, Spain).*

Introduction Soccer is a team sport which is characterized by an intermittent activity profile that implies a sudden variation of movement (Stolen et al., 2005). Change of direction (COD) performance is considered as a fundamental prerequisite to achieve sport success in soccer players (Mujika et al., 2009). Nevertheless, to assess COD in soccer, COD test are based on observational studies and have only logical validity. Therefore, the aim of the present study was to assess COD5x5m reliability and to examine the ability of COD5x5m to differ between soccer players of different ages and competitive level. Methods The present study has consisted in 2 studies that implied a total of 81 soccer male players during 2009–2010 competitive season. In the first study, 14 semiprofessional soccer players belonging at the

same team were asked to perform the COD5x5m on two identical test sessions (separated by 5-7 days) to examine test-retest reliability. In the second investigation, 81 professional and semiprofessional soccer players were tested at three different times during competitive season. COD5x5m test consisted in performing 5 x 5-m sprints with 4 45° COD as fast as possible. The best value of each player was selected to posterior analysis. Players were classified in 5 groups depending of their level: professionals (Adelante League), semiprofessionals (3rd Division), amateurs (4th Division), U17 (national level) and U18 (regional level). Results Relative and absolute reliability to TEM was 0.11 s (CL90% 0.08 to -0.17 s) and 1.5% (CL90% 1.1 to 2.3%), respectively. No significant differences existed between trial 1 and 2 to COD5x5m (6.62 ± 0.3 s vs 6.65 ± 0.4 s, respectively; TE: 0.09 (trivial)). Mean change between trials has been 0.03 s (CL90% -0.05 to 0.11 s) and ICC was 0.91 (CL90% 0.74 to 0.97). Professional players showed an almost certainly better performance than semiprofessional, amateurs and young players. Almost certainly differences were found between semiprofessional and amateur players in comparison to U17 and U18. Furthermore, a substantial difference (likely) was provided between U17 and U18 players. Discussion COD5x5m is a reliable test to assess COD in soccer players. Furthermore, COD5x5m test is able to discriminate between players of different ages and competitive level. Therefore, this ability supports its validity and use in a wide variety of soccer players. ### EFFECT OF COMBINED REPEATED SPRINT AND STRENGTH TRAINING ON REPEATED SPRINT ABILITY IN RUGBY PLAYERS

Suarez-Arrones, L.1, Tous-Fajardo, J.2, Núñez, F.J.1, Gonzalo-Skok, O.3, Mendez-Villanueva, A.4

*1Pablo de Olavide University, Seville; 2 Sport Sciences Research Group INEF Barcelona; 3Universidad San Jorge, Zaragoza; 4ASPIRE, Qatar*

**Introduction** In addition to specific improvements in repeated sprint performance, repeated sprint training might also promote adaptations leading to performance increases in single sprint performance and cardiorespiratory fitness in team sport players (Bishop, Girard, & Mendez-Villanueva, 2011). On the other hand, strength training may lead to some gains in repeated sprint performance (Bishop, et al., 2011; Buchheit, Mendez-Villanueva, Delhomel, Brughelli, & Ahmaidi, 2010). Therefore, the purpose of this study was to examine the effect of repeated sprint training and combined repeated sprint and strength training in trained rugby players. **Methods** Sixteen semi-professional, well-trained rugby players (27.0 ± 5.2 years old, 91.3 ± 15.5 kg, and 179.6 ± 7.0 cm) voluntarily accepted to participate in this study. During 6 weeks, one group performed repeated sprint training (RST, n = 8) two days a week. The other group performed repeated sprint training one day a week and on the second day performed squat resistance training (RST+SRT, n = 8) on a vibration platform. **Results** Substantial improvements in RSAbest, RSAmean, fatigue index (FI) and squat maximal power output (absolute and relative to body mass) were observed in both groups compared to the pre-test. However, the magnitude of improvements in RSAbest, RSAmean and squat maximal power output were substantially greater in the RST+SRT in comparison with the RST (ES: 0.48, 0.46 and 0.81, respectively). There were no differences between groups in FI. **Discussion** In semi-professional rugby players, 6 weeks of combined repeated sprint and strength training resulted greater improvements in both repeated-sprint ability and lower body strength than repeated sprint training alone. **References** Bishop, D., Girard, O., & Mendez-Villanueva, A. (2011). Repeated-sprint ability - part II: recommendations for training. *Sports Med*, 41(9), 741-756. Buchheit, M., Mendez-Villanueva, A., Delhomel, G., Brughelli, M., & Ahmaidi, S. (2010). ### COMPARISON OF A RAMP-INCREMENTED VO2MAX TEST PROTOCOL WITH A STEP-INCREMENTED PROTOCOL CLAMPED BY RATINGS OF PERCEIVED EXERTION

Straub, A.M.1, Midgley, A.W.2, Zavorsky, G.S.1, Hillman, A.R.1

*1: Marywood University (Scranton, Pennsylvania, USA), 2: Edge Hill University (Ormskirk, UK)*

**Introduction** Historically, there has been an interest in identifying new VO2max test protocols that improve the reliability, validity, and the utility of the test. A recent study reported that a novel 10-minute step-incremented test protocol, where the exercise intensity at each step was clamped by ratings of perceived exertion (RPE), elicited a significantly higher VO2max than a traditional step-incremented protocol (Mauger and Sculthorpe, 2012). A more recent study, however, found no significant difference (Chidnok et al., 2013). Given these contrasting findings, the main purpose of the present study was to further investigate whether an RPE-clamped protocol would elicit higher VO2max values than a ramp-incremented protocol. **Methods** Sixteen trained cyclists (12 male; age: 34.4 yr ± 7.4; BMI: 24.1 ± 2.2) performed a traditional ramp-incremented VO2max test and an RPE-clamped protocol performed one week apart in a randomized, completely counterbalanced, cross-over design. The RPE-clamped protocol replicated that of Mauger and Sculthorpe and consisted of five, 2-minute stages clamped at RPE values of 11, 13, 15, 17 and 20. In the RPE-clamped protocol, subjects were allowed to self-select the power output to maintain the RPE at a given step. After completion of both test protocols, subjects were asked which one they preferred. **Results** The mean test time was not significantly different between the two test protocols (p = 0.09). There was no difference in VO2max (3.86 ± 0.18 L·min<sup>-1</sup>; p = 0.9) between the two protocols. Test preference did not appear to have an effect on test outcome for VO2max (p = 0.81) or peak power output (p = 0.24). There was no significant mean differences for peak power output (Ramp: 330 ± 71 W, Clamp: 317 ± 97 W; p = 0.21), maximal minute ventilation (p = 0.97), maximal respiratory exchange ratio (p = 0.09), maximal heart rate (Ramp: 171 ± 12 bpm; Clamp: 172 ± 10 bpm; p = 0.51), or post-test blood lactate concentration (p = 0.58), however, RPE at peak effort was significantly higher during the RPE-clamped protocol compared to the ramp protocol (p < 0.01). **Discussion** Unlike Mauger and Sculthorpe's untrained subjects, our trained cyclists did not elicit a higher VO2max in the RPE-clamped protocol. In fact, the two tests were similar in length and elicited almost identical physiological and performance responses, despite achieving a significantly higher perceived exertion in the RPE-clamped protocol, suggesting that an RPE-clamped protocol may be of value in the exercise science field as a regular maximal testing protocol. **References** Chidnok, W, et al. ### THE EFFECT OF HIGH INTENSITY INTERMITTENT TRAINING BY THE RUNNING ON ENDURANCE PERFORMANCE IN BALL GAMES

Takimoto, M., Umemura, Y., Iga, T.

*Chukyo University(Aichi, Japan), Chukyo University(Aichi, Japan), Nagoya University(Aichi, Japan)*

**Introduction** When we provide some physical training program of ball games, it is easier to provide running program than it is actually to provide bicycle program for athletes during sports practice at the field. Previous study (Tabata et al.) reported that short-term bicycle ergometer training increased endurance performance. We need to have training program for easy in the field. Thus, we have developed from bicycle training program to running training program. The aim of this study was to estimate the effect of this program. **Methods**

Twenty five male soccer players were divided into three groups (A: bicycle ergometer training, B: running training, C: Control). A and B group performed maximum effort training 3 day/week for 2 weeks and technological practice of soccer. Training of A consisted of seven sets of 20-s exercise at an intensity of a load of 7.5% of body weight with a 10-s rest between each bouts. Training of B consisted of seven sets of 100m running with a 10-s rest between each bouts. C was only technological practice. Oxygen uptake, onset of blood lactate accumulation (OBLA), wingate anaerobic test (WAnT), Yo-Yo intermittent recovery test (YYIR2) were measured at pre and post training. Results There were no interactions. On the other hand, OBLA, WAnT, and YYIR2 increased in post training. These were no significantly higher than those in pre training. Discussion Gibala et al. and Hazell et al. reported that 2 weeks of intermittent training increased oxygen uptake. In this study, there were no effects of training program on endurance performance. The reason may be related effects of technological practice of soccer. There were no differences due to training programs in the results. However, only six training have the potential of effective for improvements in OBLA, WAnT, and YYIR2. Reference Tabata et al. *Med Sci Sports Exerc.* 1996 Oct;28(10):1327-30. ### THE EFFECTS OF AN ECCENTRIC HAMSTRING STRENGTHENING PROGRAM ON H/Q RATIO IN 10-11-YEAR OLD FEMALE HANDBALL PLAYERS

Schuth, G.1, Bognár, G.1, Dömötör, E.1, Petrekanits, M.1, Váczi, M.2, Cselkó, A.2, Tihanyi, J.1

1 *Semmelweis University, 2 University of Pécs*

**Introduction** During drop jumps with increasing drop heights, the activation level of the quadriceps (Q) increases, but the hamstrings' (H) does not, so the strain on the anterior cruciate ligament (ACL) increases (Ford 2011). The torque of the H does not increase after the age of 11 significantly in women athletes (Barber-Westin 2006). We aimed to apply specific strength training for H muscles to increase the H/Q ratio. **Methods** We measured the eccentric (EC) peak torque of the H at 60 °/s, and the concentric (CC) H and Q peak torque at 60 and 180 °/s constant angular velocities by 22, 10-11 year-old women handball players in Multicont-II dynamometer. We calculated the functional H/Q ratio in 60 °/s, and the conventional H/Q ratio in 60 and 180 °/s for both legs. We measured the jumping height using a contact mat during counter-movement jumps (CMJ) without arm swing. The players were randomly assigned to either a training (EC, n=13, 11,28±0,52 years) group, who carried out progressive body-weight eccentric H strength training twice a week (Nordic hamstrings, 2\*5-3\*15 repetitions) or a control group (KO, n=9, 10,89±0,50 years) who took part only in the handball training. After 10 weeks data of the same variables were collected. **Results:** The EC H peak torque using 60 °/s increased significantly in both groups, as well as the CC Q peak torque in 60 and 180 °/s and the CC H peak torque in 180 °/s in the EC group (p≤0,05). The functional H/Q ratio on 60 °/s increased significantly in the control group in the right leg (p≤0,05). We did not find any other differences in the groups. The jumping height increased significantly in the EC group (18,25±2,29 cm-22,48±2,64 cm, p<=0,001). **Conclusion:** The first half of the study was during the preparation phase of the year, maybe this was the reason of the increase of the torques in the control group. The CMJ jump height increased significantly only in the training group. It seems that the recovery time for the experimental group was too short after training intervention and therefore the H/Q ratio did not increased significantly. Also, it can be imagined that ten weeks were not enough to result in significant alteration in muscle strength of H which is in agreement with the findings of Kramer and Fleck (2005). It is unknown why the control group increased the H/Q ratio without specific H training. To solve this problem further studies are needed. **References** Ford KR, Myer GD, Schmitt LC, Uhl TL, Hewett TE. (2011) *J Appl Biomech.* 27(3):215-22. Barber-Westin SD, Noyes FR, Galloway M. ### EFFECT OF TWO DIFFERENT STRENGTH TRAINING METHODS ON CYCLING PERFORMANCE IN HIGHLY TRAINED VETERAN CYCLISTS

Kristoffersen, M.1, Ryngøye, A.2, Andersen, S.1, Gundersen, I.1, Stogstad, T.1, Rørstad, S.1, Andersen, J.1, Welde, B.2

1 *Bergen University College, Bergen; Norway. 2 Nord-Trøndelag University College, Levanger; Norway*

**Introduction** Cycling has been a fast growing veteran sport. In efforts to improve cycling performance many veteran cyclists perform strength training. This study aimed to investigate effects of two different strength training methods on cycling performance. **Methods** 23 highly trained male cyclists (age: 47±7 yr; VO2max: 57±6 ml·kg<sup>-1</sup>·min<sup>-1</sup>; body fat: 11±4%) participated in a 9 week pre-to post-test training intervention. The participants were randomised to one of three groups: strength training with 4 repetition maximum (RM) in 4 series (4RMG, n=9), 20 RM in 4 series (20RMG, n=7) and a control group (CG, n=7). The training intervention consisted of leg press with two sessions per week in addition to normal endurance training. Pre- and post-tests: VO2max, lactate threshold (LT<sub>watt</sub>), 20 minutes time-trial test (TT<sub>watt</sub>), maximal leg strength with left and right foot separately (1RM<sub>LPL</sub>, 1RM<sub>LPR</sub>) and submaximal leg press with a load at 80% of 1RM in pre-test (LPL80, LPR80). VO2max, LT<sub>watt</sub> and TT<sub>watt</sub> were performed on a Velotron bike (DynaFit Pro). Heart rate was measured using a Polar RS 800 CX. VO2 was measured using a Jaeger Oxycon Pro. Lactate was measured using a Lactate Scout device. Strength tests were performed in apparatus from Cybex International, and body composition with InBody 720. **Results** No significant effect from pre- to post test was found for VO2max, body mass and percent body fat (p=0.07). TT<sub>watt</sub> and LT<sub>watt</sub> increased from pre- to post- test by 14.9±13.6 W and 24.7±19.9 W, respectively, for all subjects pooled (both p<0.001) with no differences between groups. Maximal leg strength increased from pre- to post test (1RM LPR: +5.0±5.6 kg; 1RM LPL: 4.1±6.2 kg; both p<0.001). Interactions were found for the group factor, showing that the 20RMG was superior to the CG in 1RM LPR (diff.: +9.1±2.8 kg, p=0.02) and to the 4RMG (diff.: +6.4±2.4 kg, p=0.048) and CG (diff.: +11.3±2.6 kg, p=0.001) in the 1RM LPL. In the submaximal strength tests, there was a pre- to post test increase both for the LPR80 (+6.0±7.7 reps, p<0.001) and the LPL80 (+4.7±7.9 reps, p=0.003). Significant interactions for the group factor showed that the 20RMG increased LPR80 compared to both the 4RMG (diff.: +10.5±3.2 reps, p=0.01) and the CG (diff.: +13.8±3.5 reps, p=0.003), and LPL80 compared to the 4RMG (diff.: +10.1±3.6 reps, p=0.04). **Discussion** Strength training over 9 weeks in addition to regular cycling exercise does not have any effect on cycling performance in highly trained veteran cyclist compared with cycling alone. Strength training with 20 RM produced greater effect on muscular endurance than both 4RMG and CG and was superior to the CG in enhancing 1RM.

### DETERMINANTS OF ACCELERATION IN TEAM HANDBALL YOUNG PLAYERS: DOES A 45° ANGLE MATTER?

Meletakos, P., Noutsos, K., Nikolaidis, P.T.

*University of Athens*

**Introduction** Acceleration is an important parameter in team handball (TH) and it occurs during the game, not only in straight line, but also with changes of direction. The aim of this study was to examine the anthropometric and physiological factors that influence the acceleration performance either in straight line or with an angle of 45° on the right or on the left in young TH players. **Methods** Twenty-one TH

players (age  $15.6 \pm 0.8$  years, weight  $69.5 \pm 9.9$  kg and height  $1.75 \pm 0.06$  m) were tested for body fat (BF), sit-and-reach test, squat (SJ) and countermovement jump, Bosco test, Force-velocity test, Wingate anaerobic test and three conditions of 10-m sprint: in-line (A), with an angle of  $45^\circ$  in the middle of the sprint distance on the right (B) and on the left (C). A repeated measure ANOVA compared performance among the three conditions. A stepwise regression analysis was performed to investigate variables that predict performance in the three conditions of acceleration. Results A repeated measures ANOVA with a Greenhouse-Geisser correction determined that mean acceleration performance differed statistically significantly between A, B and C condition ( $p < 0.001$ ,  $\eta^2 = 0.64$ ). Post-hoc tests using the Bonferroni correction revealed that A condition elicited faster acceleration than B ( $-0.13$  s ( $-0.17$ ;  $-0.08$ ), mean difference (95% CI)) and C ( $-0.13$  s ( $-0.18$ ;  $-0.08$ )). SJ was the best predictor of A acceleration, and BF the second predictor, together explaining 70% of the variance of performance in this condition. In conditions B and C, we found different predictors (maximal velocity assessed by the Force-velocity test and mean power in Bosco test, respectively) and smaller multiple correlation coefficients in the models that predict acceleration (44% and 52%, respectively). Conclusions These findings indicate different performance between acceleration in straight line and acceleration with angle of  $45^\circ$ , but not between right and left angles. The regression analysis revealed that there are different predictors of acceleration performance among the conditions we used, and, therefore, TH coaches and trainers should focus on the training of the physiological predictors of acceleration depending on which mode of acceleration they target.

### AGE-RELATED DIFFERENCES IN SPRINT STEP CHARACTERISTICS IN HIGHLY TRAINED YOUNG SOCCER PLAYERS

Simpson, B., Al Haddad, H., Buchheit, M., Di Salvo, V., Mendez-Villanueva, A.

*ASPIRE*

**INTRODUCTION** Acceleration and maximum running speed are considered to be determined by a combination of specific physiological, metabolic, biomechanical, and morphological factors. However, our current knowledge on how acceleration and maximum sprinting speed develops in children and adolescents is still limited. Therefore, the aims of this study were to describe the step characteristics 1) between two different age and maturity groups (i.e., pre- and post-peak height velocity) and 2) fastest and slowest within each age group of young elite soccer players. **METHODS** Sprint performance and step characteristics of fifty-five highly-trained young male soccer players (Under 14 (U14),  $n=33$ ; Under 18 (U18),  $n=22$ ) were measured via the Optojump system (Microgate, Bolzano, Italy). Contact time (CT), stride rate (SR), step length (SL) and flight time (FT), were extracted during the acceleration (Acc; first 6 steps) and the peak velocity (PV; fastest 10 m split time) phases of the 40 m sprint. **RESULTS** During the Acc phase, U18 players have substantially shorter CT ( $0.15 \pm 0.01$  vs.  $0.18 \pm 0.01$  s, effect size (ES)=1.26, 90% confident limits (CL) [0.73;1.79]), higher SR ( $4.47 \pm 0.18$  vs.  $4.19 \pm 0.23$  Hz, ES=1.17, 90% CL [0.66;1.69]), and higher SL ( $1.37 \pm 0.10$  vs.  $1.30 \pm 0.14$  m, ES=0.94, 90% CL [0.42;1.45]) to the U14 players. Similarly, during the PV phase, U18 players have substantially shorter CT ( $0.12 \pm 0.01$  vs.  $0.14 \pm 0.01$  s, ES=1.42, 90% CL [0.89;1.95]), higher SR ( $4.51 \pm 0.21$  vs.  $4.19 \pm 0.21$  Hz, ES=1.51, 90% CL [0.99;2.04]), and higher SL ( $1.94 \pm 0.13$  vs.  $1.80 \pm 0.14$  m, ES=1.36, 90% CL [0.83;1.90]) to the U14 players. The U18 faster players have substantially shorter CT ( $0.11 \pm 0.01$  vs.  $0.12 \pm 0.01$  s, ES=1.86, 90% CL [0.78;2.95]), higher SR ( $4.63 \pm 0.28$  vs.  $4.43 \pm 0.123$  Hz, ES=0.79, 90% CL [-0.31;1.88]), higher SL ( $2.04 \pm 0.16$  vs.  $1.84 \pm 0.08$  m, ES=1.40, 90% CL [0.30;2.50]) and higher FT ( $0.11 \pm 0.01$  vs.  $0.10 \pm 0.01$  s, ES=0.75, 90% CL [-0.34;1.84]) during PV. While during the Acc phase SL was substantially higher ( $1.50 \pm 0.13$  vs.  $1.31 \pm 0.10$  m, ES=1.28, 90% CL [0.18;2.38]). These players were lighter ( $59.2 \pm 7.2$  vs.  $64.5 \pm 7.4$  kg, ES=0.66, 90% CL [-0.42;1.75]) and had similar height ( $1.71 \pm 7.7$  vs.  $1.70 \pm 5.4$  m, ES=0.08, 90% CL [-0.99;1.15]) than the slower U18 players. Whereas, the faster U14 players were heavier ( $54.2 \pm 9.7$  vs.  $38.3 \pm 4.4$  kg, ES=1.86, 90% CL [0.87;2.86]) and taller ( $1.64 \pm 9.5$  vs.  $1.50 \pm 6.9$  m, ES=1.81, 90% CL [0.84;2.78]) than the slower U14 players. **DISCUSSION** Between-group differences in all step characteristics were observed in both Acc and PV phases, suggesting similar stride factors underline age-related differences in sprint performance. When comparing slowest to fastest in U18 players, differences in Acc performance was mainly mediated by differences in SL. Differences in sprinting ability (both Acc and PV) between the fastest and slowest U14 soccer players were largely mediated by differences in SL. However, the larger height and body mass observed in the fastest U14 players suggests that anthropometrical factors might be behind these differences.

### QUANTIFYING THE INFLUENCE OF A HYPER-THERMIC ENVIRONMENT ON SOCCER SPECIFIC PHYSIOLOGICAL AND PERFORMANCE CAPACITY UTILISING A VALIDATED SOCCER NON-MOTORISED TREADMILL PROTOCOL

Aldous, J.I, Akubat, I.2, Christmas, B.I, Watkins, S.I, Coull, N.I, Warren, L.I, Taylor, L.I

*University of Bedfordshire*

**1**University of Bedfordshire, Bedford, UK, **2**Newman University, Birmingham, UK **Introduction** Playing soccer in the heat can result in high body temperatures, accelerating the development of fatigue, thus decreasing performance compared to similar activity in a temperate environment. Utilising an individualised and validated non-motorised treadmill soccer simulation (intermittent soccer performance test (iSPT) – Aldous et al, 2012 – in review) facilitates quantification of maximal performance capacity in temperate and hot environments. This study aims to assess the maximal physiological performance of soccer players in a hot (30°C, 30% RH; HOT) and temperate control environment (18°C, 50% RH; CON). **Methods** 8 male soccer players reported to the laboratory on 5 occasions. Visit 1-3: 3 familiarisation sessions. 4-5: iSPT (90 min duration 45 min - 1st half, 15 min - half time, 45 min - 2nd half). Participants completed iSPT on two occasions in CON and HOT. Relevant physiological (Heart Rate (HR), skin (Tsk) and rectal (Tre) temperature), perceptual (Ratings of Perceived Exertion (RPE) and thermal sensation (TS)) measures were recorded continuously and at 5 min intervals respectively. Body mass and hydration status were assessed pre and post iSPT. Changes in blood lactate and plasma levels were measured every 15 min. Results were analysed using a two way repeated measures ANOVA. Results Tmu (CON:  $38.4 \pm 0.07$  °C, HOT:  $39.2 \pm 0.02$  °C,  $P=0.03$ ) and Tre (CON:  $39.27 \pm 0.05$  °C, HOT:  $39.55 \pm 0.03$  °C,  $P=0.03$ ) were significantly greater in HOT compared to CON. Total distance (TD) covered (CON:  $9172.67 \pm 253.91$  m, HOT:  $8876.2 \pm 328.95$  m,  $P=0.004$ ), and sprint distance (SD) (CON:  $1063 \pm 19.94$  m, HOT:  $1047.52 \pm 6.28$  m,  $P=0.04$ ), were significantly greater in CON compared with HOT. Fatigue index (FI) between halves for TD covered (CON:  $64.39 \pm 55.33$  m,  $P < 0.001$ ; HOT:  $83.32 \pm 35.12$  m,  $P=0.04$ ) was greater in HOT compared to CON, but no change was observed for SD (CON:  $17.42 \pm 21.33$  m,  $P < 0.001$ ; HOT:  $25.63 \pm 13.01$  m,  $P=0.06$ ). **Discussion** A significant reduction in overall TD covered and SD was reported in HOT compared to CON. FI for TD covered between halves was greater in HOT compared to CON, however, this was not apparent for SD. Heat stress has shown to lower the work rate of players in HOT reducing oxygen delivery and aerobic energy turnover within the exercising muscles, provoking fatigue (Grantham et al, 2010). An individual's true maximal performance in CON is decreased in HOT. The data presented is the first utilising a validated and reliable soccer simulation (iSPT), quantifying decrements in performance between CON and HOT. ## INTERPRETATION OF PEAK POWER ASSESSMENTS IN YOUNG SOCCER PLAYERS

Severino, V.1, Coelho-e-Silva, M.J.1, Simões, F.1, Duarte, J.1, Pereira, J.R.1, Valente-dos-Santos, J.1, Rebelo-Gonçalves, R.1, Castagna, C.2, Figueiredo, A.J.1

(1) University of Coimbra, Portugal; (2) Football Training and Biomechanics Lab, Italian Football Federation (FIGC), Technical Department, Coverciano (Florence), Italy

Background: Although episodes of anaerobic effort occur on a smaller scale during the game, they play a decisive role in performance. By inference, anaerobic fitness seems to be an important parameter for success in elite soccer. This study examined the relationship between peak power outputs and body size descriptors before and after adopting an allometric modelling approach. Methods: The sample was composed by 42 male soccer players (13.9±0.6 yrs, 164.4±9.3 cm, 53.9±10.3 kg). Fat free mass was measured by air displacement plethysmography and thigh volume estimated using the anthropometric equation proposed by Jones and Pearson (1969). Peak output was determined using the Wingate test (WAnT). Correlation of Pearson determined the association between peak output and several size descriptors (body mass, fat free mass, and thigh volume). Power function ratios were obtained using ANCOVA. Results: WAnT peak output was 671.9±178.2 Watt. Absolute values of WAnT-peak were correlated with body mass (+0.90, p<0.01), fat free mass (+0.90, p<0.01) and thigh volume (+0.85, p<0.01). Exponents were b=1.21 (95% CI, 1.02-1.40) for body mass; b=1.17 (95% CI, 1.00-1.34) for fat free mass, and b=0.91 (95% CI, 0.71-1.11) for thigh volume. After allometric modelling the correlations were near zero (-0.20 to 0.00, p>0.05), which mean that it was possible to obtain size free model of WAnT peak output. Conclusions: WAnT seemed to be substantially correlated with total and regional size descriptors and the interpretation of maximal short-term fitness derived from the above mentioned cycling protocols performed in a seated position claim for appropriate models as an alternative to traditional approaches that express WAnT output in watt per unit of body mass. Jones & Pearson (1969). *J Physiology*. 204: 63-66 Supported by Fundação para a Ciência e Tecnologia – PhD Grant SFRH/BD/69447/2010

## PROFILING YOUNG SOCCER PLAYERS BY PLAYING POSITION: BODY SIZE, BODY COMPOSITION, MATURATION AND SHORT-TERM MAXIMAL EFFORT

Severino, V.1, Coelho-e-Silva, M.J.1, Simões, F.1, Duarte, J.1, Pereira, J.R.1, Valente-dos-Santos, J.1, Rebelo-Gonçalves, R.1, Castagna, C.2, Figueiredo, A.J.1

(1) University of Coimbra, Portugal; (2) Football Training and Biomechanics Lab, Italian Football Federation (FIGC), Technical Department, Coverciano (Florence), Italy

Background: Specialization by playing position is a relevant topic in the discussion of long-term athletic development. Physical and functional characteristics of young soccer players by playing position are less extensive in literature compared to available information in adult soccer. The current study profiles adolescent soccer players as defenders, midfielders and attackers on body size, composition and short-term maximal effort. Methods: The sample is composed of 74 male soccer players (14.9±1.2 yrs, 169.4±0.1 cm, 60.0±11.4 kg). Body composition was assessed by air displacement plethysmography. Biological maturation was given by current stature expressed as % of predicted mature stature (PMS). Short-term maximal performance (peak and mean outputs) was derived from the Wingate Test (WAnT). ANCOVA (decimal age as covariate) compared participants by playing position. Significance was set at p<0.05. Results: Mean values for defenders, midfielders and forwards were, respectively: 172.4 cm, 168.0 cm, 165.7 cm (p<0.01) for stature; 63.6 kg, 59.2 kg, 56.1 kg (p<0.01) for body mass; 57.0 kg, 52.9 kg, 50.5 kg, p<0.01) for fat-free mass; 95.4%, 95.1%, 94.8% (p=0.586) for %PMS; 804, 752 watt, 700 watt, (p<0.05) for WAnT-peak; 562 watt, 528 watt, 495 Watt (p<0.05) for WAnT-mean. Conclusions: Defenders tended to be larger in body size, including fat free mass, and obtain better performance in the WAnT. The current results correspond to the baseline of a longitudinal study that will inform about the developmental changes of WAnT outputs during adolescent years for the total sample and by playing position. ## CARDIORESPIRATORY RESPONSES OF TRAINED CEREBRAL PALSY CYCLIST DURING EXHAUSTIVE SEVERE EVENT: A CASE STUDY

Weissland, T., Lepretre, P.M.

Université Picardie Jules Verne

Introduction de Groot et al. (2012) reported a lower strength but similar maximal oxygen uptake (VO<sub>2</sub>) and the associated power (pVO<sub>2</sub>peak) in untrained adults with cerebral palsy (CP) compared to healthy counterparts. Ludberg (1978) also attributed the poor mechanical performance in CP to the extra O<sub>2</sub> cost required for muscle changes during cycling exercise and fatigue to reduced VO<sub>2</sub> (Bar-Or 1986). Muscle strength and O<sub>2</sub> delivery may be limiting factors in CP for exercise. The aim of this study was to determine the ability of trained subject with CP to attain and maintain a high VO<sub>2</sub> value during exhaustive constant cycling event. Method On separated days, a French para-cycling team member with CP performed on cyclus2 ergometer (RBM, Germany): 1) an incremental test (GCT) to determine maximal values of VO<sub>2</sub>, cardiac output (CO), heart rate (HR) and pVO<sub>2</sub>peak; 2) a time to exhaustion at pVO<sub>2</sub>peak (tlim) after 30-min warm-up. Respiratory and cardiac parameters were continuously measured by gas exchange analyzer (K4b2, Cosmed, Italia) and impedance (Physioflow, Manatec, France). Modeling data (f1) and oxygen deficit (DO<sub>2</sub>) were calculated according to Demarle et al. (2001). Result Maximal values of VO<sub>2</sub>, CO and HR measured during tlim (6min05) corresponded to 59.1% (35.6 vs. 60.2mL.O<sub>2</sub>.min<sup>-1</sup>.kg<sup>-1</sup>), 93.3% (21.9 vs. 23.5L.min<sup>-1</sup>) and 100% (210 vs. 209bpm) of the peak GCT values. The low VO<sub>2</sub> response was explained rather than a weak value of tidal volume (tlim: 0.92 vs. GCT: 1.68L), which rose continuously during tlim, rather than breath frequency (tlim: 81.6 vs. GCT: 72.2breath.min<sup>-1</sup>), which after abrupt increase dropped until exhaustion. Other cardio-respiratory responses to tlim were fitted to a mono-exponential model. t1HR was shorter than t1VO<sub>2</sub>, which was greater than t1CO. DO<sub>2</sub> was equal to 4.77LO<sub>2</sub> Discussion In trained CP, tlim was similar to data previously reported in trained healthy subjects (Billat et al. 1996) what contrasted to premature fatigue in untrained CP attributed in the weakness of endurance muscle strength (de Groot et al. 2012) or a high O<sub>2</sub> cost of locomotion (Ludberg 1978). Ventilation rather than CO also explained the low value of VO<sub>2</sub> during sustained severe exercise with regard to GCT. Respiratory muscle fatigue induced by warm-up and competitive limb muscle recruitment at the onset of strenuous exercise could explain VO<sub>2</sub> responses. Reference Bar-Or O. **PREVALENCE OF INJURIES AMONG HANDBALL PLAYERS**

Bedo, B.L.S., Manechini, J.P.V., Silva, S.R.D.

*University of São Paulo*

**Introduction** The handball is characterized as a contact sport with a high potential of injury (Akgun et al., 2008), and to identify and describe the injury problem is an important first step to prevent them (Olsen et al., 2006). The main purpose of this study was to identify the prevalence of injuries in male and female team handball players, as well their diagnosis. **Methods** Handball players, 63 male ( $21.2 \pm 5.3$  years) and 59 female ( $19.9 \pm 5.3$  years), from three different teams (São Paulo/Brazil) participated in this retrospective study. They were interviewed by the researchers, and a specific questionnaire was used (DE ROSE, TADIELLO, DE ROSE JR, 2006). The injuries related were also classified in acute or chronic according Yang et al. (2012). The results are presented as absolute and relative values. **Results** The number of injuries related was 218, and the most common injury type was sprains ( $n = 38$ ). The body region more affected by injuries was the lower limb (62%), with the knee and ankle showing similar number ( $n = 58$ ). It was verified a greater number of acute injuries ( $n=110$ ) in relation to chronic ( $n=52$ ). **Discussion** The main findings of this study were that the acute injury is higher in handball players, and that injuries occurred mainly in the knee and ankle joints (Olsen et al., 2006). In the future, more studies would aid in establishing a prevention program. **References** Akgun, U. et al. (2008). *Knee Surg Sports Traumatol Arthrosc*, 16(5), 522–530. De Rose, G. et al.
