## Congress Presidents

- Natàlia Balagué, Carlota Torrents (ESP)

## ECSS Executive Board

- Sigmund Loland - President (NOR)
- Hans Hoppeler - Past President (SUI)
- Marco Narici – President Elect (GBR)
- Romain Meeusen (BEL)
- Gisela Sjøgaard (DEN)
- Tim Cable (GBR)

## ECSS Scientific Board

- Anton Wagenmakers - Chair (GBR)
- Flemming Dela - Co-Chair (DEN)
- Jan Cabri - Secretary (NOR)
- Joan Duda (GBR)
- Paul Greenhaff (GBR)
- Martin Halle (GER)
- José Antonio López Calbet (ESP)
- Erich Müller (AUT)

## ECSS Scientific Committee

- Natàlia Balagué (ESP)
- Wilhelm Bloch (GER)
- Annalisa Cogo (ITA)
- Nenad Dikic (SRB)
- Taija Finni (FIN)
- Daniel Green (GBR)
- Michael Grey (GBR)
- Markus Gruber (GER)
- Jørn Wulff Helge (DEN)
- Ylva Hellsten (DEN)
- Luc van Loon (NED)
- Mike McNamee (GBR)
- Maria Francesca Piacentini (ITA)
- Janice L. Thompson (GBR)
- Nicole Wenderoth (BEL)

## ECSS Office

- Thomas Delaveaux
- Elias Tsolakidis
- Steffen Neubert
- Juliane Melber
- Tuulia Hokkanen

### **Local Scientific Committee**

- Rosa Angulo
- Natàlia Balagué
- Alfonso Blanco
- Joan Cadefau
- Andreu Camps
- Marta Castañer
- Francesc Corbi
- Francesc Cos
- Assumpta Ensenyat
- Pere Lavega
- Eloisa Lorente
- Xavier Peirau
- Jordi Porta
- Joan Riera
- Rosa Rodríguez
- Joan Solé
- Susanna Soler
- Anna Vilanova

### **Additional reviewers**

- Duarte Araújo
- Roser Cussó
- Guadalupe Garrido
- Myriam Guerra
- Casimiro Javierre
- Daniel Memmert
- Susana Monserrat
- Carme Porcar
- Anna Puig
- Nicolás Terrados
- Alfonsas Vainoras
- Josep Lluís Ventura

## **Organizing Committee**

- Agustí Boixeda
- Jordi Borrell
- Elena Gil
- Xavier Iglesias
- Vicente Javaloyes
- Alfredo Joven
- Pere Manuel
- Mercè Mateu
- M. José Montilla
- Felip Santamaria
- Cristófol Salas
- Jordi Solà
- Rafael Tarragó
- Carlota Torrents
- Lorena Torres
- Josep Vilà

# Welcome

---

Dear congress participant,

Since its creation one of the main aims of the ECSS has been to contribute to the unification of sport science. However, the tremendous growth in the field has produced further fragmentation. Is it possible to unify these fragmented areas? Are there common principles that bind them?

Reductionism has dominated research for over a century and has provided a wealth of knowledge, yet it is increasingly clear that a discrete biological function can only rarely be attributed to an individual molecule. Indeed, most biological characteristics arise from complex interactions: between proteins, cells, organisms, groups, societies, etc. A key challenge in the twenty-first century is therefore to understand the structure and dynamics of these complex interactions, as this will surely foster a new and better understanding between the different scientific disciplines.

The 2013 ECSS Congress in Barcelona seeks to help sport science make its own leap forward towards a comprehension of ourselves not as part of a technical world but as interacting parts of a consistent and coherent whole: nature. The 18th Annual Congress of the ECSS aims to contribute to the development of global approaches in the different specialized areas and to provide an even broader view of sport science. Hopefully, by moving from the whole to the parts and vice versa, sport scientists will be able to find the best paths through the field.

Barcelona is an open city: open to the sea, to culture, to the world and to science. What better place in which to join forces in unifying sport science.

Benvinguts a Barcelona,

Bienvenidos a Barcelona,

Welcome to Barcelona!

Natàlia Balagué & Carlota Torrents

*Congress Presidents*

# Table of Contents

## PS-HS01 Sport Science, in the World of Science

---

### SPORT SCIENCE, IN THE WORLD OF SCIENCE

Saltin, B.

*Rigshospitalet and University of Copenhagen, Denmark*

In the world of science, sport science is one of the fields that have changed dramatically over the last century. From having had a sports medicine focus the science component has taken over and become enlarged; now encompassing most academic disciplines ranging from philosophy over biomedicine to advanced technology, sometimes also in combination. Ever since I published my first paper in 1960 and defended my thesis in 1964 I have been close to this transformation and I have noticed how my field, human physiology, has changed stepwise in many universities, first into exercise science and later into sport science. Regardless of these paradigmatic modifications, I have continued to do what I was taught. Thus, in this presentation I will highlight one area where major advances have been possible thanks to the reintroduction of the muscle biopsy technique and the developments of biochemical and molecular methods. Muscles from humans could be studied, unravelling both contractile and metabolic adaptations at the muscle fibre and subcellular levels, including key factors for the mechanisms by which these adaptations are regulated and their functional role. To me an important source of information and perspective originates from a study in Greenland. During 42 days Danes were crossing the ice with 5-7 daily hours of strenuous skiing and pulling a sledge. They were compared to traditional Inuit. Our hypothesis was that the higher fat combustion capacity in the Inuit was to be explained by key differences in their skeletal muscle metabolic machinery in both arms and legs. The 42 days of skiing on the ice improved the fat combusting capacity in the Danes' muscles, but they did not reach "Inuit status" when it came to some critical enzymes and the relative role of fat oxidation. The question is then: why not? Until the complete answers have been found, the researchers' task is not fulfilled. The fact that sport science today is hypothesis driven is one important reason why the field has got a voice in the world of science. For this voice to be heard and appreciated, the "why" and "how" questions of sport science also have to be attacked and solved.

## OVERVIEW OF THE ROLE OF FREE RADICALS AND ANTIOXIDANTS IN PHYSICAL EXERCISE

Gratas-Delamarche, A.

*University of Rennes2*

Since the mid-70 when searchers (Davies et al. 1982) demonstrate that single bouts of exhaustive exercise can induce an acute state of oxidative stress, intensive researches have been conducted to clarify the role of oxidative stress in the exercise- adaptations of the human body. Oxidative stress was first defined by Sies (1985) as an « imbalance between the production of reactive oxygen species (ROS) and the occurrence of cell antioxidant defenses ». Since then, research in this area has grown spectacularly, showing that high levels of ROS produced during intense exercise result in oxidative stress and are associated with muscle damage and impaired muscle function. Exercise mode, intensity, and duration, as well as training and antioxidant intakes (AO) impact the extent of oxidation. Although a single bout of exercise often leads to an acute oxidative stress, in accordance with the principle of hormesis (Radak et al. 2008), such an increase appears necessary to allow for an up-regulation in endogenous antioxidant defenses. Now it is clear that humans that engage in long-term heavy exercise are more resistant to oxidative stress (Machefer et al. 2007). Evidence is growing that the continued presence of a small stimulus, such as low concentrations of ROS, can induce the expression of antioxidant enzymes and other defense mechanisms (Gomez- Cabrera et al. 2008). Thus within a concentration range, ROS are "friends" rather than "foes". Based on the abundant research done on this topic (Pternelj and Coombes 2011) this review seeks to give recommendations in daily antioxidant intakes for sportmen and active people. Nowadays there is a lack of evidence-for justifying antioxidant supplementation during usual exercise training. An adequate intake of vitamins and minerals through a varied and balanced diet remains the best approach to maintain the optimal antioxidant status in exercising individuals. References Sies H.: In: Oxidative stress, London: Academic Press; 1985: 1-8 Davies KJ, Quintanilha AT, Brooks GA, Packer L. Biochem Biophys Res Commun. 1982;107(4):1198-205. Pternelj TT, Coombes JS. ## ANTIOXIDANTS IN EXERCISE: WORSE THAN USELESS?

Gomez-Cabrera, M.C.

*University of Valencia*

Exercise causes oxidative stress. Antioxidants may reduce the adverse effects of exercise-induced reactive oxygen species (ROS). However, ROS are not only toxic but rather play an important role in cell signalling and in the regulation of gene expression in skeletal muscle. Thus, the supplementation with antioxidant vitamins during training has been recently questioned. Training studies conducted to determine whether antioxidant vitamins improve exercise performance have generally shown that supplementation is useless (1-3). However, recent evidence shows that antioxidants may have detrimental effects on performance. As early as 1971, it was shown that vitamin E supplementation (400 IU/d for 6 wk) caused unfavourable effects on endurance performance in swimmers (4). Malm and co-workers showed the deleterious effects of ubiquinone-10 supplementation on the performance of humans after a high-intensity training program (5). In 2002, it was shown that supplementation of racing greyhounds with 1g vitamin C a day for 4 wk significantly slowed their speed (6). Moreover, in a human study, the negative effects of ascorbic acid supplementation on the adaptive responses of endogenous antioxidant enzymes and stress proteins were demonstrated (7). Furthermore, it has been shown that supplementation with ascorbic acid to prevent delayed onset muscle soreness after exercise, does not preserve muscle function but hinders the recovery process thereby being detrimental to future performance (8). In an animal study, we found that vitamin C supplementation decreases training efficiency because it prevents exercise-induced mitochondrial biogenesis (9). These results have been subsequently confirmed in humans. Dr. Ristow's research group showed that antioxidant supplementation with vitamins C and E prevents the induction of molecular regulators of insulin sensitivity, mitochondrial biogenesis, and endogenous antioxidant defense by physical exercise (10). A large proportion of athletes take vitamin supplements, often large doses, seeking their beneficial effects on performance (11). The complete lack of any positive effect of antioxidant supplementation on physiologic and biochemical outcomes consistently found in human and animal studies raises questions about the validity of using oral antioxidant supplementation during training. ## ANTIOXIDANT SUPPLEMENTATION AND EXERCISE PERFORMANCE

Radak, Z.

*Semmelweis University*

In toxicology, hormesis is a dose response phenomenon characterized by a low dose of stimulation, high dose of inhibition, resulting in either a J-shaped or an inverted U-shaped dose response, which is a non-monotonic response. Recently we have extended the hormesis theory to free radical species which, level significantly modulated by physical exercise and we proposed that the effects of exercise in the context of free radicals can be described by the hormesis curve (1). Therefore, supplementation of antioxidants "on the

malfunctional side" of hormesis curve could be beneficial and can lead to delayed fatigue, enhanced performance and/or better regeneration. 1. Radak et al. *Biogerontology* 2005 6:71-5.

#### TRAINING INCREASES MUSCLE CARNOSINE LOADING BY BETA-ALANINE SUPPLEMENTATION

Bex, T., Chung, W., Baguet, A., Stegen, S., Derave, W.

*University Ghent*

TRAINING INCREASES MUSCLE CARNOSINE LOADING BY BETA-ALANINE SUPPLEMENTATION Bex, T.1, Chung, W.1,2, Baguet, A.1, Stegen, S.1, Derave, W.1 1: GHENT University (Ghent, Belgium), 2: Victoria University (Canberra, Australia) Introduction Carnosine occurs in high concentrations in human skeletal muscle where it works as a proton buffer and calcium regulator (Derave et al, 2010). Therefore, increased muscle carnosine concentration in athletes likely promotes high-intensity exercise performance. Beta-alanine (BA) supplementation over 4-10 weeks has consistently been shown to augment muscle carnosine concentration with 40–80%, but the effect of concomitant training on the loading efficiency is poorly understood. A one-legged training study found that carnosine loading after BA supplementation was not influenced by isokinetic training with limited training volume (Kendrick et al, 2009). Therefore, the aim of the present study was to investigate whether muscle carnosine loading via BA supplementation is enhanced by prolonged exercise training, by comparing loading in arm and leg muscles that are specifically trained in different athlete groups. Methods Participants (n=24; 9 cyclists, 7 swimmers and 8 controls) were supplemented with 6.4g/day of slow-release BA (Carnosyn, Natural Alternative International) for 23 days. Athletes were well-trained at baseline and trained at least 8 hours a week in their specific sports (cycling or swimming) during the supplementation period, whereas the controls were sedentary throughout. Measurements (before and after supplementation) included carnosine content in soleus, gastrocnemius medialis and deltoid muscles by proton magnetic resonance spectroscopy (1H-MRS). Results Cyclists (p = 0.026) and swimmers (p = 0.032) have a significantly higher absolute increase of carnosine after BA supplementation in the leg muscles compared to controls. In the deltoid muscle, a higher absolute increase of carnosine was found in the group of swimmers compared to cyclists (p = 0.025) and controls (p = 0.073). The highest relative increases in muscle carnosine were observed in the soleus muscles of cyclists (+94%) and the deltoid muscles of swimmers (+93%). Discussion We have shown that muscle carnosine loading is more pronounced in endurance-trained vs. untrained muscles. We observed a nearly doubling of muscle carnosine content in just 23 days in specifically trained muscles (calf muscle of cyclists and arm muscle of swimmers), which is markedly faster than ever observed (Derave et al, 2010). It remains to be determined whether differences in loading efficiency are due to the acute effects of muscle contractile activity on BA uptake and/or carnosine synthesis, or to the beneficial structural and metabolic properties of muscle induced by prior training. #### REGULATION OF PGC-1 $\alpha$ AND FNDC5 EXPRESSION IN HUMAN SKELETAL MUSCLE: INFLUENCE OF EXERCISE VOLUME AND PROTEIN CONTENT OF THE DIET

Ponce-Gonzalez, J.G.1, Losa-Reyna, J.1, De La Calle-Herrero, J.1, Perez-Suarez, I.1, Santana, A.1, Holmberg, H.C.2, Calbet, J.A.L.1

*1. UNIVERSITY OF LAS PALMAS DE GRAN CANARIA. 2. SWSRC, Mid Sweden Univ, Sweden*

PGC-1 $\alpha$  overexpression in mouse skeletal muscle induces FNDC5, a membrane protein that is cleaved and secreted as irisin. Irisin causes browning of subcutaneous fat, increases basal VO<sub>2</sub>, reduces body weight and increases insulin sensitivity (Boström et al. 2012). In humans, it has been reported that FNDC5 is induced by exercise in skeletal muscle (Boström et al. 2012) and reduced with weight loss after bariatric surgery (Huh et al. 2012). The molecular and endocrine mechanisms that control muscle FNDC5 expression in humans remain unknown. Aim: To determine the role played by PGC-1 $\alpha$  in human skeletal muscle FNDC5 expression and to determine whether exercise and the protein content of the diet blunt the expected reduction in FNDC5 expression induced by weight loss. Methods: PGC-1 $\alpha$  and FNDC5 mRNA, and the protein levels of AMPK $\alpha$  (total and phosphorylated), PGC-1 $\alpha$  and SIRT3 (under PGC-1 $\alpha$  control) were determined in skeletal muscle by Real Time PCR (with two housekeeping genes) and Western blot, before (PRE), after four days of prolonged exercise with caloric restriction (PE+CR), and three days later under control diet (isenergetic with PRE) with reduced exercise (CD), in 15 overweight men. Muscle biopsies were obtained from both deltoid and one vastus lateralis muscles (135 biopsies in total). During PE+CR, subjects performed 45 min of one-arm cranking (at 15% of their maximal intensity) followed by 8 h walking each day, and only ingested 0.8 g per kg of body weight per day of either whey protein (n=8) or sucrose (n=7). Results: Compared to PRE, the whole-body fat mass and lean mass were reduced by 2.9 and 1.1 kg after PE+CR (P<0.05) while basal metabolic rate remained at the same level. AMPK $\alpha$  phosphorylation was increased by 26 and 54%, after PE+CR and CD, respectively in all muscles (P<0.05). PGC-1 $\alpha$  protein expression was reduced by 17% and mRNA by 26% (PRE vs CD, P<0.05). There was a good correlation between the mean values of PGC-1 $\alpha$  protein and mRNA expression levels (r=0.75, P<0.05, n=8). Compared to PRE, FNDC5 mRNA expression was decreased by 41 and 44% (after PE+CR and CD, respectively, P<0.05). Exercise, prevented the reduction of PGC-1 $\alpha$  and FNDC5 mRNA in the legs but not the arms. Similar changes were observed in SIRT3 protein expression which was related to PGC-1 $\alpha$  protein (r=0.94, P<0.001, n=8). FNDC5 mRNA paralleled PGC-1 $\alpha$  mRNA (r=0.90, P<0.001, n=8) and protein expression (r=0.92, P<0.001, n=8). The type of supplement ingested had no influence on PGC-1 $\alpha$  and FNDC5 mRNA changes. Conclusion: FNDC5 expression in human skeletal muscle appears to be under tight control by PGC-1 $\alpha$ . A negative energy balance causes an overall reduction of FNDC5 expression in the musculature which is attenuated by prolonged (several hours) but not short (45 min) low intensity exercise. Basal metabolic rate does not appear to be under control by muscular FNDC5 expression in humans. Granted by MEC (DEP2010-21866).

**FACTORS INFLUENCING SERUM CAFFEINE CONCENTRATIONS FOLLOWING CAFFEINE INGESTION**

Skinner, T., Jenkins, D., Leveritt, M., McGorm, A., Bolam, K., Coombes, J., Taaffe, D.

*The University of Queensland (Brisbane, Australia)*

**Introduction** The majority of studies investigating the potential for caffeine to improve exercise performance have used a dose of 3-6 mg/kg caffeine administered 1 h pre-exercise based on the assumption that peak circulating levels are achieved 1 h following ingestion, and that peak levels will provide the greatest ergogenic benefit. However, between-individual variations in caffeine concentrations following ingestion have been reported to be ~79% (Balogh et al., 1992). Therefore, the aim of this study was to determine whether differences in training status, body composition and/or usual caffeine intake influenced serum caffeine concentrations following caffeine ingestion.

**Methods** Trained cyclists and triathletes (n=14) and active (n=14) males aged 18-40 years (a) consumed a high carbohydrate meal the night before testing; (b) fasted overnight ( $\geq 12$  h); (c) refrained from caffeine consumption (including substances that potentially affect the metabolism of caffeine) and alcohol for 48 h; and (d) maintained a hydrated state. On arrival at the laboratory participants ingested a high carbohydrate meal (2.0 g/kg carbohydrates, 42.4 $\pm$ 0.6 kJ/kg) prior to consuming 6 mg/kg anhydrous caffeine. Peak, total and time to peak serum caffeine concentrations were determined from venous blood samples at baseline and 6 time-points over 4 h following intake. Body composition was assessed by dual energy x-ray absorptiometry and usual caffeine intake by a questionnaire. Results Peak serum caffeine concentrations (36 $\pm$ 7  $\mu$ mol/L) occurred 135 $\pm$ 36 minutes following ingestion. Trained cyclists/triathletes had similar (p>0.05) body composition but significantly lower (p=0.028) peak serum caffeine concentrations compared to active individuals (trained cyclists/triathletes=32 $\pm$ 5  $\mu$ mol/L, active=38 $\pm$ 8  $\mu$ mol/L). Percent body fat was significantly associated with area under the serum caffeine concentration curve (r=0.414, p=0.036) but not peak (r=0.345, p=0.085) or time to peak serum caffeine concentration (rho=0.147, p=0.474). When all participants were divided into tertiles according to daily caffeine intake there were no significant differences in peak (p=0.618), time-to-peak (p=0.225) or total serum caffeine concentrations (p=0.444).

**Discussion** Three findings from the study were evident: 1) highly trained endurance athletes exhibit lower peak caffeine concentrations than active males following caffeine ingestion; 2) higher % body fat was associated with higher concentrations of caffeine in the blood for 4 h following caffeine ingestion, and 3) the amount of caffeine consumed in a typical week does not appear to influence the concentration of caffeine in the blood following ingestion. Identification of the optimal conditions to ensure peak availability of caffeine within the blood and/or overcoming some of the variation in how individuals respond to caffeine requires consideration of the training status and body composition of the athlete.

**MUSCLE CARNOSINE LOADING DOES NOT ENHANCE ENDURANCE CYCLING PERFORMANCE**

Chung, W.I, Baguet, A.I, Derave, W.I

*Ghent University*

**Introduction** To date, many studies show increased muscle carnosine concentrations and improved exercise performance with beta-alanine supplementation [1]. Most of these studies utilise short duration, high-intensity exercise protocols (< 20 minutes) as muscle carnosine is most commonly regarded as a pH buffer. However, improved muscle contractile function associated with increased muscle carnosine concentrations may also enhance endurance performance [2]. Therefore, we investigated the effect of beta-alanine supplementation on 1-h cycling time trial performance.

**Methods** Well-trained male cyclists (Age = 30.9  $\pm$  7.7 yr, VO<sub>2</sub>peak = 60.7  $\pm$  7.7 ml.min<sup>-1</sup>.kg<sup>-1</sup>; mean  $\pm$  SD) were supplemented with 6.4 g.day<sup>-1</sup> of either slow-release beta-alanine (BA; n=14) or placebo (PLA; n = 13) for six weeks. Muscle carnosine concentration (measured via proton magnetic resonance spectroscopy) in soleus and gastrocnemius, 1-h cycling time trial performance and physiological data during exercise were compared between baseline and post-supplementation. Results Muscle carnosine content was increased in both soleus (161%) and gastrocnemius (142%) after beta-alanine supplementation. No ergogenic effect of BA was found (p = 0.621), with both groups performing worse post-supplementation. BA was 1.9 seconds slower (p = 0.069), while PLA was 2.4 seconds slower (p < 0.01) in 1-h time trial performance following supplementation. No significant differences, induced from exercise, were found in blood bicarbonate and lactate, heart rate and RPE values.

**Discussion** Despite the largest ever reported increases in muscle carnosine concentrations, no ergogenic effect of beta-alanine supplementation was demonstrated on endurance cycling performance in well-trained male cyclists. Currently, the ergogenic benefit of beta-alanine supplementation seems to be limited to short duration, high-intensity exercise performance, which is likely related to the role of carnosine in pH homeostasis.

**KAYAK ROWING PERFORMANCE AND MUSCLE FUNCTION IS UNAFFECTED BY BETA-ALANINE SUPPLEMENTATION IN ELITE KAYAKERS**

Bech, S., Richter, E., Kiens, B., Nordsborg, N.

*University of Copenhagen*

**INTRODUCTION:** Beta-alanine supplementation may improve performance in untrained and moderately trained athletes (Smith et al. 2011), but only few studies have investigated elite level athletes Baguet et al. 2010). (The purpose of this study was to investigate the hypothesis that beta-alanine supplementation would improve 4-5 min intense exercise performance, repeated sprint ability and the ability to maintain a high muscular force generation.

**METHODS:** 10 males and 6 female national elite kayakers (age = 19.1 $\pm$  0.7 yr, height = 1.80 $\pm$  2.9 m, body mass = 76.0 $\pm$  3.5 kg, VO<sub>2</sub>max=4.1 $\pm$ 0.3) were randomly assigned in a double blinded manner to either placebo (PL) or a  $\beta$ -alanine (BA) treatment (6.4 g/day for 8 weeks). Participants performed a 1000 m test on day 1 and a 5x250m interspersed by 3 minutes rest on day 2. Before and after the 1000m test three 5 seconds maximal voluntary contractions (MVC) were completed and this were also done before and after the 5x250 and one 5 second MVC between each 250m. After 10 minutes of rest, a 2 minute MVC was performed followed by a time to exhaustion (TTE) at 40% of MVCpre. A muscle biopsy (Bergstrom needle modified with suction) was obtained from biceps brachii. Data were analyzed using repeated-measures ANOVA and the level of significance was set at P<0.05.

**RESULTS:** The 1000m performance was similar at baseline (BA: 255.0 $\pm$ 7.7 s; PL: 259.3 $\pm$ 9.7 s) and after 8 weeks supplementation (BA: 252.8 $\pm$ 6.6 sec (p=0.34, compared to baseline); PL: 259.4 $\pm$ 9.5). Likewise 5x250m mean power was similar in all conditions. Two minutes MVC peak force and fatigue index were also similar before and after beta-alanine supplementation. In addition, TTE at 40% of maximal MVC was also similar between groups at baseline (BA: 86.0 $\pm$ 4.8 sec; PL: 108.0 $\pm$ 20.3 sec) and after supplementation (BA: 104.8 $\pm$ 21.4 s; PL: 115.? $\pm$ 16.9 sec).

**DISCUSSION:** Kayak performance and muscle function was similar before and after eight weeks of beta-alanine supple-

mentation in Danish national level elite kayak rowers. Due to the relative low number of subjects, the small changes seen in 1000m for the BA group (255.0±7.7 s at baseline and 252.8± 6.6 s after 8 weeks) and the TTE at 40% MVC (86.0±4.8 sec at baseline and 104.8±21.4 sec after 8 weeks) may reach statistical significance if more subjects are included. ### **EFFECTS OF A CARBOHYDRATE AND CAFFEINE GEL ON INTERMITTENT ENDURANCE PERFORMANCE IN RECREATIONAL TRAINED MALES**

Cooper, R., Naclerio, F., Allgrove, A., Larumbe-Zabala, E.

*University of Greenwich*

Introduction Intermittent endurance performance has been shown to improve with the ingestion of carbohydrate and caffeine. However, when caffeine and carbohydrate are combined their additive effects seem to be less clear. We investigated the effects of ingesting carbohydrate gels with and without caffeine on a ~90-min, 4 blocks intermittent endurance test (IET), in recreationally athletes. Methods 12 males (age 23±3 years, height 179±6 cm, body mass 79±10 kg) ingested three different doses of gel containing respectively 25 g of carbohydrate with (CHOCAF) or without (CHO) 100 mg of caffeine or a non-caloric placebo (PL) 1 h pre, immediately prior to start, and before the third block (~43 min) of the IET. Each block involved eleven sets of three repetitions of 60 m performed at <60; 80 and 60% of maximal aerobic speed respectively and one 15 m sprint. Blood glucose, rates of perceived exertion (RPE) and fatigue index (FI=100 x (slowest 15 m time – fastest 15 m time)/fastest 15 m time) were analysed. Results Glucose showed significant higher values (p<0.05) at block 2 and 3 for both CHOCAF and CHO while only for CHOCAF respect to PL at block 4. Additionally CHOCAF showed a better significant FI score (5.0±1.7) compared with CHO (7.6±2.6; p=0.006) and PL (7.4±2.4; p=0.005), a lower RPE (14.2±2) compared to PL (15.3±2; p=0.003) and a trend in respect to CHO (14.9±2.3; p=0.056) only after the 3rd block. No other significant interaction effects were observed. Discussion In conclusion, ingesting a gel containing 25 g carbohydrate with 100 mg caffeine 1 h before, prior and during an IET is effective to temporarily reduce fatigue and RPE while maintaining higher glucose levels at the final stages of an intermittent high intensity exercise. ### **IS-PM13 Exercise and Training in COPD Patients \***

#### **GAS EXCHANGE DURING EXERCISE IN PATIENTS WITH COPD**

Barbera, J.A.

*Hospital Clinic, University of Barcelona*

Changes in arterial oxygen tension (PaO<sub>2</sub>) during exercise are highly variable in COPD. Assessments of ventilation-perfusion (VA/Q) relationships have shown that VA/Q distributions usually improve or remain unaltered during exercise, they do not worsen. Distributions of both ventilation and blood flow are more homogeneous on exertion than at rest. Nevertheless, some COPD patients, particularly those with more advanced disease, present a significant fall in PaO<sub>2</sub> during exercise. Such a decrease in PaO<sub>2</sub> has a multifactorial origin, although the most important is the ability to increase ventilation. Due to the ventilatory impairment, COPD patients have limited ability to increase ventilation during exercise that might be insufficient to offset increased CO<sub>2</sub> production leading to hypercapnia. Furthermore, limited ability to increase ventilation impedes the physiological shifting of the perfusion distribution towards alveolar units with higher VA/Q ratios, an effect that compensates for the impact of the fall in PvO<sub>2</sub>, which normally occurs during exercise, on end-capillary PO<sub>2</sub>. In turn, the value of PvO<sub>2</sub> is determined by the ability to adequately increase the cardiac output to attend metabolic demands. Therefore, any concomitant cardiovascular disease will further reduce exercise PvO<sub>2</sub>, the effect of which is further amplified by the underlying VA/Q inequality. In COPD, there is no significant limitation in the diffusion of oxygen from the alveoli to the capillary blood during exercise. In summary, the variable effect of exercise on PaO<sub>2</sub> in COPD is determined by the complex interaction between intrapulmonary VA/Q relationships and the ventilatory and cardiovascular responses.

#### **OXYGEN AVAILABILITY IN THE BLOOD OF FOOTBALL PLAYERS DURING 12 DAYS OF ACCLIMATISATION TO 3600M**

Wachsmuth, N.B., Schmidt, W., Kley, M., Spielvogel, H., Aughey, R., Gore, C., Buchheit, M., Bourdon, P., Soria, R., Jimenes, J., Garvican, L.A.

*University of Bayreuth*

Introduction: Playing international football games at La Paz (3600m) is still under debate and many teams opt for a "fly in, fly out" strategy to use the 'physiological window' within the first hours at altitude, where performance is assumed to be less compromised. The key factor limiting performance at altitude is the reduced oxygen availability due to decreased arterial PO<sub>2</sub> (PaO<sub>2</sub>) and lower arterial oxygen content (CaO<sub>2</sub>). The aim of this study was to monitor the time course of changes in PaO<sub>2</sub> and CaO<sub>2</sub> and the corresponding haematological

adaptive responses in soccer players during 12 days of altitude acclimatisation. Methods: 39 football players of 2 teams, the Australian U16 National team (A: n=20, 16.0 ±0.4 years, sea level residents) and a Bolivian junior team native to La Paz (B: n=19, 18.1 ±1.0 years, participated in the study. Both groups stayed for 6 days at Santa Cruz (430m) followed by an altitude exposure (A=12 days) to La Paz (3600m). Haemoglobin mass (Hbmass), blood volume (BV), haemoglobin concentration (Hb), Hb-oxygen saturation (SO<sub>2</sub>), CaO<sub>2</sub>, and the acid base status were measured at sea level, 2h after arriving at 3600m (except Hb-mass) and up to 12 days (A) or 16 days (B) at altitude. Results: Hbmass (A:11.6 ±0.7g/kg, B:12.8 ±0.8g/kg) was significantly lower (p≤0.001) in A and slightly increased by 2.7 ±3.1%; p≤0.01 until day 12. It did not change in B, neither after descent to sea level nor at day 16 after return to altitude. Compared to sea level, BV decreased in both teams at altitude (A:-7.8 ±7.6% after 12 days, B:-4.6 ±3.6% after 16 days; p≤0.001). SO<sub>2</sub> was markedly reduced 2h after arrival at altitude (A:84.6 ±3.0% B:87.6 ±2.3%; p≤0.001) and increased the following days (A:90.4 ±1.7%, B:91.0 ±1.5%; p≤0.001). CaO<sub>2</sub> was clearly reduced directly after ascent (A:-2.3 ±0.7 ml/100ml; B:-2.1 ±0.8 ml/100ml; p≤0.001). In A, it was overcompensated at day 12 (+1.7 ±1.2 ml/100ml; p≤0.001) while in B baseline values were achieved at day 16. PaO<sub>2</sub> dropped to 43.9 ±2.6 mmHg in A and 48.2 ±3.4 mmHg in B immediately after arrival at altitude and increased to 56.1 ±2.2 mmHg (A) after 12 days and 60.0 ±2.6 mmHg (B) after 16 days (both p≤0.001), respectively. Conclusion: In A and in B oxygen availability (CaO<sub>2</sub> and PaO<sub>2</sub>) was lowest immediately after arrival at altitude. A physiological window allowing best performance at altitude at this time seems to be unlikely. The overcompensation of CaO<sub>2</sub> and the increase in PaO<sub>2</sub> until day 12 suggest a longer acclimatization process to be more beneficial than the "fly in, fly out" strategy. However, 12 days of acclimatisation are not sufficient to achieve the adaptive status of football players native to altitude.

### ARE RESTRICTIONS IN BLOOD FLOW AND OXYGEN SUPPLY TO THE HUMAN BRAIN A MECHANISM BY WHICH DEHYDRATION IMPAIRS MAXIMAL EXERCISE CAPACITY?

Trangmar, S.J.1, Chiesa, S.T.1, Stock, C.G.1, Kalsi, K.K.1, Secher, N.H.1,2, González-Alonso, J.1

BRUNEL UNIVERSITY

Introduction: During maximal exercise, a reduction in blood flow to the human brain may contribute to the development of fatigue by lowering O<sub>2</sub> supply and diminishing cerebral O<sub>2</sub> availability (1,3). It is presently unknown if dehydration exacerbates the influence of circulatory strain upon the human brain sufficiently to compromise cerebral VO<sub>2</sub>. We tested the hypothesis that dehydration accelerates the reductions in cerebral blood flow during incremental exercise, but without impairing brain VO<sub>2</sub>. Methods: Ten cyclists (VO<sub>2</sub> peak 59 ± 2 mL/kg/min) performed 3 incremental cycle ergometer exercise tests in a warm environment (35°C) in the following conditions: 1) euhydrated (control; maximal work rate (WR<sub>max</sub>) 336 ± 14 W), 2) dehydrated after 2 hours of sub-maximal cycling without fluid ingestion (DEH; 3.1 ± 0.3 % body mass loss; 222 ± 10 W), and 3) rehydrated after 1 h passive recovery with full fluid replacement (REH; 294 ± 15 W). Cerebral blood flow and velocity were assessed in the internal carotid artery (CBF) and middle cerebral artery (MCAv). Blood samples were obtained from the brachial artery and left internal jugular vein to measure a-vO<sub>2</sub> differences and for the calculation of VO<sub>2</sub>. Results: During control, CBF and MCAv increased from rest to 40% WR<sub>max</sub> (17 ± 2%; P<0.01) and declined gradually thereafter to baseline values. During DEH, CBF and MCAv declined earlier and were 12-23% lower than at the same workload in control; however, the a-v O<sub>2</sub> diff and O<sub>2</sub> extraction were higher (P<0.05), resulting in a similar brain VO<sub>2</sub> between conditions. The flow and oxygenation responses during REH were similar to control. In all trials, the declines in CBF and MCAv and vascular conductance during intense and maximal exercise were strongly correlated to reductions in PaCO<sub>2</sub> (r<sub>2</sub> ≥0.74, P≤0.01). This suggests PaCO<sub>2</sub> has a role in the observed cerebral vasoconstriction (2,4). Discussion: The present findings demonstrate that dehydration accelerates the decline in blood flow and O<sub>2</sub> supply to the human brain during incremental cycling exercise to the limit of tolerance. However, VO<sub>2</sub> was not compromised because of compensatory increases in cerebral O<sub>2</sub> extraction. A compromised brain VO<sub>2</sub> is therefore an unlikely mechanism underpinning the impaired exercise capacity in dehydrated individuals. However, it remains possible that dehydration impairs maximal exercise capacity independently of disturbances in aerobic metabolism. Supported by the Gatorade Sports Science Institute, PepsiCo, USA. ### ALTITUDEOMICS: PROLONGED EXPOSURE TO HIGH ALTITUDE AFFECTS THE SEVERITY OF SUPRASPINAL FATIGUE AND CORTICOSPINAL EXCITABILITY

Twomey, R.1, Goodall, S.2, Amann, M.3, Ross, E.Z.1, Deckerle, J.1, Lovering, A.4, Romer, L.M.5, Subudhi, A.6, Roach, R.6

1U-Brighton (UK), 2U-Northumbria (UK), 3U-Utah, 4U-Oregon, 5U-Brunel, (UK), 6U-Colorado

Introduction Severe, acute hypoxia leads to an increased development of supraspinal fatigue during whole body exercise. However, corticomotor responses to fatiguing exercise in prolonged hypoxia are not well understood. Cerebrovascular adaptations during acclimatisation may attenuate the severity of the acute response. We assessed cortical excitability and fatigue following cycling exercise after acute and chronic exposure to hypoxia. Methods Seven recreationally-active participants performed an identical bout of constant-load cycling (131±39 W, 10.1±1.4 min) on 3 separate occasions: 1) to exhaustion in acute normobaric hypoxia (AH; PIO<sub>2</sub>, 73.8±0.2 mmHg), 2) sea-level (SL; PIO<sub>2</sub>, 147.1±0.5 mmHg), and 3) after 14 d in chronic hypoxia (Mt. Chacaltaya, Bolivia) (CH; 5,260 m, PIO<sub>2</sub>, 75.7±0.1 mmHg). Arterial haemoglobin saturation (SaO<sub>2</sub>), cerebral oxygenation and blood velocity in the left middle cerebral artery (MCAv) were measured throughout exercise. Before and immediately after each trial, responses to transcranial magnetic stimulation and supramaximal electrical femoral nerve stimulation were obtained to assess corticospinal and neuromuscular function, respectively. Results For the knee extensors, maximum voluntary force and potentiated twitch force decreased after exercise in AH and CH, but not at SL (P<0.05). Cortical voluntary activation did not differ between conditions pre-exercise (94±7%, P=0.31), but was significantly reduced post-exercise in AH (-11%, P=0.01), though not at SL (-4%, P=0.30) or in CH (-6%, P = 0.17). Corticospinal excitability (resting motor evoked potential (MEP)) was twofold greater in CH compared to AH and SL (P<0.05). Post-exercise MEP amplitude was significantly reduced from pre-exercise baseline in CH but not in AH or at SL. In the final minute of exercise, SaO<sub>2</sub> was significantly lower (P<0.01) in AH (61±6%) than CH (82±5%) and SL (97±3%). The degree of cerebral deoxygenation during exercise in AH was greater than observed in SL and CH (P<0.05). Discussion Exercise-induced supraspinal fatigue, as quantified via changes in cortical voluntary activation, was alleviated after a period of acclimatisation to high altitude in comparison to exacerbated levels in acute hypoxia. This may be related to 1) an increased corticospinal excitability and 2) greater cerebral oxygenation, mediated by an improved cerebrovascular response to exercise, following prolonged exposure to high altitude. These novel data suggest that improvements in exercise performance after acclimatisation to hypoxia might, in part, be explained by an attenuated development of central fatigue.

### MUSCLE ISCHEMIC PRECONDITIONING REDUCES FEEDBACK FROM GROUP III AND IV MUSCLE AFFERENTS

Angius, L.1,2, Crisafulli, A.1, Hopker, J.2, de Paula Caraça Smirmaul, B.3, Concu, A.1, Marcora, S.M.2

**INTRODUCTION** The primary aim of this study was to test the hypothesis that muscle ischemic preconditioning (MIP) reduces feedback from group III and IV muscle afferents measured indirectly by muscle metaboreflex. The second aim was to investigate whether the hypothesized reduction in afferent feedback (Crisafulli et al, 2011) causes a reduction of rating of perceived exertion (RPE) as predicted by the afferent feedback model of PE (Marcora, 2009) **MATERIAL AND METHODS** Nine healthy subjects visited the laboratory three times in a single-blind, randomized and counterbalanced experimental design. In a preliminary day they underwent a one leg incremental test up to exhaustion to detect Wmax then an experimental (EXP) and control (SHAM) session in separated days. To test muscle afferent activity, two post-exercise muscle ischemia (PEMI) were executed. PEMI involved: 3 min of baseline, 3 min of exercise at 70% of Wmax, 3 min of thigh occlusion followed by 3 min of recovery. MIP treatment during EXP or SHAM was executed between the two PEMI sessions. MIP involved 3 cycles of occlusion of 5 min at 220 mmHg separated by 5 min of reperfusion. During the SHAM session, occlusion was 20 mmHg. Cardiac output (CO), mean arterial pressure (MAP) and RPE during exercise were monitored during both PEMI sessions. **RESULTS** CO and MAP responses were significantly reduced after MIP (CO =  $6.92 \pm 1.81$  vs  $5.79 \pm 1.39$  l•min<sup>-1</sup> and MAP=  $109.25 \pm 9.85$  vs  $103.70 \pm 10.43$  mmHg). RPE was not affected by MIP ( $15.67 \pm 1.87$  vs  $15.56 \pm 2.07$ ). None of the parameters reported any statistical changes in the SHAM condition. **DISCUSSION** This study shows for the first time that MIP reduces feedback from group III and IV muscle afferents as indicated by a significant reduction in muscle metabo-reflex. Despite this reduced afferent feedback, RPE was unchanged. This finding provides further experimental evidence that feedback from III and IV muscle afferents is not a sensory signal for PE. **REFERENCES** Crisafulli A. et al J Appl Physiol. 2011 Aug;111(2):530-6. ### THE INFLUENCE OF BODY WEIGHT ON THE PULMONARY OXYGEN UPTAKE KINETICS IN PRE-PUBERTAL CHILDREN DURING TREADMILL EXERCISE

McNarry, M., Faulkner, J., Westrupp, N., Lambrick, D.

Swansea University

**Introduction** The prevalence of childhood obesity has increased at an alarming rate and is currently considered one of the most serious public health challenges of the 21st century (WHO, 2013). Whilst strategies to curtail and reverse this trend are acknowledged as being required, our understanding of the influence of obesity on exercise performance, and its mechanistic basis, is limited. Specifically, excess fat may exert a unique effect on performance; obese individuals exhibit a considerable functional limitation in motor activity yet their skeletal muscles are exposed to an inherent chronic strength training stimuli due to the excess weight (Salvadeo et al. 2010). The purpose of this study was therefore to assess the influence of obesity on the oxygen uptake (VO<sub>2</sub>) kinetics of pre-pubertal children during exercise. We hypothesised that obese (OB) children would demonstrate significantly slower VO<sub>2</sub> kinetics than their normal weight (NW) counterparts during moderate and heavy intensity exercise. **Methods** 18 OB ( $9.8 \pm 0.5$  y;  $24.1 \pm 2.0$  kg•m<sup>2</sup>) and 19 NW ( $9.7 \pm 0.5$  y;  $17.6 \pm 1.0$  kg•m<sup>2</sup>) children completed a graded-exercise test to volitional exhaustion and two constant work rate treadmill tests at both moderate (90% gas exchange threshold) and heavy ( $\Delta 40\%$ ) exercise intensities. Pulmonary gas exchange variables were measured throughout. Parameters describing the dynamic O<sub>2</sub> response were derived using a mono-exponential model with a time delay, constrained to exclude the visually identified slow component during heavy exercise. **Results** During moderate exercise, the phase II  $\tau$  (OB:  $30 \pm 13$  cf. NW:  $22 \pm 7$  s), mean response time (OB:  $35 \pm 16$  cf. NW:  $25 \pm 10$  s), phase II gain (OB:  $156 \pm 21$  cf. NW:  $111 \pm 18$  mL O<sub>2</sub>•min<sup>-1</sup>•km<sup>-1</sup>) and oxygen deficit (OB:  $0.36 \pm 0.11$  cf. NW:  $0.20 \pm 0.06$  L) were significantly lower in the NW children (all  $P < 0.05$ ). During heavy intensity exercise, the  $\tau$  (OB:  $33 \pm 9$  cf. NW:  $27 \pm 6$  s;  $P < 0.05$ ) and phase II gain (OB:  $212 \pm 61$  cf. NW:  $163 \pm 23$  mL O<sub>2</sub>•min<sup>-1</sup>•km<sup>-1</sup>;  $P < 0.05$ ) were similarly lower in NW children. A slow component was observed in all participants during heavy intensity exercise but was not influenced by weight status. **Conclusion** This study demonstrates that weight status significantly influences the dynamic VO<sub>2</sub> response at the onset of treadmill exercise in pre-pubertal children and highlights that the deleterious effects of being obese are already manifest pre-puberty. 1. ### EXERCISE TRAINING PREVENTS RIGHT VENTRICULAR DYSFUNCTION AND MALADAPTIVE REMODELING IN EXPERIMENTAL PULMONARY ARTERIAL HYPERTENSION

Moreira-Gonçalves, D.1,2, Fonseca, H.2, Ferreira, R.3, Padrão, A.1,3, Vasques-Nóvoa, F.1, Gonçalves, N.1, Vieira, S.2, Moreno, N.1, Silva, A.F.1, Ferreira-Pinto, M.1, Schmidt, C.2, Bovolini, A.2

**Introduction:** Right ventricular failure (RVF) is the most common cause of death in patients with pulmonary arterial hypertension (PAH) (Bogaard et al., 2009). Growing evidences suggest that targeting RVF may be of benefit (Drake et al., 2011). Exercise training (ExT) is cardioprotective in left ventricular failure but its impact on RVF remains unknown. We investigated the effects of ExT on right ventricular response of rats submitted to monocrotaline (MCT)-induced PAH at several time points. **Methods:** Male Wistar rats were randomly divided in the following groups: i) sedentary injected with MCT (60 mg/kg, sc) or vehicle (SED+MCT and SED+Control), ii) 4 weeks-exercise training before MCT or vehicle injection (EXbefore+MCT and EXbefore+Control), iii) 4 weeks-exercise training after MCT or vehicle injection (EXafter+MCT and EXafter+Control) and iv) 2 weeks-exercise training after 2 weeks of MCT or vehicle injection (EXtreat+MCT and EXtreat+Control). After ending their respective protocols, animals were submitted to an exercise tolerance test and to RV echocardiographic (ECO) and hemodynamic evaluation. Samples from right ventricle and lungs were collected for histological, protein and RT-PCR analysis. **Results:** ExT improved exercise tolerance in all MCT-exercised groups. ECO revealed improved cardiac output in all MCT-exercised groups, but significantly only in EXbefore+MCT and EXafter+MCT. ExT protected against diastolic dysfunction and prevented RV maladaptive remodeling (normal SERCA2a protein levels, beta/alpha MHC isoform, ET-1 and VEGF mRNA). All MCT-exercised groups showed reduced cardiac fibrosis and inflammation. In contrast to SED+MCT, we found preserved activity and lower oxidative damage of the mitochondrial complex V. Survival rate was enhanced in all MCT-trained groups. **Discussion:** Our data suggest that ExT (performed at different time points of PAH-induced RV chronic pressure overload) averts cardiac dysfunction, modulates the main signaling pathways involved in RVF (Bogaard et al., 2009), and improves survival. These observations suggest that the exercise-induced benefits previously described in left ventricular failure (Conraads and Beckers, 2010) can be extended to RVF. **References** Bogaard HJ, Abe K, Vonk

#### NEUROMUSCULAR ELECTRICAL STIMULATION ATTENUATES MUSCLE ATROPHY DURING LEG IMMOBILISATION

Dirks, M.L., Wall, B.T., Sniijders, T., Verdijk, L.B., Van Loon, L.J.C.

*Maastricht University Medical Centre + (MUMC+)*

**Introduction** Short periods of bed-rest or immobilisation, due to illness or injury, result in substantial skeletal muscle atrophy. Recently we have shown that a single session of neuromuscular electrical stimulation (NMES) increases muscle protein synthesis rates. We hypothesized that daily NMES can be used as an effective interventional strategy to prevent muscle atrophy during a short period of muscle disuse. **Methods** Twenty-four healthy young ( $22.9 \pm 0.7$  y) males participated in the present study. Volunteers were subjected to 5 days of one-legged knee immobilisation by means of a full leg cast with (NMES group;  $n=12$ ) or without (CON group;  $n=12$ ) supervised NMES sessions (40 min sessions performed twice daily). Two days prior to and immediately after the immobilisation period, single slice CT-scans of the quadriceps, DXA-scans, and single leg 1-Repetition Maximum (1RM) strength tests were performed to assess muscle cross-sectional area (CSA), leg lean mass, and leg muscle strength, respectively. Furthermore, muscle biopsies were taken to assess muscle fibre cross-sectional area (CSA), muscle fibre type specific satellite cell (SC) content, and mRNA and protein expression of selected genes. **Results** In the CON group, immobilisation reduced quadriceps CSA by  $3.5 \pm 0.5\%$  ( $P < 0.0001$ ), leg lean mass by  $0.8 \pm 0.6\%$  (representing  $147 \pm 72$  g lean tissue loss;  $P = 0.07$ ) and muscle strength by  $9.0 \pm 2.2\%$  ( $P < 0.05$ ). In contrast, no significant muscle loss was detected during immobilisation in the NMES group in terms of either quadriceps CSA ( $-0.8 \pm 0.4\%$ ;  $P = 0.07$ ) or leg lean mass ( $+1.9 \pm 0.7\%$ ;  $P < 0.05$ ). Changes in type I or II muscle fibre size or SC content were not detectable in either group. Muscle MAFBx and MuRF1 mRNA expression were increased following immobilisation in the CON group only ( $+48\%$ ;  $P < 0.001$ , and  $+56\%$ ;  $P < 0.05$ , respectively) whereas expression levels either declined ( $-34\%$ ;  $P < 0.01$ ) or did not change in the NMES group, respectively. Immobilisation led to an increase in myostatin mRNA expression in the CON group ( $+68\%$ ,  $P < 0.05$ ) but remained unchanged in the NMES group. No significant changes in myostatin protein content were observed. Myogenin and MyoD mRNA expression increased over time ( $P < 0.05$ ) but only reached significance in the NMES group ( $P < 0.05$ ), while myogenin protein content was elevated in the NMES group only ( $P < 0.05$ ). **Discussion** In conclusion, NMES represents an effective interventional strategy to attenuate muscle mass loss during a short period of muscle disuse. We speculate that this is attributed to a combination of a stimulation of muscle protein synthesis, suppressed muscle protein breakdown and an increased potential for SC differentiation.

#### VASTUS LATERALIS FASCICLE BEHAVIOUR DURING ECCENTRIC CYCLING IN RELATION TO MUSCLE DAMAGE

Peñailillo, L., Blazevich, A., Nosaka, K.

*Edith Cowan University*

**Introduction** Eccentric exercise induces muscle damage, but confers a protective effect on subsequent bouts of the same or similar exercise (1). The mechanisms underpinning this protective effect are unclear. It is possible that muscle-tendon behaviour during exercise is not the same between the initial and secondary eccentric exercise bouts. B-mode ultrasound technique has been used to assess muscle-tendon behaviour in vivo during exercise (2). The present study used the ultrasound technique to compare between the first and second eccentric (ECC) cycling bouts for vastus lateralis (VL) fascicle behaviour in relation to muscle damage. **Methods** Eleven untrained men ( $27.1 \pm 7.0$  y) performed two bouts of ECC cycling (ECC1, ECC2) for 10 min (60 rpm) at 65% of the maximal concentric cycling power output ( $190.8 \pm 44.2$  W) separated by 2 weeks. Maximal voluntary isometric contraction strength of the knee extensors (MVC) and visual analogue scale (VAS) for muscle soreness were assessed before and 1-2 days post-exercise. An ultrasound probe was attached to the middle portion of the VL to record muscle movements during ECC cycling. Surface electromyogram (EMG) was recorded from the VL, and cycling torque and knee joint angle were measured during exercise. Three revolutions at 1 and 10 min of cycling were averaged for the fascicle behaviour, and 10 revolutions were averaged for peak EMG amplitude (EMGpeak). Fascicle length (Lf) and angle ( $\theta_{fas}$ ) were determined using the trigonometric method, and muscle-tendon unit (MTU) length and tendinous tissue (TT) length were estimated (2). Changes in these variables were compared between ECC1 and ECC2 by two-way repeated measures ANOVAs and paired t-tests. **Results** Peak VAS was greater ( $P = 0.000$ ) after ECC1 ( $32.3 \pm 23.5$  mm) than ECC2 ( $8.0 \pm 9.0$  mm), but decreases in MVC (e.g. 8% at 1 day post-exercise) were not significantly different between bouts. Peak torque was consistent for 10 min, and was not different between bouts. EMGpeak did not change significantly over time and was not different between bouts. The magnitude of fascicle elongation during ECC2 was  $19.2 \pm 30.1$  mm smaller than that of ECC1 at 1 min ( $P = 0.03$ ), but this was not the case at 10 min.  $\theta_{fas}$  did not change significantly over time and was not different between bouts. MTU length changes were not different between bouts, but the Lf changes were 3.2% smaller ( $P = 0.036$ ), and TT changes were 6.1% greater ( $P = 0.07$ ) relative to the MTU length changes during ECC2 compared with ECC1 at 1 min. **Discussion** These results indicate that fascicles were lengthened less during ECC2 than ECC1, and elongation of TT tended to be greater during ECC2 than ECC1 for the same MTU length changes. It seems that less fascicle strain was imposed during ECC2 than ECC1, which could be related to the less muscle soreness after ECC2 and one of the mechanisms of the protective effect. **References** 1) McHugh (2003) *Scand J Med Sci Sports* 13:88-97 2) Finni et al. ## ARCHITECTURAL AND MORPHOLOGICAL ADAPTATIONS TO ECCENTRIC VS. CONCENTRIC CONTRACTIONS: POSSIBLE UNDERLYING MECHANICAL AND BIOCHEMICAL MECHANISMS

Franchi, M.V., Atherton, P.J., Reeves, N.D., Flück, M., Mitchell, W.K., Selby, A., Beltran-Valls, M.R., Narici, M.V.

*University of Nottingham*

**Introduction** We investigated the architectural, functional, and molecular responses of human skeletal muscle to concentric (CON) or eccentric (ECC) training protocols, performed on a leg-press machine. **Methods** 12 male volunteers were randomly assigned to two different groups performing either a CON or ECC training regime (3xwk for 10-wk, 4x8-10 repetitions at 80% of CON and ECC 1-RM). MR imaging was used to evaluate muscle volume and anatomical cross-sectional area was measured in the proximal, mid and distal portions of the VL. Ultrasound was used to determine muscle architecture (fascicle length, Lf; pennation angle, PA). An additional fourteen male subjects performed a single bout of CON or ECC exercise for determining acute molecular signalling responses (in biopsies taken from VL 30 min after a bout of CON or ECC). This post-exercise biopsy time-point was chosen to gauge 'remodelling pathways' (i.e. MAP Kinases), inflammation (TNF-signaling), anabolism (mTORC1) and catabolism (MuRF-1/MAFBx). The MAPKs were of particular interest since previous works suggested that molecular programs of ECC vs. CON signaling and growth are distinct [1, 2]. Immuno-blotting was used to assess phosphorylation/ abundance of signaling targets. Results Changes in muscle Vol (+8 CON vs. +6% ECC) and maximal voluntary contraction (MVC) (+9 CON vs. +11 % ECC) were similar in both groups. Lf increased significantly after ECC but not CON (+12 vs. +5%) and PA increased markedly after CON (+30 vs. +5%). Hypertrophy in the distal and mid part of the VL was different between the groups (CON +2 vs. ECC +8%; ECC +7 vs. CON +11%, respectively). **Discussion** In terms of whole-muscle hypertrophy, despite the ~1.2 fold greater training load of the ECC group, similar increases in VOL and MVC in were found after training. However, distinct architectural changes were found between the two loading regimes: increases in Lf were greater after ECC than CON while in contrast, PA increased more in CON vs. ECC. These adaptations (in accordance with [3]) reflected differences in fascicle behaviour in the two contraction modes, (i.e., lengthening in ECC vs. shortening CON). When examining regional hypertrophy, the changes in architecture induced by the two regimes induced preferential growth in the distal region of VL for ECC while for CON, VL growth occurred mainly at mid-belly. In terms of signaling, while MAPK activation (i.e., p38MAPK, ERK1/2, p90RSK) was exclusive to ECC, neither mode affected AKT-mTOR or inflammatory signaling. To conclude, hypertrophy in response to CON vs. ECC yields distinct architectural and regional adaptations, rather than in whole-muscle growth (despite the greater loading intensity of ECC protocol). These morphologic and architectural changes to ECC vs. CON were associated with discrete acute fascicle behaviour, which we speculate to underlie the preferential activation of MAPK signaling, and perhaps the ensuing distinct muscle adaptations. **References** 1- Kehat et al. *Circ Res*, 2011 2- Wretman et al. *J Physiol*, 2001 3- Reeves et al. *Exp Physiol*, 2009

## THERMOREGULATORY RESPONSES OF ATHLETES WITH A SPINAL CORD INJURY DURING INTERMITTENT WHEELCHAIR EXERCISE IN COOL CONDITIONS

Griggs, K., Leicht, C., Price, M., Goosey-Tolfrey, V.

*Loughborough University*

**Introduction:** Individuals with a spinal cord injury (SCI) have impaired thermoregulatory control, resulting in a loss or reduction in sweating capacity and an inability to make effective vasomotor adjustments. Individuals with high level cervical lesions (tetraplegia, TP) possess a greater impairment in thermoregulatory control than individuals with lower level lesions (paraplegia, PA). Although the thermoregulatory responses of athletes with SCI have been reported, no data has compared the responses of athletes with TP and PA during an intermittent sprint protocol (ISP). The purpose of this study was to investigate the thermoregulatory responses of athletes with TP and PA during intermittent wheelchair exercise and recovery. **Methods:** Eight wheelchair rugby players with TP (lesion level C4/5-C6/7, body mass  $65.2 \pm 4.4$  kg,  $VO_{2peak}$   $1.55 \pm 0.37$  L.min<sup>-1</sup>) and eight wheelchair basketball players with PA (lesion level T4-S1, body mass  $68.1 \pm 12.3$  kg,  $VO_{2peak}$   $1.92 \pm 0.47$  L.min<sup>-1</sup>) completed a 60 min ISP at maximal effort on a wheelchair ergometer, followed by 15 min of passive recovery in cool ambient conditions ( $20.6 \pm 0.1^{\circ}\text{C}$  and  $39.6 \pm 0.8\%$  relative humidity). Core temperature (T<sub>core</sub>, telemetry pill), mean (T<sub>sk</sub>) and individual skin temperatures were measured throughout. Heat storage (HS) was calculated every 15 mins. **Results:** Sprint speed ( $3.16 \pm 0.59$  m/s and  $3.51 \pm 0.44$  m/s for athletes with TP and PA, respectively) was similar between groups. There were larger increases in T<sub>core</sub> and T<sub>sk</sub> for athletes with TP compared to athletes with PA during exercise and recovery ( $p < 0.05$ ). Back, chest, lower arm and forehead skin temperatures all increased during recovery in athletes with TP compared to a decrease in athletes with PA ( $p < 0.05$ ). Heat storage was higher in athletes in TP ( $p < 0.05$ ), with end of recovery values of  $3.42 \pm 1.42$  J.g<sup>-1</sup> and  $-0.51 \pm 1.30$  J.g<sup>-1</sup> for athletes with TP and PA, respectively. **Discussion:** The results of this study show that athletes with TP experienced a greater increase in T<sub>core</sub> and T<sub>sk</sub> in comparison to athletes with PA. Although only exercising in cool conditions, this suggests athletes with TP have a greater inability to dissipate heat than athletes with PA during intermittent sprint exercise and recovery, possibly due to the greater loss of sweating capacity. This is also reflected by the gain in HS for athletes with TP and the net loss for athletes with PA by the end of the recovery period.

## THE ROLE OF THERMAL AND TOUCH SENSE IN THE PERCEPTION OF SKIN WETNESS AT REST AND DURING EXERCISE IN DIFFERENT ENVIRONMENTS

Filingeri, D.1, Redortier, B.2, Hodder, S.1, Havenith, G.1

1: *Loughborough University (Loughborough, UK)*, 2: *Oxylane Research, (Villeneuve d'Ascq, France)*

**Introduction** The type and amount of physical activity an individual performs is influenced by the level of comfort achievable with the surrounding environment (Vanos et al., 2012). Skin wetness has been shown to be a critical determinant of thermal and clothing comfort (Fukazawa et al., 2009). Clarifying the neurophysiological bases of wetness perception (WP) is critical to improve sporting garments' design and thus comfort. WP seems to result from the integration of temperature (cold) and mechanical (pressure) inputs. The aim of this study was to investigate the role of thermal and touch sense in the WP. **Methods** Six cold-dry stimuli [3 temperatures (4, 8, 15°C lower than local skin temperature) X 2 pressures (7 and 10 kPa)] were applied (10 sec) on the bare, upper and lower back of 11 (8F/3M) participants using a thermal probe (contact surface: 25cm<sup>2</sup>), during 5 experimental conditions: rest 22°C; rest 33°C; low intensity cycling (30W) 22°C; moderate intensity cycling (60W) 22°C; moderate intensity cycling 33°C. No information about the stimuli was given to participants. Mean and local skin temperature, thermal, wetness and pleasantness sensations (perceptual scales) were recorded. **Results** Different cold-dry stimuli produced significantly different ( $P < 0.05$ ) levels of local skin cooling (range: -0.7 to -4°C). Cold-dry stimuli were reported as wet at least once by 9 out of 11 participants. Stimuli applied with a mechanical pressure of 7 kPa, producing a skin cooling rate of 0.36°C/s, induced the most frequent (59.7% of times) cold-wet sensations. When applied with a pressure of 10 kPa, they were less often

(45.8% of times) perceived as cold-wet ( $P=0.09$ ). No effect of conditions was observed on WP. Same cold-dry stimuli produced displeasure during resting at 22°C and pleasure during exercise at 33°C. Discussion Cold sensations play a primary role in characterizing the WP. The touch sense interacts in the perception of cold-dryness/wetness, with greater pressures decreasing WP. Daanen (2009) proposes 0.05°C/s to 0.2°C/s as the cooling rate evoking WP when water evaporates from the skin. We observed a greater cooling rate (0.36°C/s) for WP resulting from contact with a cold-dry surface. Thus, sensory integration seems to vary according to the type of cooling (evaporative vs. direct contact). No effect of conditions was observed, suggesting the level of skin cooling and mechanical pressure as critical determinants of WP. References Daanen, H. (2009). #### IS-BN05 Specificity in strength training in elite sport \*

##### SPECIFICITY IN STRENGTH TRAINING NEEDS TO FOLLOW THE PRINCIPLE OF COORDINATIVE AFFINITY

Müller, E.

*University of Salzburg*

In elite sports the quality of conditioning training can be improved, above all, by using special technique-specific exercises. Numerous studies prove that the training of general conditioning leads to considerable improvements of particular physical parameters. However, training of this kind hardly succeeds in increasing competitive capacity. On the other hand, it could be shown in many cases that the use of technique-specific means of training - parallel to general conditioning training - leads to considerable improvements of performance also among athletes with many years of training experience (Manolopoulos et al., 2006; Manuel et al., 2010; C. Hrysomallis 2012; Mueller et al. 2000). Consequently, it is important to direct one's attention to the development of highly specific means of training. This applies chiefly to so-called seasonal sports such as alpine ski racing. For the development of specific training exercises the principle of kinematic and kinetic correspondence has to be taken into consideration. This principle states that the special exercises must be in harmony with those parameters of movement which characterise the structure of competition technique. A coordinative affinity between training and competition exercises has the advantage that it results in favourable training stimuli in the musculature relevant to the specific movement. It has the further advantage that the specific neuronal mechanisms are developed, which improve the strength usability in concrete execution of movement, as defined by the technique-specific muscle innervation schema. Sport biomechanics deals with the development of sport specific training devices and exercises. The necessity of using highly specific means of training mainly applies to what are called seasonal sports such as alpine ski racing. Ski racing is one of those sports which makes high demands on technical and physical abilities. This is made even more difficult by the fact that technique-specific training can only be performed on snow which is difficult to execute during the summer season. Therefore the use of exercises which imitate the racing technique on snow is very important during the preparation period in summer. In various studies we were able to develop training devices which make the performance of skiing specific exercises possible. Using biomechanical methods we were able to prove that these exercises come very close to the kinetic and kinematic structure of the racing techniques on snow.

##### DANGEROUS LIAISONS OF STRENGTH AND ENDURANCE TRAINING. CAN BE MINIMIZED?

Izquierdo, M.

*Public University of Navarra*

Different studies have found compromised adaptation of strength, especially muscle power, when both strength and endurance were trained at the same time. Several strategies or mechanisms have proven effective in reducing the interference phenomenon of concurrent strength and endurance training as follows (1-4):

- Short training phases (5 weeks) using highly concentrated training loads (>50% of the total training volume) and which focus on the development of only two target fitness components in each training phase (i.e. one for strength and another for endurance), result in a more effective training stimulus for the improvement of performance in highly trained athletes when compared with a more traditional training periodization approach (2).
- Avoidance of the simultaneous development of muscle hypertrophy (8–10 RM) and aerobic power can reduce the interference phenomenon due to both training intensities inducing opposite adaptations on the same peripheral components. In contrast, due to the compatible training-induced adaptations associated with strength and power and aerobic power, as well as the compatible effects of development of maximal aerobic power, muscle hypertrophy and strength and power stimulus, no interference effects should be expected during the concurrent development of these fitness components (4).
- The residual fatigue caused by a previous endurance session could reduce and/or impair the quantity and quality of subsequent strength training sessions. For highly trained athletes, the strength training sessions should be placed before the endurance sessions, or at least separating both types of training sessions by more than 8 hours. Performing extra endurance training sessions at submaximal intensities that involve mainly non-specific muscle groups, may allow high-level athletes to achieve muscle peripheral adaptations, while the specific muscle groups recover for subsequent sessions of greater intensity (1,3).
- The training to repetition failure approach should be avoided in athletes at any performance level. A concurrent strength and endurance training program using a moderate number of repetitions for not to repetition failure training provides a favorable environment for achieving greater enhancements in strength, muscle power and specific performance when compared with higher training volumes of repetition to failure. The training for the not to repetition failure approach speeds up recovery from strength training, allowing rowers and paddlers to perform subsequent endurance training sessions of higher quality (3).

**IS IT GOOD TO TRAIN TO FAILURE IN ELITE SPORTS?**

Gorostiaga, E.

*Studies, Research and Sport Medicine Center, Government of Navarra*

The high-intensity dynamic resistance training method in which subjects perform repetitions to muscle failure is very popular among professionals who prescribe exercise and is recommended as the main method for optimal strength gains by several scientific associations. However, the question of which of the two training stimuli (failure vs. non-failure) is the most effective for exercise prescription and optimal strength and power gains has not yet been resolved. We have found that 5 sets of 10 repetitions to failure of bilateral leg press exercise interspersed by 2 min resting pauses demanded a maximal effort and caused a disruption of cellular homeostasis, as reflected by a marked decrease in power output, a state of energy deficiency and a decline in skeletal muscle phosphate potential. However, when the number of repetitions in each set was reduced by 50%, a much lower decrease in muscle PCr content (~15% vs. 80% decline) was observed, with only modest increases in muscle lactate and no measurable changes in muscle levels of ATP and IMP. This was associated with no changes in peak power output throughout the exercise sets while ATP synthesis matched ATP utilization and energy balance and cellular homeostasis were maintained. In the last 15 years several studies have found contradictory results comparing training that leads to repetition failure vs non-failure in untrained and trained subjects performing isometric or dynamic contractions with the upper or lower extremities. Some studies have compared the effects of 8 to 16 weeks of dynamic high resistance training to failure vs. non-failure in the knee extensor movement in untrained recreational weight trainers and top level male subjects. Their results indicate that high-intensity resistance training not to failure enables a favorable environment for achieving greater enhancements in maximal strength or power and muscle power output of the knee extensors when compared to a training to failure approach. The lower degree of fatigue incurred and the higher average movement velocities developed may explain the superior adaptations in strength and power gains observed in the non-failure compared to the training to failure group. These results suggest that in order to improve performance in the majority of activities with great demands of muscle strength and power of the lower extremities, a program of dynamic resistance exercise which minimizes fatigue and discomfort and is characterized by not training to repetition failure, low metabolite accumulation and excellent energy balance and cellular homeostasis, may be a more effective, efficient and safe option compared with training designed to maximize fatigue or metabolite accumulation.

**15:00 - 16:30****Oral presentations****OP-PM30 Physiology [PH] 7****HEAVY-INTENSITY INTERVAL TRAINING INCREASES CIRCULATING PROGENITOR CELL MOBILISATION BUT REDUCES FLOW-MEDIATED DILATION IN OVERWEIGHT/OBESE WOMEN**

Harris, E., Weeks, A., Birk, G., Khalil, A., Ferguson, C., Lawton, C., Dye, L., Birch, K.M.

*University of Leeds*

Introduction Interval exercise training (INT) is reported to exert greater benefits to cardiovascular (CV) health than continuous exercise training (CON; 1,2). However, in previous studies the exercise intensity domain of INT and CON have not been confirmed. Thus, it is unknown whether these benefits would occur if both groups exercised in the same intensity domain. Therefore, we compared the effects of intensity and work matched INT and CON in a population at risk of CV disease on endothelial function and circulating progenitor cells (CPCs; markers of endothelial repair). Methods 20 sedentary overweight/obese women (age 42±3 yrs, BMI 31.9±3.6 kg/m<sup>2</sup>) completed 12 weeks of either INT (n=10) or CON (n=10) on a cycle ergometer, twice/week. Exercise sessions were performed in the heavy-intensity domain and both groups were matched for work by adjusting the CON session duration. Brachial artery flow-mediated dilation (FMD), shear rate area under the curve for 60s from cuff release (AUC60) and double positive (CD45dimCD34+) and triple positive (CD45dimCD34+KDR+) CPCs were assessed pre and post-training. Results Following INT, FMD significantly reduced (pre 0.28±0.09mm, post 0.21±0.07mm) whereas CON had little effect (pre 0.25±0.1mm, post 0.24±0.1mm; group x time interaction p=0.05). Although not significant (p>0.05), resting brachial artery diameter increased with INT (pre 3.40±0.7mm, post 3.49±0.63mm) but did not change with CON (pre 3.43±0.49mm, post 3.44±0.56mm). Shear rate AUC60 reduced with INT (pre 40698±14395a.u, post 29709±11103a.u) whereas CON had little effect (pre 35921±12231a.u, post 35636±15245a.u; group x time interaction p=0.05). CD45dimCD34+ CPCs increased post INT (pre 6±3 /100000 leukocytes, post 11±6 /100000 leukocytes) with no change post CON (pre 12±6 /100000 leukocytes, post 10±3 /100000 leukocytes; group x time interaction p=0.03). Training had no effect on triple positive CPCs (p>0.05). Discussion INT was a potent stimulus for initiating change in vascular health in overweight/obese women, whereas CON had little effect. The reduction in FMD following INT may be explained by the reduction in post cuff release shear rate or remodelling of the brachial artery. The increase in double positive CPCs suggests an increase in the capacity for vascular repair following INT. Since training groups were matched for work and exercise intensity, the mechanisms involved in the potential superior benefits of INT are yet to be elucidated, but may involve the repeated increments in shear stress brought about by the work-rate oscillations. **EFFECT OF 60 MINUTES INTERMITTENT HYPOXIC EXPOSURE SESSION ON OXYGEN UPTAKE KINETICS IN HEAVY INTENSITY CYCLING EXERCISE**

Minhalma, R.1, Beckert, J.2, Alves, F.1

*1: CIPER, FMH, UTL (Lisboa, Portugal), 2: CEDOC, FCM, UNL (Lisboa, Portugal)*

INTRODUCTION Passive exposures to hypoxia interspersed with training bouts in normoxia is a model known as intermittent hypoxic exposure (IHE). However the effects of normobaric hypoxic exposure in subsequent exercise remain unclear. The aim of this study was to test the hypothesis that a previous IHE would be associated with an increase in the slow component of oxygen uptake kinetics (VO<sub>2</sub>K) while performing heavy intensity cycling. METHODS Eight triathletes (37+7,8 yrs, 71,5+5,5Kg, 179+5,3cm) performed a pre-post controlled

trial in two different conditions, the first condition implies the realization of a hypoxic treatment corresponding to a 11.7% FIO<sub>2</sub> (i.e. 4500m) and the second condition a placebo treatment in normoxia. The subjects perform four square wave transitions at 40%Δ (heavy domain) determined after a maximal incremental test, two before the IHE and two after the IHE, with 45 minutes of passive rest, according to Burnley et al. 2006. VO<sub>2</sub>K was estimated using a double exponential regression mathematical model. Amplitudes for exponential terms (A1 and A2), time delays (td1 and td2), and time constants (T1 and T2) were assessed, each one representing the fast(1) and slow(2) components of VO<sub>2</sub>K. Significance was set at p≤0.05. RESULTS A2 and T2 increased in exercise after IHE exposure, by 3 ml/m and 180s, respectively, when compared to pre exposure values. In this condition there was no significant effect on the A1, td1 and the T1 of the first component. In contrast, in the exercise after normoxic exposure, the A1 decreased 2,7ml and T1 also decreased by 3s with no change in the second component parameters. DISCUSSION The reduction in VO<sub>2</sub> cost expressed by a lower A1, concomitant with the decrease in the slow component, after normoxic exposure, may be due to the priming exercise effect (Burnley et al. 2006). However in post-hypoxic heavy exercise conditions, this effect seems to be overridden by factors yet to identify, These results indicate that there must be an additional effort to monitor and control the influence of acute hypoxic exposure on immediate subsequent tolerance to exercise and performance. ### EFFECT OF SPRINT TRAINING: TRAINING ONCE A DAY VS. TWICE A DAY UNDER CONDITION WITH SAME TRAINING VOLUME

Ijichi, T., Hasegawa, Y., Morishima, T., Sasaki, H., Kageta, T., Mori, A., Goto, T.

*Ritsumeikan University*

Introduction Endurance training twice every second day demonstrated greater increases in endurance capacity and muscle glycogen level when compared with equivalent training once daily (Hansen et al., 2005). The authors suggested that lower muscle glycogen level during second bout of training session in a same day would be involved with augmented muscle adaptation. However no information is available whether similar adaptation will occur in high-intensity sprint training program. Therefore, the present study compared effects of sprint training between "training once a day" and "training twice a day" under condition with equivalent total number of training session. Method Twenty healthy men were assigned to either training once a day group (SINGLE) or training twice a day group (REPEATED). The SINGLE conducted sprint training session once a day (5 days / wk). The REPEATED conducted two bouts of training session in a same day, separated with rest period of 1 hour (2-3 days / wk). Each training session consisted of three consecutive 30s maximal pedaling with 10 minute rest between sets. The training was maintained for 4 wk, and the total number of training session (20 sessions) was equivalent between the groups. Before and after training period, two bouts of 30s maximal pedaling test, VO<sub>2</sub>max and blood lactate kinetic test were performed. Result Both groups showed significant increases in peak and mean power output during repeated two bouts of 30s maximal pedaling (P < 0.05). In particular, mean power output during second bout was improved dramatically in both groups, but the effect was significantly greater in the REPEATED than in the SINGLE (P < 0.05). The result from VO<sub>2</sub>max test showed similar increases in VO<sub>2</sub>max and time to exhaustion in both groups (P < 0.05). However, the REPEATED increased significantly onset of blood lactate accumulation (OBLA) whereas no change was observed in the SINGLE. Discussion In the present study, peak and mean power output during two bouts of 30s maximal pedaling increased in both groups. Greater improvement of attenuated power output during second bout of pedaling was found in the REPEATED. Also, the REPEATED showed a significant increase in OBLA after the training period. A possible reason for augmented training adaptation in the REPEATED may be enhanced lactate metabolism capacity during the repeated two bouts of maximal pedaling. Conclusion These results indicate that sprint training "twice a day" enhances consecutive 30s maximal pedaling performance and lactate metabolism when compared with "training once a day" consisting of equivalent number of training session and training period. ### SHORT DURATION HIGH INTENSITY/LOW VOLUME RESISTANCE TRAINING HAS A SUPERIMPOSABLE EFFECT ON AKT, 4EBP1 AND S6 COMPARED TO A MORE TIME COMMITMENT LOW INTENSITY/HIGH VOLUME RESISTANCE

Paoli, A.1,2, Moro, T.1, Blaaw, B.1, Sabbadin, M.2

*1:Dept. Biomedical Sciences (University of Padova, Italy) 2: Human Movement Sciences School (University of Padova, Italy)*

Introduction Resistance training (RT) affects anabolic signalling molecule phosphorylation but, considering the numerous variables of RT, the differences between training modalities has been yet poorly investigated. We aimed to determine if any differences exist between an high-intensity resistance training (HIRT) technique and a traditional resistance training (TRT) on Akt, 4EBP1 and S6 signalling pathway. Methods 12 healthy and physically active subjects (ages 21,92±1.16 yrs, BMI 22,85±2,24) performed in two different moments and with different legs HIRT and TRT. HIRT consisted in 2 sets at the leg extension performed with the following technique: 6 repetitions, 20 seconds rest, 2/3 repetitions, 20 secs rest, 2/3 repetitions with 2 min 30secs rest between the sets. TRT consisted of 4 sets of 15 repetitions with 1 min 15 secs of rests between the sets. Biopsies from the vastus lateralis were taken one week before training (T<sub>0</sub>) sessions, immediately after training (T<sub>0</sub>), 6 hours after (T<sub>6</sub>) and 24 hours after (T<sub>24</sub>). Western blot analysis to examine anabolic signalling molecule phosphorylation was performed on Akt, 4EBP1 and S6. Results No significant differences was not found at any of time points after exercise in AKT and 4EBP1 phosphorylation. There was a significant increase in S6 phosphorylation at T<sub>6</sub> both in HIRT and TRT. S6-P remained at higher level even at T<sub>24</sub>. Discussion Our findings suggest that a less time commitment resistance training technique is, at least, equally effective to induce an increase in S6-P. The increase of the phosphorylated form of S6 without a concomitant increase of AKT-P could be explained with the different biopsies timing (after 6 hours in our experiment, after 1, 2 hours in other researches)3,4 or with an AKT-independent S6 phosphorylation5,6. **NONINVASIVE EVALUATION OF MUSCLE OXYGEN SATURATION DURING HIGH-INTENSITY CONSTANT LOAD CYCLING.**

Van Beekvelt, M., Rasdal, V., Skovereng, K.

*Norwegian University of Science and Technology (NTNU)*

Introduction Near-infrared spectroscopy (NIRS) is a noninvasive optical method that enables us to measure changes in oxygenation and hemodynamics in a continuous manner directly within the muscle. More recently, the development of the equipment has enabled us to measure a quantitative measure for (muscle) tissue oxygen saturation. In this study, NIRS was used to investigate the relationship between the individual maximum desaturation level that can be obtained by a vascular occlusion during rest and the desaturation levels that occur during prolonged high intensity work. Methods Eight healthy subjects performed a maximum desaturation test followed by a 30-min constant load cycling test. Cycling was done on an electro-magnetically braked cycle ergometer at 75% of maximum aerobic power (MAP). Near-infrared spectroscopy (NIRS) was used to define the maximum desaturation level of the vastus lateralis muscle (VM) for each individual, by application of a vascular occlusion (280 mmHg; 10 min) while seated in a comfortable semi-supine position. During cycling, NIRS, oxygen consumption (VO<sub>2</sub>) and heart rate (HR) were measured continuously, while blood lactate levels ([La-]b) were measured every 5 minutes. Results Preliminary results show baseline VL muscle saturation levels of  $69.9 \pm 6.8$  % (range: 61.3-80.2%). Maximum desaturation after 10 minutes of occlusion was  $19.5 \pm 13.7$  % (range: 2.9-41.7%). Delta desaturation was  $50.5 \pm 15.6$  % (range: 27.1-73.4%). At the start of exercise, tissue saturation levels were back to baseline values ( $69.3 \pm 7.3$  %, range: 55.8-79.6%), while at the end of 30 minutes high intensity cycling, tissue saturation reached a minimum of  $41.8 \pm 14.5$  % (range: 16.2-59.1%), though values decreased to  $19.2 \pm 5.6$  % (range: 13.5-27.4%) during 20 s of occlusion 1 min prior to the end of cycling. Discussion/Conclusion Although prolonged fatiguing high intensity exercise did not fully deplete muscle oxygen stores, short-duration occlusion (10 s) seemed to deplete muscle O<sub>2</sub> levels to a functional minimum, equal to the maximum desaturation attained under resting conditions. Variability in the response to both 10 min of occlusion and 30 min of high intensity cycling exercise seemed primarily due to inter-subject differences. Further analysis of the data might reveal a relationship between tissue saturation response and systemic changes in pulmonary O<sub>2</sub> uptake, heart rate and/or lactate levels.

**ARE THE MOOD CHANGES DURING HIGH-INTENSITY INTERVAL TRAINING RELATED TO CHANGES IN AEROBIC CAPACITY?**

Saarijoki, T.1, Hannukainen, J.1, Eskelinen, J.J.1, Savolainen, A.1, Heinonen, I.1, Virtanen, K.1, Kemppainen, J.1, Kapanen, J.1, Knutti, J.1, Nummenmaa, L.2, Kalliokoski, K.K.1

*1) University of Turku, Finland, 2) Aalto University, Helsinki, Finland*

Introduction High-intensity interval training (HIT) is a time-efficient strategy for promotion of health by physical exercise. This type of training is mentally rather demanding and may cause changes in mood which may be related to the outcome of the training. Accordingly, we investigated the effects of two weeks of high-intensity interval training on different mood parameters and their relation into the changes in aerobic fitness. Methods Twenty six sedentary middle-aged men (age:  $47 \pm 5$  years, BMI:  $26.0 \pm 2.6$ , VO<sub>2</sub>max:  $33.9 \pm 4.2$  mL/kg/min) were recruited into the study. They were randomly divided to train six sessions within two weeks in HIT group (n=13, training: 4-6 x 30 s / 4 min) and aerobic exercise training (AET) group (n=13, 40-60 min at 60 % VO<sub>2</sub>max). During the exercise subjective exertion was assessed using the Borg's Rating of Perceived Exertion (RPE) scale and perceived pleasure and arousal were assessed using The Self-Assessment Manikin (SAM) rating scale. Participants' mood ratings were recorded on the Finnish version of the Perceived Stress Questionnaire and the Positive and Negative Affect Schedule (PANAS) and a visual analog scale (VAS) prior to and immediately after each training session. One subject from both groups abandoned the study due to personal reasons. Results VO<sub>2</sub>max increased significantly and similarly between the groups (HIT: 6.2 % and AET: 4.1 %). Subjective exertion and agitation during training sessions increased significantly more in HIT than in AET group (P<0.05), but subjective pleasantness changed similarly in both groups. Relative to the AET group, the HIT group reported after the training sessions higher levels of perceived stress, decreased positive affect, significantly more depression, exhaustion, uptightness, and irritation (all P<0.01) and less motivation (P<0.05). However, both groups were similarly more satisfied after the training sessions (P<0.05) and satisfaction even improved during the training period (P<0.05). In the HIT group the changes in VO<sub>2</sub>max correlated negatively with the changes in exhaustion (r=-0.78, p=0.002) and uptightness (r=-0.81, p=0.001) and positively with the changes in satisfaction (r=0.62, p=0.03). Discussion These findings show that HIT is emotionally much more demanding than AET. Interestingly, despite of that, subjects in HIT group were similarly more satisfied after the training sessions than subjects in AET and both groups become more satisfied during the whole training period. Relatively strong correlation findings suggest that training success may be more related to mood changes than previously anticipated.

**15:00 - 16:30****Invited symposia****IS-SH01 Understanding sport participation in Europe \*****SPORT PARTICIPATION IN FINLAND – SOCIOLOGICAL INTERPRETATIONS**

Vehmas, H.

*University of Jyväskylä*

Sport participation is an important part of today's societies for various reasons. Firstly, sport participation is inseparably linked with contemporary citizens' health conditions. Secondly, participation functions as an important tool for socialization at various forms and levels. Thirdly, as one of the most frequently practiced leisure activities worldwide sport participation has several economic implications for creating employment and other forms of economic opportunities, both locally and globally. Sport participation varies from country to country, and even within one nation there are sometimes clear differences in the frequencies, intensities and forms of participation. For example Finland has had among the highest levels of participation in Europe over the years, whereas in South-East Europe participation

rates have generally been lower. At the same time some countries, for example Switzerland, show great regional differences in participation. The aim of this presentation is to outline a theoretical basis for sociological explanations that would contribute to understanding more precisely what factors and reasons seem to explain high participation levels in Finland. It is suggested that this way both national and comparative data could be used more effectively for sport participation and wellbeing promotion purposes in different countries. For this purpose Bourdieu's construction of habitus serves as an applicable theoretical basis. Sport participation is a construction of the individual action, structural determinants, cultural meanings and societal functions. For the sporting habitus formation data collection needs to be made about the definitions, perceptions and motives of sport participation; the roles of public, commercial and non-profit sectors in creating preconditions for participation; and about the historical, cultural and societal characteristics of sporting nations in question.

### **SPORT PARTICIPATION AND CULTURAL CHANGE. A COMPARATIVE ANALYSIS FOR SOME EUROPEAN COUNTRIES**

Llopis-Goig, R.

*University of Valencia*

**Introduction** Although in recent decades there has been a general increase in sports practice and a growing expansion of different sport facilities, the sport participation rates of the European population still differ considerably between countries, as several surveys have shown, specially the 2004 Eurobarometer 62.0 and the 2009 Eurobarometer 72.3. While Northern and Western Europeans generally have higher participation rates, in Southern and Eastern Europe sport participation has remained at lower levels. Given that since the ratification of the European Sport for All Charter (Council of Europe, 1975) policymakers have striven to provide wide access to sport for everyone across Europe, the persistence of these differences is a challenge to Social Sciences. Why do these differences between countries remain? Why are there such large differences in the sport participation rates of certain social groups? Following the framework of Inglehart and Welzel (2005), this communication suggests that the persistence of these differences cannot solely be explained by economic or sport policy related factors, and it provides some hypotheses about cultural influences that could be involved. **Methods** The analysis is based on data from the 'Leisure Time and Sport' module, collected within the International Social Survey Programme (ISSP) in 2007. This module was developed between 2003 and 2006 and fielded in 36 countries, of which 22 are European countries. This ISSP-survey is the first systematic world-wide comparative survey on the topic, and it contains questions on leisure time and sport activities, the gratification individuals get from them, and related personal items such as weight, subjective health and happiness. **Results** The results are presented in three steps. First, differences among countries on the main sport participation indicator are analysed. Second, further analyses of differences are carried out for certain groups (women, elderly people...). Third, all of these differences are analysed in relation to the socioeconomic development level of each country (level of industrialization, share of workforce in the industry...) and some cultural factors (cultural tradition, religion, individualism orientations). To do this, several bivariable and multivariable statistical analyses are performed. Analyses are conducted country by country and also through clustering in homogeneous groups. **Discussion** The analysis showed large differences between European countries, with these differences being greater in the case of some specific social groups. On the other hand, the regression analysis confirmed the importance of cultural variables in differences in sport participation among European countries. The communication will provide some theoretical reflections on the importance of these findings. **References** Council of Europe (1975): The European Sport for All Charter. ### **UNDERSTANDING DIFFERENCES IN SPORT PARTICIPATION AND PHYSICAL ACTIVITY IN EUROPE**

Breedveld, K.

*Mulier Institute*

Over the years, in most Western countries, participation in sports and physical activity has grown considerably. Yet, policy makers all over the world continue to struggle with the same issues. Despite a general growth in participation levels, low SES-groups continue to lack behind when it comes to participation in either sports, PA or indeed many other social fields (like e.g. culture). This paper goes into the determinants of that social-inequality, particularly in sports and in PA, but also looking at other fields like culture, politics and volunteering. From these, we look for factors, motivations and barriers that occur in all the fields, pointing to a common overarching theme. From this, the paper aims at shedding light on the question on how to combat social-inequality in sports and PA, or perhaps on whether we can even expect this gap to be closed. In so doing we will explore the concept of life-style, both as a means for changing behaviour and as a factor explaining why behaviours are often very reluctant to change, and very likely to remain different between social groups.

#### **A CRITICAL PEDAGOGY FOR SCHOOL PHYSICAL EDUCATION: PROSPECTS FOR CHANGE**

MacPhail, A.

*University of Limerick*

This presentation focuses on the related aspects of (1) an equitable, culturally-relevant education for all students, (2) the ways in which teachers can build a consensus among their students of the necessary behaviors for building and maintaining a productive class environment, and (3) the consideration of prejudices and bias. These aspects, related to a caring pedagogy (Noddings, 1992), equity pedagogy (McGee-Banks & Banks, 1995) and critical pedagogy (Giroux, 1988), are essential before a teacher can effectively encourage pupils to consider involvement in a learning community that share similar values and are committed to each other's learning, growth and welfare. Caring and culturally relevant pedagogies are discussed with respect to providing culturally-relevant and equitable curriculum in

school physical education. Building and sustaining (student) learning communities (Brophy, 2012) in school physical education is explored as a way in which to encourage school physical education changes in practices informed by students.

### **A CRITICAL PEDAGOGY FOR PETE: PROSPECTS FOR CHANGE**

Martínez Alvarez, L.  
*University of Valladolid*

Critical Pedagogy (CP) and Sociocritical research have a visible, although minority, presence in schools and Teacher Education (for a recent review, see Devis, 2012). Despite it is difficult to deny the contemporarity of several of its analysis and foundations, starting with the necessity to tackle unjust and inequitable practices, Critical Pedagogy (or critical pedagogies), is often seen as an out-of-date approach to education. It is not that teachers, teacher educators or prospective teachers are insensitive to injustice, but they quite frequently take for granted that schooling provides equal opportunities for all, so they consider that many of the principles stated by CP are already part of the core of (in our case) Physical Education. That is to say: the mere fact that Physical Education is on the curriculum implies that emancipation, inclusiveness, equal opportunities, and so on are on its way; its a matter of time exerting its effect. In a sense, the triumph of the discourse warn us about the necessity of rethinking the meaning of these words, since the real impact of CP is reached not just assuming its principles, but rethinking them critically to work for emancipation. Rethinking implies a personal search in our own thoughts and the contexts in which they take its significance. As Kirk says, "this is a multi-level process that only becomes authentic when it is realized in the practical daily activities of individuals." (Kirk, 2006, p. 257) In this symposium, I'll argue that Critical Pedagogy is still relevant for PETE and for school Physical Education. Even more, it can be a path to avoid Physical Education risk of extinction due to its irrelevance (Kirk, 2010). CP is relevant for PETE because it can provide an approach to revisit the embodied ideologies that construct us as teachers. CP is relevant for Physical Education because it offers a more complex framework to understand education and the way educators can take part on the emancipation process. I will present an example of how teacher educators, physical education teachers and prospective physical education teachers can work collaboratively within the CP approach, linking knowledge production, professional development and social intervention. This action took place in a school attended mainly by students of the gypsy minority. The resistences offered by these students shocked the physical education teacher (new in the school) and the pre-service students that were doing their practicum with her. Along with a teacher educator, they explored critically how they embodied a hegemonic PE, and became aware of how their values and acts was made from this perspective. In doing so, they tried to learned how physical education can be relevant for the present of these gypsy students and for their future(s) and tried to detect ways of alienation that inadvertently Physical Education and school inflict to these children.

### **A CRITICAL PEDAGOGY FOR PHYSICAL EDUCATION FUTURES: PROSPECTS FOR CHANGE**

Kirk, D.  
*University of Bedfordshire*

As societies are increasingly disfigured by growing inequality, the presenters in this symposium argue for a critical pedagogy to secure a future that will enable physical educators to contribute to a reduction in inequality, to social justice and to the empowerment of all students. In his book *Physical Education Futures* (Routledge, 2010), David Kirk argues that without radical reform physical education is unlikely to survive in a form that can promote education for social justice. He proposed that reform must happen synergistically on three fronts: school physical education, PETE, and the school as an institution. Informed by a view of critical pedagogy outlined briefly by the Chair, this symposium examines the prospects for change in each of these areas. Each presentation considers the current situation, threats and opportunities, and in light of this analysis weighs the prospects for change in terms of the three futures scenarios outlined in Kirk's book: 'more of the same', 'radical reform', and 'extinction'. The speakers will present a coordinated symposium in which they will explore the interrelationships between their topic and the other two topics, thereby revealing the complexity of change and the need for coordinated struggle across each front. They will consider the prospects for teachers of physical education, teacher educators and student teachers, and members of school communities to engage in struggles to bring about change from the bottom-up.

#### **THE ROLE OF PHYSICAL ACTIVITY IN THE LIGHT OF AN AGEING EUROPEAN WORKFORCE**

Van Mechelen, W.  
*VU University Medical Center*

Prevalence rates of physical inactivity are high worldwide, as are associated non-communicable chronic diseases. Physical inactivity has been identified as the fourth leading independent risk factor for global mortality (6% of deaths globally). In the WHO European Region physical inactivity: is estimated to account for nearly one million deaths per year, i.e. 10% of the total and accounts for 8.3 million disability-adjusted life-years (DALYs - about 5% of the total). These epidemiological trends not only have impact on morbidity and mortality, but by consequence also on the associated direct and indirect cost. The latter primarily due to lost productivity costs. In addition we are in the western world confronted with an ageing society and a need for delayed retirement age. From both these perspectives it is important to keep the European workforce fit, vital and healthy. A way to do this is by worksite health promotion programmes, also stimulating physical activity and reducing sedentariness. Purpose of this talk is to present an overview of cost-effective worksite physical activity promotion programs, in the light of an ageing European workforce.

**EVALUATING THE IMPACT OF BLOOD FLOW RESTRICTION TRAINING ON VASCULAR FUNCTION**

Horiuchi, M., Sato, T., Takada, S., Kadoguchi, T., Okita, K.

*Yamanashi Institute of Environmental Sciences*

Introduction As low intensity training with blood flow restriction (BFR) leads to muscle hypertrophy despite with lower mechanical stress, BFR training may be a novel means for aged people to prevent sarcopenia. However, there is insufficient evidence regarding the impact of BFR training on vascular function. Thus, to clarify the potential safety of BFR training for vascular function as well as the advantages of this training is needed. Methods Study 1: Fourteen young males participated in this study. For training, unilateral plantar flexion exercise at 20% of 1-RM with BFR and a pressure of 1.3 times systolic blood pressure (SBP) was used. Training was conducted 3 days/wk for 4 wk. Muscle cross sectional area (MCA), 1-RM, and systemic vascular function assessed by beta-stiffness were measured pre and post training. Study 2: Sixteen young males were divided into either a jump training with BFR group (n = 8) or without BFR group (n = 8). A bilateral squat jump with a pressure of 200 mmHg was used. Training occurred 4 days/wk, for 4 wk. Muscle strength and beta-stiffness were measured pre and post training. Results Study 1: Although MCA and 1-RM increased significantly (5.0% and 13.7% vs. pre training,  $p < 0.05$ ), beta-stiffness remained unaltered. Study 2: Muscle strength in both groups remained unchanged. However, jump training with BFR significantly improved beta-stiffness (6.3 to 5.5 a.u.,  $p < 0.05$ ) without changes in arm SBP. Discussion Accumulation of metabolites contributes to muscle strength (Scott et al., 1995) and our results reveal that a greater amount of muscle metabolites was induced by BFR (Suga et al., 2009). These alterations in metabolites increased MCA and 1-RM in study 1. Only whole body BFR training improved beta-stiffness. However, low intensity and local muscle training with BFR was insufficient as a stimulus to improve beta-stiffness. One explanation is the different recruited muscle mass. A previous study indicated that arterial remodeling via blood flow changes is endothelium dependent (Rudic et al., 1998), suggesting that greater hyperemic blood flow after cuff deflation may be related to the improvement beta-stiffness caused by exercise-induced increases in systemic blood flow (Green et al., 2004). Collectively, these results suggest that BFR training might be useful for aged people who cannot perform recommended high-intensity resistance exercises. Because obvious increases in muscle mass and strength without degeneration of vascular function could be obtained by BFR training, even if an extremely low-intensity load was applied. **ACUTE EFFECT OF INCREASED PARTICIPATION IN ACTIVITIES OF DAILY LIVING ON POSTPRANDIAL LIPAEMIA IN POSTMENOPAUSAL WOMEN**

Miyashita, M., Takahashi, M.

*Tokyo Gakugei University*

Introduction A "super-aging society" is one of the major issues being faced by Japan with 40 percent of the population expected to be over 65 years old by 2050 or so. Preventing elderly people from becoming limited in performing activities of daily living is an important health objective for maintaining their quality of life. Thus, it is important to consider lifestyle modifications which may be effective in reducing repeated daily episodes of exaggerated postprandial lipaemia, a risk factor for cardiovascular disease (Cohn, 1998), since there is an increased incidence of cardiovascular disease in middle-aged and older populations, particularly postmenopausal women. Thus, the aim of our study was to examine the acute effect of increased participation in activities of daily living on postprandial lipaemia in postmenopausal women. Methods Ten postmenopausal women, aged  $63 \pm 4$  years (mean  $\pm$  SD), completed two trials in a randomised order: 1) control trial and 2) active trial. On Saturday and Sunday of the control trial, participants maintained their usual lifestyle. On Saturday and Sunday of the active trial, participants were asked to increase their activities of daily living above their usual lifestyle levels (i.e. activity time did not fix). For the determination of physical activity levels, participants were asked to wear a uniaxial accelerometer for 4 consecutive weeks. On Monday of each trial, participants rested and consumed test meals for breakfast and lunch. Capillary blood samples were collected in the fasted state (0 h) and at 2, 4 and 6 h postprandially on day 2. Results The frequencies of performing moderate to vigorous physical activity (i.e.  $\geq 3$  metabolic equivalents) determined by the accelerometer were higher in the active trial than in the control trial ( $27.9 \pm 3.8$  vs.  $12.2 \pm 2.1$  min/weekend for the active and control trials respectively, paired t-test,  $P = 0.009$ ). Area under the capillary triacylglycerol concentration vs. time curve was 13% lower in the active trial than in the control trial ( $8.8 \pm 3.8$  vs.  $10.1 \pm 3.9$  mmol $\cdot$ 6h/L for the active and control trials respectively, paired t-test,  $P = 0.024$ ). Discussion Increased participation in activities of daily living was effective in attenuating postprandial lipaemia in postmenopausal women. Future studies should examine whether chronic changes in total daily activity time and/or sitting time over several weeks/months under free-living conditions have beneficial effects on activities of daily living and quality of life in older populations. **15:00 - 16:30****Oral presentations****OP-SH05 Psychology [PS] 1****THE RELATIONSHIP BETWEEN THE OBJECTIVELY RATED COACH-CREATED MOTIVATIONAL CLIMATE, AND ATHLETES' BASIC PSYCHOLOGICAL NEEDS AND SPORT ENJOYMENT.**

Smith, N.1, Tessier, D.2, Tzioumakis, Y.3, Appleton, P.1, Quested, E.1, Duda, J.L.1

1: *University of Birmingham (UK)*, 2: *University of Grenoble, (France)*, 3: *University of Thessaly (Greece)*

Introduction Self-determination theory (SDT) predicts the extent to which the coach-created climate is autonomy supportive and/or controlling will contribute towards the degree to which athletes experience satisfaction of the basic needs of autonomy, competence and relatedness, and in turn, positive emotional responses. The relationship between athletes' self-reported perceptions of the coach-created motivational climate (as conceptualised in SDT) and athletes' basic need satisfaction (BNS) and associated outcomes is well understood. However, little is known about the implications of the objectively-measured features of the motivational climate for athletes' motivation related processes and associated outcomes. Thus, this research examined the relationship between objectively rated coach autonomy

support and controlling features of the environment, and athletes' self-reported BNS and sport enjoyment. Method 53 grassroots football coaches (Mage = 37.74 years) and 672 players (Mage = 11.32 years) took part in the study. During the first 10 weeks of the season, the coach was filmed during a training session and athletes completed a questionnaire assessing their autonomy, competence and relatedness need satisfaction and enjoyment in football. Recordings were split into four equal time periods and trained observers coded the potency of the autonomy supportive and controlling features of the climate using the Multi-dimensional Motivational Climate Observation System (MMCOS). Results Analyses suggest that observed autonomy support was positively related to players' autonomy need satisfaction ( $\beta=.36$ ,  $p=.008$ ), and observed controlling features of the coaching environment emerged as a significant negative predictor of players' sense of relatedness ( $\beta=-.34$ ,  $p=.013$ ) and enjoyment ( $\beta=-.31$ ,  $p=.025$ ). Relatedness was a significant positive predictor of enjoyment ( $\beta=.56$ ,  $p<.01$ ). Mediation analysis demonstrated relatedness partially mediated the relationship between observed controlling behaviour and player enjoyment ( $p=.029$ ). Discussion Findings demonstrate when coaches are observed to coerce behaviour by being controlling, players report lower levels of relatedness and consequently enjoy their sport less. Given that players' enjoyment in sport has been associated with important health-related outcomes, it seems important that coaches try and avoid emphasising a controlling motivational environment. In future, SDT-based coach education programmes that focus on encouraging more adaptive motivational environments may also wish to educate coaches about how to reduce the negative implications of emphasising maladaptive, controlling coaching practices.

### LONGITUDINAL EXAMINATION OF THE RELATIONSHIPS BETWEEN COACH INTERPERSONAL STYLE, PSYCHOLOGICAL NEED SATISFACTION AND MOTIVATIONAL REGULATIONS IN YOUNG FOOTBALLERS

González, L., Castillo, I., Tomás, I., Fabra, P., Balaguer, I.

*Universitat de València*

Self-determination theory (SDT; Deci & Ryan, 2000) holds that the understanding of human motivation requires consideration of the degree to which basic psychological needs for competence, autonomy, and relatedness are satisfied. Autonomy supportive contexts foster satisfaction of these needs and, in turn, will facilitate intrinsically motivated behaviours. Previous research has examined the interplay between these variables through cross-sectional studies using composite measures of need satisfaction and self-determined motivation. Extending the literature, the purpose of this study was: (1) to examine the relationship between changes in coach autonomy support to changes in the 3 needs satisfaction and in each motivation regulation over a football season, and (2) analyse the mediational effect of need satisfaction between coach autonomy support and motivation regulations. 597 male footballers ( $M = 12.58 \pm 0.54$  years) completed a questionnaire pack tapping the variables of interest at two time points (beginning and end of the season). Results of structural equation model revealed that changes in autonomy support predicted positive and significant changes in the satisfaction of the needs for competence ( $\beta=.13$ ), autonomy ( $\beta=.48$ ) and relatedness ( $\beta=.55$ ). Moreover, changes in the need for competence positively related to changes in intrinsic motivation ( $\beta=.17$ ) and identified regulation ( $\beta=.11$ ) and negatively predicted amotivation ( $\beta=-.13$ ). Unexpectedly, changes in competence need satisfaction were positively associated with changes in extrinsic regulation ( $\beta=.10$ ). Changes in the need for autonomy were a positive predictor of changes in intrinsic motivation ( $\beta=.23$ ) and identified regulations ( $\beta=.25$ ). Changes in autonomy need satisfaction were positively linked to changes in introjected ( $\beta=.24$ ) and external regulations ( $\beta=.16$ ), and changes in the need for relatedness were a positive predictor of changes in intrinsic motivation ( $\beta=.18$ ). Results also provided support for the full mediational role of the three psychological needs in the relationship between autonomy support and motivational regulations. According to SDT, results show the importance of promoting autonomy supportive atmospheres to facilitate satisfaction of young footballers basic psychological needs and intrinsic motivation. Future studies could further analyse the positive relation of satisfaction of the needs for competence and autonomy with more controlled forms of motivation. ### THE ROLE OF COACHES IN FACILITATING MENTAL TOUGHNESS IN ADOLESCENT ENDURANCE ATHLETES.

Mahoney, J.W.1,2, Ntoumanis, N.2, Mallett, C.J.1, Gucciardi, D.F.3

1: UQ (Brisbane, Australia), 2: UoB (Birmingham, United Kingdom), 3: CUT (Perth, Australia)

Introduction Employing qualitative methodologies, researchers have indicated that coaching environments that support athlete autonomy and avoid controlling sanctions underscore mental toughness development (Gucciardi et al., 2009). These types of environments can be understood more broadly in light of self-determination theory (SDT). The aim of our study was to substantiate previous findings by quantitatively investigating the relationship between different coaching environments on mental toughness and associated outcomes in adolescent athletes. We hypothesised that autonomy-supportive coaching environments would positively correlate with mental toughness through the satisfaction of psychological needs. Further, we hypothesised that mental toughness would correlate positively with well-being and performance and negatively with ill-being. Method Two hundred and fifty-six adolescent endurance runners (139 male, 117 female; Mage =14.43 years of age, SD = 1.96) recruited from schools and clubs throughout Australia (N = 175) and the UK (N = 81) completed a battery of questionnaires: the Sport Climate Questionnaire, the Basic Psychological Needs Satisfaction in Sport Scale, the Mental Toughness Index, the Depression, Anxiety and Stress Scale, and the Mental Health Continuum Short Form. Performance data, in the form of competition times, were also obtained. Results Structural equation modelling revealed that autonomy-supportive coaching environments correlated positively with needs satisfaction. Needs satisfaction related with mental toughness in the expected fashion. Further, mental toughness significantly correlated with well-being and ill-being as expected, but not performance. Interestingly, performance and well-being were significantly correlated. Discussion Mental toughness in adolescent athletes could be fostered through the provision of autonomy-supportive coaching environments that satisfy athletes' psychological needs. Researchers could extend our findings by employing experimental methodologies to investigating how encouraging coaches to create autonomy-supportive environments affects mental toughness in adolescent athletes over time. ## THE EFFECT OF A SELF-DETERMINATION THEORY BASED EXERCISE INTERVENTION ON PHYSICAL ACTIVITY LEVELS IN RHEUMATOID ARTHRITIS PATIENTS

Yu, C.1, Rouse, P.1,2, Veldhuijzen Van Zanten, J.1,2, Metsios, G.2,3, Ntoumanis, N.1, Kitas, K.3, Duda, J.L.1

*University of Birmingham1 Dudley Group of Hospitals NHS Trust2 University of Wolverhampton3*

Introduction Exercise has been shown to reduce cardiovascular disease risk in patients with Rheumatoid Arthritis (RA) . Little is known about the effect of a prescribed gym-based exercise intervention on levels of physical activity (PA) in patients with RA, particularly leisure time PA. Self-determination Theory<sup>2</sup> holds that individuals are more likely to adopt and maintain PA when their autonomous motivation for engagement is enhanced. The present study examined the effects on objective and self-reported PA between an exercise programme supplemented with SDT-based PA promotion consultations and a standard exercise programme. Method To date, 88 RA patients (27 male, 61 Female, Mage= 54± 13 years) were recruited to participate in a structured 3-month exercise programme. The participants were randomly assigned to either: (1) an intervention arm (N=46)entailing a structured exercise programme customised for RA patients plus autonomy supportive consultations to promote PA engagement within/outside of the programme, or (2) a control arm(N=42)comprised of the structured exercise programme only. Valid objective PA data were obtained from 21 patients. Given the current sample size, changes in objective and subjective PA were investigated via dependent t-tests. Results Analyses revealed self-reported leisure time PA to decrease over the course of the exercise programme in the control arm (t=2.57, p=.014). Objective sedentary behaviour was significantly reduced (t=2.13, p<.05) and there were trends for PA at a light level (t=-1.94, p=.066) to increase T1 to T2. No significant changes in objective MVPA or step counts were observed in either arm. Conclusion Analyses of preliminary data revealed that there was a reduction in objective sedentary behaviour in RA patients and increase in subjective leisure time PA when autonomy supportive consultations were combined with 3 months of gym-based exercise. This ongoing RCT will further explore the sustainability of these changes in PA as a result of the exercise + SDT-grounded psychological intervention, and the impact of any changes in patients' autonomous motivation on PA. ## PHYSICAL EDUCATION TEACHERS SELF-DETERMINED MOTIVATION TOWARDS THEIR CLASSES

Coelho, L.1, Matos, R.1, Cubo Delgado, S.2

*1: IPL (Leiria, Portugal), 2: UNEX (Badajoz, Espanha)*

Introduction This study analyses Physical Education (PE) teachers' self-determined motivation towards their classes in Leiria, Portugal. Given the fact that there has been growing concern in recent years about the low level of young peoples' participation in physical activity (PA), we would like to know if teachers' motivation level shows to be a contributing factor. Methods Forty one PE teachers with qualification certificate from high institution (21 males and 20 females) from eight Leiria (Portugal) district schools volunteered to participate in the study. They were recruited from government-run basic and high schools. They all taught students from 10 to 18 years of age. Self-determined motivation was assessed through the application of a previous validated questionnaire (SIMS; Guay, Vallerand, & Blanchard, 2000). A four item dimension was added to reflect introjected regulation, following Taylor and Ntoumanis (2007) example. Results On a scale from 1 to 7, teachers reported average intrinsic motivation of 6,1 ± 0,8. Identified regulation was 5,6 ± 0,96. Introjected regulation was 3,7 ± 1,4. External regulation was 2,9 ± 1,4. Amotivation was 2,0 ± 1,0. Intrinsic motivation and identified regulation were the two most significant factors indicated to justify this teaching activity, while the rest have a distinctive lower influence. Discussion Results clearly indicate high levels of PE teachers' self-determination towards their classes. When comparing data between genders, no significant statistical differences were found on any type of regulating factor, whether intrinsic, extrinsic and amotivation. This allows us to conclude that teachers' gender has no impact on teachers' overall self-determination towards their classes. When comparing data between schools, no significant statistical differences were found on any type of regulating factor, allowing us to conclude that schools characteristics has no influence on teachers' overall self-determination towards their classes. This was equally found for teachers' chorological age. Point out that the more intrinsic the motivation regulating factor is, higher the values presented. Based on this results, we can exclude this variable (teachers self-determined motivation towards their classes) as having any relation with concerning low level of young peoples' participation in PA by PE influence. ## PERFECTIONISM SUB-BELIEFS AND PSYCHOLOGICAL WELL- AND ILL-BEING IN ATHLETES WITH AND WITHOUT HEARING IMPAIRMENTS

Ho, M.S.H., Appleton, P.R., Duda, J.L., Cumming, J.

*University of Birmingham*

Introduction Past literature (Stoeber & Childs, 2010) has considered whether the sub-beliefs of self-oriented perfectionism (SOP) and socially-prescribed perfectionism (SPP) are adaptive or maladaptive. To provide further insight into this issue in sport, we examined the relations between perfectionism sub-beliefs (perfectionistic striving [PS], importance of being perfect [IBP], conditional acceptance [CA] and others' high standards [OHS]) to indices of well- and ill-being. As there is limited sport psychology research on disabled athletes, particularly deaf athletes, the second aim was to determine whether these relations vary across hearing and deaf athletes. Methods Participants were 205 hearing (Mage = 18.8, SD = 3.9) and 212 deaf (Mage = 27.3, SD = 9.3) athletes. Athletes were asked to complete a questionnaire including validated scales assessing well-being (positive affect [PA], subjective vitality [SV], and global esteem [GE]) and ill-being (perceived emotional and physical exhaustion [PEPE] and negative affect [NA]). Results As hypothesised, PS was negatively correlated with ill-being indicators and positively correlated with well-being indices in both groups. IBP was positively associated with all indicators of ill-being in deaf athletes and with all indicators of well-being in hearing athletes. PS had higher positive correlations with the markers of well-being and higher negative correlations with ill-being indicators than IBP. For the SPP sub-beliefs, CA was negatively associated with all indicators of well-being and positively associated with NA in hearing athletes. In the deaf sample, CA was negatively associated with GE. No significant correlations were found for OHS in the hearing sample, but PA and SV were positively associated with OHS in the deaf sample. Furthermore, CA had higher positive correlations with ill-being and higher negative correlations with well-being indices than OHS. Discussion Our findings indicate that PS could promote well-being and CA could induce ill-being in hearing and deaf

athletes. This supports recent arguments by Gotwals et al. (2012) on the adaptive nature of PS and Hall et al.'s (2012) proposals regarding the maladaptive nature of CA in sport. Our findings also show that IBP and OHS can be positive or negative, depending on whether the athlete has a hearing impairment. The sub-belief of IBP may be maladaptive for deaf athletes compared to their hearing counterparts. It is speculated that deaf athletes may be less satisfied with their goal progress and thus the importance placed on achieving perfection leads to greater ill-being. Regarding OHS, previous research by Campbell and Di Paula (2002) also revealed that OHS was uncorrelated with well- and ill-being indices in hearing students, supporting our findings concerning hearing athletes. Little is known about the correlates of OHS in deaf people, but it is speculated that deaf athletes consider others' expectations as a form of social support which fosters psychological health in deaf athletes.

### PS-PL01 Does Pain Produce Gain? \*

#### UNCERTAINTIES REGARDING SOME OF THE EXPECTED BENEFITS OF REGULAR EXERCISE

Bouchard, C.

*Pennington Biomedical Research Center*

From a public health perspective, regular exercise is beneficial for everyone. This view is based on cross-sectional and longitudinal epidemiological studies and on observed average responses in exercise intervention studies. However, this notion needs to be critically evaluated considering the body of data on human variation in response to regular exercise. The concept of individual differences in the response to exercise was first defined three decades ago in a series of experiments with monozygotic twins and nuclear families. A powerful way to investigate the biological basis of human variation in the response to regular exercise is to use transcriptomic and genomic technologies. Whole-genome transcriptomics from skeletal muscle samples yielded a panel of 29 transcripts whose abundance profile accounted for 58% of the variance in VO<sub>2</sub>max gains among 24 sedentary men trained for 6 weeks, and these findings were replicated in a second study. A genome-wide association study was undertaken in the HERITAGE Family Study based on 324,611 single nucleotide polymorphisms (SNPs). Multivariate regression analyses showed that the top 21 SNPs explained 49% of the variance in VO<sub>2</sub>max trainability. A predictor score was constructed based on allelic composition at these SNPs, with a theoretical range from 0 (no beneficial alleles) to 42 (two copies of the beneficial alleles at all 21 loci). The difference in VO<sub>2</sub>max trainability between those carrying 9 or less of these alleles and those carrying 19 or more was threefold. Similar observations have been made for the training-induced changes in exercise hemodynamic, insulin and glucose, and lipid and lipoprotein traits. These results suggest that it may eventually be possible to predict who will benefit the least or the most from regular exercise for common cardiometabolic risk factors or physical performance. An examination of the response distribution for risk factor traits to regular exercise in HERITAGE yielded suggestive evidence that there were adverse responders. Further exploration in five other exercise intervention cohorts revealed that the prevalence of adverse responders reaches about 10% for a given risk factor while about 7% among almost 1,700 adults experienced multiple adverse responses. It is critical to be able to identify molecular predictors of the ability to respond to regular exercise not only for our understanding of the underlying biology, but also to screen individuals at risk of developing potentially harmful response patterns and to define realistic expectations at the individual level. It is simply not true that adverse responders, nonresponders, and low responders have failed to exercise hard enough. It is time to move away from the "no pain, no gain" model and to embrace the personalized exercise medicine paradigm.

#### UNIFICATION OF CONCEPTS AND MEASURES FOR CAPTURING THE MOND CONTROL OVER THE MOTION SYSTEM

Tenenbaum, G.

*Florida State University*

Of great concern is how well one may perform tasks under conditions of intense pressure or high cognitive workload, and how decision-making skills may be influenced when emotions and time-based pressures call for immediate actions to be taken. Under such conditions without properly integrated emotional responses, cognitive processes and subsequent behaviors could potentially make a dangerous or even fatal decision. This presentation examines how relationships between emotions, cognitive processes, and motor behaviors change under stress and lay out a framework that details how linkages may alter under specific conditions of perceived pressure. Is it the case that stronger emotional control can mediate the cognitive-motor relationship and result in better performance? What are the underlying mechanisms that enable or prevent efficient courses of action from occurring? Though sound theories have been put forth and extensive research has been devoted to investigate these questions, most of those initiatives have not taken an integrative approach to examine how the emotional, cognitive, and motor systems interact. More specifically, the structural components of human performance, such as emotional processes (i.e., feelings, mood), cognitive processes and structures (e.g., knowledge architecture, long-term working memory), motor processes (coordination, endurance), and the neurophysiological basis of these structural components (i.e., activation of cortical areas) have been studied independently. This presentation provides a conceptual framework to address the integration across these systems, and proposes a unified theoretical framework that offers an improved understanding of human performance as well as helping to generate scientifically valid applications.

#### **EVALUATION OF FOOD PROVISION AND NUTRITION SUPPORT AT THE LONDON 2012 OLYMPIC AND PARALYMPIC GAMES.**

Pelly, F.1, Meyer, N.2, Pearce, J.2, Burke, L.4, Burkhart, S.1

*1:USC (Queensland Australia), 2:University of Colorado (Colorado USA) and United States Olympic Committee, 3:High Performance Sports NZ (Auckland New Zealand), 4:AIS (Canberra Australia).*

**Introduction** Over the past thirty years there has been an increasing emphasis on the food provision and nutrition support for athletes at major competition events such as the Olympic Games. While evaluation of this service has been conducted at previous events (Pelly et al., 2009; Burkhart and Pelly, 2013), expert opinion of this process has not been investigated. Therefore, the aim of this study was to evaluate the food provision and nutrition support at the London 2012 Olympic (OG) and Paralympic Games (PG) from the perspective of nutrition experts attending the event. **Methods** Experienced nutrition professionals who attended the London 2012 OG's and PG's were invited to complete an online survey and rate on a Likert scale of 1 'very poor' to 5 'very good', the dining hall menu, food for specific situations, cultural requirements, dietary regimens, and nutrition support. Open-ended questions were included to explore responses in more depth and allow suggestions for improvement. **Results** While factors such as variety, freshness, cultural and religious representation and temperature rated highly ('average' to 'good'), specific items (in particular, gluten free items, sports bars, meal replacement/high energy drinks, and snack bars) were rated as poorly represented on the menu. Mean low ratings were also received for provision of recovery items ( $M=2.1$ ,  $SD=0.78$ ), food for travelling to ( $M=2.7$ ,  $SD=1.00$ ) and at venues ( $M=2.8$ ,  $SD=1.17$ ), and ability to take snacks out of the dining hall ( $M=2.7$ ,  $SD=0.95$ ). While nutrition labelling of individual items was supported, the use of websites and applications for accessing information about the menu was suggested as a better service for athletes. **Discussion** While the general consensus of experts was that the menu met the needs of most athletes, several areas of improvement were noted. These included refining food provision to better cater for athlete recovery (dairy and snack items, and food provided outside of the village), weight management (modification of recipes to low fat) and catering for therapeutic needs (gluten free). These results are supported by previous studies on athletes' opinion of food provision at past events (Pelly et al., 2011; Burkhart and Pelly, 2013), are in line with current evidence for competition and recovery, and therefore should be a focus for future events. **References** Burkhart S, Pelly F.(2013). *Int J Sport Nutr Ex Metab*,23,11-23. #### **WEIGHT STATUS IN PRIMARY SCHOOL CHILDREN: THE ACTUAL VERSUS THE PERCEIVED BY PARENTS**

Leitão, R.1,2, Lopes, A.1, Freitas, H.1, Pereira, S.1

*1: School of Education at Polytechnic Institute of Viana do Castelo. 2: Research Centre on Child Studies at University of Minho.*

**Introduction** Parental perception of their child's overweight is considered to be a crucial factor for its management. In Portugal, the most recent data revealed that childhood overweight has reached an alarming dimension. Therefore, we aimed to examine the parental perception of their children's weight status. Given the limitations of body mass index (BMI) as an index of adiposity, we further used a measure of excess central adiposity. **Methods** This study involved a convenience sample of 110 parent-child dyads from two public primary schools in Viana do Castelo (Northern Portugal). The mean age (SD) of children and parents was 8.7(0.6) and 38.2 (4.7) years, respectively. Anthropometric assessment (weight, height and waist circumference) was performed during physical activity sessions at school setting. Parent self-reported perception data was obtained through administered questionnaires. Children's actual weight status (BMI-based) was defined by the International Obesity Task Force standards (Cole et al., 2000; 2007). A waist-to-height ratio (WHtR)  $\geq 0.5$  was used as cut-off for excess central adiposity (McCarthy and Ashwell, 2006). **Results** There was a poor agreement between the actual children's weight status and the one perceived by parents, as indicated by a Kappa of 0.37 ( $P<0.001$ ). The combined prevalence of overweight and obesity (BMI-based) was 33.6%, whereas only 12.7% of parents perceived their children as overweight. None of the participants objectively classified as obese (3.6%) was recognized as so by their respective parents, but all thin children (3.6%) were. Excess central adiposity was found in 42.7% of the total sample, with no significant differences between boys (20.0%) and girls (22.7%,  $P=0.8$ ). Misconception of excess central adiposity is of great concern, since 69.6% of parents of children with a WHtR $\geq 0.5$  perceived their children as having normal weight. **Conclusion** The misclassification observed shows that parents tend to underestimate overweight and obesity. Lack of recognition of excess central adiposity seems to be even more problematic. **References** Cole T, Bellizzi M, Flegal K, Dietz W (2000). A study of central fatness using waist-to-height ratios in UK children and adolescents over two decades supports the simple message - 'keep your waist circumference to less than half your height'. *Int J Obes (Lond)* 30: 988-992.

#### **NUTRITIONAL ASSESSMENT OF HIGH INTENSITY TRAINING COLLECTIVE: STATUS OF VITAMINS**

García Hortal, M., Molina-López, J., Ortiz, M., Sáez-Pérez, L., Planells del Pozo, M.E.

*Faculty of Pharmacy, University of Granada*

**Introduction** Vitamin deficiencies and nutritional excess alter performance and the optimization of results. Unbalanced diets and bad eating habits cause adverse effects, so nutrition is important to control high intensity athletes because their increased energy expenditure

requires a huge intake. The aim of this study was to evaluate the nutritional status focused on vitamins in a young male adult collective trained with high intensity tests. For that, we made an assessment of the nutritional evaluation, intake habits, anthropometric measures and physical tests. Methods This is a cross-sectional study. Twelve men, aged  $25.8 \pm 4.2$  years, participated in the study voluntarily. Real kcal intake was measured with NUTRIBER software, the anthropometry with TANITA and specific methodology, and the physical condition was tested with practical exercises (2000m run, high jump, a circuit and pull-ups). SPSS 7.0 program was used to determine the bivariate Pearson's correlation between vitamins and other parameters. Probability level for statistical significance was set at  $\alpha=0.05$ . Results The Recommended Dietary Allowance (RDA) of Energy, Protein, Lipids, Carbohydrates, Vitamin B2, Vitamin B6 and Vitamin C were 76.1, 219.9, 80.8, 63.1, 116.4, 140.4 and 194.2, respectively. Vitamins B2 ( $r=0.771$ ;  $p=0.005$ ) and B6 ( $r=0.727$ ;  $p=0.011$ ) were directly correlated with pull-ups. Significant associations ( $r=0.617$ ;  $p=0.033$ ) were found between lipids and carbohydrates intake. Also, significant correlations were found between the intake of Calcium, Proteins and Carbohydrates, and the latter with Selenium ( $r=0.609$ ;  $p=0.036$ ). Energy intake was directly correlated with the intake of macronutrients and the intake of Selenium ( $r=0.591$ ;  $p=0.043$ ). The intake of protein was correlated with Vitamin C ( $r=0.655$ ;  $p=0.021$ ). There was also a high correlation between the intake of Protein and Vitamin B2 ( $r=0.895$ ;  $p<0.001$ ) and Vitamin B6 ( $r=0.915$ ;  $p<0.001$ ). Protein intake was also directly correlated with the intake of Vitamin E ( $r=0.756$ ;  $p=0.004$ ) and pull ups ( $r=0.784$ ;  $p=0.004$ ). Discussion According to the results, the group studied shows imbalances in nutrient intake that given the association can alter the availability of other macro and micro nutrients, affecting the results on training. For that reason, nutritional counseling and the nutritional optimization are necessary as well as monitoring these types of collectives. ## PROTEIN DISTRIBUTION AND QUANTITY AMONGST ELITE RUGBY PLAYERS

MacKenzie, K.I, King, N.I, Byrne, N.I, Slater, G.2

1. Queensland University of Technology 2. University of the Sunshine Coast

Introduction: Optimising protein intake to promote gains in skeletal muscle mass (SMM) is considered important by many athletes (Phillips et al, 2007). Research has suggested that muscle protein synthesis may be optimised by a single 20g protein dose (approximately  $0.3\text{g}\cdot\text{kg}^{-1}$  body mass) with no further stimulation at higher doses (Moore et al, 2007). One acute study reported enhanced muscle protein synthesis when protein was consumed after resistance training as several small 20g doses, rather than larger, less frequent doses (Areta et al, 2012). This study aimed to examine self-reported protein distribution and dose in elite development rugby union athletes. A secondary aim was to assess the relationship between protein distribution and changes in fat-free mass (FFM) over a rugby pre-season. Methods: 25 athletes ( $20.5 \pm 2.3$  yrs;  $100.2 \pm 13.3$  kg) completed a 7d food diary. Food portion guides and Foodworks v.6.0.2562 (2009) were used to quantify food intake. Protein distribution scores were calculated as the number of times an eating occasion (>15 minutes apart) achieved a target amount of protein (20g or individually calculated target based on  $0.3\text{g}\cdot\text{kg}^{-1}$  i.e.  $30.0 \pm 4.0$ g) averaged per day. FFM was measured by dual energy x-ray absorptiometry. Results: The mean number of eating occasions was  $5.6 \pm 1.0$ . The protein distribution scores for 20g and calculated protein target were  $3.8 \pm 1.0$  ( $68 \pm 18\%$  of eating occasions) and  $2.8 \pm 1.1$  ( $50 \pm 20\%$  of eating occasions) respectively.  $2.0 \pm 0.9$  ( $36 \pm 16\%$ ) of all eating occasions exceeded the calculated protein target by more than 50%. The effect of 20g protein distribution score on changes in FFM was not significant ( $p=0.15$ ); regression analysis was impacted by statistical power and multicollinearity. Discussion: This study provides evidence that rugby players select a meal plan that includes larger, less frequent doses of protein. However, it is unclear whether protein distribution impacts on chronic changes in FFM. Chronic studies monitoring associations between dietary intake and protein distribution on changes in FFM or SMM pose several methodological and analytical challenges. Acute studies may assist by clarifying the optimal protein distribution and protein doses for changes in indicators of SMM synthesis. Further research is warranted to assess the impact of protein dose and distribution, with consideration of other dietary intake variables, on chronic changes in body composition amongst rugby union athletes. ## GLYCAEMIC INDEX BREAKFASTS AFFECT CONGITION BUT NOT LUNCH INTAKE IN ATHLETIC MALES

Wu, D.M.Y., Bowtell, J.L., Williams, C.A.

University of Exeter

Introduction Low blood glucose concentration [Glu] is associated with impaired cognition and hunger whilst elevated [Glu] improves cognitive response time. Attention and memory are better in adolescent (Cooper et al. 2012) and older adults (Nilsson et al. 2009) after low vs high glycaemic index (GI) foods, but the effects of breakfast GI on cognitive function and appetite in active male adults have not been explored. Methods Sixteen athletic males (mean  $\pm$  SD; age  $24.4 \pm 3.6$  y, BMI  $22.9 \pm 3.3$  kg/m<sup>2</sup>) participated in a randomised cross-over study providing a low GI (LGI) (42.2) and a high GI (HGI) (72.4) breakfast. The breakfast contained 1 g carbohydrate per kg body mass matching contents of protein, fat and fibre; and caloric density. Participants started the 25-min rapid information process task (RIPT) and Stroop Colour Word Task (SCWT) 15 min post-meal. Three rounds were completed with a 15-min break in between. Appetite score (AS) using visual analogue scales and capillary [Glu] were monitored regularly. An ad libitum HGI lunch was provided 3 hours post-breakfast. Results The area under the curve of the HGI [Glu] was higher than that of the LGI [Glu] until 90 min post-breakfast ( $585 \pm 61$  vs  $627 \pm 64$  mmol/L min,  $p = 0.029$ ). Peak [Glu] were observed prior to task 1 (LGI vs HGI:  $6.9 \pm 1.1$  vs  $8.1 \pm 1.2$  mmol/L,  $p = 0.003$ ). The LGI and the HGI [Glu] returned to the baselines at 90 min and 105 min respectively. The number of correct-wrong response of HGI task 1 RIPT was negatively associated with its pre-task 1 [Glu] ( $r = -0.68$ ,  $p = 0.003$ ). The HGI task 2 and the LGI task 3 SCWT interference scores were negatively associated with the HGI pre-task 2 [Glu] (90 min) ( $r = -0.56$ ,  $p = 0.025$ ) and the LGI pre-task 3 [Glu] (105 min) ( $r = -0.53$ ,  $p = 0.036$ ) respectively. The HGI pre-lunch [Glu] was lower than its baseline ( $4.0 \pm 0.17$  vs  $4.3 \pm 0.13$  mmol/L,  $p < 0.001$ ). Although there was no difference in AS between trials, both pre-lunch AS were positively associated with the LGI ( $r = 0.51$ ,  $p = 0.045$ ) and the HGI ( $r = 0.66$ ,  $p = 0.005$ ) lunch intakes per kg fat free mass. Discussion A HGI breakfast is not advised if a demanding cognitive task shortly follows the meal. High post HGI breakfast [Glu] reduced the number of correct response whilst the decline in attention was delayed after LGI vs HGI breakfast. The difference in the GI in breakfasts did not affect the lunch energy intake. Hence, as for adolescent and older adults, a LGI breakfast appears to support better cognitive function in athletic adult males. References Cooper, S. B., Bandelow, S., Nute, M. L., Morris, J. **THE ANALYSIS OF BODY COMPOSITION AND NUTRITIONAL STATUS IN ROWERS**

Rilova, N.1,2, Khafizova, G.1,2, Mustafina, L.1, Mudarisova, R.1, Lutfullin, I.1, Mavliev, F.1, Almetova, R.1, Biktimirova, A.2, Ahmetov, I.1

1: Volga Region State Academy of Physical Culture, Sport and Tourism (Kazan, Russia) 2: Kazan State Medical University (Kazan, Russia) 1: Volga Region State Academy of Physical Culture, Sport and Tou

**Introduction** The improvement of athletic performance and the level of adaptation to physical performance are provided with the control of the body weight and composition and range of biochemical parameters (Banfi G, 2012). This study aimed to analyze the nutritional status, body composition, as well as the hormonal and lipid profiles of Russian rowers. **Methods** Twenty Russian sub-elite rowers (15 males and 5 females; aged 20.8±2.0) were examined with professional body composition analyzer Tanita MC-980 (Japan), blood tests and questionnaire survey. **Results** Analysis of the questionnaires revealed that 65% of athletes had balanced and complete diet, 35% of athletes have pointed to the lack of dietary fiber and protein products. Seventy percent of the athletes took food 3-4 times a day, 10% - only 2 times a day. Thirty five percent of respondents completely avoided fizzy drinks, 35% of athletes consumed them about once a week, 20% - once a month, and 10% - 1-2 times a year. It was established that 20% of the athletes had chronic gastritis, and 5% - gastric ulcer in their past medical history. Lean body mass in males and females was 67.09±7.5% and 52.95±3.11%, respectively; proportion of body fat in males and females was 10.65±4.55% and 23.18±4.24%, respectively. Furthermore, basal metabolism rate (2063±270.2 vs. 1637±59.31 kcal) and total body water (64.5±2.71 vs. 55.35±2.53%) was larger in males than in female athletes. Analysis of lipid profile of rowers: the average concentration of the total cholesterol was 4.13±0.64 mmol/l, low-density lipoproteins - 2.49±0.47 mmol/l. The average value of the high-density lipoproteins was 1.27±0.23 mmol/l, indicating that rowers had reduced levels of the HDL in comparison with the reference ranges (normal range > 1.55 mmol/l). Analysis of the hormonal profile of female athletes showed appropriate levels of all hormones with reference ranges (cortisol 360.8±68.75 nmol/l, total testosterone 1.54±0.44 nmol/L and free testosterone 0.99 (0.41-3.92) pg/ml). had The mean values of cortisol, total testosterone and free testosterone in males was 458.8±151.4 nmol/L, 19.56±5.98 nmol/l, and 13.5 (5.04 -57.85) pg/ml, respectively. **Discussion** In conclusion, our study revealed that rowers had significant nutritional deficiencies. A reduction in the level of high-density lipoproteins in the blood serum of the majority of athletes was determined. It is important to emphasize that the changes in lipid and hormonal profiles were primarily found in male athletes. **References** Banfi G, Colombini A, Lombardi G, Lubkowska A. Metabolic markers in sports medicine. *Adv Clin Chem*. 2012

**08:30 - 10:00****Oral presentations****OP-PM40 Sports Medicine [SM] 1****FATIGUE EFFECTS ON SENSORIMOTOR CONTROL IN ATHLETES WITH AND WITHOUT FUNCTIONAL ANKLE INSTABILITY**

Steib, S.1, Hentschke, C.1, Pfeifer, K.1, Zech, A.2

1: University of Erlangen-Nuremberg (Erlangen, Germany), 2: University of Hamburg (Hamburg, Germany)

**Introduction** Sensorimotor control is acutely affected by fatiguing exercise (Paillard, 2012). Further, deficits exist in individuals with functional ankle instability (FAI) (Hertel, 2008). It is unclear whether the presence of ankle instability increases the magnitude of fatigue-induced sensorimotor control alterations. **Methods** 57 athletes, 19 individuals with FAI, 19 ankle sprain copers and 19 non-injured controls participated in this study. Center of pressure sway velocity in single-leg-stance (vCOP), time to stabilization (TTS) in a unilateral jump-landing task, maximum reach distance in the star excursion balance test (SEBT) and passive ankle joint position sense (JPS) were assessed in a randomized, counterbalanced order before and immediately after a fatiguing treadmill running exercise. A three factorial linear mixed model was specified for each of the main outcomes to evaluate the effects of a previous ankle sprain ('FAI', 'coper'), exhausting exercise ('fatigue') and their interactions ('fatigue' x 'FAI', 'fatigue' x 'coper'). Effect sizes (ES) were calculated as Cohen's d. **Results** In unfatigued condition, the FAI group demonstrated lower SEBT scores in anterior (p=.004; ES=-0.38) and lateral direction (p=.026; ES=-0.30) compared to controls. No pre-fatigue differences existed between copers and controls for any outcome measure. TTS, SEBT and vCOP, but not JPS, were negatively affected by fatigue in all groups. Copers suffered significantly larger pre-fatigue to post-fatigue reductions in anterior reach direction compared to the FAI (p=0.007; ES=-0.36) and control group (p=0.052; ES=-0.26). No other significant group by fatigue interactions existed. However, the FAI group demonstrated the largest fatigue effects in medial SEBT (p=0.002; ES= -0.42) and medial-lateral TTS (p≤0.001; ES= 0.63). **Discussion** Physical fatigue caused sensorimotor control impairments in athletes with a history of an ankle sprain. Although effects were small, the presence of ankle instability appeared to increase fatigue-induced alterations of postural control. **References** Paillard T. (2012). *Neurosci Biobehav Rev*, 36(1), 162-176. Hertel J. (2008). *Clin Sports Med*, 27(3), 353-370.

**RELATIONSHIP BETWEEN NEUROPSYCHOLOGICAL PERFORMANCE AND OCCURRENCE OF KNEE INJURIES IN TEAM SPORTS**

Dallinga, J., Does, H.T.D., van der Benjaminse, A., Lemmink, K.A.P.M.

University Medical Center Groningen and University of Applied Sciences (Groningen, Netherlands)

**Introduction** Determining risk factors is crucial for the prevention of injuries (Van Mechelen et al., 1992). Recently, attention has been paid to neuropsychological screening for knee injuries. Reaction time in anterior cruciate ligament (ACL) injured players was slower compared to uninjured players (Swanik et al., 2007). The aim of this study was to compare neuropsychological performance at baseline between elite team players with and without a knee injury during the subsequent season. **Methods** Fifty male (age=22.9 ± 3.9 y, height=193.5 ± 7.9 cm, mass=87.1 ± 10.6 kg) and 19 female (age=21.5 ± 2.9 y, height=175.9 ± 7.3 cm, mass=69.0 ± 11.7 kg) elite team players participated in this study. At baseline, the determination test (DT) and peripheral perception test (PP) of the Vienna Test System (Schuhfried, Moedling, Austria) were used to calculate reaction time and accuracy of reactions. In the consecutive season injuries were reported by team physical therapists (Fuller et al., 2006). Student t-tests were used to analyze differences between injured and uninjured players. **Results** Seven acute (10.1% of players) and 11 overuse knee injuries (17.4% of players) were reported. A slower reaction time was found in

athletes that sustained an overuse knee injury compared to uninjured athletes ( $645.45 \pm 63.46$  ms vs  $614.56 \pm 54.55$  ms,  $p < 0.05$ ). Players that sustained an overuse knee injury showed fewer reactions in total ( $237.67 \pm 11.33$  vs  $244.56 \pm 13.22$ ,  $p < 0.05$ ) and fewer reactions on time ( $189.67 \pm 21.15$  vs  $200.91 \pm 17.77$ ,  $p = 0.03$ ) compared to uninjured players. Finally, fewer reactions in total were found in players that sustained an acute knee injury compared to uninjured players ( $235.14 \pm 8.47$  vs  $244.29 \pm 13.25$ ,  $p = 0.04$ ). Conclusion A slower reaction time and lower accuracy of reactions were shown in players that sustained an overuse injury compared to uninjured players. No speed-accuracy trade-off was seen (Pachella, 1974), since a slower reaction time to stimuli was accompanied by fewer reactions. A lower accuracy was reported in players that sustained an acute knee injury compared to uninjured players. Reaction time and accuracy of reactions seem potential screening tools for knee injuries. The mechanism behind the relation between neuropsychological performance and knee injury needs further examination. References Fuller CW, Ekstrand J, Junge A, et al. ### **MODERATE ENDURANCE EXERCISE IN SICKLE CELL DISEASE PATIENTS: EFFECTS ON OXIDATIVE STRESS, NITRIC OXIDE BIOAVAILABILITY AND ENDOTHELIAL ACTIVATION**

Faes, C.1, Martin, C.1, Connes, P.2,3, Balayssac-Siransy, E.4, Hivert, L.1, Bogui, P.4, Pialoux, V.1

1 University of Lyon 1, France; 2 University of French West Indies, Pointe à Pitre, France; 3 PRES Sorbonne, Paris Cité, France; 4 University of Felix Houphouët Boigny, Abidjan, Ivory Coast

**Introduction** Sickle cell disease (SCD) is a genetic disease leading to the synthesis of abnormal hemoglobin (HbS). When deoxygenated, HbS polymerizes causing the sickling of red blood cells (RBCs). The recurrent painful vaso-occlusive crisis caused by the rigid and sticky sickle RBCs leads to severe organ damages. Intense exercise is often contra-indicated by health care professionals in SCD patients because the metabolic changes could promote RBC sickling. Nevertheless, few studies investigated the effects of exercise in SCD. The aim of this study was to test the effects of a mild-moderate endurance exercise on oxidative stress, nitric oxide bioavailability and endothelial activation biomarkers in SCD patients and non-SCD controls. **Methods** Twelve SCD patients and 15 healthy subjects (CONT) were enrolled in the study. They completed a 20 minutes duration submaximal cycling exercise at the same absolute intensity (50W). Before (Trest) and after the exercise (Tex), blood was sampled and plasma markers of oxidative stress (AOPP, MDA, nitrotyrosine), antioxidant activity (SOD, GPx, catalase, FRAP), endothelial activation (sVCAM-1, sICAM-1, sP-selectin, sE-selectin, sL-selectin) and NO bioavailability (NOx) were investigated. Results Plasma levels of sVCAM-1 and nitrotyrosine were significantly higher ( $P < 0.001$ ) and NOx, AOPP were significantly lower ( $P < 0.05$ ) in SCD compared to CONT subjects. While SOD and catalase did not differ between the two groups, GPx and FRAP concentrations were higher in SCD than CONT subjects at any time ( $P < 0.05$ ). sVCAM-1, sICAM-1 and MDA concentrations increased similarly in the two groups with exercise ( $P < 0.05$ ). The exercise did not induce significant changes for the other plasma markers. **Discussion** Although the exercise intensity was considered mild-moderate, plasma vascular adhesion molecules and MDA concentrations increased in both groups between Trest and Tex. In SCD patients, such increase may further increase the risks for vaso-occlusive complications. Concurrently, we however observed lower plasma AOPP in SCD patients that could be accounted for higher plasma total antioxidant capacity. Overall, this study is the first to report that mild-moderate exercise increases oxidative stress and endothelial activation in SCD patients. Based on the present data, care should be taken by SCD patients to practice safety moderate effort.

### **FOREARM DEOXYGENATION USING A HANDGRIP TEST IN SEVERE MITOCHONDRIAL MYOPATHY AND MCARDLE DISEASE**

Celie, B.1, Boone, J.1, Smet, J.2, Vanlander, A.2, De Bleecker, J.3, Van Coster, R.2, Bourgois, J.1

Ghent University

1Department of Movement and Sports Sciences, Ghent University, Ghent, Belgium 2Department of Pediatrics, Division of Pediatric Neurology and Metabolism, Ghent University Hospital, Ghent, Belgium 3Department of Neurology, Ghent University Hospital, Ghent, Belgium **Introduction** Mitochondrial myopathy (MM) describes mitochondrial diseases predominantly affecting skeletal muscle. The glycogen storage disease type V or McArdle describes a metabolic disorder, caused by a myophosphorylase deficiency. The validity and reliability of near infrared spectroscopy (NIRS) in skeletal muscle at rest and during exercise was reported earlier in literature. Therefore we propose a handgrip exercise protocol using NIRS for evaluation of microvascular oxygen extraction in patients with MM and McArdle disease. The reliability of this protocol has been established in a previous study (Celie et al., 2012). **Methods** Three groups of subjects were studied: 6 patients with McArdle disease, 11 patients with severe MM and 11 age- and gender-matched untrained healthy controls. The protocol started with arterial occlusion of the forearm by external compression until a steady state for deoxy[Hb+Mb] (100%-value) was reached. Deoxy[Hb+Mb] is the amount of unloaded hemoglobin and myoglobin (in  $\mu\text{M}$ ) and is considered as an index of oxygen extraction. Thereafter, a dynamic handgrip exercise protocol was used until exhaustion. The changes in deoxy[Hb+Mb] during each work step (i.e., the mean of the maximum 10-s) were expressed in percent. A Repeated Measures ANOVA was used to compare the increase in deoxy[Hb+Mb] between McArdle- and MM patients and healthy control subjects. Results A significant main effect ( $p < 0.001$ ) was found for groups indicating that the increase in deoxy[Hb+Mb] showed a significant different pattern for all populations. In the post hoc analysis significant deoxy[Hb+Mb] differences were found between MM patients and healthy controls ( $p < 0.001$ ) and between McArdle patients and healthy controls ( $p = 0.034$ ). No significant deoxy[Hb+Mb] difference was found between MM and McArdle patients ( $p = 0.112$ ). **Discussion** In accordance with the incremental cycle ergometric protocol in Grassi et al. (2007) we found an impaired oxygen extraction in McArdle and MM patients. NIRS can be confirmed as a valuable tool to detect impaired oxygen extraction, which can be useful in screening and follow up of patients. Important advantages of this handgrip exercise protocol are the small cost and low cardiovascular load, as some patients suffer from cardiomyopathy. ## RELATIONSHIP BETWEEN CARDIORESPIRATORY FITNESS AND QUALITY OF LIFE IN RESPONSE TO A LIFESTYLE INTERVENTION STUDY IN BREAST CANCER SURVIVORS

Travier, N.1, Guillaumo, E.2, Agudo, A.1, Oviedo, G.R.3, Fonseca, A.1, Javierre, C.2

1-Catalan Institute of Oncology (ICO-IDIBELL), Barcelona, Spain; 2-University of Barcelona, Barcelona, Spain; 3-University Ramon Llull, Barcelona, Spain

**Introduction** Physical activity (PA) in breast cancer (BC) survivors may improve quality of life (QoL). Nevertheless, it is unclear whether PA interventions of moderate-to-high intensity could promote significant changes in cardiorespiratory fitness (CRF) and whether changes in CRF and QoL could be related<sup>2</sup>. The aim of the present study was to assess changes in QoL and CRF during a diet and PA intervention in BC survivors and to investigate the possible relation between these changes. **Methods** The intervention of this 12-week single-arm pre-post pilot study involved group-based sessions: one-hour weekly diet sessions delivered by a nutritionist and 75-minute bi-weekly PA sessions of moderate-to-high intensity led by experienced PA monitors. This intervention, conducted in 2012 at the Catalan Institute of Oncology (Barcelona, Spain), was designed to promote weight loss, and therefore targeted at overweight/obese women, aged 18 to 75, who had recently (up to 6 months previously) completed chemotherapy and/or radiotherapy for a non-metastatic BC. CRF and QoL were assessed before and after the intervention and compared using paired t-tests. Stepwise linear regression models, including CRF variables, weight change and participants' characteristics, were used to assess the independent association between changes in CRF and changes in QoL. **Results** Among the 37 BC survivors (out of 42) who completed the intervention, significant changes in CRF and QoL were observed. Peak O<sub>2</sub> uptake respect to body weight (mL.kg<sup>-1</sup>.min<sup>-1</sup>) increased from 19.0±2.8 to 24.0±4.1 (p<0.001) while workload respect to body weight (watts.kg<sup>-1</sup>) increased from 1.30±0.28 to 1.72±0.34 (p<0.001). The increase in workload respect to body weight was independently associated with increases in physical, mental and general health as well as with a decrease in fatigue. **Discussion** This lifestyle intervention in BC survivors improved participants' QoL and CRF and suggested possible relationships between CRF and QoL. Future research is needed to confirm these associations and design and promote lifestyle interventions that will improve BC survivors' QoL. **References** 1. Bicego D, Brown K, Ruddick M, et al. ## COMPARISON BETWEEN THREE COMMON AND EFFECTIVE ENDURANCE TRAINING PROTOCOLS ON EXERCISE CAPACITY IN CORONARY ARTERY DISEASE

Tschantcher, M., Eichinger, J., Egger, A., Dröse, S., Haller, U., Niebauer, J.

Paracelsus Medical University, Salzburg

**Introduction** Endurance training is a key component of cardiac rehabilitation and recommended in treatment guidelines of all major professional societies [Heran 2011, Piepoli 2012]. During the past decades different endurance training protocols have been studied [Rognmo 2004, Helgerud 2011], however, a head-to-head comparison between the most effective modes, i.e. continuous endurance training (CET), high-intensity interval training (HIIT), and pyramid training (PYR), has not yet been performed in patients with coronary artery disease (CAD). **Methods** In this prospective, randomized study three isocaloric training protocols were compared: 1) CET (n=18): 31min at 65-75% HRpeak according to the European Guidelines of Cardiac Rehabilitation; 2) HIIT (n=17): 4x4min intervals at 85-95% HRpeak, each followed by 3min of active recovery at 60-70% HRpeak (25min total); and 3) PYR (n=19): three repetitions (each 8min) of gradual load increase and subsequent decrease from 65-95-65% HRpeak, supplemented by 2min recovery in between pyramids at 65% HRpeak (28min total). All protocols included 5min of warm-up and cool-down at 60-70% HRpeak. Supervised training was performed 3x/week for 6 weeks on cycle ergometers. Primary endpoint was physical work capacity during maximal ergometry. **Results** All protocols led to highly significant increases (p<0.001) of exercise capacity (begin vs. end: CET: 132W vs. 160W (21,2% increase); HIT: 148W vs. 180W (21,6%); PYR: 130W vs. 160W (23,1%)), without statistically significant differences between protocols. **Discussion** Our data clearly show that 6 weeks of exercise training leads to significant improvement in exercise capacity by >20%, regardless of the mode of endurance training. Therefore exercise training can be even more individualized and thus tailored to the specific preferences and needs of patients, which might have a positive impact on patients' compliance. **References** Heran, B.S., et al., *Cochrane Database Syst Rev*, 2011(7):CD001800 Piepoli, M.F., et al., *Eur J Prev Cardiol*, 2012 Rognmo, O., et al., *Eur J Cardiovasc Prev Rehabil*, 2004. 11(3): p. 216-222 Helgerud, J., et al., *Int J Sports Med*, 2011. 32(1): p. 54-9

### OP-PM47 Training and Testing [TT] 1

#### NON-INVASIVE DETECTION OF VENTILATORY BREAKPOINTS DURING FIELD TESTING IN RUNNING

Heyde, C.1, Leutheuser, H.2, Röcker, K.3, Gollhofer, A.1

1: DSSS (Freiburg, Germany), 2: DSG-PRL (Erlangen, Germany), 3: APH (Furtwangen, Germany)

**Introduction** Determination of the Ventilatory Threshold (VT) is one of the key parameter in cardiopulmonary fitness testing and individual training guidance (Gaskell et al. 2001). However, mainly due to methodological problems, neither the detection of VT nor Respiratory Compensation Point (RCP) is established in the field. Therefore, the aims of this study were to validate an available Respiratory Inductance Plethysmography (RIP) device (LifeShirt™ Garment, Wilhelm et al. 2003) during running exercise as well as to establish a novel statistical method for computerized detection of significant breakpoints in ventilation during a graded ramp test (RT) in the field. **Methods** During an incremental test (IT) on treadmill until voluntary exhaustion, breath-by-breath data recorded by RIP were compared to flow measurements at the orifice in 186 healthy subjects. VT, RCP and Lactate Threshold (LT) were determined as described by Beaver et al., 1986 and Roecker et al., 1998. Within 3 weeks around the IT two additional RT on track were performed, while subjects worn a RIP garment and speed was controlled. During RT slope changes in ventilation were determined as significant breakpoints (BP1 and BP2). Validity of RIP in

measuring breathing rate (fR) and tidal volume (Vt) was examined by means of  $R^2$  and equivalence statistics (Jones et al. 1996). Speed at LT and RCP were compared respectively to speed values at BP1 and BP2 in RT by examining Pearson's  $r$ . Test-Retest reliability of individual determined BP1 and BP2 between both RT was examined by equivalence statistics. Results Means of  $R^2$  ( $\pm$ SD) in fR and Vt respectively were  $0.96\pm 0.04$  and  $0.91\pm 0.05$  ( $p < .01$ ) whereat 99% and 96% of all breaths were measured within  $\pm 20\%$  limits of equivalence. After analyzing a random sample of 28 subjects, individual speed at LT and RCP correlated significantly to speed at BP1 ( $r=0.79$ ,  $p < .05$ ) and BP2 ( $r=0.72$ ,  $p < .05$ ), respectively. Speed values at BP1 and BP2 between both RT were equivalent within  $\pm 10\%$ . Discussion RIP is able to determine ventilatory timing and volume nearly equivalent to flow meter under conditions of various running speeds. Novel statistical methods applied on RIP data may enable detection of ventilatory breakpoints in field supportive for cardiopulmonary fitness testing and individual training guidance outside the lab. ## A RANDOMIZED CONTROLLED TRIAL TO INVESTIGATE THE EFFECTS OF TRAINING IN THE FUNCTIONAL MOVEMENT CIRCLE FOR ELDERLY ON FALL-RELATED RISK FACTORS

Morat, T., Mechling, H.

*German Sport University Cologne*

**Introduction** Guidelines of fall prevention recommend in particular balance and resistance training to positively influence risk factors for falls (Sherrington et al., 2008). To facilitate the transfer of exercises to movements in daily life, functional tasks of daily living (=FT; for example stair climbing) were embedded in the Functional Movement Circle for Elderly (FuMoC-E) – in addition to systematic balance and resistance training exercises. The aim of this study was to analyse the effects of training in the FuMoC-E (IG1) in comparison to resistance and balance training without FT (IG2) and a control group (CG). **Methods** In this randomized controlled trial, 35 community-dwelling older adults aged 60 years and older were recruited. Participants were randomized into one of the three groups: IG1 (n=12), IG2 (n=11) trained over six months (twice a week) and the control group (n=12) maintained their usual activities. The primary outcomes were 1-repetition maximum test (= 1RM test) in leg and chest press, modified Timed Up and Go Test (modTUG: a: normal; with an additional b: cognitive and c: motor task), Maximal Step Length Test (MSLT), Chair Rise Test (CRT) and Multisurface Obstacle Test for Older Adults (MSOT; Morat et al., 2013). These parameters were measured at baseline, after three and six months. **Results** Six months after baseline, IG1 (+9%; +20%) and IG2 (+16%; +23%) improved in the 1RM test (in leg press; chest press (significantly)) in comparison with the control group (-4%; -4%) ( $p=.06/p=.01$ ). Concerning measures of functional mobility, modTUG showed changes in IG1 (a: +8%; b: +9%; c: +4%), IG2 (a: +5%; b: 0%; c: +2%) and CG (a: -2%; b: -6%; c: -3%) with significant improvements of IG1 (a:  $p=.003$ ; b:  $p=.004$ ) and IG2 (a:  $p=.034$ ). Results of MSLT displayed significant differences of IG1: +12% ( $p=.001$ ) and IG2: +8% ( $p=.021$ ) in comparison to CG: 0% ( $p=.022$ ). In MSOT, IG1 (+11%,  $p < .001$ ) enhanced performance with significant group differences at T3 in opposition to IG2 ( $p=.014$ ) and CG ( $p < .02$ ). **Discussion** The findings demonstrate that training in the FuMoC-E was an effective training program for the tested older adults to improve strength and functional performance after six months of training. The additional component of functional movements of daily life showed significant improvements in variables of functional performance than a sole resistance and balance training. Training in the FuMoC-E could address both strength and functional performance. **References** Morat T, Kroeger D, Mechling H. (2013). *Eur Rev Aging Phys Act*. DOI 10.1007/s11556-013-0121-0. ## A NEW MODEL FOR ESTIMATING PEAK OXYGEN UPTAKE BASED ON POST-EXERCISE MEASUREMENTS AND HEART RATE KINETICS IN SWIMMING

Schuller, T., Rodríguez, F.A., Iglesias, X., Barrero, A., Chaverri, D., Hoffmann, U.

*German Sport University Cologne*

**Introduction** We aimed to assess the validity of a mathematical model based on heart rate (HR) and post-exercise  $\dot{V}O_2$  measurements for estimating peak  $\dot{V}O_2$  at the end of a swimming exercise. Its physiological rationale relies on the assumption that during the immediate recovery the systolic volume and the arterio-venous  $O_2$  difference remain practically constant for a certain period. According to Fick's principle, this leaves HR as the main parameter for changes in  $\dot{V}O_2$  (Drescher et al., 2010). **Methods** 34 elite swimmers performed 3x200 m at increasing submaximal speeds, followed by a maximal 200-m swim.  $\dot{V}O_2$  was measured breath-by-breath using a portable gas analyser (K4 b2, Cosmed, Italy) connected to the swimmer by a respiratory snorkel. HR was measured from RR intervals (CardioSwim, Freelap, Switzerland). Data were time aligned and 1-s interpolated.  $\dot{V}O_2$  at the end of exercise [ $\dot{V}O_2(\text{end})$ ] was the average of the last 20 s during the swim, and recovery  $\dot{V}O_2$  was the post-exercise 20-s average [ $\dot{V}O_2(0-20)$ ]. The model calculates a virtual  $\dot{V}O_2$  at time (t) of recovery [ $\dot{V}O_2(t)$ ], using the quotient between the peak HR during the last 10 s of the swim [HR(0)] and the 1-s interpolated value at (t) [HR(t)], multiplied by the 1-s interpolated  $\dot{V}O_2$  value at (t) [ $\dot{V}O_2(t)$ ], resulting in:  $\dot{V}O_2(t) = \text{HR}(0) / \text{HR}(t) \cdot \dot{V}O_2(t)$ . Different  $\dot{V}O_2$  average values were calculated for different recovery intervals (0-20, 5-20, 10-20, 15-20, and 10-15 s). **Results**  $\dot{V}O_2(\text{end})$  (mean  $3547 \pm$  SD  $692$  ml/min) was different from  $\dot{V}O_2(0-20)$  ( $3431 \pm 685$ ) (mean diff.  $-116$ , 3.3%,  $p=0.001$ ). All virtual  $\dot{V}O_2$  values were highly correlated with ( $R^2=0.86$  to  $0.96$ ,  $p < 0.001$ ), and not different from  $\dot{V}O_2(\text{end})$ . Best estimates (mean diff.  $< 0.5\%$ ) were delivered by  $\dot{V}O_2(0-20)$  ( $3564 \pm 698$ ,  $R^2=0.96$ ,  $\text{SEE}=120$ ) and  $\dot{V}O_2(5-20)$  ( $3559 \pm 705$ ,  $R^2=0.94$ ,  $\text{SEE}=121$ ). **Discussion** The difference between peak  $\dot{V}O_2$  at the end of the exercise and during recovery supports the need for the model, while the lack of differences and high correlation between peak  $\dot{V}O_2$  and the estimated post-exercise  $\dot{V}O_2$  support its basic physiological assumption, avoiding the uncertainty of the backward extrapolation method (Rodríguez, 1999). In conclusion, the proposed mathematical model for peak  $\dot{V}O_2$  estimation based on post-exercise measurements, which takes into account both HR and  $\dot{V}O_2$  off-kinetics, provides valid results when observing some limitations. **References** Drescher U, Essfeld D, Hoffmann U. **VALIDITY OF SUB-MAXIMAL ERGOMETER TESTS FOR ESTIMATING MAXIMAL AEROBIC CAPACITY IN CHILDREN**

Ekblom, Ö.

*Swedish School of Sport and Health Sciences*

The aerobic capacity in children is a central factor in youth sports due to its close relation to performance. Poor aerobic capacity has also been linked to increased prevalence of cardio-metabolic risk factors, increased risk for depression in adulthood and cognitive function and development. However, assessment of aerobic capacity using maximal tests poses a great challenge in unaccustomed children, and therefore different forms of sub maximal tests are frequently used. The aim was to compare validity between different cycle ergometer based methods for aerobic fitness testing in 11-12 yrs old children. Subjects (n=62) performed a bout of sub-maximal work on a mechanically braked cycle ergometer (893E; Monark Exercise, Vansbro, Sweden). Work rate was set to elicit a heart rate between 140 and 170 bpm. Åstrand-Rhyming (Å-R) nomogram-based values (unadjusted, age-adjusted and maximal heart rate adjusted) and values obtained using the Woynarowska and the Olgyn- Binyildiz methods were compared. Direct measurement was used as criterion method, using computerized metabolic system with mixing chamber (Oxycon Pro, Erich Jaeger GmbH, Germany). Correlation coefficients between measured values and the different Å-R based estimates varied between 0.734 and 0.753, with SEEs varying between 386 mL x min<sup>-1</sup> and 398 mL x min<sup>-1</sup> and CVs between 16.9 % and 19.8%. Unadjusted and maximal heart rate Å-R data gave a mean underestimation of 346 mL x min<sup>-1</sup> (19.0%) and 396 mL x min<sup>-1</sup>, respectively. Using similar method as Åstrand to correct for age related error, a proposed factor for age adjusting in 12 years-olds is 1.19. Multiplying unadjusted Å-R data by 1.19 gave a mean overestimation of 23 mL x min<sup>-1</sup>. The Olgyn Binyildiz-method correlated stronger with measured values (r=0.865) and gave a relatively small SEE (298 mL x min<sup>-1</sup>) and CV (14.7%), but resulted in a large underestimation by 660 mL x min<sup>-1</sup> or 27.8 %. Using the method proposed by Woynarowska to adjust obtained Å-R data increased correlation to 0.865, slightly decreased SEE (340 mL x min<sup>-1</sup>) and CV (17.2%) and generated a mean difference of 14 mL x min<sup>-1</sup>, thus smaller than the other methods. In studies with a test-retest design the use of the Olgyn Binyildiz-method is justified due to its low random error. On the other hand, in studies aiming at comparing data with those obtained with direct measurements or absolute values in larger groups, the Woynarowska or possibly the age adjusted Å-R method may be the primary choice due to their limited systematic error. Depending on the aim of a study, researchers must carefully make a decision on which method to select. Astrand PO, Ryhming I. (1954) Journal of applied physiology. 7:218-21 Binyildiz PO (1980) Eur J Appl Phys 43:213-9 Woynarowska B (1980) Eur J Appl Phys 43:19-23

**LIPID MOBILISATION AND RESPIRATORY QUOTIENT DURING REST AND EXERCISE IN YOUNG AND ELDERLY AFTER 2 WEEKS OF UNILATERAL IMMOBILISATION**

Vigelsoe, A., Gram, M., Noerregaard, J., Wiuff, C., Kuhlman, A.B., Dela, F., Helge, J.W.

*University of Copenhagen*

Background: During exercise lipids are a major fuel for skeletal muscle. Here we study lipid mobilisation and respiratory quotient (RQ) across the leg during rest and at moderate intensity exercise after 14 days of one leg immobilisation (IM) using the other leg as control (CON). Methods: Healthy young (Y) (n=14; age 23±1 yr (mean±SEM); 24±0.4 kg/m<sup>2</sup>; 45±1 ml O<sub>2</sub>/min/kg; bodyfat (BF%): 20±2%) and elderly (E) (n=12; age 68±1.2 yr; 27±0.2 kg/m<sup>2</sup>; 32±2 ml O<sub>2</sub>/min/kg; BF%: 29±2%) males were included. The subjects had one leg immobilised for 2 weeks with a DONJOY® cast. After immobilisation arterio(A)-venous(V) catheters were inserted in the brachial artery and femoral veins. A-V differences across the leg were measured at rest (-15 and 0 min) and during dynamic knee-extensor exercise in two independent one-leg kicking-ergometers (30 and 45 min). There was no difference in the absolute, (20±1 and 19±1 Watt for Y and E, respectively) or relative workload between YIM/YCON and EIM/ECON (55±3/49±3% and 50±3/47±5% of Wattmax, respectively). Blood flow was measured by ultrasound Doppler. VO<sub>2</sub>, FFA -uptake, VCO<sub>2</sub> and glycerol -release were calculated by Fick's principle. RQ was calculated from the ratio of V-A VCO<sub>2</sub> and A-V VO<sub>2</sub> -difference. Results: Y had lower BMI and BF% but higher VO<sub>2</sub>max compared to E (P<0.05). After 2 weeks of immobilisation leg lean mass (LLM) was higher (P<0.05) in YCON (10.5±0.3 kg) compared to YIM, ECON and EIM (10.1±0.3kg, 9.4±0.4kg and 9.4±0.3kg), respectively. At rest the RQ was higher (P<0.05) in YIM/YCON compared to EIM/ECON (0.93±0.04/0.92±0.04 and 0.84±0.02/0.84±0.02, respectively). However, during exercise the RQ for EIM/ECON increased to the level of YIM/YCON (0.92±0.02/0.92±0.02 and 0.92±0.02/0.91±0.02, respectively). At rest free fatty acid (FFA) uptake and glycerol release did not differ between YIM/YCON and EIM/ECON (FFA: -1.01±0.32/-1.04±0.38 and 0.20±0.70/0.60±0.80 μM/min/kg LLM; glycerol: 0.6±0.1/0.5±0.1 and 0.4±0.1/0.4±0.1 μM/min/kg LLM, respectively). During exercise FFA uptake increased (P<0.05) for both groups, with a larger increase (P<0.05) in the EIM/ECON compared to YIM/YCON (7.30±1.40/6.30±1.50 compared to 2.01±0.99/2.69±0.83 μM/min/kg LLM, respectively), whereas leg glycerol release only increased (P<0.05) from rest to exercise in YIM/YCON, but not in EIM/ECON (1.6±0.3/1.3±0.2 and 0.4±0.2/0.4±0.2 μM/min/kg LLM, respectively). Conclusion: Intriguingly, 2 weeks of complete leg immobilisation was not sufficient to induce changes in RQ across the leg during rest and exercise. Further, our findings imply that during exercise elderly utilize relatively more exogenously derived fatty acids per lean mass compared to young subjects.

**EFFECT OF PHYSICAL EXERCISE ON POSTURAL CONTROL IN PATIENTS WITH HIP OSTEOARTHRITIS**

Miller, R., Steinhilber, B., Haupt, G., Janssen, P., Grau, S., Krauss, I.

*University Hospital Tuebingen*

Introduction Numerous studies have identified Osteoarthritis (OA) induced changes as a factor that impairs postural stability (i.e. Hinman et al., 2002). Resulting balance deficits are associated with higher risk of falls (Lord et al., 2007), consequently leading to loss of independence and mobility. Physical exercise has been shown to improve postural stability in patients with OA. However, no study focuses on exercises in relation to static balance of patients with hip OA (hOA). Hence, this prospective, randomised, and placebo-controlled study aims to determine whether an exercise program specifically designed for patients with hOA can improve static postural control. Methods 218 patients with hOA (aged 59±10 years, BMI 27±4, 129 males) were randomly assigned to an exercise group (EG, n=71), a control group (CG, n=69), and a sham-ultrasound placebo group (PG, n=70). During a 12 week period, EG completed a home work-out (2/week) in addition to a weekly supervised group training. Sham-ultrasound was applied once a week, 15'. CG received no treatment. Postural control was assessed by quantifying centre of pressure (COP) velocity during single leg (SLS) and tandem stance (TS) on a plantar pressure measurement platform (Zebri Medical GmbH, Isny) before (M1) and after (M2) the intervention period. The Wilcoxon signed-rank tests were used to compare differences (M2-M1) between each of the groups (p<.05). Results There were no differences in TS (p=.90) or SLS (p=.71) of COP velocity between groups at baseline assessment. After the intervention period, participants of the EG showed significant improvement in TS compared to CG (p=.008) and to PG (p=.04). However, no significant differences were found in SLS between EG and

CG or EG and PG. Discussion This study shows that a specific exercise program designed for patients with hOA can improve static balance performance in a tandem stance position. The findings are consistent with results that have also shown improvements in postural stability measures of patients with hOA. Thus, Rasch et al. (2010) reported effects on balance in bilateral but not in unilateral standing conditions after total hip replacement. An explanatory approach for the improvements in TS but not in SLS may be the greater number of failed attempts in SLS compared to TS. This assumption agrees with an observation of Fox et al. (1996), who determined that SLS is not feasible for patients with hip fracture due to the great number of failed attempts. References Fox K, Felsenthal G, et al. (1996). #### RESPONSE INHIBITION ALTERS PERCEPTION OF EFFORT INDEPENDENTLY OF NEUROMUSCULAR ALTERATIONS

Pageaux, B.1, Lepers, R.2, Rozand, V.2, Marcora, S.1

*University of Kent*

1: Endurance Research Group (SSES, University of Kent, UK); 2: INSERM U1093 (Université de Bourgogne, FR) Introduction Perception of effort (PE), defined as "the conscious sensation of how hard, heavy, and strenuous exercise is", is known to be a determinant of endurance performance (Marcora, 2009a). Recent studies demonstrated the negative effect of cognitive tasks involving response inhibition (RI) on PE during subsequent physical tasks (Marcora et al., 2009b; Pageaux et al., 2012). RI is a component of cognitive control, and it refers to the inhibition of inappropriate motor or emotional responses. These studies found higher PE independently of any alteration of the cardiorespiratory and metabolic responses to exercise. However, higher PE may be due to a negative effect of RI on neuromuscular fatigue. The aim of this study was to investigate this hypothesis. Methods Neuromuscular function was assessed in two different conditions: 1) pre and post a cognitive task involving RI (incongruent Stroop Task) to exacerbate PE; 2) pre and post a control cognitive task with no RI (congruent Stroop task). Both cognitive tasks lasted 30 min followed by 6 min of submaximal cycling at 80% of peak power output, and a third assessment of neuromuscular function. Rate of perceived exertion was measured during cycling. Results are presented as means  $\pm$  SEM, and analyzed by two-way repeated-measure ANOVAs. Results Neither cognitive tasks induced any central or peripheral fatigue ( $P > 0.05$ ). During cycling, subjects rated PE higher after the cognitive task involving IP (IP  $13.9 \pm 0.3$ , control  $13.3 \pm 0.4$ ). Cycling induced a similar decrease in maximal voluntary contraction (IP  $-13.4 \pm 4.3$  %, control  $-11.9 \pm 3.2$  %), voluntary activation level (IP  $-6.4 \pm 3.2$  %, control  $-6.3 \pm 2.4$  %) and resting twitch (IP  $-34.1 \pm 3.8$  %, control  $-34.7 \pm 3.3$  %) in both conditions. Discussion These results confirm the link between RI and PE. Moreover this study provides the first experimental evidence that the negative effect of RI on PE is independent of any neuromuscular alteration. Indeed, RI did not induce any central fatigue, and neuromuscular fatigue induced by cycling was similar in both conditions. These results suggest that RI and PE share some common neurobiological mechanisms, and that activities involving RI should be avoided before endurance competitions. References Marcora SM (2009a). #### IMPACT OF NEUROMUSCULAR ELECTRICAL STIMULATION CURRENT CHARACTERISTICS ON NEUROMUSCULAR FATIGUE

Neyroud, D., Dodd, D., Gondin, J., Maffiuletti, N.A., Kayser, B., Place, N.

*University of Geneva*

Introduction Neuromuscular electrical stimulation (NMES) for rehabilitation and strength training purposes usually involves short pulses (50-400  $\mu$ s) at low-to-moderate tetanic frequencies (20-50 Hz), hereafter referred to as conventional (CONV) NMES (1). With CONV NMES motor units are recruited in a random, non selective and spatially fixed way, and a common problem is exaggerated muscle fatigue in comparison to voluntary contractions (2). NMES with larger pulse width ( $\sim$ 1 ms) at a higher frequency ( $\sim$ 100 Hz) (wide pulse high frequency, WPHF) may in part recruit motor units according to the size principle via a spinal reflex pathway, which could potentially minimize muscle fatigue (1). The aim of the present study was to test the hypothesis that muscle fatigue would be lower following WPHF compared to CONV NMES. Methods Fourteen healthy subjects (11 men and 3 women, aged  $27 \pm 4$  yrs) participated to two experimental sessions performed in a random order (WPHF and CONV NMES). WPHF (100 Hz-1 ms) and CONV (25 Hz-50  $\mu$ s) NMES was delivered to the triceps surae (20 repetitions with an on:off ratio of 20:40 s, at an initial target force of 10% of maximal voluntary contraction force (MVC)). The pre-post NMES decline in MVC force was considered as index of muscle fatigue. Voluntary activation level (VAL, twitch interpolation technique) and potentiated doublet force were used as indexes of central fatigue and peripheral fatigue, respectively. Results The reduction in MVC force (WPHF:  $-7.0 \pm 2.7$ %; CONV:  $-6.2 \pm 2.5$ %;  $p < 0.01$ ) and in doublet force (WPHF:  $-8.0 \pm 4.0$ %; CONV:  $-7.4 \pm 6.1$ %;  $p < 0.001$ ) were similar between conditions, whereas no change was observed for VAL ( $p > 0.05$ ). The 20 evoked contraction force-time integral was lower for WPHF than for CONV (WPHF:  $1086 \pm 834$  N.s vs. CONV:  $1898 \pm 559$  N.s,  $p < 0.001$ ). Further, force-time integral was reduced by contraction 2 in WPHF ( $p < 0.001$ ), whereas no reduction was observed in CONV ( $p > 0.05$ ). Conclusion Contrary to our hypothesis, we found a similar level of muscle fatigue, which can be mainly attributed to peripheral impairment, following both CONV and WPHF NMES despite differences in force-time integral induced by WPHF in comparison to CONV. These findings therefore suggest a random motor unit recruitment in both conditions. 1. Collins DF, Burke D, and Gandevia SC. J Physiol 538: 289-301, 2002. 2. Maffiuletti NA. **DOES TRUNK STRENGTH CORRELATE WITH THE ONSET TIMING OF ANTICIPATORY POSTURAL ADAPTATIONS?**

Voglar, M., Sarabon, N.

*University of Primorska, Science and research center Koper*

**Introduction** Upright posture in human is an ongoing process of sensory-motor control. Stability is defined as ability to maintain the position or to continue intended movement, when perturbation occurs. Some perturbations are predictable and in such cases central nervous system induces anticipatory postural adaptations (APAs) which precede the perturbation. Fast voluntary arm rise represent expected perturbation, often used in protocols for APAs assessment (Bouisset and Do, 2008). The purpose of this study was to investigate if the strength of the trunk muscles and the onset timing of the trunk APAs are correlated. We hypothesized that there will be less delay between the trunk muscle activation and the beginning of the hand movement in subjects with stronger trunk muscles. **Methods** Seventeen healthy volunteers (5 female and 12 male; age  $29.6 \pm 6.4$  years; height  $173.6 \pm 7.8$  cm; weight  $73.4 \pm 9.8$  kg), without spinal or neurological disorder, participated in the study. Each subject performed 30 repetitions of fast voluntary arm raises in simple reaction time conditions to visual clue. Activation of 4 back and 4 abdominal muscles was recorded by means of surface electromyography. On the separate session, isometric strength of trunk flexors and extensors were measured in standing position with pelvis fixated. Results In all subjects trunk extensors were activated before the initiation of the hand movement and before the activation of the flexors ( $p < 0.001$ ). Pearson's correlation coefficient showed moderate negative correlation between the APAs of extensors and strength of the extensors ( $r = -0.619$ ,  $p = 0.011$ ) and the flexors ( $r = -0.498$ ,  $p = 0.049$ ). Onset timing of the trunk flexors activation was not statistically significantly correlated with the strength of the extensors ( $r = -0.439$ ,  $p = 0.089$ ) or flexors ( $r = -0.273$ ,  $p = 0.306$ ). **Discussion** Results supported the hypothesis and showed that there is about 38% of the common variance between the strength of trunk extensors and latency between activation of the trunk extensors and the beginning of hand movement. These findings are in agreement with the similar impulse hypothesis which suggests that in a fatigued muscle the reduced force capacity is compensated by increased latency of APAs (Strang and Berg, 2007). The candidate mechanism may be functional adaptation by the central nervous system to preserve postural stability. Although some mutual influence can be expected, both entities should be trained complementarily in terms of rehabilitation, prevention and performance. **References** Bouisset, S., and Do, M. C. (2008). *Neurophysiol Clin.* Dec;38(6):345-62. Strang, A. J., and Berg, W. P. (2007). *Exp Brain Res*, 178(1), 49-61.

**NEUROMUSCULAR CONTROL OF LEG STIFFNESS FOLLOWING SOCCER-SPECIFIC EXERCISE**

Oliver, J.L., De Ste Croix, M.B.A., Lloyd, R.S., Williams C.A.

*Cardiff Metropolitan University*

**INTRODUCTION** Little is known about potential changes in the control of rapid SSC actions following soccer-specific exercise. As strong associations have been demonstrated between neural feedforward and feedback mechanisms and leg stiffness in a non fatigued state (Oliver and Smith, 2010), it was hypothesised that changes to these mechanisms would influence leg stiffness following exercise. **METHODS** Ten youths aged  $15.8 \pm 0.4$  years participated in the study, completing 10 s of two-legged hopping at their preferred frequency pre and post 42 min of soccer-specific exercise. Leg stiffness was calculated via double-integration of vertical force-time data. Surface EMG was recorded from the Vastus Lateralis (VL) and Soleus (SOL) of the dominant leg. EMG data was smoothed using a linear envelope employing Butterworth fourth order zero lag filters (20 Hz high pass, 50 Hz low pass). EMG activity was normalized by integrating data during ground contact and calculating the contribution during specific phases; feedforward background activity (0-30 ms, BGA) and short (31-60 ms), medium (61-90 ms) and long (91-120 ms) latency reflexes, as well as during braking and push-off phases. **RESULTS** There was no significant change in stiffness following the soccer exercise ( $26.6 \pm 10.6$  versus  $23.9 \pm 7.0$  kN,  $p > 0.05$ ), with half the group showing an increase and half a decrease in stiffness (range  $-16.5$  to  $6.6$  kN change). Mechanically, changes in stiffness were primarily explained by altered centre of mass displacement ( $r = 0.90$ ,  $p < 0.01$ ) as opposed to changes in peak GRF ( $r = 0.58$ ,  $p > 0.05$ ). Changes in stiffness following exercise were strongly related to the change in BGA contribution in both the SOL ( $r = 0.94$ ,  $p < 0.05$ ) and the VL ( $r = 0.90$ ,  $p < 0.05$ ) and changes in SOL activity during braking ( $r = 0.88$ ,  $p < 0.05$ ), while relationships with changes to reflex contribution were mostly moderate in strength. **DISCUSSION** Forty-two minutes of soccer-specific exercise lead to individualised responses in alterations to leg stiffness. These changes appear driven by feedforward mechanisms given the strong association between the change in stiffness and the change in BGA. Changes in BGA may also modulate the total amount of muscle activity during the eccentric braking phase and consequently influence leg stiffness by altering centre of mass displacement. This may be both a performance and injury concern for those individuals who experienced a lowering of leg stiffness during exercise; with reduced feedforward activity potentially leading to some yielding upon ground contact. **REFERENCES** Oliver, J.L. & Smith, P. (2010). *Neuromuscular control of hopping in boys and men. Journal of Electromyography and Kinesiology*, 20:973-979

**CENTRAL AND PERIPHERAL CONTRIBUTIONS TO FATIGUE AFTER 4-KM, 20-KM AND 40-KM CYCLING TIME TRIALS**

Thomas, K., Goodall, S.G., Stone, M.R., Howatson, G., St Clair Gibson, A., Ansley, L.

*Northumbria University*

**Introduction** Fatigue is defined as an exercise-induced decrease in maximum voluntary force, or an inability to sustain exercise at a required force (Gandevia, 2001). The contribution of central and peripheral mechanisms to fatigue is largely task-dependent. Few studies have estimated these contributions to the fatigue observed during self-paced locomotor exercise. Moreover, none have assessed the degree of supraspinal fatigue. The aim of this study was to assess the aetiology of fatigue during self-paced cycling exercise of different durations. **Methods** Thirteen well-trained male cyclists ( $VO_{2max}$ ,  $4.26 \pm 0.38$  L min<sup>-1</sup>) completed 4-km, 20-km and 40-km simulated time trials (TT) in a randomised, counterbalanced order. Neuromuscular function was assessed pre- and post- each TT. Participants completed isometric maximum voluntary contractions (MVC) of the knee extensors with femoral nerve stimulation delivered during and 2 s post to assess voluntary activation (VA) and potentiated quadriceps twitch force (Q<sub>tw</sub>.pot). Transcranial magnetic stimulation (TMS) was delivered to the motor cortex at rest and during contractions at 100%, 75% and 50% MVC to measure corticospinal excitability and cortical voluntary activation, respectively (Goodall et al., 2009). **Results** Mean time to complete 4-km, 20-km and 40-km was  $5.96 \pm 0.20$  mins,  $31.84 \pm 1.04$  mins and  $65.76 \pm 2.18$  mins, respectively. Exercise resulted in significant global fatigue in all TTs, with no difference in the drop in MVC between trials. The 4-km was characterised by a greater degree of peripheral fatigue (40% reduction in Q<sub>tw</sub>.pot) compared to the 20-km and 40-km (31 & 29% reductions, respectively). In contrast, the longer TTs were characterised by a greater degree of central fatigue, evidenced by a greater reduction in VA (-12% and -10% for 20-km and 40-km vs. -6% for 4-km). Supraspinal fatigue contributed ~50% to the observed fatigue in the 20-km and 40-km and 32% in the 4-km. Corticospinal excitability was reduced post-trial in the 20-km and 40-

km but not in the 4-km. Discussion These data demonstrate the aetiology of fatigue during self-paced exercise is task-dependent, with a greater degree of peripheral fatigue evident in short (<6 mins) TTs and an increased contribution of central fatigue in longer TTs (>30 mins). The increased central fatigue in longer time trials is accompanied by an increased contribution of supraspinal fatigue, and a decrement in the integrity of the brain to muscle pathway. These findings provide novel insight in to the regulation of exercise intensity during self-paced locomotor exercise. References Gandevia SC. (2001). *Phys Reviews*, 81, 1725-1789. ### PERCEIVED EXERTION, TIME OF IMMERSION, AND PHYSIOLOGICAL CORRELATES IN ELITE SYNCHRONIZED SWIMMING DURING COMPETITION

Rodríguez-Zamora, L., Iglesias, X., Iruñia, A., Barrero, A., Chaverri, D., Rodríguez, F.A.

*INEFC-Barcelona Sports Sciences Research Group, Institut Nacional d'Educació Física de Catalunya, Universitat de Barcelona (Barcelona, Spain)*

Introduction The physiological response during competition in elite synchronized swimmers has been recently described (Rodríguez-Zamora et al., 2012). The rating of perceived exertion (RPE) appeared to be a fair indicator of internal load and discriminated between elite junior and senior swimmers. Here we aimed to examine the relationship between RPE, heart rate (HR) response, blood lactate, and immersion (IM) time in elite synchronized swimmers during competition. Method 17 elite synchronized swimmers (17.9±3.5 years) performed a total of 30 routines during an official national championship in the free (FS) and technical solo (TS) and free (FD) and technical duet (TD). HR was measured from RR intervals (CardioSwim, Freelap, Switzerland). Peak blood lactate (La) was measured during recovery (min 3, 5, 7, and 10). RPE was assessed using the Borg's category-ratio CR-10 scale after each performance. All routines were recorded using a digital video camera at a rate of 50 Hz and a time resolution of 0.02 s. A recording instrument was used to identify and time IM intervals. Differences between routines were assessed using one-way ANOVA. Pearson correlation coefficients (R) were calculated, and multiple regression models (MRM, Rm) were used to predict RPE from physiological parameters. Results Mean (±SD) RPE scores were 7.7±1.1 and did not differ among routines, as did not any of the HR parameters. A significant relationship (R, P<0.05) was found between RPE and La (0.50), pre- (0.37), minimum (-0.53), range (0.45), and 3- (0.44) and 5-min (0.45) post-exercise HR, number of IM (0.33), total time immersed (0.58), and number (0.50) and total IM time over 10 s. MRM revealed that minimum pre- and 5-min post-exercise HR, total time immersed over 10 s, and La accounted for 62% of the variance in RPE (Rm= 0.79; P< 0.001; SEE= 0.72). Discussion This is the first study to reveal a clear association between RPE and the frequency and duration of immersions during competitive SS. This is likely due to central factors which are thought to be linked to RPE, such as are the sensations primarily associated with the cardiorespiratory system resulting from tachycardia, tachypnea, and dyspnoea (Pandolf, 1978). RPE appears also related to the magnitude of bradycardic events and post-exercise blood lactate and HR, thus reflecting the psycho-physical stress imposed both by the intensity of dynamic exercise and the repeated prolonged breath-holding intervals during competition. ### OP-BN10 Motor Learning [ML] 1

#### THE CONTEXTUAL INTERFERENCE EFFECT IN PERCEPTUAL-COGNITIVE TRAINING

Broadbent, D.1, Causer, J.1, Ford, P.R.1, Williams, A.M.2

*1: LJMU, 2: Brunel University*

Introduction When multiple motor skills are practiced in a blocked manner it creates less contextual interference (low CI) compared to when multiple skills are practiced in a random order (high CI). Practice with low CI results in better performance during practice, whereas high CI leads to better retention and transfer of skill, referred to as the CI effect (Shea and Morgan, 1979). However, in contrast to the large body of work exploring the CI effect in motor skill learning, its effect on the training of perceptual-cognitive skills, such as anticipation, has not been explored, despite their key role during expert performance in sport. The aim of this study was to examine the relative effectiveness of low and high CI practice schedules when attempting to acquire anticipation skill in tennis using video-based simulation training. Methods Participants were required to anticipate shot direction when viewing life size video filmed from a first person perspective of opponents playing tennis shots occluded at ball-racket contact. Response accuracy scores were recorded at a pre-test, during acquisition, and at two delayed retention tests (7-days, 2-months). An on-court test was used to measure transfer of learning. During acquisition, one group practiced under low CI (n=9) in which the three types of tennis shot were practiced in separate blocks, whereas the other group practiced under high CI (n=9) in which the three shot types were practiced in a quasi-random order. Data were submitted to analysis of covariance, with pre-test scores as a covariate. Results There were no between-group differences on the pre-test or during acquisition. However, the high CI group had significantly (P<.01) higher response accuracy scores compared to the low CI group at the retention tests (7-days = 72% vs. 64%; 2-months = 62% vs. 56%) highlighting the benefits of random compared to blocked practice schedules for acquiring perceptual-cognitive skills. Moreover, decision times were significantly (P<.01) faster in the high CI group (94 ms) compared to the low CI group (248 ms) on the 7-day field transfer test, although this advantage disappeared on the 2-month field transfer test. Discussion This study is the first to examine the relative effectiveness of low and high CI practice schedules in perceptual-cognitive training. The CI effect was found to extend beyond motor skill learning to the training of anticipation. A high CI practice schedule led to improved retention and transfer of learning when compared to a low CI schedule, providing support for the findings of Shea and Morgan (1979). Findings suggest that perceptual-cognitive training programs should consider a high as opposed to low CI practice schedule. References Shea, J. B. and Morgan, R. L. (1979). *Jou of Exp Psych: Hum Learn and Mem*, 5, 179-187.

## THE COUPLING BETWEEN GAZE BEHAVIOUR AND OPPONENT KINEMATICS DURING SUCCESSFUL ANTICIPATION OF BADMINTON SERVES

Alder, D.I, Ford, P.R.I, Causer, J.I, Williams, A.M.2

1 *Liverpool John Moores (Liverpool, UK)*, 2 *Brunel (London, UK)*

**Introduction** Past research examining gaze behaviours has identified areas of an opponent's body that experts fixate vision upon during anticipation in sport (e.g., Williams and Elliott, 1999). However, scientists have devoted less effort to identifying when this postural information becomes available across the phases of an opponent's movement, how participants use it, and how it changes across different types of opponent actions. The aim of this study was to investigate the kinematic differences between two types of badminton shots (long and short serves) and then to examine whether players fixate vision upon that discriminating kinematic information during successful anticipation. **Methods** A full body kinematic analysis of four expert badminton players was undertaken as they completed long and short serves. Movement distance and peak acceleration of each marker were analysed in paired t-tests. Video of these players serving was used to create a life-size, first person perspective film containing 72 trials occluded at racket-shuttle contact. Expert (n = 8) and novice (n = 8) badminton players viewed the film whilst wearing an eye movement registration system and anticipating serve direction. Anticipation accuracy was analysed in an independent t-test. Visual fixation locations were analysed in a 2 Group x 2 Response Success x 4 Location ANOVA. **Results** Kinematic analysis revealed the movement contained two phases: the preparation and execution phase. During the execution phase, there were between-shot differences in movement distance and peak acceleration for the wrist, elbow, racket and shoulder (all P's < .05), but not at other body locations or in the preparation phase. Anticipation accuracy was higher (P<.01) in the expert (55 out of 72 trials) compared to the novice group (38 out of 72 trials). During the execution phase, the experts fixated upon the racket or wrist in more trials (68 out of 72 trials) than the novices (53 out of 72 trials) (P < .05), whereas for the other locations and in the preparation phase there were no differences. Moreover, during the execution phase, these two locations were fixated upon significantly more (P < .05) in successful (41 out of 72 trials) versus unsuccessful trials (19 out of 72 trials), whereas the other locations were not. **Discussion** This study was the first to show that expert performers fixate their gaze more frequently during the execution phase of movement on areas that had been identified in the kinematic analysis as discriminating shot types. Our data support and extend previous research (e.g., Williams and Elliott, 1999) by showing when postural information becomes available across the phases of a movement and how participants use it. Findings may be used as an intervention in training to change visual search and improve anticipation. **References** Williams, A.M., Elliott, D. (1999), *J Sport & Ex Psych*, 21, 362-375

## MUSCLE COORDINATION DURING BENCH PRESS IN UNTRAINED AND EXPERT POWER LIFTERS

Kristiansen, M., Madeleine, P., Hansen, E.A., Samani, A.

*Aalborg University*

**Introduction** Neural and muscular adaptations to resistance training result in increased strength. Part of these adaptations is thought to be related to improvements of the muscle coordination. The aim of the present study was to elucidate the role of expertise level on muscle synergies involved in bench press. We hypothesized that expert power lifters (EXP) would display less inter-individual variability in muscle synergies compared to untrained individuals (UNT). **Methods** Nine male UNT and 10 male EXP completed three sets of eight repetitions at 60% of 3 repetition maximum in bench press. Muscle synergies were extracted from surface EMG data from 8 muscles in 21 bench press cycles using a non-negative matrix factorization algorithm. A muscle synergy can be characterized by a synergy activation coefficient and a muscle synergy vector. The synergy activation coefficient reflects the strength of a muscle synergy within the entire movement while the muscle synergy vector reflects the activity of single muscles within a muscle synergy. A cross-correlation function was computed for the muscle synergy vector and the synergy activation coefficient for all participants in each group. The maximum of the cross-correlation function (rmax) was calculated as an index of similarity. **Results** Two muscle synergies accounted for more than 90% of the overall data variability. Muscle synergy 1 represented the concentric phase of the bench press, while muscle synergy 2 represented the eccentric phase. Cross correlations for synergy activation coefficient 2 were 0.82 (0.64;0.89) and 0.59 (0.46;0.81) (Median rmax (25th;75th percentile)) (P=0.001) in UNT and EXP, respectively. Median rmax for muscle synergy vector 2 was 0.58 (0.21;0.81) and 0.24 (0.02;0.60) (P=0.008) in UNT and EXP, respectively. **Discussion** Contradictory to our hypothesis, EXP showed larger inter-individual variability in muscle synergies than UNT as reflected by the lower rmax values of the synergy activation coefficient and the muscle synergy vector during the eccentric phase of the bench press. This is in line with a growing part of motor control literature reporting an increase in variability with experience, allowing participants to benefit from the motor redundancy (Latash et al 2002; Van Emmerik et al 2002). In this sense a large variability can be viewed as the possibility of changing muscle coordination while still satisfying the constraints of the task. Thus, EXP were more capable of utilizing the motor redundancy in the eccentric phase than UNT. **References** Latash ML, Scholz JP, Schöner G. ## THE EFFECT OF EXPERTISE ON COORDINATION VARIABILITY DURING A DISCRETE MULTI-ARTICULAR ACTION

Stannard, R., Robins, M.

*Nottingham Trent University*

**Introduction** When investigating the relationship between task expertise and movement variability, contrasting findings have been reported in scientific literature (e.g. Darling and Cooke, 1987; Wilson, et al., 2008; Robins, et al., 2008). These equivocal reports could be due, to task constraints influencing variability magnitudes. Whilst some research has used static accuracy-based tasks (Darling and Cooke, 1987), more complex, dynamic multi-articular movements tasks have also been used (Wilson, et al., 2008; Robins, et al., 2008). Currently there is a lack of research examining task expertise-movement variability during such dynamic movement tasks, and ultimately how movement variability can be used functionally to satisfy the specific constraints on action. Therefore, the purpose of this study was to examine the interaction of expertise and coordination variability during a dynamic basketball shooting task. **Methods** Male university basketball players (n=8) with varying basketball experience (scoring between 35-80% of pre-test shots) performed 20 shots from a distance of 4.25 metres after a dribbling movement of 6.5 metres. Kinematic data was collected from a seven-camera motion capture system sampling at 200Hz. 14mm reflective markers attached to upper limb anatomical landmarks allowed calculation of shoulder, elbow and wrist angular displacements. Coordination variability for the wrist-elbow, elbow-shoulder, and wrist-shoulder joint couplings were produced using the normalised root mean squared difference (NoRMS) approach. Providing a metric by which the degree of consistency may be assessed, as such, one measure of stability of the underlying coordination. Quadratic regression analysis was used to identify the poten-

tial relationship between joint coupling coordination variability and shooting score. Results The quadratic regression values for the wrist-elbow joint coupling was 0.1609 ( $p=0.48$ ), elbow-shoulder, 0.1109 ( $p=0.66$ ), and wrist-shoulder, 0.6467 ( $p=0.02$ ) with respect to shooting performance score. Discussion Similar to previous research, task performance and coordination variability demonstrated an U-shaped relationship (Wilson, et al., 2008). Intermediate skilled participants displayed the lowest coordination variability; whilst higher skilled participants demonstrated higher functional variability owing to adapting to perturbations (Hamill, 1999). Least skilled participants revealed variability that is less functional and evident of less stable movement patterns. Additional research is needed, to further understand the task expertise-movement variability relationship for different task constraints. References Darling W.G, Cooke J.D. ## INFLUENCE OF THE AMOUNT OF PRACTICE ON THE CONSOLIDATION OF MOTOR MEMORY IN FORCE FIELD ADAPTATION TASKS

Stockinger, C., Focke, A., Diepold, C., Stein, T.

*Karlsruhe Institute of Technology*

Introduction Force field adaptation experiments are a common tool to investigate the consolidation of motor memories (Shadmehr and Brashers-Krug, 1997). Several studies showed that catch trials, on which the disturbing forces are suddenly turned off, have a positive effect on consolidation when learning two opposing force fields one day apart (Shadmehr and Brashers-Krug, 1997; Overduin et al., 2006). In contrast, consolidation was not observed for more complex force field tasks (viscosity of 35 Ns/m instead of 10-13Ns/m), not even in combination with catch trials (Focke et al., 2012). However, for different motor tasks, an increase of learning trials showed positive effects on consolidation (Krakauer et al., 2005). Therefore, we investigated whether the amount of practice influences the consolidation of motor memories in force field adaptation tasks with a comparatively high complexity. Methods Subjects (N=42) performed 2d center-out reaching movements at a robotic manipulandum in a force field A (day 1) followed by an interfering force field B=-A (day 2) and retest in force field A (day 3). The velocity-dependent viscous curl force field (35 Ns/m) was directed clockwise (A) or counterclockwise (B). Subjects were randomly assigned to four groups, performing either 256 movements (L0, L1) or 640 movements (M0, M1) per block. The groups L1 and M1 pseudo-randomly received catch-trials (~19%) whereas groups L0 and M0 performed all trials in the force field. We quantified performance by the enclosed area between hand trajectory and straight line joining start and target point. Results Neither for the groups L0 and M0 (no catch trials) nor for the groups L1 and M1 (catch trials) a significant effect of the amount of practice was found. None of the groups showed consolidation of force field A when learning the interfering force field B. Discussion Our results indicate that the amount of practice in complex force field adaptation tasks does not influence consolidation processes. An increase of learning trials appears not to be sufficient to compensate a more complex task in order to achieve resistance to interference and therefore to observe consolidation. Potentially, anterograde interference effects avoid detection of consolidation processes. Therefore, further studies should concentrate on controlling possible effects of anterograde interference through the use of washout trials. ## COGNITIVE TRAINING DURING 14-DAY PHYSICAL INACTIVITY IMPROVES DUAL-TASK WALKING

Marusic, U.1,2, Kavcic, V.3, Gerzevic, M.1, Piacentini, M.F.4,2, Meeusen, R.2, Pisot, R.1

*University of Primorska*

1: Institute for Kinesiology Research, SRC, UP, (Koper, Slovenia), 2: VUB (Brussels, Belgium), 3: Institute of Gerontology, WSU (Detroit, USA), 4: IUSM (Rome, Italy) Introduction: Prolonged immobilization or inactivity which follows sports injuries and surgery could lead to serious motor dysfunction preventing a quick recovery and causing elevated costs for a national health care system. Recent studies show that sustained spatial navigation training modifies hippocampal volumes in humans and protects it from age-related decline (Lovden et al. 2012). Therefore, it is important to develop interventions to reduce the deterioration of the motor output during immobilization or inactivity. This study tested a cognitive based intervention during 14-days bed rest (BR) on walking performance with and without a dual-task. To the best of our knowledge this was the first BR study with a cognitive training intervention. Methods: Fourteen older male adults (59.7±3.5 years) volunteered for a controlled longitudinal interventional BR study. To study the effect of cognitive training, we randomly split the subjects into 2 groups: a cognitive training group (CTG; N=6) that trained virtual maze navigation for 50 minutes a day and a control group (CG; N=8) that watched documentaries. Gait parameters were measured with the OptoGait system (Microgate, Italy). To measure the effect of cognitive training on gait we used percent of change in gait speed between normal walking (self-selected speed) with and without dual task [(dual-norm)/norm\*100] (Montero-Odasso et al. 2012). Between-groups (CTG vs. CG group) and within-groups (pre- vs. post-BR) differences were tested with the 2x2 mixed ANOVA. Results: There were no significant differences ( $p=0.44$ ) between the CTG and CG before the BR. However, after the BR the CTG showed significantly higher ( $p=0.02$ ) change of walking speed as compared to the CG (+8.6±7.0% and -1.1±5.8%, respectively). Further, within-group analysis showed for CTG, but not for CG, significantly increased change of walking speed ( $p<0.001$ ) from pre-BR to post-BR (-13.4±5.7% and +8.6±7.0%, respectively). In other words, the results showed that after BR in CG there was a decrease (1.29±0.23 vs. 1.25±0.15 m/s) while in CTG there was an increase (1.08±0.18 vs. 1.17±0.14 m/s) in walking speed with dual-task. Discussion: The results of this study demonstrate that cognitive training during 14-days BR significantly prevents a decrease of gait performance in dual-task walking. Our findings suggest a possible link between cognitive training intervention and motor output and represent new perspectives of basic research regarding novel methods for preventing declines in gait performance due to prolonged immobilization or inactivity. **08:30 - 10:00****Oral presentations****OP-BN09 Coaching [CO] 1 Coaching****RELATIVE AGE EFFECTS IN ELITE JAPANESE SWIMMER: A LONGITUDINAL STUDY OF SEX, AGE AND PERFORMANCE**

Yoshimi, J.1, Nomura, T.2, Takagi, H.1

*University of Tsukuba*

Introduction Relative age effects (RAEs) occur in annual age-groups and are widely observed phenomenon not only in education fields but also in athletic fields as a difference of educational achievement and imbalance distribution on birth month (Kawaguchi., 2006, Cobley et al., 2009). From the point of player development, not only personal adolescence (early or late mature) but also the birth month effects as relative different growth in same annual age-groups and effect as advantage or disadvantage to performance, competitive experience and training environment. In Japan, swimming is one of popular sports so that children start learning on their early age, thus competitive swimming could make the RAEs phenomenon stronger in competitive swimming. Therefore, the aim of this study was to analyze longitudinal effect of RAEs on sex, age and performance in elite Japanese swimmers. Methods All data (swimmer's personal information and their race records) of JAPAN SWIM championships (2004 to 2008) were provided by the JAPAN SWIMMING FEDERATION SCIENCE COMMITTEE. Swimmers were divided into 4 categories of age (12-14, 15-17, 18-21, over 22years old) and date of months (Jan. to Mar., Apr. to Jun., Jul. to Sep., Oct. to Dec.). Who born at April 1st was operate as born in March (April 2nd is the first date of birth for enter school). Rate of change on records were calculated by same swimmer, same event, consecutive competitions and best record in a competition. Kruskal-Wallis test was used to compare between groups. Statistical significance was set at  $P < .05$ . Results Distribution of birth month in swimmers (737 male, 711 female) were not equal (male Apr.-Jun. 31.1%, Jan.-Mar. 17.6%, female Apr.-Jun. 29.6%, Jan.-Mar. 18.2%). There was a negative relation between the age and the ratio of breaking records (12-14y 254.6%, 16-17y 180.1%, 18-21y 151.0%, 22-y 105.3%), but no significant differences were found in rate of change on records with sex, age and date of months. Discussion Strong RAEs was found in a distribution of swimmers of Japanese elite swimmers, but not in performance with sex, age and birth month. A limitation of this study was that we could not compare the biological age of each swimmer. But in Japan, many swimming competitions which developing level participate are held through the year and it doesn't have particular cut-off date because the first day of each competitions are the cut-off date. The particular cut-off date is one of reason to cause RAEs (Musch et al., 2001), so the result indicating the indirect effect of school system. References Daiji Kawaguchi(2006). **VALIDITY ISSUES IN SELECTIONS OF TOP LEVEL SPORT TEAMS**

Johansson, A.

*Umeå university*

VALIDITY ISSUES IN SELECTIONS OF TOP LEVEL SPORT TEAMS Introduction The purpose of the study was to increase the knowledge of selections of athletes to top-level sport teams and analyse them from a validity perspective. Selections to top level sport teams are highly important for the persons involved in them as well as for the sport organizations and the credibility of the sports. Methods 14 semi-structured interviews were performed with top-level coaches (selectors) highly involved in the selection processes in the individual sport alpine skiing (n=6) and in the team sport soccer (n=8). The theoretical frame work was the evolved validity concept including content and criterion evidence as well as reliability (Kane, 2006). Key issues concerned the goals and the criteria involved in the selection processes, how the processes were performed and the coaches perceptions about the outcomes and consequences of the selections. Results The results demonstrate large differences in the explicitness of the selection criteria and in coaches' beliefs about the importance of having and communicating criteria. This has implications for the validity of the selections with regard to both what is really used as the grounds for the selections and how stable those grounds are. All coaches emphasised the importance of the selection criteria being formulated in such a way that they gave the coaches opportunities to influence the judgements themselves and stated that their eyes and their feelings were their most valuable selection tool. Ranking lists, physical test results and statistics were said not to give enough information about the athletes, as numbers could never give a complete picture of a person or a performance. Still quite some of the team's selections were based mostly on ranking lists. If the system allowed, quite a few coaches would choose an athlete with good behaviour and a favourable personality over an athlete with better sports skills. This could be discussed in relation to previous studies indicating that only psychological factors seem to be able to explain maintained success (Abbott & Collins, 2004). Discussion The results display validity issues that might affect the outcome of the selection processes and raises questions for more research concerning research-based guidelines to help coaches and sport organisations develop valid selection processes. None of the coaches had any education concerning selections and many of them regarded the selection processes as difficult, which further points to a need for continued research about selection processes. **COACHES INFLUENCE SUCCESS BY MENTAL ROTATION IN BASKETBALL**

Schul, K.1, Memmert, D.1, Jansen, P.2,1

*German Sports University Cologne - 1. GSUC (Cologne, Germany), 2. UR (Regensburg, Germany)*

Introduction Many team sports incorporate timeouts during a game. To date no research exists evaluating the costs of mental rotation on tactical behavior in team sports notably related to timeouts. According to the alignment effect in spatial cognition research extra cognitive costs are needed to encode information by mental rotation (Levine, Jankovic, & Palij, 1982). The present research attempts to investigate if the alignment of the tactic board in timeouts influences the performance of basketball players. Methods We designed two studies that offered a computer based timeout simulation. After watching a videoclip of a timeout the participants had to recall the corresponding

pattern from five different options. In our first study we examined if experts differ from novices and in our second study we investigated if experts could recall the stimuli better when they were shown in the players point of view instead of upside down. Results The observation of 22 international basketball matches showed that information given by coaches on a tactic board is usually presented from the coaches point of view resulting that players have to mentally rotate timeout instructions. Our first study showed that basketball experts (59%) were significantly better than novices (43%) in recalling specific basketball patterns ( $t(19) = 2,57, p < 0.021$ ). Results of the second study revealed that basketball experts achieved significantly better results in recalling patterns when they were shown in the players' perspective (84%) instead of a mirror inverted coaches' perspective (76%) ( $x^2(2, N = 16) = -2.68, p < .01$ ). Discussion One context in team sports that has seen relatively little empirical research is that of timeouts although this aspect of the game arouses increasing interest in the field of sport psychology. Research in the past concerned with the coaching process itself rather than with the inputs and outputs of coaching (Gómez et al 2011). The main finding of our studies is that coaches should give their tactical instructions most suitable by drawing instructions in the players' perspective. Although this might be too difficult or circumstantial at least they should turn the tactic board towards the players before they finish the timeout. This would give the players a last opportunity to review the tactical orders. Our findings also strongly recommend to be utilized in future coaches education. References Gómez, M. A., Jiménez, S., Navarro, R., Lago-Penas, C., Sampaio, J. (2011). Effects of coaches' timeouts on basketball teams' offensive and defensive performances according to momentary differences in score and game period. *European Journal of Sport Science*, 11, 303-308. ### THE EFFECTS OF 6-WEEKS TRAINING PROGRAMME ON PHYSICA FITNESS IN SEMI-PROFESSIONAL FEMALE HANDBALL: CASE STUDY

Skarbalius, A.

*Lithuanian Sports University*

Introduction Due to increasing the competitive period in modern handball it is highly important to prepare players' performance potential to appropriate level (Gorostiaga et al., 2006). The question is what duration and what kind of training programme would be suitable in semi-professional female handball in order to adapt physical capacity in a simple and effective manner for match demands. Methods The duration of 6-weeks of training programme in preparatory period was applied for 12 semi-professional female field handball players (age  $21.4 \pm 2,7$ ; height  $176.4 \pm 5.6$ cm; body mass  $69.5 \pm 5,5$ ; sporting experience  $9.3 \pm 2.1$ ). VO<sub>2</sub>max, Yo-Yo intermittent endurance level I & level II (IE1, IE2) and Yo-Yo intermittent recovery level I & level II (IR1, IR2) (Bangsbo et al., 2008) tests were measured pre and post preparatory period. Results VO<sub>2</sub>max increased by 10.5% ( $p < 0.001$ ), Yo-Yo IE1 by 13.5% ( $p < 0.001$ ); Yo-Yo IE2 by 9.7% ( $p < 0.001$ ), Yo-Yo IR1 by 7.7% ( $p < 0.01$ ), Yo-Yo IR2 by 8.9 ( $p < 0.001$ ). Discussion In order to solve multiple training goals related to team sports (Gamble, 2010) like handball the content of training programme was applied: specificity (integral) 19.8%, physical 16.4%, technical and tactical 19.7%, theoretical 10.2%, warming-up 17.8%, and recovery 16.1%. The loads were applied in such a way: 33 training days, 47 training sessions, 6 matches, total 4887 minutes. We can conclude that such kind of duration, applied training loads, content, allowed to solve multiple training goals (Zatsiorsky, Kraemer, 2006) in semi-professional female handball. At the same time we have to emphasize that alteration of volume and intensity of training sessions and sequence of microcycles are highly important. References Bangsbo J., Iain, FM., Krstrup P. (2008). *Sports Med.* 38 (1): 37–51. Gamble P. (2010). *Strength and Conditioning for Team Sports*. London & New York, Routledge. Gorostiaga E. M., Granados C., Ibanez J., Gonzalez-Badillo J. ### THE ANALYSIS OF SPORT EXPERIENCE BY AGE AND GROUP ON THE DEVELOPMENT OF BALANCE CONTROL: A STUDY BY ACCELEROMETRY

Oliveira, A.R., Gallagher, J.D., Oyen, A.S.

*Universidade Estadual de Londrina*

Introduction The purpose of this study was to determine the relationship between a motor skill postural and focal components (Frank & Earl, 1990) and moving balance. Increased motion and reduced smoothness of head and trunk in the medial-lateral plane might be related to decreased balance skills for children, especially after 7 years of age, a period where it is expected that they demonstrate an adult pattern of balance control strategies (Yack et al., 1992). The study investigated the influence of sport experience on the development of balance control. Methods The sample involved sixty female subjects (6-, 12-, and 19-years old). In each age group there were 10 gymnasts and 10 non-gymnasts. There were 10 subjects in each age x experience group. Younger gymnasts would stabilize their head in space in a manner similar to the older subject but with increases in complexity the young gymnasts would respond similarly to their age group peers. The instruments were a scale with stadiometer, three tri-axial accelerometers (ADXL150/EM-3, 5g, Analog Devices, Norwood, MA) placed on head, hip and ankle, a footswitch, a line on the floor, a balance beam, and an AD computer. The tasks were: walk on a line on the floor (3.68 m long, 10.0 cm wide), over a white obstacle, walk across a balance beam, and over an obstacle. The dependent variables were Root Mean Square and Index of Smoothness for acceleration harmonics of the head and trunk in three planes of movement: vertical, anterior-posterior, and medial-lateral,  $p < 0.05$ . Results The ANOVA table values for the RMS indicated that when the factor age was analyzed there were differences in the trunk in the AP 5.25 (.01) and VT 10.95 (.01) planes; for group (gymnasts x non-gymnasts) the differences were on the head in the AP 5.57 (.02) and VT 10.25 (.01) planes. No differences were observed when analyzed group x age. The ANOVA table values for the IS indicated no differences for age, group and group x age for head and trunk in the ML, AP and VT planes of movement. Discussion Age differences existed for the non-gymnasts but not the gymnastic group. The gymnasts changed their trunk and ankle motion in preparation to walk over an object whereas the non-gymnasts did not. When walking over the object the gymnasts stabilized their heads. Thus there was support for experience influencing the development of a stabilization of the head in space strategy. Experience influenced balance control across age and task in the experiment. ## RELIABILITY ANALYSIS OF THE SCORING JUDGES SYSTEM IN SNOWBOARDING HALPIPE: WORLD CHAMPIONSHIP AND OLYMPIC GAMES.

Perez Ruiz, J., Muñoz Jimenez, J.

*Universidad de Extremadura*

**INTRODUCTION** Snowboarding is a Olympic Sport included in the Olympic program since 1998, in Nagano Games, through the International Olympic Committee and the International Ski Federation (Popovic & Morrow, 2008). It's a massively practiced winter sport, which moving important economical resources, with a significant scientific and technological development. The Olympic Snowboard competition has three disciplines; Slalom, Boardercross and Halfpipe (FIS, 2008). The last one, Halfpipe, athletes have to perform a series of aerial acrobatic maneuvers above a special track in the snow, while five judges subjectively assess the performance of different technical elements of the sport, assigning a final score exercise (Harding & James, 2010). The exercises are evaluated following basic rule set, in section 6 of the "Judges' Manual" (FIS, 2009). These rules are designed to ensure the objectivity of the judges in their scoring. One important aspect of the scoring system is the elimination of highest and lowest of the five evaluations of judges, adding the remaining three. Despite these indications, we find that "Judges manual" is less detailed about the description of the exercises and their difficulty as can happen in other sports where the final performance result is also subject to the valuation of judges. The main aim of this study is to make a first approach to this sporting context, analyzing the reliability of Snowboard Halfpipe scoring system. **METHOD** The data used are in the FIS database ([www.fis.com](http://www.fis.com)). We record the score for all Olympics Games and World Championship, from 2003 through 2011 (N=1423). The statistical analysis is made with IBM-SPSS Statistics 19 software. The reliability was measured with Cronbach's alpha (AC) and ICC (Interclass Correlation Index) **RESULTS** Results show high levels of reliability regardless of the selected variables (Competition: Olympic Games A.C = ,979 ; ICC= ,9,05. World Championship A.C= ,974 ; ICC= ,882 / Gender: women A.C= ,977; ICC= ,896 / men A.C= ,974; ICC= ,881 / level of qualification: qualification A.C= ,974; ICC= ,882. semifinal A.C= ,990; ICC= ,954. Final A.C= ,973; ICC= ,878 / Round: 1ª A.C= ,977; ICC= ,897. 2ª A.C= ,974 ; ICC= ,882) **CONCLUSIÓN** Results show high levels of reliability in spite of a less concision of judge manual, compared with other sport judge manuals. **REFERENCES** Harding, J. ##### TIME-COURSE OF TRANSCRIPTOMIC CHANGES IN SKELETAL MUSCLE DURING RECOVERY FROM ENDURANCE EXERCISE

Neubauer, O.1,2, Sabapathy, S.2, Lazarus, R.3,6, Desbrow, B.2, Ashton, K.4, Wessner, B.1, Peake, J.5, Cameron-Smith, D.7, Wagner, K.H.1,2, Haseler, L.2, Bulmer, A.2

1: Univ. Vienna, AUT; 2: Griffith Health Institute/Univ.; 3: Baker IDI Heart&Diabetes Inst.; 4: Bond Univ.; 5: QLD Univ. of Technology; 2-5: AUS; 6: Harvard Medical School, USA; 7: Univ. Auckland, NZ

**Introduction** Re-programming of gene expression is fundamental for skeletal muscle adaptations in response to endurance exercise (1, 2). However, no data is available on systemic gene expression changes beyond 48 hours post-exercise. This study aimed to investigate the changes in the muscle transcriptome throughout recovery and beyond 48 hours after an exercise trial (EXTRI; two hours of continuous cycling and running). We hypothesised that the time-course of transcriptomic changes in skeletal muscle would reflect the cross-talk with accumulating leukocytes (3), and the signalling pathways involved in acute stress, recovery, and adaptive responses to endurance exercise. **Methods** Eight healthy, endurance-trained, male subjects participated. Skeletal muscle and blood samples were taken one week before the EXTRI, 3, 48, and 96 hours post-EXTRI under standardized conditions. RNA was extracted from skeletal muscle. Differential gene expression was evaluated using Illumina microarrays, and validated with qPCR. Gene set enrichment analysis identified enriched molecular signatures chosen from the Molecular Signatures Database. **Results** At 3 hours post-EXTRI, 102 gene sets were up-regulated (FWER p-value<0.05) including groups of genes related with leukocyte migration, immune and chaperone activation, the activation of transcription factors and the striated muscle activator of Rho signalling (STARS) pathway. At 48 hours post-EXTRI, 19 gene sets were enriched, and two gene sets related to actin cytoskeleton remodelling were up-regulated (FWER p-value<0.05). The pre- to 48 hour post-EXTRI gene expression fold-change of the macrophage-specific CD68 gene in the muscle correlated with plasma myoglobin changes ( $r=0.85$ ;  $P<0.01$ ). At 96 hours post-EXTRI, 83 gene sets were enriched (FWER p-value<0.05), 80 of which were up-regulated including groups of genes related with chemokine signalling, proteolysis, and interactions with the extracellular matrix (ECM). **Discussion** This study provides novel insights into the muscular transcriptomic responses to endurance exercise, indicating a biphasic recovery pattern, potentially related to the accumulation of leukocytes (3). The 96 hours post-exercise transcriptome indicates sustained inflammatory processes and extensive remodelling of the muscular ECM. **References** 1. Coffey V, Hawley J (2007). Sports Med 37. 2. ### THE ACUTE ANGIOGENIC TRANSCRIPTIONAL RESPONSE TO LOW LOAD RESISTANCE EXERCISE WITH BLOOD FLOW RESTRICTION

Hunt, J.E.1,2, Taylor, C.1, Martin, N.1, Player, D.1, Lewis, M.P.1, Ferguson, R.A.1

1 Loughborough University, 2 University of Gloucestershire

**Introduction** Physiological angiogenesis is a graded response mediated by ischemic, metabolic, shear and/or mechanical stress (Egginton, 2011). Distortion to these stimuli during low load resistance exercise with blood flow restriction (BFR) may affect the magnitude and phenotype of angiogenesis. Measuring gene expression of VEGF and other growth/transcription factors will verify the presents of an angiogenic response and provide information of potential mediating stimuli. **Methods** In a repeated measures cross over design, six healthy moles (age; 26±2 yrs, height; 184±6 cm, body mass; 83±11 kg) performed 4 sets of bilateral knee extension exercise at 20% 1RM [set 1: 30 reps, set 2: 15 reps, set 3: 15 reps, set 4: continued to fatigue] with (BFR) and without (CON) blood flow restriction (110mmHg). Muscle biopsies were obtained from the vastus lateralis before, 2 and 4 hours post-exercise. Angiogenic gene expression for VEGF, VEGF-R2, HIF-1α, PGC-1α, eNOS and MMP-9 was determined using real-time RT-PCR and expressed relative to GAPDH mRNA. Omnibus tests and targeted pairwise comparisons were used to assess differences within and between conditions. Data are presented as fold-change from rest (mean ± SD). **Results** BFR exercise enhanced mRNA expression of VEGF at 2 h ( $5.2 \pm 2.8$  vs  $1.7 \pm 1.1$ ,  $P = 0.02$ ) and 4 h ( $6.8 \pm 4.9$  vs.  $2.5 \pm 2.7$ ,  $P = 0.012$ ) compared to CON. Despite an increase in mRNA expression following BFR exercise (Friedman's ANOVA,  $P < 0.05$ ), peak changes in VEGF-R2 ( $5.0 \pm 4.9$  vs.  $1.5 \pm 0.8$ ), HIF-1α ( $2.6 \pm 1.1$  vs.  $1.8 \pm 1.8$ ), PGC-1α ( $5.9 \pm 2.8$  vs.  $2.1 \pm 1.7$ ) and eNOS ( $4.9 \pm 4.5$  vs.  $1.8 \pm 2.7$ ) mRNA were not significantly different to CON. Only PGC-1α ( $3.2 \pm 1.7$  vs.  $1.5 \pm 0.9$ ) mRNA was enhanced at 4 h relative to CON ( $P = 0.046$ ). MMP-9 mRNA was not altered in response to BFR or CON exercise. **Discussion** In support of previous investigations (Larkin et al. 2012) our study finds that BFR potentiates the VEGF mRNA response to low load resistance exercise. The up-regulation of VEGFR-2, PGC-1α, HIF-1α and eNOS mRNA expression following BFR exercise demonstrates a targeted angiogenic response potentially mediated through enhanced metabolic, ischemic and shear stress stimuli. In contrast, MMP-9 mRNA expression was unchanged reflecting the limited development of muscular tension/stretch during low load and volume resistance protocols. **References** Egginton, S. (2011). *Acta Physiologica*, 202 (3), 225–239. Larkin, K.A, Macneil, R. G., Dirain, M., Sandesara, B., Manini, T. M., Buford, T. W. (2012). *Med Sci Sport Exerc*, 44 (11), 2077–2083.

### AGING IMPAIRS MYOGENIC PRECURSOR CELL EXPANSION AND MUSCLE RECOVERY AFTER IMMOBILITY-INDUCED ATROPHY IN HUMAN SKELETAL MUSCLE

Suetta, C., Frandsen, U., Mackey, A.L., Jensen, L., Hvid, L.G., Beyer, M.L., Petersson, S.J., Schrøder, H.D., Andersen, J.L., Aagaard, P., Schjerling, P., Kjaer, M.

Glostrup Hospital, University of Copenhagen, Bispebjerg Hospital and Center of Healthy Aging, University of Southern Denmark, Odense Hospital

**Introduction** Recovery of skeletal muscle mass from immobilisation-induced atrophy is faster in young than older individuals [1], yet the cellular mechanisms remain unknown. We examined the cellular and molecular regulation of muscle recovery in young and old human subjects subsequent to 2 weeks of immobilisation-induced muscle atrophy. **Methods** Re-training consisted of 4 weeks of supervised resistive exercise in 9 older (OM: 67.3yrs, range 61-74) and 11 young (YM: 24.4yrs, range 21-30) males. Measures of myofiber area (MFA), Pax7-positive satellite cells (SC) associated with type I and type II muscle fibres, as well as gene expression analysis of key growth and transcription factors associated with local skeletal muscle milieu were performed after 2 weeks immobilisation (Imm) and following 3 days (+3d) and 4 weeks (+4wks) of re-training. **Results** OM demonstrated no detectable gains in MFA (VL muscle) and no increases in number of Pax7-positive SCs following 4 wks re-training, whereas YM increased their MFA ( $p < 0.05$ ), number of Pax7-positive cells, and had more Pax7-positive cells per type II fibre than OM at +3d and +4wks ( $p < 0.05$ ). No age-related differences were observed in mRNA expression of IGF-Ea, MGF, MyoD1 and HGF with re-training, whereas myostatin expression levels were more down-regulated in YM compared to OM at +3d ( $p < 0.05$ ). **Discussion** In conclusion, the diminished muscle re-growth after immobilisation in elderly humans was associated with lesser response in satellite cell proliferation in combination with an age-specific regulation of myostatin. In contrast, expression of local growth factors did not seem to explain the age related difference in muscle mass recovery. ### DYNAMIC CHANGES IN DNA METHYLATION STATUS IN PBMCs FOLLOWING AN ACUTE BOUT OF EXERCISE: POTENTIAL IMPACT OF TEMPORAL ELEVATION IN IL-6 CONCENTRATIONS

Robson-Ansley, P., Saini, A., Toms, C., Ansley, L., Walshe, I., Nimmo, M., Curtin, J.

Northumbria University

The aim of our study was to examine the relationship between interleukin-6 (IL-6) concentrations and DNA methylation in the peripheral blood mononuclear cells (PBMCs) of trained runners after a bout of prolonged, strenuous exercise. Eight healthy trained males completed a treadmill run at 60%  $\dot{V}O_{2\max}$  for 120 min followed by a 5 km time trial in a fasted condition. Whole blood samples were taken prior to, immediately and 24 h following exercise. From these samples, PBMCs were isolated for analysis and plasma IL-6 concentrations were measured. DNA methylation from extracted DNA was analysed using the Illumina 27k methylation beadchip platform. Global DNA methylation status was unaltered immediately and up to 24 hours following a bout of prolonged exercise in comparison to pre-exercise. Despite no change in global DNA methylation, we found that plasma IL-6 concentrations were significantly related to the DNA methylation status of 11 individual genes. Our study provides novel data suggesting that exercise-induced increases in IL-6 can alter the DNA methylation status of certain genes although the physiological relevance of these preliminary findings requires further study.

## THE ASSOCIATION OF GENES INVOLVED IN THE ANGIOGENESIS-ASSOCIATED CELL SIGNALLING PATHWAY WITH RISK OF ANTERIOR CRUCIATE LIGAMENT RUPTURE

Rahim, M.1, Gibbon, A.1,2, Hobbs, H.3, O'Cuinneagain, D.3, van der Merwe, W.1,3, Dandara, C.2, Posthumus, M.1, Collins, M.1,4, September, A.V.1

1ESSM, UCT (Cape Town, South Africa); 2Division of Human Genetics, UCT, (Cape Town, South Africa); 3Sports Science Orthopaedic Clinic (Cape Town, South Africa); 4ESSM, MRC (Cape Town, South Africa)

**INTRODUCTION:** Genetic factors have been implicated with risk of anterior cruciate ligament (ACL) ruptures. Angiogenesis plays an important part in the pathogenesis of several human diseases and is regulated by several growth factors. Increased levels of angiogenic cytokines and growth factors have been observed in degenerative ligaments. The aim was to investigate if genes encoding proteins involved in angiogenesis-associated cell signalling are associated with ACL injury risk. **METHODS:** A genetic-association study was conducted on 234 control participants (CON) and 188 participants with ACL ruptures (ACL). All participants were genotyped for the NGFB rs6678788, VEGFA rs699947, VEGFA rs1570360, VEGFA rs2010963, KDR rs2071559, KDR rs1870377 & HIF1A rs11459465 polymorphisms. Statistical analyses were conducted to determine any significant differences ( $p < 0.05$ ) in genotype and allele frequency distributions between the CON and ACL groups as well as CON and NON subgroup (participants with a noncontact mechanism of injury). **RESULTS:** VEGFA rs1570360 genotype frequency distributions were significantly different between the CON and ACL groups ( $p = 0.046$ ) with the GA genotype significantly over-represented in the CON group ( $p = 0.015$ , OR: 1.66; 95% CI: 1.11-2.48). VEGFA rs2010963 C allele was significantly higher in the CON group compared to the ACL group ( $p = 0.002$ ; OR: 1.69; 95% CI: 1.28 to 2.23) and compared to NON subgroup ( $p < 0.001$ ; OR: 2.19; 95% CI: 1.58 to 3.02). Furthermore, the VEGFA rs699947 A allele was significantly over-represented in the CON group in comparison to the NON subgroup ( $p = 0.036$ ; OR: 1.39; 95% CI: 1.03 to 1.89). KDR rs2071559 G allele was significantly lower in the CON group compared to the ACL group ( $p = 0.002$ ; OR: 1.70; 95% CI: 1.28 to 2.25) and in comparison to the NON subgroup ( $p = 0.007$ ; OR: 1.73; 95% CI: 1.27 to 2.37). No significant associations were noted for the remainder of the polymorphisms either between CON vs. ACL or CON vs. NON groups. **CONCLUSION:** These novel findings provide preliminary evidence suggesting that variants within the VEGFA and KDR genes may be implicated in the pathophysiology of ACL ruptures; therefore highlighting the potential biological significance of the angiogenesis-associated cell signalling pathway in the aetiology of ACL ruptures.

#### SPORT CONSUMPTION IN GERMANY

Alfs, C.

Johannes Gutenberg University Mainz

**Sport Consumption in Germany Introduction** No reliable data on the sport outside of sport clubs in Germany is available. Therefore, this research, based on the study of Preuss, Alfs & Ahlert (2012), focuses on the consumption of sport by German private households in the years 2009 and 2010. The invested time and related expenditures for sport participation and the interest in sport are analysed. This provides representative data about the whole of sport in Germany, including the number of people participating and/or being interested in the different forms of sport, how much they spend and in what categories, socio-demographics and related consumption patterns. Further, determinants of sport participation, sport interest and the expenditures related to both are identified and analysed. **Methods** Using a combination of CATI and CAWI surveys, a total of  $n = 17,455$  residents of Germany were interviewed from Oct 2009 to Mar 2011. The sample was representative for Germany in the dimensions age, gender and state of residence. 71 forms of sport, characteristics of participation, 32 (participation) and 18 (interest) categories of expenditures were surveyed. Results 52.8% of the German population participates in sport, 33.5% do so on a weekly basis. Participation does not decline with age, but moves to different forms of sport. Males are more active at younger age, women from age 35 up. The most popular sports are bicycling, running, swimming, fitness and hiking. Football, as the first team sport, is the sixth most practised form of sport. Participation-related expenditures amounted to 112.6 bn. in 2010. 30% of these expenditures were for transportation, 20% for sport-related vacations, 13.3% for equipment and 10% for (entrance) fees. Apparel accounted for 9% and shoes for 5.6% of the expenditures. 35% of males and 21% of females in Germany spend money on their interest in sports, predominantly for Football, followed by Handball, motorsport and ice hockey. Overall, 26 bn. was spent in 2010 on the interest in sports, with 40% being spent on tickets, 20% for catering and accommodation, 15.5% on media and another 10% on transportation. The analysis of the determinants of participation, interest and expenditures is still being done at this early point, but results will be available for the conference in June. **Discussion** Almost 75% of all sport activities take place in self-organized ways outside of sport clubs. The data from this research is finally able to provide reliable evidence of this large part of sport that was not well researched before. The data will be used by German sport politics to plan and build infrastructure for sport and promote a physically active population. The attested economic dimension of sport-related expenditures can support the whole sport sector. **References** Preuß, H. Alfs, C. & Ahlert, G. (2012). #### COSTS AND BENEFITS OF DECEPTION: THE CASE OF PROFESSIONAL BASKETBALL PLAYERS AND REFEREES

Morgulev, E., Azar, O., Lidor, R., Sabag, E., Bar-Eli, M.

Ben-Gurion University of the Negev

Numerous investigations demonstrated how even extremely experienced performers in sport can be influenced by various environmental factors, hence perform non-optimally. We selected five hundred incidents of collisions between attacker and stationary defender (offensive foul situations) from games of the Israeli Super League. The incidents were analyzed by three independent groups of three experts (elite basketball referees). The first group decided whether the defender was able to remain standing (i.e., chose voluntarily to fall); the second group was requested to make a referee's judgment (e.g., offensive foul, defensive foul, technical foul for intentionally

falling defender – “flop”); and the third group focused on collisions where the defender remained on his feet, and decided for each incident if an offensive foul was committed. Real game decisions were compared to the expert answers. Environmental information for each incident was assessed. Our findings indicate that players usually tried to deceive the referees by exaggerating the collision and falling on purpose; this resulted in slightly higher percentage for offensive fouls awarded, but overall reduced the effectiveness of the defense. The referees were able to some extent to distinguish between deceptive and non deceptive falls. Based on the sufficient differences between laboratory and game decisions we concluded that certain “environmentally dangerous” calls were avoided by referees.

## THE EVOLUTION OF THE ATHLETIC DEPARTMENT IN CATALAN UNIVERSITIES DURING THE PERIOD 2003-2007

Requesens, A.

*9equip*

**INTRODUCTION** The Athletic department of the universities offers a fundamental service to the sport system in Catalonia. The study details the economic reality of the Athletic department throughout the evolution of the income and expenditures of the users during the period 2003-2007. **METHODS** The income of all the Catalan universities during the studied period have been valued and compared according to their users, after developing a unique model to collect the economic data of all the athletic departments of these universities. Through the simple statistical, we have extracted the regression lines and the correlation coefficients of the income and the expenses versus the users in both cases. **RESULTS** The slope of the linear regression line in income is  $m = 214.94x$  and the slope of the linear regression line in expenditure is  $m = 260.41x$ . Whether the relationship between income and users and between expenditure and users shows a linear trend, the correlation coefficient between income and users is 0.96 and the coefficient of correlation between expenditure and users is 0.98. **DISCUSSION** Although both parameters show a linear trend in the studied period, the expenditure line shows a greater slope, unlike income, and so a higher expense ratio. During the studied period, there was an increase in the users' expenditure in terms of their income. Despite these differences are minimal, the correlation coefficient is balanced in both relationships and therefore, in the overall evolution among the different parameters, this has been balanced. Our proposal is cost containment and finding new avenues of revenue for the athletic department to achieve balanced accounts. **REFERENCES** ALVAREZ-SANTULLO PLANAS, L.; MARTÍNEZ ORGA, V. ## CONTEXTUAL AND AGE GROUP EFFECTS IN POSITIVE DEVELOPMENT OF YOUTH SOCCER PLAYERS

Santos, A.J., Gonçalves, C.E.

*University of Coimbra*

**Introduction** During the sport participation the youth athlete establish relations that could influence his development. The specificity of the contexts, such as demographic and organizational culture, could exert different influences. The development assets framework pretend to promote successful adults, promoting resilience and inhibiting risk-behaviors (Benson, 2002). The adhesion and maintenance in sport is due to the enjoyment that the athletes experience in these activities (Vlachopoulos, Karageorghis, & Terry, 2000). The values express through the sport attitudes are important due to the possibility of transference for daily life actions (Shields & Bredemeier, 2009). We pretend to verify the contextual and age effects on sources of enjoyment, development assets and sport attitudes of youth soccer athletes. **Methodology** The sample was selected by convenience being composed by 135 subjects with ages between 12 and 18 years ( $M=15.29$ ,  $SD=1.64$ ) from the clubs analyzed by Santos and Gonçalves (2011). They responded to the Sources of Enjoyment in Youth Sport Questionnaire, Developmental Assets Profile and Sport Attitudes Questionnaire. Results It was verified age effects in Convention and in Positive Identity. There are contextual effects in Self-referenced competencies, Effort expenditure, Affiliation with peers, Convention and Commitment. The combined model context and age group present differences in Unsportsmanship. **Discussion** The age differences could be due to the time involved in sport which can lead to a development of athlete-identity mixed with self-identity. The athletes from rural amateur club are in a disadvantage educational context. **Conclusion** Coaches, managers and politicians should take in attention the specific differences of the contexts to improve the youth development. ## WINNING WITHOUT CONSEQUENCES: TENDENCIES OF DOPING AND ENHANCEMENT

Knechtl, S.

*Centre of Sport Science; University of Vienna*

**Introduction** The prevalence of doping in public society, especially in recreational sports like for example fitness centre and running events, is an emerging problem with serious impacts on people's health. These days, if you are keen to be better, work harder and/or train longer, the drugs available are much more effective and easier to get than they have ever been – and are less likely to make someone feel bad after taking them, no matter what side-effects they may cause. Besides the typical doping-drugs, also nutritional supplements and evermore medicine to boost individual physical and cognitive performance, are gaining on broad interest and permanent use. If taken by the civil society, this practices are often called „enhancement“. **Methods** The paper aims to review the latest publications on the field of doping (and enhancement). A hermeneutic approach offers the possibility of comparing different views and review current discussions. **Results** There is still the fatal problem of defining what doping explicitly is and where to draw a line between doping and „pushing“ his-/herself performance, respectively enhancement. Neither the sanctions for doping are well-regulated, nor is the current prevention system satisfyingly developed. The danger which emanates from using those substances as a healthy person is not really embraced by the broad public mass. Scientific research and results about the long-term effects are still missing. The current situa-

tion of doping and enhancement as well as their influencing factors from an ethical and sociological view as well as the risks and dangers of misuse should be shown. As a result, a future prospect could be developed and further actions could be considered. Discussion It becomes clear that a separation of doping and enhancement is not reasonable or even possible. The ethical, social and juridical aspects of doping shown in the paper could not be differentiated from the same aspects of enhancement. Nevertheless, the use of the terms doping and enhancement for a further dispute seems to be suggestive. References Bostrom, N. & Roache, R. (2008). Ethical Issues in Human Enhancement. ## DEVELOPMENT, VALIDATION AND APPLICATION OF A QUESTIONNAIRE ABOUT THE ISSUE OF INTERSEXUALITY IN SPORT COMPETITION

Scarpa, S.

*University of Padua*

**Introduction** An event that occurred during the Athletics World Championships held in Berlin in 2009 raised serious questions about traditional categories of sports competition, based on gender differences. The condition of Caster Semenya, winner of the women's 800 metres gold medal, and a suspected hermaphrodite, raises anthropological and ethical issues which cannot be easily solved. The 'paralysis' of IAAF - who were unable to decide whether the athlete should be allowed to keep the gold medal or not (until medical examinations gave an answer) - is completely understandable. It is not an easy decision - taking away the medal would be viewed as insulting the dignity of hermaphrodites, whereas allowing the athlete to keep the medal would destroy traditional categories (hermaphrodites would be able to choose which category they wish to compete in and therefore their condition would be considered as nature's gift). Are there any criteria to establish a person's sexual identity? Can there be cases in which male and female polarities coexist in a single individual? In which category should hermaphrodites compete? After an interdisciplinary approach supported by a multi-level analysis which permitted to examine all the possible solutions, the aims of this study were to develop, to validate and to apply a Questionnaire about the issue of Intersexuality in Sport Competition (Q-ISC). **Methods** The Q-ISC was developed as a multidimensional instrument after a review of the literature and discussion with specialists of the field. The questionnaire is composed by 35 items (Likert scale) in order to assess the following 5 factors: Free Choice, Third Category, The Most Difficult, Standard, No Solutions. The questionnaire was administered to 524 university students (382 female, 142 male) aged 19-30 (M=22.24). **Results** Statistical analysis (Cronbach's Alpha: from .78 to .93; Exploratory Factor Analysis, Confirmatory Factor Analysis, factor analysis on the single factors: from .441 to .894; indexes assessing data fit to the model: RMSEA=.0593, NFI=.928, NNFI=CFI=.955, GFI=.884, AGFI=.861, PGFI=.740) showed a good validity and reliability of the instrument, confirming the factor structure, and invariance across gender and age. Interesting data emerged also from descriptive statistics, analysis of variance, differences of gender, sexual orientation, sports participation, university education. **Discussion** Our results indicate that the Q-ISC has good measurement properties of the five factors. The fifth factor (No Solutions) obtained the highest mean scores, while the second (Third Category) and the third (The Most Difficult) obtained the worse scores. Participants appear to consider possible three of the five perspectives, giving credit to the complexity of the problem. **References** Butler J. (2009). *Wise Distinctions*. #### DECISION MAKING AND GAZE BEHAVIOUR IN BEACH VOLLEYBALL DEFENSIVE ACTIONS: MOVING JUST IN TIME!

Kredel, R., Lienhard, O., Klostermann, A., Koedijker, J., Hossner, E.J.

*University of Bern*

**Introduction** In recent years several studies highlighted the importance of visual perception in decision-making in sports (for an overview, see Mann et al., 2007). The current study investigated decision making and gaze behaviour in beach volleyball defensive actions with an automated gaze and behaviour analysis, allowing for measuring a high number of participants with a high number of trials in a relatively natural and dynamic setting. It is hypothesized that perceptual and behavioural expertise in beach volleyball defensive actions is characterized by a „Moving-just-in-time“-Strategy, allowing for maximization of information pick-up before action initiation. **Methods** 16 female and 16 male Swiss Elite players, as well as 16 female and 16 male Swiss Near-elite players were subjected to 12 videos with 20 attacking scenes each (10 diagonal smashes, 5 cut shots, 5 line shots; randomized) shown from the perspective of a defensive player on a 3x4m projection screen. In half of the videos participants were required to react as they would do on the field (Action condition). The other half of the videos were under temporal occlusion (occlusions: -40 ms, -120 ms, -200 ms, -280 ms before ball hand contact) in which participants were instructed to call the specific attack variation (Occlusion condition). In both conditions decision accuracy as well as gaze (EyeSeeCam, Vicon-integrated) was recorded. Further, in the action condition decision time was calculated on the basis of participants' kinematics (using Vicon). **Results and Discussion** Elite-players demonstrated a higher decision accuracy in the Occlusion condition,  $F(1, 59) = 7.87, p < .01, \eta^2 = 0.33$ , as well as in the Action condition,  $F(1, 59) = 5.22, p < .01, \eta^2 = 0.21$ , compared to Near-elite players. Thus, Elite players were better able to anticipate the attack variation. Despite their superior anticipation skills, data from the Action condition show that Elite players actually initiate their defensive movements later compared to Near-elite players,  $F(1, 59) = 18.53, p < .01, \eta^2 = 0.24$ . Combined, the data suggest a "Moving-just-in-time- strategy", in which Expert players start their defensive movements at the optimal intersection between the maximization of information pick-up from the opponent's movement in relation to their own physical capabilities and simultaneously minimizing chances for opponents to adapt their attack variation. This hypothesis is further supported by the gaze

data, which show that Elite players have a higher fixation probability right before movement initiation when compared to Near-elite players. Reference Mann, D. T. Y., Williams, A. M, Ward, P., & Janelle, C. M. (2007). Perceptual-cognitive expertise in sport: A meta-analysis. *J Sport Exerc Psychol*, 29, 457-478.

### **EMOTION IN DECISION MAKING: THE CASE OF SPORT REFEREEING**

Rix-Lièvre, G., Récopé, M., Boyer, S., Grimonprez, M.

*Clermont University - Blaise Pascal University*

**Introduction:** Many researches have focused on referee decision making; few have taken their emotions into account. When emotions are studied, they are usually assessed through questionnaires filled out before or after the game. Results only provide information on how the referees relate to their emotions. Our aim is to study how emotions contribute, during the match, to referees' judgment acts. Referees' judgment acts show and impose on the players what is possible (Rix, 2005). We seek to determine whether 1) a negative affect arises from the referees' relationship to the unfolding game; 2) judgment acts are able to end this unsatisfactory situation. **Method:** We have investigated 4 games in a professional rugby championship. Each game was filmed from the stands, the referee was equipped with a head-mounted camera, and a self-confrontation interview was realized. The head-mounted video was used during the interview in order to foster an experiential immersion. **Results:** We analyzed the interview excerpts in which the referee reported affective dissatisfaction. It revealed two distinct cases. In the first case, affective dissatisfaction was related to an abnormal situation. The referee showed what was abnormal and overcame his dissatisfaction through a judgment act. In the second case, affective dissatisfaction was related to a paradoxical situation. The return to a satisfactory state occurred when a norm became predominant to determine the normality/abnormality of the situation within its unfolding. **Discussion:** Dosseville et al. (2011) suggested that the perception of players' action provokes an emotion that will guide the decision. Our results support partially this proposal. Negative affect was the basis for the referees' judgment acts: what was perceived as abnormal in the moment or in the dynamics of the situation led the referee to whistle. But it is not the perception of action that causes an emotion; affect is at the heart of referees' perceptions of player activity. Every perception is an assessment of what is happening in terms of personal well-being (Lazarus, 2001). This appraisal is not the result of deliberation; it is instantaneous and results from a mostly unconscious and embodied process. These proposals might lead some authors to denounce bias in refereeing judgments and to find an affective explanation of biases in perception and/or categorization. Instead we emphasize the implacable logic of emotion and its rationality (Lazarus, 2001); we claim the necessity to investigate this rationality to better understand referee naturalistic decision making. **References:** Dosseville F., Laborde S., Tractlet A. & Koffi P.E. (2011) *STAPS* 93(3), 51-60. Lazarus R.S. (2001) in Scherer, Schorr & Johnstone, *Appraisal processes in emotion*, Oxford University Press. Rix G. (2005) *Sc. & Mot.* 56(3), 109-124.

### **SELF-GENERATED EMOTIONS AND THEIR INFLUENCE ON SPRINTING ABILITY: AN INVESTIGATION OF HAPPINESS AND ANXIETY**

Rathschlag, M., Memmert, D.

*German Sport University Cologne*

**Self-generated Emotions and Their Influence on Sprinting Ability: An Investigation of Happiness and Anxiety** **Introduction:** Emotions and their regulation appear to be a fruitful area for improving performance and for this reason have more recently become a focus of extensive research in sports (Hanin, 2000). In sprint competitions only a few hundredths of a second can decide on whether athletes get a medal or not. Regardless of a good physical preparation for competition situations, athletes are often searching for further possibilities to improve their performance. This paper will help to answer the question if sprinters can benefit from the regulation of their emotions directly before the competition and if this regulation can help to improve sprinters' performance. The main purpose of the study was to examine the effects of self-generated emotions on sprinting times within Lazarus' (2000) cognitive-motivational-relational (CMR) theory framework. **Method:** Using self-generated emotions as emotion induction method, 26 sport students were asked to recall personal emotional episodes before the sprints. We used a within-subject design and therefore, all participants took part in three emotion induction conditions (happiness, anxiety, and an emotion-neutral state) and we measured their sprinting times over a distance of 40 meters under the respective emotion induction conditions. **Results:** We found a main effect for emotion induction ( $F(2, 50) = 3.42, p < .041, \eta^2 = .12, \text{power} = .61$ ). Follow-up Bonferroni corrected pairwise comparisons indicated a significant difference between the happiness condition and the emotion-neutral condition ( $p < .012$ ), indicating that participants in the happiness condition ran significantly faster when compared with the emotion-neutral condition. The emotion-neutral and the anxiety condition did not differ significantly ( $p = 1.000$ ). The happiness and the anxiety condition did also not differ significantly ( $p = .214$ ). **Discussion:** From a practical sport perspective it seems to be helpful for athletes to self-generate the emotion happiness before the sprint to enhance physical performance. Further research is needed to replicate and extend study findings. **References:** Hanin, Y. L. (Ed.). (2000). *Emotions in sport*. Champaign, IL: Human Kinetics. Lazarus, R. S. (2000). ### **GOAL PERSPECTIVE AND PHYSICAL FITNESS**

Mehus, I.

*Norwegian University of Science and Technology*

**Introduction.** Researchers have found that task orientation is positively related to intentions towards physical activity and exerted effort, (Duda & Hall, 2001). Furthermore, Tzetis et al. (2002), found that children high in task orientation participated more in vigorous physical activity (VPA), regardless of their ego orientation. However, authors hypothesize that results could have been different in a highly competitive environment. Tests of physical fitness are extensively used in sport and physical education, and are regarded highly competitive. The present study investigates the effect of goal orientation on physical fitness when controlling for age, gender and objectively measured VPA. **Methods.** Participants (N=107) were students taking part in an introductory course in Sport Science. The mean age of the participants was 21 years (SD=1.9), and 50.5% were female. To measure aerobic fitness, participants were required to run around a volleyball court for three minutes, demanding two full stops for each lap. Total distance served as a measure of aerobic fitness. VPA was measured using an Actigraph GT1M accelerometer (Actigraph LLC, Pensacola, FL, USA). Students were instructed to wear the monitor for 6 consecutive days. Dispositional goal orientations were measured using the Perception of Success Questionnaire (POSQ; Roberts, Treasure & Balague, 1998). **Results.** Participants wore the accelerometer for a mean of 4.8 days (SD=1.3). Time in VPA reached a mean of 8.9 minutes pr. day (SD=8.9). The regression model explained 46.1% of the variance in physical fitness (adjusted R<sup>2</sup>), and turned out statistically significant ( $F(5, 106)=19.13, p<.001$ ). Gender, ego orientation, and time spent in VPA were statistically significant predictors ( $p<.05$ ), whereas age

and task orientation were not. Discussion. In this study physical fitness could also be regarded as a measure of exerted effort in a highly competitive situation. Contrary to some other studies, the level of task orientation has no impact on fitness/effort. However, together with gender and time in VPA, ego orientation is a significant predictor of fitness. Results indicate that high ego orientation predicts a high level of physical fitness and exerted effort. Results are further discussed within the theoretical framework of AGT. References Duda, J. ## GOAL ORIENTATION IN SPORT AND PREFERRED COACHING STYLES AMONG YOUNG ATHLETES

Mohd Rasyid, N., Tengah, R., Abdul Aziz, S.

*Sultan Idris Education University*

**Introduction** The objective of this research was to identify goal orientation and preferred coaching styles of the young athletes from Malaysian Sports Schools. This study also examined goal orientation and preferred coaching styles among young athletes based on gender differences, age, and type of sport participated. **Methods** Instruments used in this study were Task and Ego Orientation in Sport Questionnaire (TEOSQ) and the athlete's preferred version of the Leadership Scale for Sport (LSS). Subject were young athletes from Malaysian Sport School age 13 to 18 years old (N = 854). **Results** The findings showed that young athletes were more inclined toward Task orientation rather than Ego. t-test and ANOVA analyses revealed significant differences for goal orientation based on gender, age and types of sports. Boys were found to be high in both Task and Ego orientation than girls. Younger athletes (under 15 years) are more task-oriented as compared to senior athletes (under 18 years). Individual sport athletes were found to be more Ego oriented than team sport athletes. The most preferred coaching styles were Training and Instruction, followed by Democratic, Social Support, and Positive Feedback. Autocratic behaviour was the least preferred coaching style. The result also indicated that there was a significant different ( $p < .05$ ) in coaching style based on gender and age group. Male athletes preferred more Autocratic and Positive Feedback as compared to female athletes. Senior athletes ( $\geq 21$  years old) preferred Training and Instruction and Social Support, while the young athletes ( $\geq 18$  and 15 years old) preferred Autocratic coaching style. **Discussions** Young athletes from Malaysian Sport School were found to be more task-oriented than ego. This augur well for the future of sport in Malaysia as task-oriented athletes are often associated with positive self-image (Biddle, Wang, Kavussanu & Spray, 2003). The findings of this study was in agreement with the previous studies that training and instruction coaching style is the style of coaching that often preferred by athletes meanwhile Autocratic style was the least popular (Sullivan, & Kent, 2003). In conclusion, to improve the commitment and achievement of the young athletes in sports the authorities involved in the development and planning of the sport programme should know and understand the athletes goal and their preferred coaching styles. **References** Biddle, S.J.H., Wang, C.K.J., Kavussanu, M., & Spray, C.M. #### THE EFFECT OF EXERCISE TRAINING INTENSITY ON FAT OXIDATION, NEAT, AND APPETITE IN OVERWEIGHT/OBESE MEN

Alahmadi, M.A.1, Hills, A.P.2, King, N.A.3, Byrne, N.M.3

*1King Saud University, 2Griffith University, 3Queensland University of Technology*

**Introduction** It is important to ensure exercise intensity is appropriately prescribed, and to identify and monitor potential compensatory behavioural responses to exercise training. Therefore, the aim was to compare the impact of two different intensities of 4 weeks of exercise training on fat oxidation, non-exercise activity thermogenesis (NEAT), and appetite in overweight and obese men. **Methods** Using a cross-over design, 11 participants (BMI =  $29 \pm 4$  kg/m<sup>2</sup>; age =  $27 \pm 4$  y) were randomly assigned initially to: [1] a low-intensity (45% O<sub>2</sub>max) exercise training (LIT) or [2] a high-intensity interval (alternate 30 s at 90% O<sub>2</sub>max followed by 30 s rest) training (HIIT) 40-min duration, three times a week. Participants completed four weeks of supervised training for each training period, with a two week washout period in between. At baseline and the end of each exercise period, O<sub>2</sub>max, fat oxidation, and NEAT were measured. Fat oxidation was measured by indirect calorimetry during a standard 30-min continuous exercise bout at 45% O<sub>2</sub>max. NEAT was measured for 7 consecutive days using an accelerometer (RT3) the week before, at week 3 and the week after training. Subjective appetite sensations and food preferences were measured using visual analogue scales, immediately before and after the first exercise session every week for four weeks. **Results** The mean fat oxidation rate at baseline for both LIT and HIIT was  $0.14 \pm 0.08$  g.min<sup>-1</sup>, increasing to  $0.178 \pm 0.04$  g.min<sup>-1</sup> after four weeks of LIT and  $0.183 \pm 0.04$  g.min<sup>-1</sup> after HIIT. There was no significant difference in fat oxidation between LIT and HIIT, but there was a trend for fat oxidation to increase during exercise after HIT ( $P = 0.08$ ). The mean NEAT (counts.min<sup>-1</sup>) was  $45 \pm 18$  at baseline,  $55 \pm 22$  and  $44 \pm 16$  during training, and  $51 \pm 14$  and  $50 \pm 21$  after training for LIT and HIIT, respectively. Although not statistically significant ( $P = 0.08$ ), NEAT was 20% lower during week 3 of exercise training in HIIT compared with LIT. There were no statistically significant differences between LIT and HIIT in appetite ratings or preferences for high-fat sweet foods. **Conclusion** The results suggest that after 4 weeks of training there was no differential effect of exercise intensity on appetite or food preferences. However, there was some suggestion that compared with LIT, HIIT may lead to greater improvements in fat oxidation during a constant load exercise, but may also reduce non-exercise physical activity during the training program.

### MUSCLE WATER DEFICIT DOES NOT INCREASE GLYCOGENOLYSIS DURING INTENSE EXERCISE

Fernández-Elías, V.E., Hamouti, N., Ortega, J.F., Mora-Rodríguez, R.

*Universidad de Castilla-La Mancha*

Exercise that results in increases in body temperature accelerate muscle glycogen use. Several factors could be responsible for the increased anaerobic glycolysis; i) increased muscle temperature (T<sub>m</sub>), ii) stimulation of glycogen phosphorylase (PHOS) by epinephrine, iii) hypovolemia reducing cardiac output and allosterically activating PHOS. Purpose: To determine if muscle water deficit is an additional factor stimulating glycogen use during prolonged exercise in the heat. Methods: Seven endurance-trained males (VO<sub>2</sub>max = 55±3 mL • kg<sup>-1</sup> • min<sup>-1</sup>) dehydrated by 4.6±0.3% after 150 min of cycle-ergometer exercise in a hot-dry environment (33±1 °C) followed by a 4 hours recovery period. During recovery, in one occasion subjects ingested 400 g of a carbohydrate syrup (HYPO trial) and in another two occasions the 400 g of carbohydrates were accompanied by a fluid load to recover all fluid losses (i.e., 3.1 L; EU trials). Finally, subjects exercised intensely (75% VO<sub>2</sub>max) for 40 min in three different conditions: a) hypohydrated-thermoneutral (25±1 °C) environment (HYPO); b) euhydrated-thermoneutral environment (EUNEUTRAL) and c) euhydrated-hot (36±1 °C) environment (EUHOT). Muscle biopsies from vastus lateralis were collected prior and at the end of intense exercise and heart rate (HR) and intestinal temperature (T<sub>INT</sub>) were continuously monitored during the trials. Results: Before the high intensity exercise bout, muscle glycogen content was similar in the three trials (~434±22 mmol/kg dm) but muscle water content was lower in the HYPO trial (i.e., 357±5 mL/100g dm) than in the EU trials (389±9 and 386±10 mL/100g dm for EUNEUTRAL and EUHOT, respectively; P<0.05). After the 40 min of intense exercise, T<sub>INT</sub> increased similarly in HYPO and EUHOT (39.2±0.15 and 39.2±0.19°C respectively). Glycogen use was also similar during HYPO vs. EUHOT (172±32 and 185±37 mmol/kg dm, respectively) despite large differences in muscle water content. In contrast, during EUNEUTRAL, HR (161±4 beats/min), T<sub>INT</sub> (38.5±0.18°C) and glycogen use (117±20; P<0.05) were significantly lower than both during HYPO and EUHOT. Conclusion: These data suggest that thermal and cardiovascular stress stimulates glycogenolysis rate during exercise while muscle water deficit has a minor role. References: 1. Febbraio M.A. et al. (1994). Effect of heat stress on muscle energy metabolism during exercise. *JAP*; 77(6):2827-31.

### EXERCISE-INDUCED DEHYDRATION, INDEPENDENT OF HYPERTHERMIA, DOES NOT INFLUENCE PERFORMANCE OR NEUROMUSCULAR DRIVE DURING A MAXIMAL EFFORT, 5KM CYCLE TIME TRIAL

Cannon, J.I., Stewart, C.I., Wickham, J.I., Whyte, D.2, Marino, F.E.2,1

*Charles Sturt University CSU (Bathurst, Australia), ACU (Melbourne, Australia)*

**INTRODUCTION** Exercise in hot conditions can result in hyperthermia, which may reduce neuromuscular drive and exercise performance. However, exercise-induced dehydration may also contribute to reduced neuromuscular drive and exercise performance independent of elevated core temperature (T<sub>c</sub>). Despite this, the effect of exercise-induced dehydration on neuromuscular drive and exercise performance independent of thermal strain is not known. This study examined the effect of exercise-induced dehydration independent of hyperthermia on time to completion and neuromuscular drive during a maximal effort 5km, self-paced cycle time trial. **METHODS** In a counterbalanced design, seven (7) males (age 23.0 ± 4.3 years and peak power output 371 ± 57 W) completed two trials one week apart. Both trials involved initial assessments for maximum voluntary torque (MVT) and the level of voluntary activation (VA) of the right knee extensors followed by a 2-2.5 hour dehydration exercise protocol that reduced body mass by 3.8 ± 0.5 kg. Participants then had a 2 hour recovery period where they rested and either consumed water equivalent to 115% of the fluid lost or remained dehydrated. Following this, the MVT and VA assessments were repeated after which participants completed a maximal effort 5km, self-paced cycle time trial (TT). Performance data, T<sub>c</sub> and heart rate (HR) were monitored throughout each TT. EMG were also sampled from the vastus lateralis, vastus medialis, and biceps femoris of the right limb throughout each TT and were analysed for root-mean-square (RMS) and spectral compression ratio (SCR). **RESULTS** After the recovery period and prior to the TT, pre-dehydration values for MVT, VA, T<sub>c</sub> and HR were re-established and these were not different between trials (p> 0.05). No differences in the time to complete the TT were observed between trials (p> 0.05). HR and the rating of perceived exertion during the TT increased with time in both trials (p< 0.05) and the changes observed were comparable between trials (p> 0.05). In both trials, power output at 2km, 3km and 4km was lower than immediately after the start of exercise (p< 0.05); but at 5km returned to the level seen immediately after the start of exercise (p> 0.05). RMS and SCR were unchanged across all intervals for all muscles in both trials (p> 0.05). T<sub>c</sub> was higher at 4km and 5km in both trials (p< 0.05); however, T<sub>c</sub> did not exceed 37.9 ± 0.2°C in either trial. **CONCLUSION** These findings demonstrate that exercise-induced dehydration independent of hyperthermia may not influence exercise performance or neuromuscular drive during maximal effort, self-paced tasks of moderate duration. Such data demonstrate resilience of the neuromuscular system to imbalances in internal fluid homeostasis.

### A-GALACTO-OLIGOSACCHARIDES <A-GOS> PREVENTS SKELETAL MUSCLE ATROPHY IN STREPTOZOTOCIN-DIABETIC RATS THROUGH A REDOX-SENSITIVE MECHANISM.

Ferrando, B.I.2, Derbre, F.I, Vincent, S.I, Groussard, C.I, Lefevre-Orfila, L.I, Gómez-Cabrera, M.C.2, Viña, J.2, Gratas-Delamarche, A.I

**Introduction:** Skeletal muscle atrophy is a debilitating consequence of multiple chronic diseases such as type 1 diabetes mellitus (T1DM). It reduces treatment options and positive clinical outcomes as well as compromising quality of life and increasing morbidity and mortality. Oxidative-inflammatory cascade is recognized to play a key role in the pathogenesis of diabetes, and also in skeletal muscle atrophy. Interestingly, α-galacto-oligosaccharides (α-GOS) are prebiotics that selectively alter the composition of gut microbiota and exhibit strong antioxidant and anti-inflammatory effects in vitro (Efstathiou and Fathi 2010). Because T1DM is characterized by a pro-oxidant and pro-inflammatory state (Tran, Oliver et al. 2012), we designed the present study to test the hypothesis that α-GOS can limit skeletal muscle atrophy, oxidative stress and inflammation in a model of streptozotocin-induced type 1 diabetes. **Methods:** Twenty-seven male Wistar rats were divided into control placebo, streptozotocin-diabetic rat groups (STZ) supplemented or not with α-GOS. They received water (placebo groups) or water diluted α-GOS (20 mg/kg/day) daily for a period of 8 weeks. At the end of the protocol, blood was obtained by venous puncture into heparin-containing tubes. Tibial anterior muscle was removed, weighted and analyzed to determine oxidative stress and inflammatory parameters. **Results:** Relative to the control group, STZ rats exhibits skeletal muscle atrophy (-56%), hyperglycemia, insulin deficiency and a trend to higher plasma fructosamine levels, a marker of glycated proteins. α-GOS treatment partially prevents the loss of muscle mass, reduces plasma fructosamine levels compared to STZ rats. In skeletal muscle, STZ treatment down-regulates MnSOD protein content, increases p38 MAPK activation and inflammatory markers (i.e. NF-κB and TNF-α). Interestingly, α-GOS partially

prevents MnSOD down-regulation and p38 MAPK activation, but fails to influence inflammatory marker levels. Discussion: Our results suggest that oxidative stress, but not through inflammation pathway, play a role in diabetes-induced skeletal muscle atrophy.  $\alpha$ -GOS supplementation partially prevents the loss of muscle mass due to T1DM, probably by limiting oxidative stress and p38 pathway activation. ### ACUTE EFFECT OF AEROBIC EXERCISE ON POSTPRANDIAL LIPAEMIA IN OBESE ADULTS ACCORDING TO THE POLYMORPHISM -3826 A/G IN THE GENE FOR UNCOUPLING PROTEIN 1

Reischak-Oliveira, A., Pezzi, F., Bijoldo, J.M., Moreira, D.C.

*Universidade Federal do Rio Grande do Sul*

**Introduction** Hypertriglyceridaemia is a common feature in obesity and can be characterized by elevated triglycerides in fasting state or postprandial. There are evidences the polymorphism -3826 A/G gene UCPI affect the lipid profile (OH et al., 2004). Furthermore, exercise improves the postprandial lipaemia (Stensel et al. 2006; Katsanos et al., 2004). The purpose of this study was to identify the effects of an acute bout of aerobic exercise on postprandial lipaemia in obese adults according to. **Methods** Thirty-six young adults of both sexes were split into groups: Eutrophic A/A (EAA, n = 10), Eutrophic A/G (EAGs, n = 8), Obese A/A (OAA, n = 8) and obese A/G (OAG, n = 10). Study volunteers attended the laboratory on four sessions. In the first session, a blood sample was collected to DNA extraction and genotyping, through PCR. In the second session the aerobic power (VO<sub>2</sub>peak) was evaluated and in the third and fourth session the volunteers performed the tests in a randomized sequence (exercise or control test) with an interval of seven days. In both trials a standard hyperlipidic breakfast (41.3%) was offered. The exercise protocol consisted of cycling at an intensity equivalent to 60% of VO<sub>2</sub> peak for 45 minutes with a pedalling cadence between 60 and 80 rpm. Blood samples were collected after 12 hours fasting, and two, three, four and six hours after the standard breakfast for triglycerides, total cholesterol and LDL-c analysis. Data were analysed using SPSS version 19.0 for Windows. Two-way ANOVA was used to determine differences between groups. The Statistical significance was determined as p < 0.05. **Results** Biochemical parameters of fasting indicated significant differences between both groups Eutrophic (Total cholesterol and LDL-c) and for the Obese (Triglycerides and Total Cholesterol) when the G allele was present in the genotype. All groups showed a time effect (p = 0.000) compared with baseline. It was also evident a treatment effect (control vs. exercise). Aerobic exercise was able to decrease the postprandial triglyceridaemia in the EAA groups (p = 0.01), EAG (p = 0.03) and OAA (p = 0.000). However, surprisingly, the exercise had no effect for the OAG group (p = 0.15). **Discussion** The main contribution of this study was to show that acute aerobic exercise performed for 45 minutes at 60% of VO<sub>2</sub>peak was able to modify the triglyceridaemia in Eutrophic A/A, Eutrophic A/G and Obese A/A groups. However, the exercise had no effect on the postprandial lipaemia in the Obese A/G group. In conclusion, the exercise was not able of promoting effect in subjects with excess body fat associated with the presence of the G allele in the genotype of the -3826 polymorphism in the UCPI gene. #### THE EFFECTS OF ADDITIONAL LINES ON A FOOTBALL FIELD ON ASSISTANT REFEREES' POSITIONING AND OFFSIDE JUDGMENTS

Barte, J.C.M., Oudejans, R.R.D.

*VU University Amsterdam*

**Introduction:** Judging offside in association football is a complex task and a popular topic for discussion by coaches, players, media and football fans because the consequences of errors in judging offside can be significant. The observation point of assistant referees relative to the offside line, and the corresponding viewing angle, is an important determining factor in incorrect decisions in judging offside. For that reason, information provided by extra lines across the width of a football field (comparable to an American football field) could help assistant referees to correctly judge offside. Therefore, we investigated whether extra lines across the width of a football field influence the positioning of assistant referees and their offside judgments. **Method:** Eight expert assistant referees each judged potential offside situations played by several attackers and defenders on two different fields, one field with and one field without extra lines. The data were collected by video recording and analyzed using an interactive digital video analysis system. Relative positions of the players and the assistant referee to the offside line at the moment of passing and correctness of the assistant referee's decision were determined. The relative position of the assistant referee to the offside line and the number of erroneous decisions on the field with and without extra lines were compared using chi-square tests. **Results:** 555 (282 situations with extra lines and 273 without extra lines) potential offside situations were played. Assistant referees were positioned more often on line (p=.01) and less often far trailing (p<.001) on the field with lines compared to the field without lines. No significant differences in incorrect decisions between the fields with and without lines were found (7.6% vs. 7.9%, p=0.88). In total, the assistant referee made more incorrect decisions when leading the offside line (16.1%) rather than trailing (6.5%, p=.02) or on line (5.1%, p<.01). **Conclusion:** The extra lines resulted in better positioning of the assistant referees but not in less incorrect decisions. A possible explanation for not finding better performance results in the number of incorrect decisions is that the assistant referees first have to learn to use the information provided by the additional lines for judging offside.

**MEASURING ACCELERATIONS AND DECELERATIONS IN SOCCER-SPECIFIC MOVEMENTS**

Stevens, T.G.A., de Ruijter, C.J., van Niel, C., van de Rhee, R., Beek, P.J., Savelsbergh, G.J.P.

*VU University Amsterdam*

**Introduction** Computerized time-motion analysis has become the standard for measuring work load during training and match in team sports, particularly in soccer. Information such as total distance covered and number of sprints is used to quantify the physical load on players. Local Position Measurement (LPM) systems provide more accurate data compared to GPS. Ogris et al. (2012) reported error values of the Inmotio LPM system and found an underestimation of 1% for mean speed and an overestimation of 7% for maximum speed for straight running executed on maximal intensity. Currently, no data is available about accuracy of LPM systems regarding acceleration and deceleration characteristics of whole body movements. The main purpose of this study was to investigate the accuracy of LPM on mean and peak accelerations for accelerated and decelerated runs executed at different intensities. **Methods** Twelve male amateur soccer players (22±3 yrs; 183±8 cm; 76±7 kg) performed two kinds of straight runs: acceleration from standstill and deceleration from running to standstill, executed at three intensities: jog (~10 km/h), sub max (~17 km/h) and max (~29 km/h). LPM (Inmotio Object Tracking BV, Amsterdam, The Netherlands) sampled at 45Hz (settings as recommended by manufacturer) was compared to a golden standard: VICON sampled at 100Hz. VICON signals from markers placed upon LPM sensors on top of both shoulders were combined, low-pass filtered (1Hz Butterworth) and analyzed in XY-direction. Absolute thresholds of 0.2 m/s<sup>2</sup> (VICON) were used to define begin and end of movements. Mean and peak values were computed for acceleration and deceleration. **Results** With respect to distance and mean speed, differences between systems were small (<1% for all mean values) and mostly insignificant. No significant interaction effects were found for execution intensity. In the accelerated run, LPM overestimated ( $p < 0.05$ ) peak acceleration with 28±27% (grand mean ± SD), whereas mean acceleration was not different (0±11%). In the decelerated run, mean deceleration (0±5%) and peak deceleration (3±14%) were not different. **Conclusion and discussion** For runs from or to standstill, the LPM system provides reasonable accurate values for mean acceleration and mean and peak deceleration, but for peak acceleration LPM accuracy is limited and the variation relatively large. Nevertheless, the system may be useful in practice for quantifying mean accelerations and parameters such as summed accelerations or time spent in acceleration zones when the above error margins are kept in mind. **References** Ogris G, Leser R, Horsak B, Kornfeind P, Heller M, Baca A. (2012). Accuracy of the LPM tracking system considering dynamic position changes. *J Sports Sci.* 30(14): 1503-1511.

**SOCCER ANALYSIS OF FAST ATTACK SEQUENCES THAT END IN GOAL. COMPARING REAL MADRID AND INTER MILAN**

Barbosa, A.1, Sarmiento, H.2, Anzano, A.1, Campaniço, J.3

*1INEF (Catalunya, Espanha); 2 ISMAI (Maia, Portugal) 3 UTAD, (Vila Real, Portugal)*

**Introduction** This study aims to identify the significant repeated and regular behaviors, emerging from the diversity of game actions regarding the fast attack sequences that end in goal scored. The selected teams are Real Madrid (2010/2011) and International Milan (2009/2010), two top level teams, that share the same coach and technical team were analyzed. **Methods** To collect data, we used the instrument developed and validated by Sarmiento et al. (2010). Several offensive sequences were coded through the observation of 24 games (12 per each team) of Inter Milan and Real Madrid. The collected data were analyzed through in the SDIS-GSEQ (5.1). The determination of the motivational value of transitions between the different behaviors considered as criteria categories and object, occurred considering the pattern sequence up to the transition limit of 5, retrospectively, in other words delays of -5, since after this number, "the sequence awareness is greatly reduced" (Castellano Paulis, 2000). The analysis of data reliability was calculated by intra and inter observer agreement, and values above 0.90 for all criteria were achieved. **Results and Discussion** We verified that both teams don't activate any conduct object along delay -5 to delay -2, and didn't activated any conduct related to field zones along all delays. In retrospective terms, on IM we identified that the max-lag is on the -1 delay corresponding to the conduct object, diagonal pass to the back. In our opinion, the conduct that was activated is connected with the pass directed to player facing the opponent's goal. Relatively to RM, it evidences a short pattern. We verified that the max-lag is on the -1 delay corresponding to development by intervention from the goalkeeper of the opposing team. We think that the behavior that precedes the goal achievement is similar and consist on winning a second ball. **Conclusion** We think that the result reflect the importance of training exercise, related to the end of the offensive processes, in different field zones on the various corridors. Unpredictability is the key factor in achieving goal. However the pass towards behind and winning a second ball allows the teams to score goals. **References** Sarmiento, H., Anguera, T.; Campaniço, J. & Leitão, J. (2010). **CLASSIFICATION POWER OF SPATIAL METRICS IN INVASION TEAM SPORTS**

Fonseca, S.1, Lopes, A.1,2, Leser, R.3, Baca, A.3, Hadjileontiadis, L.4

*Universidade Lusofona, 2: CIDESD (Portugal), 3: Centre for Sport Science and University Sports, University of Vienna, 4: Aristotle University of Thessaloniki*

**Introduction:** Team sports can be studied as a multi-agent action system (Saltzman & Kelso, 1987) when described by the interactions of team-players. This interpersonal coordination is specific to task constraints (Araújo, Davids, Bennett, Button, & Chapman, 2004) and self-organised structures, like offensive and defensive patterns that describe the system's/team's behaviour, that can emerge from these complex interpersonal interactions of performers (McGarry et al., 2002). Tactical behaviour includes both individual and team tactics, and the position of every player is influenced by the tactical concept of the team (Jäger, Perl, & Schöhlhorn, 2007). A proper method of assessing tactical team performance in game sports is the observation of spatial organization (Garganta, 2009), in particular the space in the field covered by a team (Bartlett et al., 2012). Spatial metrics such as the convex hull's area, bounding rectangle's area, voronoi cells' area have been considered (Fujimura & Sugihara, 2005; Bourbousson, Sève, & McGarry, 2010; Fonseca, et al., 2012), as well as measures derived from the teams' centroid (Bourbousson, Sève, & McGarry, 2010). The purpose of this work is to measure the power of these spatial metrics to discriminate between attack and defense phases of a game. **Methods:** Four trials of an indoor small sided amateur soccer game (5vs5) played in a 33m×18m field were considered. Players and ball trajectories were collected across the duration of each trial by means of Ubisense Location System (Leser, Baca, & Ogris, 2011). The spatial metrics defined above were calculated for each team across the duration of each trial and their classification power was tested sole and in pairs. **Discussion:** Results suggest that it is possible to identify attack and defense phases of a game in invasive team sports using some of the spatial metrics considered in this study. Further research is needed to verify the current findings. **References:** Bartlett, R., Button, C., Robins, M., & Dutt-mazumder, A. (2012).

## RELATION BETWEEN DISTANCE FROM THE LEAST ADVANCED OUTFIELD DEFENDER TO HIS GOAL LINE ON ZONE OF THE PITCH WHERE THE BALL IS GAINED IN SOCCER.

Añón Gómez, A.1, Ruiz-Ruiz, C.2, Zubillaga, A.3, Fradua, L.1, Nardi, A.1, Gómez-Pérez, P.T.2

1 University of Granada, 2 University of Seville, 3 University of the Basque Country.

**INTRODUCTION** In Football it has been demonstrated that the closer to the opposing goal teams gain the ball the higher probability of scoring a goal and the lower of conceding it (Bate, 1988). However, until the present there is a lack of studies focused on ascertain in what manner teams should play to gain the ball in those zones. When defending pieces of play initiated in the opposing half, pushing up the back four line might help teams to win the ball back in advanced parts of the pitch. The aim of this study was to examine differences on distance from the least advanced outfield defender to his goal line according to the zone of the pitch where the ball is gained. **METHODS** 4 matches played by a team during the 2010/11 Liga BBVA (Spanish first football division) were monitored using the AMISCO PRO® system. The matches analysed (3 home and 1 away matches) resulted in 2 wins, 1 draw, and 1 loss. 217 defensive pieces of play initiated in the opposing half were analysed. A defensive piece of play initiated in the opposing half starts when the attacking team initiates a possession of the ball in his own half of the pitch and ends when the analysed team gains possession of the ball. Data was normally distributed and had equal variance. A one-way ANOVA test was run. The dependant variable was distance from the least advanced outfield defender to his goal line when the analysed team gained the ball. The factor was zone of the pitch where the ball was gained (1, 2, 3, 4, 5, 6). **RESULTS** LSD post hoc analysis revealed that distance from the least advanced outfield defender to his goal line was significantly higher as the ball was gained in more advanced zones of the pitch,  $F(5,211) = 182.86$ ,  $P < 0.001$ ,  $\eta^2=0.81$ . When the ball was gained in zones 1, 2, 3, 4, 5, and 6 the distance from the least advanced outfield defender to his goal line was  $11.21 \pm 5.69$ ,  $22.45 \pm 5.69$ ,  $35.38 \pm 6.32$ ,  $43.93 \pm 4.68$ ,  $48.02 \pm 7.93$ , and  $55.23 \pm 7.47$  metres respectively. **DISCUSSION** Results showed that pushing up the back four line helped teams to gain the ball in advanced zones of the pitch. This finding supports Suzuki and Nishijima (2007) notions about the benefits of pushing up the back four line when defending in order to keep the team compact and restrict the spatial temporal demands of the opposition. **REFERENCES** Bate, R. (1988). Football chance: Tactics and strategy. In T. Reilly, A. Lees, K. Davids, & W. J. Murphy (Eds.), *Science and football* (pp. 293–301). London: E & FN Spon. Suzuki, K., & Nishijima, T. (2007). ##### CARBOHYDRATE: CARBOHYDRATE INTAKE GUIDELINES AND LOW VERSUS HIGH DEBATE

Jeukendrup, A.

University of Birmingham

It has been known for a long time that carbohydrate is the main fuel for athletes in the vast majority of events. There is much discussion about training with low carbohydrate and training with high carbohydrate availability. Carbohydrate availability is increased by consuming carbohydrate in the hours or days prior to the session, intake during exercise, and refueling during recovery between sessions. This is important for the competition setting or for high-intensity training where optimal performance is desired. Carbohydrate intake during exercise should be scaled according to the characteristics of the event. During sustained high-intensity sports lasting ~1 h, small amounts of carbohydrate, including even mouth-rinsing, enhance performance via central nervous system effects. While 30–60 g/h is an appropriate target for sports of longer duration, events >2.5 h may benefit from higher intakes of up to 90 g/h. Products containing special blends of different carbohydrates may maximize absorption of carbohydrate at such high rates. In real life, athletes undertake training sessions with varying carbohydrate availability. Whether implementing additional 'train-low' strategies to increase the training adaptation leads to enhanced performance in well-trained individuals is unclear. It is clear that both training low and training high approaches seem to have some advantages and disadvantages. But how do you decide how to approach training? In this presentation the following topics will be addressed in particular: 1. Current carbohydrate intake guidelines 2. A brief summary of the evidence supporting these guidelines 3. A discussion of the train high versus train low debate 4. A recommendation on how to incorporate train high/train low into a training program

##### THE ROLES OF EXERCISE AND NUTRITION IN MAXIMIZING ANABOLISM

Phillips, S.

McMaster University

Muscle proteins are constantly and simultaneously being synthesized and degraded. This 'turnover' provides for a mechanism of constant maintenance and greater potential for changes in protein pool size. The two most potent stimuli for enhancing muscle protein synthesis (MPS) are exercise and provision of protein. While protein feeding and exercise are independent stimulators of MPS they are additive in their effect and when combined over longer periods of time sum to result in expansion of a protein pool, the most obvious

example of which is muscle fibre hypertrophy with resistive exercise (Phillips et al., 2005). The traditional dichotomy for the phenotypic adaptation induced by exercise is that endurance exercise does not lead to hypertrophy but instead results in expansion of the mitochondrial protein pool. On the other hand resistance exercise leads to muscle fibre hypertrophy (i.e., expansion of the myofibrillar protein pool) and does not change mitochondrial content. Our work has shown that in the untrained state the response to exercise is, however, rather generic and that both protein pools expand, at least acutely (Wilkinson et al., 2008). With increased specificity and time spent training with one particular exercise mode the response is 'honed' and the protein pools that are synthesized become specific (Wilkinson et al., 2008). With a focus on resistive exercise, since it is a potent countermeasure to atrophy even in small doses and an effective countermeasure to sarcopenic muscle loss, we have shown that various paradigms of resistance exercise that are non-traditional are actually effective in stimulating MPS (Burd et al., 2010; Burd et al., 2012a) and also in promoting hypertrophy (Mitchell et al., 2012). In combination with our work on optimal sources of protein to promote MPS (Tang et al., 2009; Burd et al., 2012b) we are now beginning to understand that rapidly digested high-leucine content proteins such as whey protein are remarkably effective in stimulating MPS (Tang et al., 2009; Burd et al., 2012b); we propose that this phenomenon is explained by the 'leucine trigger' hypothesis. According to this thesis the rise in intramuscular free leucine, likely through mTOR signalling, stimulates MPS. Noteworthy is the fact that slowly digested or low leucine-containing proteins are ineffective in stimulating MPS. Recent data in conditions of extreme hypertrophy, weight loss, and specific meal composition will be discussed.

#### THE RELIABILITY OF POWER OUTPUT AND PERFORMANCE TIME DURING SIMULATED DYNAMIC GRADIENT CYCLING TIME TRIALS

Clark, B.1, Paton, C.D.2, O'Brien, B.J.1

*1 University of Ballarat (Ballarat, Australia) 2 EIT (Hawkes Bay, New Zealand)*

THE RELIABILITY OF POWER OUTPUT AND PERFORMANCE TIME DURING SIMULATED DYNAMIC GRADIENT CYCLING TIME TRIALS Introduction Laboratory assessment of physiology and performance forms an integral part of athlete preparation for competition. Establishing the physiological capacity and performance standard of cyclists, allows sports scientists and coaches to formulate and implement structured training programs and subsequently assess the effectiveness of those programs. Cycling performance assessment is generally characterised by simulated time trials of various duration generally completed under controlled conditions in a laboratory. The purpose of this investigation was to establish the reliability of simulated cycling time trials completed on a course of varying gradient. Methods Twenty competitive cyclists (Age:  $32 \pm 12$  years, weight  $73 \pm 11$  kg, height  $178 \pm 5$  cm) completed four simulated cycling time trials over a 20km course with numerous and un-regimented changes in gradient (both ascents and descents). The time trials were completed over a 5 week period to establish short and long term reliability. Results Performance time was highly reliable across all trials (TT1-TT2 CV=  $1 \pm 0.5\%$ , TT2-TT3 CV=  $1.4 \pm 0.7\%$ , TT3-TT4 CV=  $1.5 \pm 0.8\%$ ). Similarly, average power output highly reliable across all trials although somewhat less so than performance time (TT1-TT2 CV=  $1.9 \pm 1.0\%$ , TT2-TT3 CV=  $2.5 \pm 1.3\%$ , TT3-TT4 CV=  $2.2 \pm 1.2\%$ ). Discussion The major finding of the present study is a new laboratory based simulated cycling time trial performed on a course of varying gradient is a highly reliable test of the performance standard of competitive cyclists. In the present study, a course was designed to closely mimic the natural changes in gradient faced by cyclists in competitive situations thus improving the ecological validity of laboratory performance assessment. The average CV for performance time (1.3%) from the new protocol investigated by this study was found to be similar to, if not lower than the average CV reported for the same measure from previous investigations on constant gradient protocols (Sporer, 2007; Zavorsky, 2007; Smith, 2001; Nooreen, 2010). Correspondingly the average CV for average power output (2.2%) was also found to be similar to or better than the average CV reported from studies on constant gradient (Sporer, 2007; Zavorsky, 2007; Smith, 2001; Nooreen, 2010) and constant gradient dynamic protocols (Abiss, 2008). #### COMPARISON OF TWO DIFFERENT TRAINING LOADS IN SPANISH ELITE FREEDIVERS.

Fernández, F.A., González-Ravé, J.M., Juárez Santos-García, D.

*University of Castilla -la Mancha*

Introduction Numerous studies conclude that training is the main reason for developing the diving response and thus increase apnea time in divers (Schagatay, 2000; Lemaitre, 2010), but there are few studies that had compared different periodized training with elite freedivers. The aim of this study was to evaluate and compare the impact of two different training loads by means body composition, lung function and of static apnea time. Methods. Ten Spanish elite freedivers ( $36 \pm 5.07$  years, BMI  $22.8 \pm 1.43$ ). The sample includes the Spanish recordman in free immersion (117 m.), the Spanish ex-recordman in static apnea (7'05") or the Spanish ex-recordwoman in dynamic apnea (144 m.). The divers were divided in two groups: Group A received a training program with Specific loads of Deep apnea (SLDA) and group B conducted a training program with Specific loads of Static apnea (SLSA). Both groups performed a program of preparation of 4 weeks with 6 weekly sessions for the training of apnea. Testing were carried out before and after to perform the training programs. We used a segmental bioimpedance analyzer (InBody 230, Biospace) to assess body composition. On the other hand we performed a spirometry test, determining the Forced Vital Capacity (FVC) and maximum expiratory volume in first second (FEV) by Spirometry (Datospir-70, Sibelmed). Static apnea test is performed after a free warm-up of ten minutes. The freediver remains in "jellyfish position" and is calculated the time that remains in apnea by two different timers. Results Body composition; Muscle mass decreased by 0.23% in A group and was increased by 2.66% in B group. Fat percentage was decreased by 5.21% in A group and decreased by 6.67% in B group. Respiratory flows; FVC was decreased by 4.78% in A group and was increased by 1% in B group. VEMS was decreased by

0.85% in A group and was increased by 2.55% in B group. Static apnea; was decreased by 20.8 seconds in A group and was increased by 2.2 seconds in B group. No significant differences were found between two groups on the dependent variables. Discussion Training in SLSA performs better but not significantly in Static Apnea, although no significant differences, the effect size can be considered large ( $\eta^2$  0.102). These differences may be relevant in competition, so it is a more determining training in delaying the rupture of apnea in this discipline. This is consistent with that seen in other studies such as Gamble (2006) which speaks of the principle of specificity in the training of apnea, and concludes that improvement in the specific training content that is trained. The general concept of specificity also appears in the study of Schagatay (2000) which compares physical training in apnea, where the results show that training effects are specific to the training conducted. (2006). *Strength & Conditioning Journal*, 28(3), 54-58.

### HALF TIME SOCCER PERFORMANCE CAN BE IMPROVED FOLLOWING SPECIFIC RE WARM UP ACTIVITIES

Zois, J., Bishop, D., Fairweather, I., Aughey, R.

*Victoria University*

**Introduction** Half-time periods provide soccer players with an opportunity to physically prepare for subsequent competitive tasks. High-intensity, short duration warm-up (WU) activities can improve subsequent physical performance when completed during the pre-game WU routine (Zois et al., 2011). However, the beneficial physical and skilled effects of similar WUs conducted during half-time rest intervals in soccer are unknown. **Methods** Eight male amateur soccer players participated with a mean age, height, body mass and maximal HR of 23.6±4.1 y, 1.73±0.5 m, 75.5±7 kg and 187±4 bpm respectively. They performed two 26-min periods of intermittent activity on a non-motorised treadmill, interspersed by 15 min of passive recovery. During the 15 min recovery period, participants performed either a 3 min small-sided game (SSG) re-WU; a 5RM leg-press re-WU, or no re-WU. Measures included counter-movement jump (CMJ), repeated-sprint ability (8x4 s sprints embedded in each intermittent activity protocol), the Loughborough Soccer Passing Test (LSPT), core temperature, blood lactate concentration, HR, and perceptual measures. Data were analysed using the effect size statistic with 90% confidence intervals, and percentage change, to determine magnitude of effects. **Results** Repeated-sprint ability in the second period improved only in the 5RM re-WU condition; on average, peak velocity, mean velocity and acceleration was 4, 3 and 18% greater. Compared to pre-intervention, only the SSG re-WU improved performance on the LSPT, 6.4% (0.6±0.8) post intervention and 6.2% (0.6±0.6) following the second activity period. Flight-time to contraction-time measured in the CMJ, improved following the 5RM re-WU compared to the SSG re-WU (9.8%, 0.5±0.3) and no re-WU (9.4%, 0.7±0.5), and remained higher post the second activity period (8.8%, 0.5±0.3 and 10.2%, 0.6±0.6, respectively). Relative maximum rate of force development measured in the CMJ, was greater in the 5RM condition following the second activity period compared to the small-sided game (29.3%, 0.7±0.5) and no re-WU (16.2%, 0.6±0.6). **Discussion** Results suggest that a 5RM leg-press re-WU completed following standardised intermittent exercise improved subsequent physical performance. In contrast, skilled based re-WUs which included SSG activity, enhanced skill execution following the standardised intermittent exercise. **References** Zois J, Bishop D, Ball K, Aughey R (2011) *J Sci Med Sport*, 14(6): 522-8

### THE DUTCH TALENT IDENTIFICATION ASSESSMENT FOR TABLE TENNIS; A REPRODUCIBILITY AND VALIDITY STUDY

Faber, I.R., Nijhuis-van der Sanden, M.W.G., Oosterveld, F.G.J.

*Saxion University of Applied Science*

**Introduction** Talent identification programs in sports can provide an optimal connection between sports, talents and personal preferences. As a result, both elite sports and sports on amateur level benefit from these programs. Assessing essential fundamental motor skills could be helpful in talent identification to estimate the potential of young athletes (Gagné, 2004; Vandorpe et al., 2012). In this context, valid and reliable tests are essential to obtain trustworthy results (Faber et al., 2011). This study aimed to investigate the reproducibility on test-item level, internal consistency, underlying dimensions, and concurrent validity of the talent identification assessment (TIDA) of the Netherlands Table Tennis Association. **Methods** In total, 113 youngsters (6-10 years) were tested using the TIDA. The TIDA consists of eight test-items measuring specific skills for table tennis: sprint, agility, vertical jump, speed while dribbling, aiming at target, ball skills, throwing a ball and eye-hand coordination. A retest was taken to test reproducibility. The initial assessments were used for estimating internal consistency and searching for possible underlying dimensions. National ranking was used to test concurrent validity. **Results** Reproducibility analyses exposed that the ICC's of six of the eight test items (sprint, agility, vertical jump, speed while dribbling, throwing a ball and eye-hand coordination) met the criteria of 0.7 for reliability and had coefficients of variation between 9.9-22.0% as agreement parameters. Chronbach's alpha valued 0.853. Principal components analysis distinguished two conceptually meaningful factors; 'ball control' and 'gross motor function'. Concurrent validity analyses demonstrated moderate but significant association between the results of the TIDA and national ranking; boys  $r=-0.53$  ( $p<0.001$ ) and girls  $r=-0.45$  ( $p=0.015$ ). **Discussion** Evaluation of the Dutch TIDA demonstrated six reproducible test items, good internal consistency and good prospects for validity. Two test-items, aiming at target and ball skills, need to be revised. Longitudinal validity studies are necessary to learn more about the discriminative ability and the predictive value of the TIDA (Vaeyens et al., 2008; Faber et al., 2011). **References** Faber IR, Nijhuis-Van der Sanden MWG, Oosterveld FGJ. ### DETRAINING OF ELITE JUNIOR TENNIS PLAYERS DURING INTERNATIONAL TOURS AND THE EFFECT OF TRAINING AND TOURNAMENT LOAD

Murphy, A.

*Charles Sturt University*

**Introduction** The competitive demands of professional tennis require players to regularly engage in extended overseas tours, making adequate physical training difficult. Accordingly, the purpose of this study was to examine the effects of a four-week international junior representative tour on physical training status. Specifically, to assess changes in fitness before and after tours, in relation to training load performed overseas. Incorporated in this analysis was training and tournament load based on match win-loss ratio and with and without a physical preparation coach present. **Methods** 30 national-level junior athletes representing Australia in a four-week international

tour were assessed within two days of departure and within two days of return. Measures involved mass, speed (5,10,20m), agility (modified 5-0-5), speed endurance (10 x 20m repeat sprint), power (vertical jump double/left/right), and endurance (20-m shuttle-run test). Training loads (duration x sRPE) were also collected in the four weeks prior to departure and for the duration of each tour. Results Analysis showed no significant change ( $p>0.05$ ) in any measures for pre compared to post tour, though effect size analysis demonstrated a moderate effect for decreased 5m and 10m speed ( $d>0.6$ ). Comparison of load prior to and during the tour showed significantly greater load completed on tour for total load and tennis only load ( $p<0.01$ ,  $d>1.4$ ). Pearson's correlations indicated significant ( $p<0.05$ ) moderate positive correlation between total tennis load and 10m, 20m sprints ( $r=0.45$ , and  $0.52$  respectively), whilst a moderate negative correlation was shown with shuttle-run test ( $r=-0.44$ ). Finally, total load ( $p<0.00$ ,  $d=1.6$ ), tennis load ( $p<0.00$ ,  $d=1.3$ ) and strength and conditioning ( $p<0.00$ ,  $d=2.0$ ) loads were all significantly greater when a physical preparation coach was present. Discussion These data suggest that junior international tennis tours of four weeks result in minimal detraining effects if total training load (match and training) are maintained; though trends for reduced speed characteristics and endurance should be noted. Whilst training load on tour may not relate to match performance, sufficient loads throughout tournaments (match or training) may alleviate fitness decrement. Furthermore, these findings also highlight greater training volume in the presence of a physical preparation coach. These outcomes assist tennis federations to make informed decisions as to the training loads and support staff required to prevent player detraining on prolonged international tours.

**OPAL-PLUS: A 3-YEAR FOLLOW-UP ASSESSING CHANGES IN PHYSICAL FUNCTION, PHYSICAL ACTIVITY AND MENTAL WELL-BEING IN ADULTS 70+ YEARS.**

Fox, K.R.

*University of Bristol*

Do not insert authors here OPAL-PLUS is a recently completed follow-up study of Project OPAL (Older People and Active Living). The aim of OPAL was to provide a comprehensive objective documentation of the nature of physical activity and function in older people in the UK, and possible determinants and consequences for health and well-being. OPAL participants were a diverse sample of 240 men and women aged 70 and over (mean age 78 years) living in a neighbourhood of low, medium or high deprivation. Follow-up (mean 38 months) resulted in 190 participants revisited (24 had died). Objective measures at both time points included 7-day accelerometry, the Short Physical Performance Battery, and body mass index. Questionnaires were used to assess frequency, mode of travel, and purpose of daily trips from home, falls confidence, food choices, and measures of health and well-being. In addition, health service usage for a period of 48 months following baseline measures was extracted from patient primary care records. This data set provides a unique opportunity to investigate patterns and levels of change in physical activity and physical function and their consequences. It also allows an estimation of the potential for maintenance of physical activity and physical function to influence subsequent aspects of health and life quality into later adult years. Prospective associations between baseline physical activity and function data will be calculated for levels of 'getting out and about', levels of well-being, morbidity, dietary habits, and their usage of primary and secondary health services at follow-up. A summary of results will be provided with particular attention paid to the relative predictive power of physical activity parameters and aspects of physical function on indicators of mental well-being.

**DEVELOPMENT AND PILOTING OF A MODEL OF NEIGHBOURHOOD SUPPORT FOR PROMOTION OF ACTIVE AGEING – PROJECT ACE**

Stathi, A.1, Withall, J.1, Fox, K.R.2, Davis, M.2, Thompson, J.L.3, Gray, S.4, Lloyd, L.2, Parkhurst, G.4

*1: University of Bath (UK), 2: University of Bristol (UK), 3: University of Birmingham (UK), 4: University of West of England (UK).*

Introduction The contribution of regular physical activity to the maintenance of older people's physical and mental health is well-established. However, older people remain the least active of all age groups. Strategies are needed to motivate older people to adopt more active lifestyles in order to sustain their capacity to undertake activities of daily living, retain good physical function, maintain social networks and enjoy later life to the full (Stathi et al., 2010). Project ACE (Active, Connected and Engaged communities) developed a low cost, pragmatic, and sustainable intervention programme in which retired volunteers promote physical activity in older adults. This paper presents the ACE intervention protocol focussing on the recruitment rate and methods. Methods Recruitment rate, study completion rate, intervention concordance and intervention fidelity are the main outcomes of Project ACE. To pilot the trial measures, physical activity (by accelerometry), well-being, neighbourhood quality of life, perceptions of competence, autonomy, relatedness, and resilience, for both intervention participants and activators are assessed. Post intervention, focus groups will explore topics related to recruitment, training and delivery of the ACE programme. Results Project ACE is a two phase, 24-month pilot study involving sedentary older adults (ACE participants), two paid coordinators (ACE coordinators) and 20 activity promotion volunteers (ACE activators). In Phase 1, the ACE intervention protocol, the activator training manual and the role of the ACE coordinators were further developed and refined. In Phase 2, sedentary older adults aged 65–85 years are recruited in two neighbourhoods in Bristol and randomised to the intervention and control groups. Recruitment methods included presentations in community events, targeted mail, leaflets and adverts in local media and organisations working with older adults. As recruitment is still in progress, the results of the effectiveness of the recruitment strategies are not available yet but they will be presented in the 18th Annual Congress of the ECSS. Discussion Project ACE has developed a well-informed and grounded intervention that has potential for generalisation throughout the UK. The results will establish whether it is possible to evaluate the ACE intervention in a definitive effectiveness and cost effectiveness trial. Sharing information about recruitment challenges in community-based physical activity interventions and choosing effective recruitment strategies will benefit researchers, funders and, ultimately, older people. **NEW EVIDENCE FOR THE POSITIVE RELATIONSHIP BETWEEN SPORTS, HEALTH AND AGEING**

Hopman-Rock, M.1,2, van Meeteren, N.2,3

*1, BodyatWork Research Center TNO VU university medical center Amsterdam; 2, TNO (Netherlands Organisation of Applied Scientific Research) Leiden; 3, Center for Care Technology Research, Maastricht*

Background. In clinical practice the use of the knowledge about the effects of sports and physical activity (PA) on health and risk of mortality, onset of co-morbidity, and delay of the onset of dependency and frailty in older adults could be enlarged. Objectives. To present the scientific evidence for the relationship of sports and PA with successful ageing using several position statements of leading organizations and other sources. Methods. Position stands of the American College of Sports Medicine (ACSM; Chodzko-Zajko et al, 2009) and the European College of Sports and Science (ECSS; Biddle et al, 2012) are used to present the latest state of the art. Other emerging literature is presented in the areas of epidemiology and PA, PA and disability, perioperative physical therapy and behavioural change (counselling and interventions). Evidence levels: A. Overwhelming evidence from RCTs and/or observational studies. B. Strong evidence from a combination of RCT and/or observational studies. C. Generally positive or suggestive evidence from a smaller number of observational studies and/or uncontrolled or nonrandomized trials. D. Panel consensus judgment. Results. In most areas of sports/PA and ageing A/B level of evidence is found. The outcome of treatment of people with several diseases and geriatric syndromes is more effective with higher-intensity exercise (e.g., type 2 diabetes, clinical depression, osteopenia, sarcopenia, muscle weakness). PA amounts in persons older than 75 years are far below what is recommended. Figures in residential care settings are even worse. Perioperative physical therapy is promising to reduce costs and patients burden. Counselling in the short term has level A evidence, but barriers to change habitual PA do exist (perceived fall risks, ageism, and the difficulties to design and implement helpful intervention programmes). European initiatives towards implementation of new insights have been undertaken ([www.eunaapa.org](http://www.eunaapa.org) ; [www.paseo.net](http://www.paseo.net)) Conclusion. More sports and PA (counselling and interventions) in older adults could be effective if barriers for implementation in clinical practice could be overcome. References. **10:20 - 11:50****Oral presentations****OP-PM24 Physiology [PH] 1****FOUR WEEKS OF REPEATED-SPRINT EXERCISE TRAINING UP-REGULATES THE NA<sup>+</sup>-K<sup>+</sup>-ATPASE B1 ISOFORM IN BOTH FAST AND SLOW TWITCH SINGLE FIBRES IN HUMAN SKELETAL MUSCLE**

Wyckelsma, V.L.1, Murphy, R.M.2, Serpiello, F.R.1, Lamboley, C.R.1, McKenna, M.J.1

*Victoria University; La Trobe University*

Introduction The Na<sup>+</sup>, K<sup>+</sup>-ATPase (NKA) is a key protein regulating membrane excitability in skeletal muscle and is upregulated after endurance, sprint or resistance training interventions. Repeated-sprint exercise (RSE) is a high-intensity short duration training modality specific to team sport activity but the effects of RSE training on molecular NKA adaptations are unknown. As human skeletal muscle is heterogeneous with respect to fibre type, it is important to ascertain whether specific fibre type adaptations occur with RSE training. This study therefore investigated four weeks RSE training on NKA isoform abundance in single skeletal muscle fibres. Methods Eight healthy participants trained three times per week for 4 weeks, each session comprising three sets of five, 4-s maximal sprints. Vastus lateralis biopsies were taken before and after training and single fibres were separated. Fibre type (myosin heavy chain Type I and IIa) and NKA isoform protein abundance ( $\alpha$ 1-3,  $\beta$ 1-3) were determined by western blotting. Results Training had no effect on the abundance of the  $\alpha$ 1- $\alpha$ 3 isoforms in Type I fibres;  $\beta$ 1 was upregulated after training ( $P=0.035$ ) with no change in the  $\beta$ 2 or  $\beta$ 3 isoforms. In Type IIa fibres, training did not effect the abundance of the  $\alpha$ 1- $\alpha$ 3 isoforms, however a tendency was detected for an increase in  $\alpha$ 1 (moderate Effect Size,  $ES=0.6$ ). The  $\beta$ 1 isoform was upregulated following training ( $P=0.05$ ); no change was found for  $\beta$ 2 or  $\beta$ 3, but there was a tendency for increased  $\beta$ 2 ( $ES$  0.4) and  $\beta$ 3 ( $ES$  0.5) in Type IIa fibres after training. Discussion Interestingly 4 weeks of RSE training did not increase the NKA  $\alpha$  isoform abundance in either Type I or IIa fibres, but did upregulate the  $\beta$ 1 isoform in both fibre types. The lack of training adaptation in NKA  $\alpha$  isoforms with RSE may reflect insufficient physiological stress induced by 4-s sprints. In contrast the upregulation of  $\beta$ 1 occurred in both fibre types and this may have implications for increasing NKA activity

**EFFECTS OF HIGH-INTENSITY INTERVAL TRAINING ON MYOCARDIAL VASCULAR FUNCTION**

Eskelinen, J.J., Hannukainen, J.C., Savolainen, A., Heinonen, I., Virtanen, K.A., Kempainen, J., Koivumäki, M., Kapanen, J., Knuuti, J., Kalliokoski, K.K.

*University of Turku*

Introduction High-intensity interval training (HIT) has recently gained popularity among recreational exercisers and it has indeed been shown that it is beneficial for health in many aspects and with much less time commitment. However, it is poorly known how this type of training effects on myocardial vascular function and we studied that. Methods Twenty-six healthy sedentary middle-aged men (age  $47 \pm 5$  years and BMI  $26.0 \pm 2.6$ ) were recruited into the study and randomly divided into the HIT ( $n=13$ ) and aerobic exercise training (AET) ( $n=13$ ) groups. Both groups trained six sessions within two weeks. A session of HIT group consisted of 4 -6 x 30 s maximal sprints (Win-gate protocol) with 4 min rest between the sprints and a session of aerobic group consisted of 40-60 min of cycling at an intensity of 60 % of  $VO_{2max}$ . Both groups increased the amount of training after every second session (4->5->6 sprints / 40->50->60 min aerobic). Myocardial blood flow was measured at baseline and during standard adenosine infusion using Positron Emission Tomography before and about 48 hours after the last training session. One subject from the both groups stopped the training prematurely due to personal reasons and for two others in the HIT group and four others in AET group blood flow measurements could not be done due to technical reasons. Thus, those measurements were successfully performed in 10 subjects in the HIT and 8 subjects in the aerobic group. Results

Both training modes increased VO<sub>2</sub>max similarly (HIT: from 34.0 ± 3.7 to 36.2 ± 4.5 ml/kg/min, AET: from 33.6 ± 4.6 to 34.9 ± 4.8 ml/kg/min, p=0.0003 for the training effect, p=0.32 for interaction). Myocardial blood flow at baseline was not different between the groups and training had no effect on it. However, training induced significantly different response between the groups in myocardial blood flow during adenosine infusion. While it increased by on average 9 % in the AET group, it decreased by 17 % in the HIT group (p=0.038 for the interaction). On the other hand, myocardial blood flow reserve - derived as the fold increase in blood flow from baseline to adenosine - did not differ between the groups and training had no significant effect on that (HIT: from 4.2 to 3.8 and AET: from 3.8 to 3.9, all p=NS). Discussion This data shows that myocardial blood flow response to a standard dose of adenosine decreases acutely after a short very intense training period in previously sedentary subjects. Probably this is a transient finding, but still it warrants further study on this issue. This finding also suggests that we should be somewhat cautious when prescribing really high-intensity exercise for the beginners who are not used to cope with that.

### MECHANICAL EFFICIENCY DURING SPRINT EXERCISE IN MAN

Morales-Alamo, D.1, Ponce-González, J.G.1, Losa-Reyna, J.1, Torres-Peralta, R.1, Perez-Suarez, I.1, de la Calle-Herrero, J.1, Rasmussen, P.2, Siebenmann, C.2, Lundby, C.2, Calbet, J.A.L.1

1 Univ of Las Palmas de Gran Canaria, Spain ; 2 Univ of Zürich, Switzerland

Introduction The mechanical efficiency (ME) is the ratio between the work performed and the energy expended to produce this work. The assessment of mechanical efficiency during high intensity exercise, when a substantial part of the energy is provided by anaerobic metabolism, is a challenge. Consequently it remains unknown with what mechanical efficiencies humans perform sprint exercise. To determine the total enthalpy during a 30 s all-out sprint exercise on the cycle ergometer (Wingate test) and the impact of acidosis on ME two experiments were carried out in nineteen men. Methods The total enthalpy and the leg and whole body MEs were calculated by combining the determination of muscle mass with the assessment of muscle metabolites, leg VO<sub>2</sub> and exchange of metabolites (direct Fick method with assessment of femoral blood flow by thermodilution and arteriovenous O<sub>2</sub> and lactate differences) during isokinetic Wingate tests performed in normoxia (PIO<sub>2</sub>=142 mmHg) and hypoxia (PIO<sub>2</sub>=75 mmHg). Results Compared to normoxia, mean power output and accumulated VO<sub>2</sub> were reduced in hypoxia by 5.5% and 33%, respectively (P<0.05). Almost 50% greater muscle lactate accumulation was observed immediately after the sprint in hypoxia (P<0.05) and consequently the muscle pH was 0.2 units lower in hypoxia than in normoxia (P<0.05). In normoxia, 19.8, 49.4, and 30.8 % of ATP was provided by ATP+PCr, the glycolysis and the aerobic metabolism. The corresponding figures for hypoxia were: 15.6, 60.2, 24.2%, respectively. The legs' mechanical efficiency was reduced by 16% in hypoxia, from 22.7± 3.4 (range: 17.2 - 27.8%) in normoxia to 19.1±4.0 (range: 14.0 - 25.1%) in hypoxia (P<0.05). The whole body ME tended to be reduced by 14% from 21.3±3.0 (range: 16.6 - 26.4%) in normoxia to 18.3±3.7 (range: 13.7 - 23.7%) in hypoxia (P=0.06). Consequently, the total energy cost of exercise per watt (total enthalpy/mean power output) was 18% higher in hypoxia than in normoxia (169.7±34.4 and 143.5±21.2 J.w<sup>-1</sup>, respectively P<0.05). In normoxia there was a linear relationship between the percentage of MHC IIA with mechanical and ATP use efficiencies, at the leg (r=0.66 and 0.76, respectively, both P<0.05) and whole body levels (r=0.73 and 0.78, respectively, both P<0.05) (Fig. 5). ME was higher during sprint than during submaximal exercise. Discussion and conclusions. In agreement with previous studies using leg extension exercise producing exhaustion in ~ 3 min (~110-130% of VO<sub>2</sub>max), the ME during sprint exercise was greater than during submaximal exercise, due to the higher energy efficiency of the anaerobic pathways. In summary, the mechanical efficiency of sprint exercise in man was determined to lie between 14 and 28%. In severe acute hypoxia the mechanical efficiency of sprint exercise is reduced likely due to the greater level of acidosis caused by a higher glycolytic rate in hypoxia than in normoxia. ### HIGH INTENSITY INTERVAL TRAINING IMPROVES INSULIN MEDIATED GLUCOSE CLEARANCE IN SKELETAL MUSCLE IN PATIENTS WITH TYPE 2 DIABETES

Skaaby, S., Pedersen, H.P., Andersen, N.B., Nielsen, M.B., Petersen, H.H.H., Helge, J.W., Dela, F.

University of Copenhagen

Objective The effect of high intensity interval training (HIIT) on skeletal muscle and insulin sensitivity is not fully established. The aims are to investigate the efficacy of HIIT for improving insulin mediated glucose clearance in skeletal muscle in patients with type 2 diabetes (T2DM) and matched healthy controls. Methods Six patients with T2DM and four healthy, age, BMI and VO<sub>2</sub> max matched controls were included (age: 58.2±2.8 and 52.5±1.8 yrs (mean ± SE); BMI: 31.3±0.8 and 28.5±0.6 kg/m<sup>2</sup>; VO<sub>2</sub>max: 26.9±1.3 and 31.3±2.6 ml/min/kg). One-legged HIIT training was performed every other day for 16 days. The protocol comprised 10 x 1 minute of exercise at a workload > 60% of one-legged VO<sub>2</sub>-peak, and heart rate > 80 % of maximal heart rate. 1 minute of exercise was followed by 1 minute of recovery. Body composition and lean leg mass before and after the training period were assessed using dual-energy X-ray absorptiometry. 40 hours after the last training session, a two-step isoglycemic, hyperinsulinemic (80 and 400 mU/min/m<sup>2</sup>) clamp was performed in combination with catheterization of the femoral veins, a brachial artery and a cubital vein. Blood flow in the femoral arteries was measured with Doppler ultrasonography. Whole body insulin stimulated glucose clearance rates were expressed per kg body weight. Metabolically speaking, the leg predominantly consists of skeletal muscle, and rates were expressed per kg lean leg mass. Differences were tested by two-way repeated measures ANOVA. Results Whole body insulin stimulated glucose clearance rates were lower (p<0.05) in T2DM vs. controls (step 1: 3.5±0.6 vs. 6.0±0.3 and step 2: 7.7±0.5 vs. 10.3±0.8 ml/min/kg). Insulin stimulated glucose clearance rates were significantly higher in trained compared with untrained legs in both subjects with type 2 diabetes (step 1: 4.4±0.6 vs. 3.6±0.5 and step 2: 9.3±1.1 vs. 7.5±0.9 ml/kg/min, both P< 0.005) and controls (step 1: 5.9±0.4 vs. 4.2±0.3, step 2: 10.2±0.7 vs. 8.2±0.6 ml/kg/min, both P< 0.005). The relative improvement was similar in the two groups. Conclusion HIIT induced 29 % and 25 % (step 1 and 2) improvement in insulin stimulated glucose clearance in skeletal muscle in T2DM and 39 % and 22 % (step 1 and 2) increase in controls after only 80 minutes of effective exercise. This time-effective training modality may be attractive in the treatment of insulin resistance and type 2 diabetes.

## ACUTE INTERVAL AND CONTINUOUS SPRINT CYCLING INCREASES ANGIOGENIC GENE EXPRESSION IN TRAINED SKELETAL MUSCLE

Taylor, C.W., Ingham, S.A., Hunt, J.E., Martin, N.R., Lewis, M.P., Pringle, J.S., Fudge, B.W., Ferguson, R.A.

*Loughborough University*

**Introduction** Low-volume sprint interval training promotes mitochondrial biogenesis as evidenced by increases in the gene and protein expression of mitochondrial enzymes (Little et al. 2010). However, it is currently unknown whether this type of exercise results in an acute angiogenic adaptive response. Thus, the primary aim of the present study was to examine the changes in gene expression for pro-angiogenic growth factors to acute low-volume sprint cycling. A secondary aim was to determine whether the magnitude of gene expression differs in response to interval versus continuous sprint cycling. **Methods** In a repeated measures cross-over design, 8 trained males (age,  $29 \pm 5$  yr; height,  $180 \pm 9$  cm; body mass,  $79.2 \pm 10.5$  kg;  $VO_{2max}$ ,  $4.5 \pm 0.5$  L·min<sup>-1</sup>) performed two cycling protocols on an isokinetic cycle ergometer (at an identically fixed pedal cadence) consisting of  $4 \times 30$  s sprint efforts interspersed by 4 min of passive recovery (INT) or a 2 min continuous sprint effort (CON). Muscle biopsies were obtained from the vastus lateralis before and 3 hours post-exercise. Angiogenic gene expression for VEGF, HIF-1 $\alpha$ , eNOS, PGC-1 $\alpha$  and MMP-9 were determined using real-time RT-PCR and expressed relative to RP-18 $\beta$ . Data were analysed using a two way repeated measures ANOVA. Data are presented as fold-change from rest (mean  $\pm$  SE). **Results** Total work was greater (53%,  $P < 0.05$ ) during INT compared to CON ( $71.16 \pm 7.28$  vs.  $46.27 \pm 2.73$  kJ, respectively). Both INT and CON increased the mRNA expression of PGC-1 $\alpha$  (7- vs. 5.5-fold,  $P < 0.05$ ), HIF-1 $\alpha$  (1- vs. 0.5-fold,  $P < 0.05$ ) and VEGF (3.5- vs. 4.5-fold,  $P < 0.05$ ), respectively, however the magnitude of fold change for either of these genes was not different between protocols. There was a trend ( $P = 0.06$ ) for greater mRNA expression for MMP-9 (0.5-fold) after both protocols, though the magnitude of expression was not different between trials. There was no difference in eNOS mRNA expression in response to either protocol. **Discussion** This study has demonstrated that an acute bout of sprint interval and continuous cycling provides a potent stimulus capable of inducing similar increases in skeletal muscle VEGF gene expression. Furthermore, our data suggest that the increases in VEGF gene expression in response to this type of exercise are potentially mediated via activation of PGC-1 $\alpha$  and HIF-1 $\alpha$  in response to increased metabolic perturbations. **References** Little, J. ## HIGH INTENSITY INTERVAL AND TRADITIONAL ENDURANCE TRAINING BOTH INCREASE INSULIN SENSITIVITY, VO<sub>2</sub>PEAK AND SKELETAL MUSCLE PERILIPIN 2 AND PERILIPIN 5 CONTENT IN SEDENTARY OBESE MALES

Shepherd, S.1, Cocks, M.1, Ranasinghe, A.2, Barker, T.2, McClean, A.2, Wagenmakers, A.J.M.1, Shaw, C.S.3

1: *Liverpool John Moores University (Liverpool, UK)*, 2: *University of Birmingham (Birmingham, UK)*, 3: *Victoria University (Melbourne, Australia)*

**Introduction:** We have recently demonstrated that both sprint interval training (SIT) and traditional endurance-based training (ET) increase skeletal muscle oxidative capacity, intramuscular triglyceride (IMTG) concentration,  $VO_{2peak}$  and whole-body insulin sensitivity in previously sedentary lean men. We also provided evidence that increases in perilipin 2 (PLIN2) and perilipin 5 (PLIN5) observed after both training modes played a role in the increased net IMTG breakdown during 1 h of endurance exercise (Shepherd et al., 2013). However, SIT requires repeated 'all-out' efforts against a very high resistance (Wingate sprints), which may not be suitable or practical for obese individuals. **Aims:** To investigate the hypotheses that in sedentary obese males high intensity interval training (HIT) at a constant load of 200%  $W_{peak}$  and ET lead to 1) similar increases in  $VO_{2peak}$  and insulin sensitivity and a similar reduction in cardiovascular risk factors; and 2) similar increases in IMTG, PLIN2 and PLIN5 content. **Methods:** Sixteen sedentary obese males ( $25 \pm 2$  y, BMI  $34.8 \pm 1.3$  kg·m<sup>-2</sup>) performed 4 weeks of either HIT (4-7 30s bursts at a constant load of 200%  $W_{peak}$  interspersed with 2 min recovery, 3d.wk<sup>-1</sup>) or ET (40-60 min cycling at ~65%  $VO_{2peak}$ , 5d.wk<sup>-1</sup>). Values are given as means  $\pm$  SEM. For analytical methods, statistical methods and power calculation see Shepherd et al. (2013). Only the main effects of training were significant and are reported. **Results:** Training increased  $VO_{2peak}$  (HIT  $7 \pm 3\%$ , ET  $12 \pm 4\%$ ;  $P < 0.05$ ) and the Matsuda insulin sensitivity index (HIT  $14 \pm 3\%$ , ET  $17 \pm 9\%$ ;  $P < 0.05$ ). Training reduced fasting plasma cholesterol (HIT  $13 \pm 6\%$ , ET  $10 \pm 7\%$ ;  $P < 0.05$ ), and fasting plasma triglyceride concentration (HIT  $16 \pm 8\%$ , ET  $10 \pm 7\%$ ;  $P = 0.06$ ). Training increased both PLIN2 (HIT  $92 \pm 19\%$ , ET  $82 \pm 23\%$ ;  $P < 0.05$ ) and PLIN5 protein content (HIT  $54 \pm 15\%$ , ET  $36 \pm 10\%$ ;  $P < 0.05$ ) in type I muscle fibres, but a non-significant increase in IMTG concentration (HIT  $51 \pm 21\%$ , ET  $31 \pm 25\%$ ;  $P = 0.086$ ) was observed. **Conclusions:** This study demonstrates that 4 weeks of HIT at 200%  $W_{peak}$  provides an effective alternative to ET to increase  $VO_{2peak}$ , insulin sensitivity and skeletal muscle PLIN2 and PLIN5 protein content and reduce cardiovascular risk factors in sedentary obese males. HIT at this high workload appears to be a tolerable and effective alternative to SIT, which is likely too demanding for this target group. **References:** Shepherd SO, Cocks M, Tipton KD, Ranasinghe AM, Barker TD, Burniston JG, Wagenmakers AJM, Shaw CS. #### IS-BN02 Feedback and feedforward interaction - the role of augmented feedback in performance (sponsored by Adidas)

##### PRACTICAL IMPLICATIONS IN LEARNING WITH FEEDBACK

Taube, W.

*University of Freiburg*

There is an ongoing debate of how augmented feedback (aF) should be used to optimize motor performance, learning, and training. Although the present talk can certainly not give conclusive advice about the "optimal provision of aF" for all disciplines, it sensitizes the audience with respect to certain essential questions of how to provide aF. The "guidance theory" (1) is most probably the best known theory in the field of motor learning dealing with the question of how aF should be applied. The theory states that "frequently provided aF is a two-edged sword" guiding the learner to optimal performance but at the same time making the learner dependent on aF. Therefore,

it is frequently suggested to provide aF with a relative frequency of less than 100%. It has to be highlighted, however, that there is increasing evidence suggesting that this theory cannot be applied without limitations to all settings. It has to be considered in this context that aF can serve different functions: it can provide information what has to be learnt (to identify the goal of the task) or it can provide information with respect to the performance (to evaluate the performance). One branch of motor learning research therefore proposed to differentiate movements into "simple" and more "complex tasks" as the guidance hypothesis may be applicable to simple but not necessarily to more complex tasks (2). Similarly, based on recent observations, the differentiation into "entirely new tasks" and "tasks that are already in the movement repertoire but have to be maximized" makes probably sense. In line with this way of argumentation, the beneficial effects of aF may – at least in certain settings – be increased when subject can self-control the provision of aF (3) or when the aF is provided in "good trials" only (4). Concerning the mode of functioning, the most wide spread assumption is that aF guides the learner to a better movement technique/strategy. Thus, aF is assumed to enable athletes to differentiate "better" from "less good trials" and consequently may allow making better interrelations of cause and action. However, alternative explanations have to be taken into consideration. There is for example good evidence that especially in tasks where performance has to be maximized aF does beneficially influence the motivational aspects of the participants. Furthermore, aF might change the focus of attention but empirical data supporting this idea are lacking. 1. Salmoni AW et al. *Psychol Bull* 95: 355-386, 1984. 2. ### BRAIN PLASTICITY IN FEEDBACK-MEDIATED LEARNING

Leukel, C., Schween, R., Lauber, B., Keller, M., Lundbye-Jensen, J., Gollhofer, A., Taube, W.

*University of Freiburg; University of Fribourg; University of Copenhagen*

In most motor learning settings sensory feedback is required to improve performance. Natural sensory feedback from different sensors of the human body (e.g. vision, proprioception) estimates the state of the body in relation to the surrounding world. In addition to natural sensory feedback a special type of feedback, called augmented or extrinsic feedback, can facilitate performance improvements. Augmented feedback refers to explicit information about the execution and/or result of a motor task, e.g. a basketball player may receive feedback about the jump height in cm after performing a lay-up. Motor learning is only possible because of the capacity of the central nervous system (CNS) to undergo plastic changes. In order to understand learning it is therefore essential to understand its underlying neural mechanisms. Particularly in learning with augmented feedback, it is consequently important to understand the learning-related mechanisms that are associated with this type of sensory feedback. This understanding may help to develop new motor learning strategies in practical settings but also to identify the underlying problems that are associated with pathology. The aim of the present talk is to identify and describe the function of CNS plasticity that is associated with motor learning with augmented feedback. A special focus is on learning-related plasticity of the primary motor cortex and the cerebellum, as these structures are important for many types of learning, including error-based skill learning and adaptation learning.

#### UNSTEADY FLOW FIELD AROUND A HUMAN UNDULATORY SWIMMER: COMPARISON BETWEEN EXPERIMENTAL 2D-PIV-RESULTS AND NUMERICAL SIMULATIONS

Hochstein, S.1, Pacholak, S.2, Brücker, C.2, Blickhan, R.1

*1:Friedrich-Schiller-University Jena, Institute of Sport Science, Motion Science (Germany); 2:TU Bergakademie Freiberg, Institute of Mechanics and Fluid Dynamics (Germany)*

Introduction In fish locomotion low gliding drag values can be achieved during active propulsion. A carefully adjusted body wave travels along the body and pumps the fluid caudal. As a result the probability of flow separation is reduced. Swimmers try to successfully copy strategies like undulatory swimming from fish locomotion during the gliding period after start and turn to maximize their swimming speed. Therefore, the aim of this study was to analyse the unsteady flow field around a human undulatory swimmer using experimental analyses (Hochstein and Blickhan, 2011) and numerical simulation techniques (Hochstein et al., 2012). Methods Time resolved Particle Image Velocimetry (2D-TR-PIV) presented the experimental flow field around a human swimmer. The path of the levitating particles (illuminated by a green laser light sheet) was monitored at 250 fps with a high speed video camera (PHANTOM V12) and hence local flow velocities were calculated using a cross correlation algorithm. The experiments were applied to different swim situations (maximum swimming and swimming after push off from the wall). The numerical simulation analysis (CFD) consisted of the use of a 3D body scan, moving mesh, moving boundary conditions and swimmer's motion function realised by Open FOAM software. Results The experimental flow field presents vortex separation in the head and mainly in the leg region as soon as the undulatory pump. Swimmer's legs interacted with vortices generated cranially. The 3D flow field of the numerical simulation validates the experimental 2D results and shows vortex rings after the up- and down stroke similar to results of von Loebbecke et al. (2009). Discussion Cranially generated vortices could pedally reuse by swimmer's legs to enhance the propulsion ("vortex re-capturing"; Hochstein and Blickhan, 2011). The CFD simulation of swimming with symmetric amplitude distribution can indicate if the human anthropometric limitations results in worse swimming performance or the swimming with asymmetric amplitudes distribution may have advantages in underwater locomotion. ### TRUNK MUSCLE ACTIVITY DURING FRONT CRAWL SWIMMING

Martens, J., Pellegrims, W., Einarsson, I., Fernandes, R.J., Staes, F., Daly, D.

*KULeuven*

**Introduction** Core stability training is of increasing interest to both researchers and coaches. Sufficient core stability is needed to balance forces generated by the upper and lower extremities separately (Hibbs et al., 2008). In swimming the development of wireless EMG has created new possibilities to study underwater muscle activity with little hinder. The purpose here was to analyze lower trunk muscle activation during front crawl swimming and examine how trunk muscle activity is related to the arm movement, swimming velocity and arm and leg coordination. **Methods** Five male swimmers (personal record 100m freestyle :  $55 \pm 4$ s) swam 2x12.5m at maximal speed without breathing using a 6-beat leg kick and no kick with a 10min rest interval. EMG was obtained with 4 wireless units (Kine @, 1600Hz). Electrodes were placed on the left and right m. Obliquus Externus (OE) and on the left and right m. Erector Spinae (ES) following the guidelines of SENIAM. Four video cameras (Sony @ Handycam DCR-HC96: 50Hz) recorded the swims in synchronization with the EMG-signal. Dartfish Prosuite @ software was used to determine stroke phases, swimming velocity and arm and leg coordination. **Results** Activation of OE was seen in both leg-kick conditions in all 5 swimmers during the first propulsive phase of the ipsilateral arm. Activation of ES occurred when the collateral arm was at 135°-180° in all 5 swimmers in both conditions. **Discussion** Because of the ipsilateral activation of OE and the contralateral activation of ES in both test conditions, it can be assumed that the muscle activation pattern is linked to arm movements. During quadruped position core stability exercises on dry land contralateral activation of OE was also seen (Bergson et al., 2010). Further research (e.g. in the butterfly stroke with symmetric arm movement) is needed to clarify which arm actions are linked to abdominal muscle activation. ES is active in trunk extension and forward rotation of the pelvis (Kaneda et al., 2009), but may also act in rotational movements (Toren, 2001). It is possible that the contralateral activation of ES during front crawl swimming is needed to stabilize the lower trunk by countering forces generated at the start of arm recovery. **References** Bergson, C.Q., Cagliari, M.F., Amorim, C.F., Sacco, I.C. ### INFLUENCE OF SPORT SURFACES ON RUNNING PATTERN OF CHILDREN AND ADULTS. NATURAL GRASS AND ARTIFICIAL TURF COMPARISON

Sanchis, M., Alcantara, E.

*ASOC. INSTITUTO BIOMECANICA VALENCIA*

**Introduction** Last generation of artificial turf for football has been developed taking into account forces and velocities of adult football player skills. The behavior of the materials used in these kinds of surfaces (rubber infill) is different depending on forces and velocities of application. These forces are higher than forces applied by children and therefore the response of artificial turf is different. The objective of this work is to analyze the effect of this different behavior on running pattern of children and adults. **Methods** Biomechanical tests were carried out with children and adults on natural grass (as reference surface), artificial turf and concrete (as rigid surface). They ran a distance of 10 m at 4 m/s ( $\pm 15\%$ ). Accelerometers in forehead and right tibia were used and electrogoniometer was located in right knee. The information obtained from the accelerometers was the maximum acceleration in tibia and forehead during the heel impact. Maximum knee flexion angle during each step was obtained from the electrogoniometer. Finally, a statistical analysis of the information was carried out. First, outliers were identified, analysed and eliminated if necessary. Descriptive statistics were obtained for all variables and an ANOVA was done to assess whether statistically significant differences among pitches for children and adults existed. **Results** Tibia accelerations measured in adults did not show differences between natural grass and artificial turf; they were significantly higher when they ran on concrete. In the case of children, lesser tibia accelerations were measured running on natural grass than on artificial turf; however, significant differences were not found between artificial turf and concrete. Forehead accelerations did not show significant differences between surfaces for children and adults. Regarding knee angles measured in adults they were significantly higher running on concrete and differences were not found between natural grass and artificial turf. Knee angles measured on children were significantly lesser on natural grass than on artificial turf and concrete. The two latter did not show any significant difference. **Discussion** Adults did not modify their running pattern on natural grass and artificial turf. However, children increased their knee flexion angle running on artificial turf as a system of protective measure due to the increase of tibia acceleration (higher impacts). From the results of this work it is possible to conclude that artificial turf for football has been developed taking into account adult requirements with the aim of simulating natural grass behavior. However, the behavior of the materials of this kind of surfaces causes impacts on children's tibia similar to concrete.

### A NOVEL INSTRUMENTED BACKSTROKE START HANDGRIP

de Jesus, K.

*University of Porto*

**Introduction** FINA approved the use of a new starting block with two horizontal backstroke handgrips. Most of the Olympics have used the highest horizontal handgrips, probably to full remove themselves out of the water. Only de Jesus et al. (2011) adapted instrumented handgrips to perform backstroke start dynamometry, although based on the old handgrips configuration. This study aimed to develop a handgrip based on the new block to assess upper limbs dynamometry on the highest horizontal handgrip position. **Methods** Two identical triaxial force plates adapted from Roesler's (2003) and two independent handgrips were designed using SolidWorks 2011. A pair of independent tubes was designed at 566mm vertically from the water level (FINA, 2012). Static and modal analysis was carried out for the force plates and horizontal handgrips using Ansys 12.1. A force plate prototype was instrumented with 24 strain gages Kyowa to register the deformations under load. Force plates were fixed on the block and handgrips were fixed on the force plates. The deformations are presented as mean values. **Results** When 8000N horizontal load was applied on the force plate centre the strain gages responsible for the anterior-posterior deformations registered  $545\mu\epsilon$ . For 8000N vertical load the responsible strain gages registered  $290\mu\epsilon$ . First natural frequency of vibration was 328Hz. For 2000N horizontal load applied on the highest handgrips, the strain gages responsible for the anterior-posterior deformations registered  $107\mu\epsilon$  and  $106\mu\epsilon$ , for medial and lateral force application, respectively. For the simulated 2000N vertical load, deformations of  $179\mu\epsilon$  and  $186\mu\epsilon$  were observed for medial and lateral force application, respectively. **Discussion** The upper limbs role was considered only to drive the centre of mass over the water (de Jesus et al., 2011), although no other force components and handgrips position were analysed beyond the horizontal on the old starting block configuration. The developed system

allows assessing independently the right and left upper limbs triaxial forces and moments on different handgrips, and it is not dependent on the force application point. Handgrips were customized to assess upper limbs dynamometry from other different backstroke and ventral starts positioning. ### FOOT STRIKE PATTERNS IN LONG-DISTANCE RUNNING: BIOMECHANICAL AND PHYSIOLOGICAL IMPLICATIONS

Ogueta-Alday, A., Rodríguez-Marroyo, J.A., García-López, J.

*University of León*

**Introduction** The possible relationships between foot strike pattern, running injuries and performance are some of the current topics of discussion (Hayes and Caplan, 2012; Kasmer et al., 2012). There is controversy about the influence of foot strike pattern on long-distance running performance (Kasmer et al., 2012). Various studies have only approached it from one point of view: performance, physiology or biomechanics (Ogueta-Alday et al., 2012; Perl et al., 2012). Therefore, the aim of the study was to analyse simultaneously the influence of the foot strike pattern on biomechanical and physiological characteristics in well-trained runners with a similar level of performance. **Methods** Twenty long-distance runners participated (range of 66:40-74:09 mm:ss in half-marathon), and were divided into two groups according to their foot strike pattern: rearfoot (RF, n=10) and midfoot/forefoot runners (MF, n=10). Anthropometric characteristics were measured (height, body mass, BMI, skinfolds, circumferences and lengths) without differences between RF and MF. Physiological (VO<sub>2</sub>max, anaerobic threshold and running economy) and biomechanical characteristics (contact and flight times, step rate and step length) were registered during both incremental and submaximal tests on a treadmill. Results No significant differences in VO<sub>2</sub>max and anaerobic threshold were obtained between both groups. However, RF were more economical than MF at submaximal speeds (57-81% of VO<sub>2</sub>max). Step rate and step length were not different between groups, but RF showed longer contact time ( $p < 0.01$ ) and shorter flight time ( $p < 0.01$ ) than MF at all speeds. Significant relationships ( $p < 0.05$ ) were found between step rate at submaximal speeds and VO<sub>2</sub>max ( $r = 0.47-0.66$ ). **Discussion** The differences in both contact and flight times are in consonance with previous studies (Hayes and Caplan, 2012; Ogueta-Alday et al., 2012), and could justify the differences in running economy. It was not clear the theoretical advantage of MF at low running speeds (<15 km/h), although further studies should analyse higher intensities. Runners with higher VO<sub>2</sub>max possibly tried to minimize the neuromuscular demands rather than the energetic expenditure by increasing step rate. Future studies about long-term effects of stride rate manipulation on running economy are necessary. References Hayes P, Caplan N. (2012). *J Sports Sci*, 30(12), 1275-1283. ### BIOMECHANICAL PREDICTORS OF PERFORMANCE IN ALPINE SKI RACING

Spörri, J., Kröll, J., Schwameder, H., Müller, E.

*University of Salzburg*

**Introduction:** Two main categories of biomechanical performance predictors have been suggested in alpine ski racing: path-related and speed-related predictors (Hirano, 2006; Supej et al., 2010). Since between these predictors a permanent trade-off has to be made, it is not a priori clear whether reaching for shorter path or higher speed is more advantageous. Only a comprehensive concept including both aspects might be able to sufficiently predict performance (Spörri et al., 2012). One such concept could be found in the time loss per elevation difference ( $dt/dz$ ), which depends on both the distance travelled per elevation difference ( $ds/dz$ ), and speed (Federolf, 2012). Speed itself depends on the entrance speed ( $v_{in}$ ) and the rate of energy dissipation per elevation ( $demech/dz$ ) (Supej et al., 2010). By combining the aforementioned predictors ( $ds/dz$ ,  $v_{in}$ ,  $demech/dz$ ) in one model, the aim of the current study was to assess their relevance for performance within a giant slalom (GS) turn. **Methods:** During a video-based 3D kinematic field measurement using six panned, tilted and zoomed cameras (50Hz), six top level racers performed several runs on a GS course. A 22 point multi-body segment model was reconstructed in 3D and centre of mass kinematics were calculated. For each run, the analysed turn was divided into four functional turn phases (p1, p2, p3, p4), according to Spörri et al. (2012). For the prediction of  $dt/dz$  phase averages by  $ds/dz$ ,  $v_{in}$  and  $demech/dz$ , two runs per subject (n=12) were entered into multiple regression models. To assess the relevance of the performance predictors within the specific turn phases, beta weights were compared. **Results:** Using the stepwise method, highly significant models emerged for all turn phases ( $p < .001$ ; Adjusted R<sup>2</sup> > .980). In all turn phases,  $v_{in}$  was of the highest relevance for the prediction of  $dt/dz$  phase averages (beta weights: -.776 (p1); -.977 (p2); -.826 (p3); -.647 (p4)). While  $ds/dz$  had the second strongest weighting in the models for p1, p3 and p4 (.603 (p1); .301 (p2); .279 (p3); .426 (p4)), during p2,  $demech/dz$  was of higher relevance for  $dt/dz$  phase average (.108 (p1); .470 (p2); .123 (p3); .110 (p4)). **Discussion:** For coaching practice, these findings indicate that starting with a certain entrance speed, which depends on the performance in the previous section, a racer should primarily aim for reducing his rate of energy dissipation while steering into the fall line (p2). Then, while steering out of the fall line (p3) and during the turn transition (p4 and p1) he should instead strive for a shorter path in order to enhance his instantaneous performance. #### REACTIVE OXYGEN SPECIES REGULATES MUSCLE SIGNALLING AND POST EXERCISE INSULIN SENSITIVITY.

Stepito, N.K.1, Trewin, A.1, Vikhe Patil, K.2, Lundell, L.2, Perry, B.1, Chibalin, A.V.2, Shaw, C.S.1, Levinger, I.1

*Victoria University*

1- ISEAL and CSES VU Melbourne Australia 2- Karolinska Institute Stockholm Sweden Introduction: There currently exists a reactive oxygen species (ROS) paradox. Specifically, it is well known that many chronic diseases (including obesity and type 2 diabetes) and their progression are associated elevated ROS and oxidative stress. Yet exercise generates ROS and oxidative stress, while effectively preventing and/or managing these diseases. Furthermore, a single exercise bout can improve insulin sensitivity for up 48-h. It is now recognised that ROS is a vital molecule in normal tissue survival, adaptation and function including insulin action in skeletal muscle, however the exact role of exercise induced ROS in protein signalling and insulin action in humans has not been fully elucidated. We therefore aim to investigate the role of exercise induced ROS on post exercise and insulin stimulated muscle signalling by scavenging ROS during a bout of cycling with the antioxidant N-acetylcysteine (NAC). Methods: Seven, healthy, consenting adults volunteered for the study. They undertook 2 two 1-h cycle sessions of 55min at 65% VO<sub>2</sub>max and 5 min at 95%VO<sub>2</sub>max followed 3-h later by a 2-h hyperinsulinaemic euglycaemic clamp (40 mIU/min/m<sup>2</sup>). In a double blind randomised design the exercise sessions were undertaken either with a primed (35 min of 125mg/kg/min) infusion of NAC (25mg/kg/min) or without (Saline infusion). Muscle biopsies were taken before infusion and immediately after exercise, as well as before and after the clamp. Serial blood samples and expired gas samples were taken throughout these trials. Insulin sensitivity was determined as an M-Value (glucose infusion rate (mg/kg/min)/ plasma insulin pM/L). Exercise and insulin action on key signalling proteins was evaluated with immuno-blotting for total and phospho-proteins. Results: NAC infusion resulted in discordant muscle protein signalling in response to exercise and insulin stimulation, where phospho (p)-ERK (p=0.10), p-mTOR (p=0.01) and p-P70S6K (p=0.10) were reduced. In contrast, p-Akt/PKB thr308 (p=0.10) and p-S6 (p=0.09) trended to higher activation. These signalling responses were associated with a 6% (M-value; 13±2 vs. 10±2; p=0.02) reduction of the post exercise insulin stimulated glucose uptake. Discussion: These data demonstrate that ROS production during exercise has an important role in regulating exercise and insulin stimulated skeletal signalling and glucose uptake in humans. Exercise induced ROS had the greatest effect on mTOR signalling, demonstrating that ROS may mediate muscle insulin stimulated glucose uptake either via alternative protein modifications that do not effect phosphorylation or via non-canonical signalling proteins. This study was funded by the VURDGS Scheme

#### A C-TO-T POLYMORPHISM IN 3'-UNTRANSLATED REGION OF CNTFR IS ASSOCIATED WITH SPRINT/POWER PERFORMANCE

Mikami, E.1,2,3, Murakami, H.4, Miyachi, M.4, Higuchi, M.1, Tanaka, M.3, Kawahara, T.5, Fuku, N.3

1: Waseda University, 2: JSPS Research Fellow, 3: Tokyo Metropolitan Institute of Gerontology, 4: National Institute of Health and Nutrition, 5: Japan Institute of sports sciences

Introduction Ciliary neurotrophic factor (CNTF) was associated with muscle performance traits (Guillet et al., 1999), and can signal by binding to its receptor (CNTFR). Previous studies suggested that a G-to-A polymorphism (rs1800169) in the second exon of the CNTF gene and a C-to-T polymorphism (rs41274853) in the 3'-untranslated region (3'-UTR) of CNTFR gene were associated with trainability of muscle strength (Walsh et al., 2009) and fat-free mass (Roth et al., 2003), respectively. Thus, the purpose of the present study was to investigate whether CNTF (rs1800169) and CNTFR (rs41274853) polymorphisms are associated with elite sprint/power athlete (SPA) status. Methods 134 elite Japanese SPA (72 national and 62 international track and field athletes) and 649 Japanese controls were genotyped for rs1800169 and rs41274853 polymorphisms using TaqMan Genotyping Assay, and genotype frequencies were compared between groups by chi-square tests. Leg extension power in control subjects were also measured by using a dynamometer and multiple liner regression analyses were conducted to determine the independent effect of these polymorphisms on muscle power. Results CNTF (rs1800169) and CNTFR (rs41274853) genotype frequencies did not differ between elite SPA and controls. However, when elite SPA were limited to international athletes, the frequency of TT genotype in rs41274853 polymorphism was significantly higher in international SPA than in controls (P=0.007 under T-recessive model). In addition, TT genotype carriers of rs41274853 polymorphism exhibited greater leg extension power than CT+CC genotype carriers in male control subjects (P=0.013 after adjusted by age and physical activity). Discussion Our results are consistent with previous association between the T allele of rs41274853 polymorphism and high fat-free mass (Roth et al., 2003). These results suggest that C-to-T substitution in the CNTFR 3'-UTR is beneficial to sprint/power athletic performance. Micro RNAs are small non-coding RNAs and post-transcriptionally regulate protein expression by binding to the 3'-UTR of target mRNAs. TargetScan software predicted that miR-675-5p targets the polymorphic site within the CNTFR 3'-UTR. Therefore, it is possible that rs41274853 polymorphism affects sprint/power performance by interfering with miR-675-5p binding. References Guillet C et al. (1999) J Neurosci, 19(4), 1257-1262. #### POLYMORPHIC VARIATION WITHIN THE ADAMTS2, ADAMTS14, ADAMTS5, ADAM12 AND TIMP2 GENES AND THE RISK OF ACHILLES TENDON PATHOLOGY; A GENETIC ASSOCIATION STUDY

El Khoury, L., Posthumus, M., Collins, M., Handley, C.J., Cook, J., Raleigh, S.M.

*The University of Cape Town*

Objective. Achilles tendon pathology (ATP) is a multifactorial condition for which genetic risk factors have been identified. The COL5A1 gene has been associated with the risk of ATP in two independent Caucasian populations. The ADAMTS, ADAM12 and TIMP2 genes encode enzymes that are important regulators of tendon homeostasis. ADAMTS2 and ADAMTS14 proteins are procollagen N-propeptidases for pro-collagen type I, type II, and type III. ADAMTS2, like COL5A1, has been linked to Ehlers-Danlos syndrome. Variants within ADAMTS5 and ADAM12 have been associated with osteoarthritis. TIMP2, a metalloprotease inhibitor, maintains homeostasis in the ECM by inhibiting ADAM, ADAMTS and MMP functions. We sought to determine whether single nucleotide polymorphisms (SNPs) within

the ADAMTS2, ADAMTS5, ADAMTS14, ADAM12 and TIMP2 genes were associated with the risk of ATP in two independent populations. Methods. 213 (115 ATP cases and 98 asymptomatic controls) South African Caucasian participants and 209 (60 ATP cases and 149 asymptomatic controls) Australian Caucasian participants were recruited for this case-control genetic association study. All participants were genotyped using TaqMan technology for the ADAMTS2 rs1054480, ADAMTS5 rs226794, ADAMTS14 rs4747096, ADAM12 rs3740199, and TIMP2 rs4789932 SNPs. Results. We report the detection of a significant ( $P=0.016$ ) genotypic association between ATP and TIMP2 rs4789932 in the combined South African and Australian cohorts. In contrast, we detected no significant association between any of the ADAMTS or ADAM SNPs with ATP in either cohort. Conclusion. Our data show for the first time that a common SNP within the TIMP2 gene is a risk factor for ATP in Caucasians.

### INVESTIGATION OF GENES INVOLVED IN THE CELL-SIGNALLING PATHWAY WITH RISK OF ANTERIOR CRUCIATE LIGAMENT RUPTURE

September, A.V.1, Rahim, M.1, Mannion, S.1,2, Hobbs, H.3, O'Cuinneagain, D.3, van der Merwe, W.1,3, Dandara, C.2, Collins, M.1,4

*1UCT/MRC ESSM, Human Biology,UCT; 2Human Genetics,UCT. 3SSOC;4MRC*

**INTRODUCTION:** Anterior cruciate ligament (ACL) injuries are multifactorial, for which a genetic component has been implicated. Genes encoding matrix remodelling proteins have been shown to be associated with risk of ACL ruptures. The aim of this study was therefore to investigate if additional genes coding for matrix remodelling proteins are associated with risk of ACL injury. **METHODS:** A pathway-based genetic-association study was conducted. Two hundred and thirty four control participants (CON group) and 188 participants with ACL ruptures (ACL group) were recruited. All participants were genotyped for the following polymorphisms: IL6 rs1800795, IL6R rs2228145, CASP8 rs3834129, CASP8 rs1045485, IL1B rs16944, PTGER4 rs4495224 and TGF $\beta$ 2 rs7550232. Statistical analyses were conducted to determine any significant differences ( $p<0.05$ ) in genotype and allele frequency distributions between the CON and ACL groups as well as the CON group and the NON subgroup (participants with a noncontact mechanism of injury). **RESULTS:** The IL6 rs1800795 genotype frequencies were significantly different between the CON group and the NON subgroup ( $p=0.002$ ). Specifically, the GG genotype was significantly under-represented ( $p=0.0008$ , OR: 2.299; 95% CI: 1.417 to 3.730) and the GC genotype significantly over-represented ( $p=0.005$ , OR: 2.043; 95% CI: 1.237 to 3.373) in the CON group in comparison to the NON subgroup. Furthermore, the frequency of the C allele was significantly higher in the CON group compared to the NON subgroup ( $p=0.005$ ; OR: 1.651, 95% CI: 1.161 to 2.348). No other significant differences in genotype or allele frequencies were noted between the CON and ACL groups or between the CON and NON groups for the remaining polymorphisms. **CONCLUSION:** This study provides preliminary evidence suggesting that polymorphisms in the IL6 gene may be implicated in the pathophysiology of ACL ruptures. Investigations into the interactions between genes involved in the cell-signalling pathway will provide greater insight into the biological importance of this cascade in the pathophysiology of ACL ruptures.

### THE ASSOCIATION OF A POLYMORPHISM WITHIN A FUNCTIONAL REGION OF THE COL5A1 GENE WITH ULTRA-ENDURANCE RUNNING PERFORMANCE AND JOINT RANGE OF MOTION

Abrahams, S.1, Posthumus, M.1, Collins, M.1,2

*1UCT (Cape Town, South Africa), 2MRC (Cape Town, South Africa)*

**Introduction:** Endurance running performance and joint range of motion are both multifactorial phenotypes and were independently associated with a single nucleotide polymorphism, rs172722 (C/T), within the COL5A1 3'-untranslated region (UTR). Two major functional forms of the COL5A1 3'-UTR have been identified and differ by seven tightly linked polymorphisms including rs12722 and a short tandem repeat polymorphism (STRP rs71746744, -/AGGG) (Laguetta et al. 2011). It has been proposed that STRP rs71746744 plays a role in the predicted secondary structures and mRNA stability of the two major forms of the COL5A1 3'-UTR, implying a regulatory role (Abrahams et al. 2013). The aim of this study was therefore to determine whether STRP rs71746744 is also associated with running performance and pre-race sit and reach range of motion (SR ROM) within a cohort of 56 km ultra-marathon road runners. **Methods:** One hundred and six (74 males and 32 females; aged 22 – 67 years) Caucasian runners who participated in either the 2009 or 2011 Two Oceans 56 km ultra-marathon were included in this study. Their SR ROM measurements, COL5A1 rs71746744 genotype and overall race times were determined. **Results:** COL5A1 rs71746744 was independently associated with running performance ( $P = 0.024$ ) and pre-race SR ROM ( $P = 0.020$ ). Moreover, the AGGG/AGGG genotype was significantly over-represented in the fastest and inflexible athletes when compared to those with either the -/AGGG or -/- genotypes. **Discussion:** It has been proposed that STRP rs71746744 is functional and, partly, regulates type V collagen synthesis (Abrahams et al. 2013). Type V collagen is an important regulator of type I collagen fibrillogenesis (Birk et al. 1990). We have proposed that changes in the type V collagen content of musculoskeletal soft tissues affects collagen fibril diameter and packing density altering the mechanical properties of tissue (Collins and Posthumus 2011). Therefore, this functional region within COL5A1 3'-UTR plays a role in improving running performance and reducing SR ROM. However, further studies are needed to investigate the effect of the rs71746744 variant on the mechanical properties of connective tissue. **References:** Abrahams, Y., M.-J. Laguetta, S. Prince & M. ### EFFECT OF CONTINUOUS COMPARED WITH ACCUMULATED EXERCISE ON INSULIN SENSITIVITY

Burns, S.F., Chan, Y.M., Balasekaran, G.

*Nanyang Technological University*

**Introduction** Expert guidelines recommend physical activity is accumulated in bouts with a minimum duration of 10 min, to achieve the 30 min per day necessary for good health (Haskell et al., 2007). Whilst the concept of accumulating exercise is attractive the evidence for its efficacy on health is limited (Murphy et al., 2009). The present study compared the effect of accumulating three 10 minute bouts of exercise with one 30 minute continuous bout of exercise on insulin sensitivity in young healthy males. **Methods** Following ethical approval, 12 healthy males (aged  $24.4 \pm 1.9$  y, BMI  $21.8 \pm 1.2$  kg/m<sup>2</sup>, maximum oxygen uptake  $43.8 \pm 6.7$  ml/kg/min, mean  $\pm$  SD) completed three 2-day trials at least 5 days apart in a randomised repeated measures design. On day 1 the participants rested (no exercise) or walked on a treadmill at 70% of maximum oxygen uptake in either three 10-min bouts (accumulated) of exercise with 20 min rest between each or one continuous 30-min bout (continuous) of exercise. On day 2, participants came to the laboratory at 0800 and consumed a 75 g oral glucose tolerance test (OGTT). Venous blood samples were obtained in the fasted state and at 15, 30, 60, 90 and 120 minutes after the

OGTT. Fasting insulin sensitivity was calculated using the homeostasis model assessment 2 index (HOMA2). Whole body insulin sensitivity was calculated from fasting and OGTT measures using the Matsuda index;  $10000 / \sqrt{(\text{fasting glucose} \times \text{fasting insulin}) \times (\text{mean OGTT glucose concentration} \times \text{mean OGTT insulin concentration})}$ . One-way ANOVA (repeated measures) with post-hoc Bonferroni comparisons were used to determine differences in fasting and whole body insulin sensitivity among trials. Data are mean  $\pm$  SD. Results Fasting insulin sensitivity (HOMA2) was significantly different among trials (no exercise,  $176 \pm 54$ ; accumulated,  $183 \pm 45$ ; continuous,  $239 \pm 103$ ) (main effect of trial,  $P=0.033$ ). Post-hoc tests were not significant but the most likely improvement in insulin sensitivity was on the continuous exercise trial compared with the no exercise trial ( $P=0.064$ ). Similarly, whole body insulin sensitivity (Matsuda) differed among trials (no exercise,  $176 \pm 54$ ; accumulated,  $183 \pm 45$ ; continuous,  $239 \pm 103$ ) (main effect of trial,  $P=0.048$ ) with post-hoc tests suggesting an improvement in insulin sensitivity on the continuous exercise trial compared with the no exercise trial ( $P=0.058$ ). Discussion These data suggest that continuous but not accumulated exercise in line with the minimal recommended duration of 30 minutes per day leads to improvements in insulin sensitivity. #### IS-SH03 Transitions and strategies in top level sport

##### APPLYING THE DEVELOPMENTAL MODEL OF TRANSITIONS IN INVESTIGATING THE CAREER DEVELOPMENT OF ELITE ATHLETES

Wylleman, P., Rosier, N., Reints, A., Tekavc, J., De Brandt, K.

*Vrije Universiteit Brussel*

Introduction Throughout their lives, athletes are faced with transitions. According to Wylleman and Lavallee's holistic athletic career model, transitions take place at different spheres of athletes' lives. During as well as after their athletic career, athletes face challenges at athletic, psychological, psychosocial and academic or vocational level. After an athletic career, athletic retirement places demands upon the athlete. However, not all athletes make it to the top; many drop out on their road to excellence, or do not reach the level required at elite senior level. Especially the transition from junior to senior elite athlete seems a challenging turning point. This presentation will consider two studies, one concerning the athletic retirement and one concerning the junior-senior transition. Method Two interview guides were developed using the holistic athletic career model as framework. For study 1, interviews were conducted with 24 Flemish former elite athletes. For study 2, interviews were conducted with high performance director of the category I sports in Flanders. Interviews were transcribed and analyzed using QSR Nvivo. Results Study 1 confirmed the existence of the four levels within the holistic athletic career model and revealed the presence of several within-career transitions not included in the model. This study also led to the identification of two other developmental levels, the financial level and the physical level. Study 2 found that in most sports there are different phases in the transition from junior athlete to senior elite athlete. Moreover, the structure of the sport and competition (e.g. from 2-3 ages at junior level to at least 10 ages at senior level) makes it difficult for junior athletes to conquer their place in the elite senior ranks. Besides this, challenges at the four levels of the holistic athletic career model were recognized. Discussion Both studies confirm the idea that athletic careers must be approached by using a holistic and lifespan perspective. Moreover, they showed that different sports have aspects in common, but also have their specificities. As a consequence, sport-specific research is required (e.g. early versus late specialization sports). In practice, career support services should help athletes to acquire the skills needed for a specific transition. During and after the junior-senior transition, athletes may be empowered by assisting them to acquire goal-setting, time-management, transitions, media, and relationship skills. Athletes who are about to plan their career end may benefit more from financial management and networking skills, and role exploration.

##### ENTERING AN ELITE SPORT TRAINING CENTER: MODALITIES OF ADAPTATION

Ledon, A., Debois, N., Rosnet, E.

*INSEP*

ENTERING AN ELITE SPORT TRAINING CENTER: MODALITIES OF ADAPTATION Aurélie Ledon a, Nadine Debois a, Elisabeth Rosnet a  
aNational Institute of Sport, Expertise and Performance, Paris, France Introduction This communication is in connection with a previous research about decision-making for entering an elite sport training center (Ledon, Debois, & Rosnet, 2009). The present research is based on the transitional adaptation from Charner and Schlossberg (1986) which underscores three categories of factors interacting during a transition: (a) the characteristics of the individual, (b) his perception of the current transition and, (c) the characteristics of the environment, above and below the transition. The main aim of the present study was to identify factors facilitating versus those constraining the adaptation in the elite sport training center. Method 31 elite athletes, (13 male athletes and 18 female athletes) aged 16 to 25 ( $M = 18,39$ ,  $SD = 3,56$ ) voluntarily participated to the study. They were both training and living in a national sport training center. 16 belong to an individual sport (athletics, karate, taekwondo, dive, skating, modern pentathlon, dive, squash) and 17 to a team sport (basketball). Semi directive interviews were carried out with the support of an interview guide, and retranscribed verbatim. Results Three different categories were identified as influencing the quality of the integration of the elite athletes in elite training center: (a) the living environment, (b) the dual career conditions and, (c) the sporting context. For each category, two sub-categories were distinguished: (a) a sub-category gathering factors facilitating the adaptation and, (b) a sub-category gathering factors constraining the adaptation. Discussion Our results confirm the role of the environment represented in the transitional adaptation model from Charner and Schlossberg (1986). The living environment, the dual career conditions and the sporting context appear as determining factors of the adaptation. These results are in accordance with the developmental model put forward by Wylleman and Lavallee (2004), which emphasizes the importance to adopt an holistic approach (e.g., taking into account both athletic, educational and social development) in the support given to athletes living and training in elite sport training centers. ### **FOREIGN FOOTBALL PLAYERS ADAPTATION TO SPANISH LEAGUES: UNTANGLING NON-NORMATIVE TRANSITIONS**

Azócar, F., Pérez, A., Pallarès, S., Torregrosa, M.

*University Autònoma de Barcelona*

**Introduction** The studies in professional athlete's adaptation involve several situations to untangle (e.g., relocation changes, injuries). Among the models in career sport life, the holistic developmental perspective on transitions faced by players (e.g., Wylleman & Lavallee, 2004) shows an image of the athletes including different levels of their lives. Stambulova, Alferman, Statler & Côté (2009) explain non-normative transitions as important and unplanned situations lived during the sport career, this transitions are less predictable (than normative transitions) and can be caused by different factors like a new professional contract, who includes a migration to a new continent/culture. This study explores the experiences of professional football players using Shinke, Gauthier, Dubuc, & Crowder (2007) reflections about cultural adaptation process throw five core motives: belonging, understanding, controlling, self-enhancement and trusting. **Methods** The participants were ten Latin-American football players who played in first and second Spanish leagues. At the moment of interview their age range was between 19 and 27 years old. The interviews were transcribed (verbatim) and then analyzed using Atlas.ti 7.0 **Results & Discussion** Analyzing the experiences associated to this transition three general contexts emerged: personal, sporting and cultural. In personal context we can find character of the player and their relationships (e.g., wife, teammates); the participants highlight the sporting experiences playing in important teams before Spain and national teams calls; and, finally, cultural context emphasize several variables like language, food, or training style. According to Schlossberg (1984) this changes must be understood throw the meaning that transitions has in each case. In this way, untangling it we must defined type of transitions, the context, and the impact in their roles, routines or assumptions. In each general context football player must cope with different changes and adapt themselves to the new situation. **References** Schinke, R., Gauthier, A., Dubuc, N., & Crowder, T. (2007). ##### **EMPOWERING AND DISEMPOWERING COACH BEHAVIOURS, PLAYERS' NEED SATISFACTION AND WELL-BEING IN THE CONTEXT OF SPANISH GRASSROOTS FOOTBALL: A MULTILEVEL ANALYSIS**

Balaguer, I.1, Castillo, I.1, Tomás, I.1, González, L.1, Fabra, P.1, Soler, M.J.P.1, Cruz, J.2

*University of Valencia, 1; Autonomous University of Barcelona, 2*

Drawing from Achievement Goal (Ames, 1992; Nicholls, 1989) and Self-determination (Deci & Ryan, 1985) theories, a hierarchical linear multilevel approach was used to examine the effects of the social environment created by the coach (i.e., its empowering and disempowering features) at the team level, and player need satisfaction at the individual level, on key indicators of indicators of young athletes well-being (subjective vitality and enjoyment). Cross-level interactions between individual and team level variables were analysed. 1612 Spanish football players (182 girls, 1427 boys and 3 gender unspecified) from different regions (Valencia, Castellón, Barcelona and Lerida) who were between 9 and 15 years old ( $M = 11.53$ ,  $SD = 1.19$ ) and represented 134 teams from 39 different clubs, completed a questionnaire assessing the variables of interest. Within-group inter-rater agreement indicated shared perceptions of the coach-created social environment among the team members, so team aggregated measures were estimated. Hierarchical linear modelling procedures revealed that at the individual level needs satisfaction of competence, autonomy and relatedness positively predicted subjective vitality, and that satisfaction of competence and relatedness were positive predictors of enjoyment. Results also showed that perceptions of an empowering climate exerted a positive cross-level influence on subjective vitality and enjoyment. Finally, a cross-level interaction effect of perceived empowering climate on the positive relationship between satisfaction of the need of competence and enjoyment was found. Interactional effects indicated that when athletes have low satisfaction of competence, they exhibited greater enjoyment in climates perceived as more highly empowering while athletes reporting high competence enjoyed playing football at similar levels whether they perceived a high or low empowering coach-created environment. This research was funded by the European Commission under the Seventh Framework Program - Health - 223600 - as part of the PAPA Project [www.projectpapa.org](http://www.projectpapa.org) **References** Ames, C. ### GENERAL SELF-ESTEEM, VITALITY AND INTENSIVE PHYSICAL ACTIVITY: EVIDENCE FOR CROSS-CULTURAL INVARIANCE OF THEIR ASSOCIATION ACROSS 5 EUROPEAN COUNTRIES

Papaioannou, A., Appleton, P., Bosselut, G., Gonzalez, L., Haug, E., Torregrosa, M., Ertesvaag, V., Jowett, G., Zourbanos, N.

*University of Northumbria*

The study examined the association of general self-esteem and vitality with youngsters' intensive physical activity and the generalizability of these associations across different European populations. The original sample of this study included 7769 youngsters aged 10-14 who participated in football teams in five European countries. These athletes reported on measures of general self-esteem, vitality and intensive physical activity one month after the start of the football season. After listwise exclusion of missing cases and elimination of athletes who reported less than a week intensive physical activity, the sample of this analysis included 6796 athletes from France (N = 974), Greece (N = 1416), Norway (N = 1051), Spain (N = 2175) and UK (N = 1180). Results from multi-sample structural equation modeling analyses established invariance across countries for factor loadings and structural covariance. Across the five countries intensive physical activity corresponded positively to general self-esteem ( $r = .21$ ,  $P < .001$ ) and vitality ( $r = .17$ ). Self-esteem was strongly related to vitality ( $r = .73$ ,  $p < .001$ ). The results support the validity of these measures across the five countries and the generalizability of findings concerning the association of intensive physical activity with self-esteem and vitality across different European populations.

### CORRELATES OF THE OBJECTIVELY ASSESSED EMPOWERING AND DISEMPOWERING FEATURES OF THE MOTIVATIONAL CLIMATE IN GRASSROOTS FOOTBALL

Sarrazin, P.1, Smith, N.2, Tzioumakis, Y.3, Tessier, D.1, Quested, E.2, Papaioannou, A.3, Duda, J.2

*1. University Joseph Fourier Grenoble; 2. The University of Birmingham, UK; 3. University of Thessaly, Greece*

The coach created motivational climate is a key concept for understanding the determinants of athletes' welfare and optimal functioning when taking part in sport. Drawing from an integrated achievement goal theory (Nicholls, 1989) and self-determination theory (Deci & Ryan, 2002) perspective, an observational system has been developed in the PAPA project to provide an objective assessment of the coach-created motivational environment in sport. This Multidimensional Motivational Climate Observation System (MMCOS) allows to code the coach created motivational climate in terms of 6 first order dimensions (i.e., controlling, task-involving, ego-involving, relatedness supportive, relatedness thwarting, structure) and 2 higher order dimensions (i.e., Empowering vs. Disempowering). Fifty-seven coaches from England, Greece and France were selected to take part in the study. Each coach was videotaped during one complete training session using a digital camcorder and microphone. Using the MMCOS their motivation climate was then coded. Correlations between coaches' motivational climate and various players' motivational variables (e.g., need satisfaction) were examined. Results showed factorial and predictive validity of the tool. Moreover, coaches tended to emphasise a more need-supportive environment than need thwarting one (i.e., 69.9% and 30.1% of the whole behaviours coded, respectively), and although coaches' interpersonal styles varied significantly across countries, the general pattern of the coach-created environment observed in the three countries had a similar profile.

#### THE WHY OF GOAL STRIVING MATTERS: THE IMPACT OF PRIMED GOAL MOTIVES ON PERSISTENCE

Healy, L.1, Ntoumanis, N.1, Stewart, B.1, Duda, J.L.1, Bond, J.2

*1: University of Birmingham (Birmingham, UK), 2: University of Rochester (Rochester, USA)*

Introduction Grounded in Self-Determination Theory, the self-concordance model (Sheldon & Elliot, 1999) posits that personal motives for goal pursuit can be autonomous or controlled. Individuals striving with autonomous motives engage in goal striving due to enjoyment or perceived importance of the goal, whereas those with controlled motives strive due to internal pressures, such as avoiding unpleasant emotions, or the expectations of important others. These diverse motives can lead to different outcomes for persistence and well-being (Sheldon & Elliot, 1999; Smith, et al.2011), with autonomous motives predicting more adaptive outcomes. Research has thus far only examined an individual's explicit personal goal motives; hence this study investigated the impact of implicit/primed goal motives on goal persistence and other important outcomes. Methods 90 athletes (47 female, M age = 19.63 years, SD = 1.14) were recruited to an incremental multi stage exercise trial on a cycle-ergometer. Prior to the trial, participants were exposed to an autonomous, controlled or neutral motivational prime. This comprised a filmed matched-gender actor describing their upcoming participation in an unrelated task. Persistence was defined as the total number of stages completed in the trial. Questionnaires assessed positive affect and interest in future engagement in a similar trial. Results Non-orthogonal contrast coding compared the controlled prime with the autonomous and neutral prime. Structural equation modelling supported a model in which, when compared to the controlled prime, autonomous ( $\beta = .38$ ,  $p = .01$ ) and neutral ( $\beta = .27$ ,  $p = .02$ ) primes predicted greater persistence. Consequently, persistence led to greater positive affect change from pre-trial ( $\beta = .42$ ,  $p < .01$ ), which in turn predicted interest in future engagement ( $\beta = .47$ ,  $p < .01$ ). Future interest was also directly predicted by the autonomous versus controlled contrast ( $\beta = .22$ ,  $p = .02$ ). Discussion The findings extend previous research by demonstrating that goal motives can be primed, and that primed autonomous goal motives can lead to greater persistence and better motivation-related outcomes, compared to primed controlled motives. Furthermore, the undermining effect of primed controlled motives was shown, as the neutral prime with no motivational content resulted in greater persistence than the controlled motives prime. Future research should investigate how primed goal motives might predict other self-regulatory responses, such as the ease of disengagement from an unattainable goal. References Sheldon KM Elliot AJ. ## HIGH INTENSITY INTERVAL AND TRADITIONAL ENDURANCE TRAINING LEAD TO COMPARABLE IMPROVEMENTS IN MOTIVATION AND WELL-BEING OUTCOMES

Kinnafick, F.E.1,2, Shepherd, S.O.1,3, Wilson, O.J.1, Shaw, C.S.1,2, Wagenmakers, A.J.M.1,3, Thøgersen-Ntoumani, C.1

1 University of Birmingham; 2 University of Northampton; 3 Liverpool John Moores University; 4 Victoria University, Melbourne Australia; 2,3,4 Current Affiliations

**Introduction** Lack of time is a salient barrier to exercise in physically inactive adults. High intensity interval training (HIT) is a time-efficient exercise approach that elicits similar beneficial metabolic and cardiovascular adaptations to traditional endurance training (ET). Given that psychological effects of exercise are key determinants of sustained behavioural engagement (Williams et al., 2008) and consequently long-term health, it is critical to measure the effect of HIT on motivation and psychological well-being. **Aim** To investigate whether an instructor-led group-based HIT intervention enhances psychological well-being to a similar extent as ET. **Methods** Using a randomised controlled design, 57 overweight, physically inactive employees of mixed gender (M age=40; SD=10; age range 25-60; BMI M=28.0; SD=0.6 kg.m<sup>-2</sup>) from a UK University and hospital were assigned to undertake HIT (n=30) or ET (n=27) exercise classes for 10 weeks. HIT consisted of repeated sprints (15-60 s duration) on a spin ergometer interspersed with periods of recovery cycling (≤25 min per session, 3x.wk<sup>-1</sup>). ET participants cycled at a constant workload (~65% VO<sub>2</sub>max) on a spin ergometer (30-45 min per session, 5x.wk<sup>-1</sup>). Attendance was recorded. Psychometrically validated scales measured well-being outcomes (positive and negative affect, subjective vitality, perceptions of health, and self-esteem) at baseline, post-intervention and at a three month follow-up. Motivational regulations for exercise were measured at baseline, week 5 and post-intervention. Using intention-to-treat principles, a series of mixed-design ANOVAs (within-subject factor = time, between-subject factor = condition), were used to analyse the data. **Results** Over time, well-being outcomes (subjective vitality:  $F(2,52)=14.269$ ,  $p<0.01$ ,  $\eta^2=.35$ ; positive affect:  $F(2,52)=15.33$ ,  $p<0.01$ ;  $\eta^2=.37$ ; negative affect:  $F(2,52)=7.13$ ,  $p<0.01$ ,  $\eta^2=.215$ ; perceptions of health:  $F(2,52)=32.22$ ,  $p<0.01$ ,  $\eta^2=.37$ ), intrinsic motivation ( $F(2,51)=7.83$ ,  $p<0.01$ ,  $\eta^2=.23$ ) and self reported total physical activity ( $F(2,49)=18.08$ ,  $p<0.01$ ,  $\eta^2=.42$ ) improved after training and remained above baseline at follow-up. Group analysis yielded no significant differences over time for any outcomes. Adherence was greater in the HIT group (HIT M=84.9% vs. ET M=70.3% sessions attended;  $p<0.05$ ). **Conclusions** Adding to known fitness and health benefits, HIT improves psychological well-being with effects similar to those experienced following ET. As superior adherence rates to HIT were observed, data suggests that HIT performed in an instructor-led group environment is an effective lifestyle intervention as it counteracts a salient barrier to exercise (lack of time), improves exercise engagement, and may consequently engender long-term health benefits. **References** Williams et al., (2008). *Psychol Sport Exerc*, 9, 231-245.

## COMPARISON BETWEEN THINK ALOUD PROTOCOL AND RETROSPECTIVE RECALL IN ASSESSING DECISION MAKING IN GOLF

Whitehead, A., Polman, R., Taylor, J.

University of Central Lancashire

The present study compares different methods of data collection and analysis for the investigation of decision making in sport. Ericsson and Simon (1993) recommend using a think aloud protocol to gauge the thought processes of performers in events. This method has rarely been used in sport research; instead retrospective reports of decisions are more common. This study examined the congruence between data collected via think aloud protocol and retrospective recall of decisions on a golfing task. Six high level male golfers performed six holes of golf whilst engaging in level 3 think aloud, this involved describing one's thoughts and explaining one's decisions during the task. After performance three semi-structured retrospective interviews were conducted, the first was immediately after performance, the second 24 hours after performance, and the third 48 hours after performance. Think aloud verbalisations and interviews were transcribed verbatim and coded. Content analysis was used to identify first and second order themes related to decision making on the golf task. A comparison of the themes identified indicated large discrepancies between the information reported during think aloud and at interview, with only 38-41% similarity in variables reported to influence decision making on each hole. These findings suggest retrospective recall of decision making is limited since relevant information is lost due to memory decay. Future research should record decision making processes in event, employing the think aloud protocol.

## WATCHING VIDEO'S AS DELIBERATE PRACTICE AMONG MOGUL SKIERS

Laurin-Landry, D.1,2, Merri, M.2, Recope, M.1

1: Clermont University; 2: University of Quebec in Montreal (Canada)

**Introduction** Deliberate practice is an activity designed to improve the current performance of an individual and has been correlated to high level of expertise (Ericsson, Krampe & Tesch-Römer, 1993). Watching videos is the only deliberate practice that differentiates expert athletes from novice athletes (Baker, Côté & Abernethy, 2003). This research investigates the development of mogul skiers' deliberate practice when observing oneself and others on video. **Methods** Retrospective and semi-directive in depth interviews were conducted with 17 mogul skiers competing nationally and internationally. Interviews focused on three thematic: how did they start mogul skiing? What was missing from their team training plan so they had to watch videos of themselves and of others? Which parameters (what, when, where, why and how) did they use to watch videos of themselves and of others at every stage of their mogul skiing participation (Côté, 1999)? **Results** Firstly, motives of deliberate observation of the best mogul skiers on video have varied along with skiers' development. During the Sampling years, observation was mostly oriented towards sport enjoyment. During the Specializing years, skiers looked at a technical and esthetic model they wanted to emulate. During the Investment Years, skiers were most likely to watch videos of others when they experienced difficulties in their training. Secondly, the information collected in looking at oneself has evolved. In the Sampling Years, skiers only noticed the errors and the aspects well executed. The Specializing Years are critical: skiers competing nationally were still watching videos the same way as in their Sampling Years whereas skiers competing internationally watched videos in order to understand the sequence of actions causing errors or success. During the Investment Years, skiers observed themselves on video to perfect the technical and esthetic skier they wanted to be. Finally, video practice varied according to their knowledge and was focused on the technique currently trained. **Discussion** The main implication of this research is that deliberate practice takes place at an early age and evolves along with athletic development. Videos are good tools for an athlete to improve his performance by allowing one to develop knowledge about his own practice and to observe the ideal technical model. **References** Côté, J. (1999). ### **DANCERS' DAILY EXPERIENCES: A BASIC NEEDS THEORY APPROACH**

Norfield, J.E., Quedsted, E., Duda, J.L., Ntoumanis, N.

*University of Birmingham*

**Introduction** Previous research (e.g. Gagne, Ryan & Bargman, 2003) grounded in Basic Needs Theory (BNT; Deci & Ryan, 2000) has found daily experiences of autonomy support and basic psychological need satisfaction to have implications for the psychological health of athletes. Building on previous research grounded on BNT (Deci & Ryan, 2000) and pulling from Duda's (in press) conceptualisation of the social environment which integrates dimensions from Deci and Ryan's work as well as achievement goal theory (Nicholls, 1989), we had two aims; firstly to examine whether dancers' perceptions of empowering (i.e., autonomy supportive, task-involving and social supportive) and disempowering (i.e., controlling and ego-involving) climates in dance classes predict post-class basic need satisfaction and thwarting and in turn, changes in affective states during classes. Secondly we aimed to examine whether dancers' typical level of contingent self-worth and fear of failure moderate the relationships between dancers' perceptions of class climates and reported basic need satisfaction and thwarting, and changes in affective states during classes. **Methods** 135 full-time vocational dancers (Mage = 15.57 years, SD = 2.48) completed an initial questionnaire measuring contingent self-worth and fear of failure and a diary before and after daily technique classes, for 5 consecutive days. Diaries measured dancers' affective states before class and perceptions of the motivational climate, basic needs and affective states post-class. **Results** Hierarchical multiple regressions on data averaged across time showed perceptions of class climates and basic need satisfaction and thwarting post-class to significantly predict dancers changes in positive affect ( $F(4,1041) = 10.22, p < .01$ ) and negative affect ( $F(4,1046) = 8.21, p < .01$ ) during classes. Hierarchical moderated regression analyses revealed contingent self-worth to moderate the relationship between perceptions of empowering climates, basic need thwarting and changes in negative affect. Fear of failure moderated the relationship between empowering climates and basic needs satisfaction and thwarting. **Discussion** This study reveals that dancers with high levels of contingent self-worth and fear of failure were less likely to experience the positive effects empowering class climates have on post-class basic needs and affective states. This study highlights the importance of future studies and interventions grounded in SDT considering the interacting role of individual differences. **References** Deci, E.L. & Ryan, R.M. (2000). *Psych Inquiry*, 11, 227-268. Duda, J.L. (in press). *International Journal of Sport and Exercise Psych*. Gagne M. & Ryan R.M., & Bargman, K. ### **HOW INCREASE PUPILS MOTIVATION TOWARDS DANCE IN PHYSICAL EDUCATION?**

Amado, D., Sanchez-Miguel, P.A., Chamorro, J.L., Gonzalez-Ponce, I., Pulido, J.J.I, Garcia-Calvo, T.

*UNIVERSITY OF EXTREMADURA*

**Introduction** Pupils' motivation during Physical Education classes is positively associated with commitment and perception of positive experiences (Lonsdale et al., 2009). Thus, due to the dance and corporal expression contents in physical education are the ones which generated more resistance (Cuéllar and Rodríguez, 2009), and based on postulates from the Self-Determination Theory (Deci and Ryan, 2000) as a conceptual framework very used in the educative context, the aim of this study was to develop an intervention program with teachers using strategies to promote autonomy, competence and relatedness support, and therefore, trying to increase pupils motivation through these contents. **Method** In the study a physical education teacher and her 47 pupils (29 girls y 18 boys), ranging in age from 14 to 18 years old, participated in the research. Regarding the total amount of the sample, 20 pupils were included in the experimental group and 27 pupils composed the control group. To assess self-determination level, the Questionnaire of Motivation in Dance and Corporal Expression was used and to measure perception of basic psychological needs support from teacher, the Adaptation to the Corporal Expression of the Questionnaire of Basic Psychological Needs Support was used. The intervention program consists of 12 dance classes with each group, using a teaching program in the experimental group with the teacher to promote competence, autonomy and relatedness support. In both groups a questionnaire was administrated to pupils in three different times, coincidence with 4th, 8th and 12th classes. **Results** Results showed that there were not significant differences at multivariate level ( $F(5, 41) = .72, p = .73; n2 = .05$ ). Nevertheless, after examine the average of the different variables analyzed in the study, an increase of teacher perception of competence and autonomy support in the experimental group regarding control group were observed. **Discussion** Regarding the obtained results, and considering the main aim of the study, it is suggested that pupils who receive a dance teaching program including several teaching strategies to basic psychological needs support, perceive changes in their teacher along the time, and so, they are more interest to increase feeling of competence and autonomy in their pupils. Therefore, it is emphasized the utility of the intervention program to promote perception of pupils about positive changes in their teacher teaching's styles, which will be showed in pupils' behaviors. **References** Cuéllar, M. ### OP-SH14 Sport Management [SM] 2

#### SPONSORSHIP STRATEGIES BETWEEN LARGE AND SMALL SPORT ORGANIZATIONS IN THE USA

Stotlar, D.

*University of Northern Colorado*

**Introduction-** This research compares sponsorship acquisition strategies of large and small university sport organizations in the US. The literature shows of the transition of marketing theory from product-orientation to market-orientation. Current sponsorship practice shows that many sponsorship programs offer defined products (a.k.a. gold, silver & bronze packages) and then attempt to find sponsors interested in their offering. **Theoretical Framework-** Kotler (2006), indicates that too many organizations define themselves myopically around the products that they produce. As applied to sport, Mullin, Hardy and Sutton (2006) detail how sport marketers focus on producing and selling products rather than identifying and satisfying consumer needs. The presentation of static sponsorship programs and platforms is clearly rooted in myopic thinking. **Methods-** In this research, a content analysis and Chi Square test were conducted on a stratified sample of large and small sport organization sponsorship offerings. The sample of organizations (N = 109) was divided into two distinct groups. Large sport organizations (NCAA BSC institutions) (N= 68) and small organizations (NCAA Div. II, III or NAIA levels) (N= 41). Data were coded and analyzed. **Results-** The results indicated significant differences between the two classifications. The large organizations (55 of 68) were represented by one of the two dominant agencies in collegiate sport marketing (IMG College [ N= 34] and Learfield Sports [ N=21]). These agencies offer market-oriented sponsorships in line with current marketing strategy, they also used a "template" format across the properties. Of the remaining institutions, 3 managed their own opportunities through a "University of XX Properties" moniker with two utilizing a product-oriented approach and 1 offering a market-oriented program. Data for the small sport organizations indicated that sponsorship opportunities were presented through product-orientation (38/41). Only 3 institutions used the market-oriented approach. The Chi Square analysis (84.85 significant  $p > .001$ ) revealed significant difference between the two groups wherein large organizations were more likely to use market-orientation. Small sport organizations were more likely to be offered via antiquated product-oriented. **Discussion** Clearly the larger sport organizations have bigger budgets and are more sophisticated than the smaller organizations. The size of the marketing staff also varies greatly from large to small organizations and larger staffs would be more able to customize the offerings and be better able to service their sponsors. The smaller organizations also have much less capacity to drive ROI (return on investment), an objective typically demanded by larger sponsors. This researcher feels that a market-oriented approach fits best with current marketing theory. However, this approach demands more time and effort that might not be available at smaller organizations.

#### THE ORGANIZATION OF SWEDISH TALENT DEVELOPMENT IN SOCCER: IMPACT ON PERFORMANCE

Söderström, T.

*Umeå university*

Söderström, T, 1, Brusvik, P, 2., Lund, S, 3 1: Umeå university, Department of Education, 2: Swedish Football Association, 3: Linneus University, Department of Education, Psychology and Sport Science. **Introduction** This study reports empirical data from a project that investigates talent development in the 24 soccer districts in Sweden. The paper draws attention to the structural dimensions of specialization (roles and activities), standardization (rules, policies, procedures) and centralization (hierarchical positions and decision making) within the districts. The purpose is to explore whether the structural dimensions are related to and impact on soccer performance. **Methods** The material that the study is based on is an analysis of organizational form (Kikulis et al., 1989), data on the number of licensed players and elite teams in the district, the district's geographical location and a compilation of all 24 districts match results against other districts at 15 years age and at the age of 16. A total of 60 matches between 2001-2011 were registered for each district. The analysis of the district organizations was based on a content analysis of documents describing the structure and implementation of talent development. The documents were classified based on the structural dimensions of specialization, standardization and centralization. **Results** The results show that the specialization in the districts varies from explicit roles and responsibilities for different actions to a low degree of specialization. Similarly, the standardization varies from extensive rules to very low with few formal policies and that centralization differs from high to low. The analysis of performance between 2001 and 2011 shows that there are both successful districts (won many matches) and less successful districts and that successful boy teams are not always followed by successful women teams in the same district. The results show that there are no significant relationships between organizational dimensions and performance. The relationship that arises is that there is a correlation between performance at 15 and 16 years of age and the number of licensed football players and number of teams at the elite level in the district for the boys. For the girls this correlation is only visible at the age of 16. **Discussion** Although no significant differences between organization and performance were found, the data indicate that larger districts are more specialized and standardized. However, there is a need for more research, both quantitative and qualitative, to enable a wider understanding of the talent development system in Swedish soccer. **References** Kikulis, I. M., Slack, T., Hinings, B., & Zimmerman, A. (1989). A structural taxonomy of amateur sport organizations. *Journal of Sport Management*, 3, 129-150.

#### TALENT DEVELOPMENT IN SOCCER: A QUESTION OF TOP-LEVEL CLUBS BUDGET AND TABLE POSITION?

Sæther, S.

*Norwegian University of Science and Technology*

**Introduction** Developing young players is regarded as an important task for most European top-level clubs, both because of team performance and economic reasons. Young players are depending on playing time on the top-level to be able to develop into elite soccer players. This article focuses on the amount of playing time for players under 20 years in the seasons 2009, 2010, 2011 and 2012 in the Norwegian premier league Tippeligaen. The players playing time was analyzed in relation to the clubs table position, to be able to see if the playing time affected the clubs table position. Furthermore, the article discusses the effects between the clubs budget, seasonal table

position and playing time for under 20 players among clubs which has been in the Tippeligaen all four seasons. Methods Data regarding the U20 players playing time (minutes played) and the clubs table position was analyzed from the webpage [altomfotball.no](http://altomfotball.no), while data on the clubs budget was collected from webpage [nettavisen.no](http://nettavisen.no) (Norwegian newspaper). This article contains two analyses. The first analysis is a descriptive analysis of playing time dividing the clubs by league position into; top 5, middle 6 and bottom 5. The second analysis examine pearsons correlation between the clubs budget, final table position and playing time for under 20 players among clubs in the Tippeligaen all four seasons. Results The results of the first analysis show a positive increase in playing time with a lowering of table position during all seasons when the seasons are compared separately, except for the 2009 season. The results from the second analysis show a strong significant ( $p < .05$ ) correlation between budgets between all seasons (.675-.983), with the exception of the 2009 versus 2012 season. On the other hand there were found few significant correlation in term of playing time, budget and table position both within and between the four seasons. Two exceptions are a positive correlation between table position in 2009 and playing time in 2012, and a negative correlation between playing time in 2009 and table position in 2011. Discussion These results indicate that there is a connection between a low level of table position and playing time for U20 players. This could indicate that clubs on the lower part of the table has a disadvantage of letting the U20 players play. In a talent development perspective, young players would have an advantage of playing for clubs on the lower part of the table in terms of opportunity for playing time. Even so, since the results showed few correlations between the three factors playing time, budget and table position the connection between these factors seems indistinct.

### THE REGULATION OF CAREERS IN SPORT INDUSTRY.

Camps, A.1, Pappous, A.2, Segui, J.1, Nebot, R.3

*1 INEFC- (Lleida, Spain); 2 University of Kent (Canterbury, UK); 3 Escola Catalana Esport (Barcelona, Spain)*

Introduction In the current setting of deregulation of the professions in Europe as a whole, and specially in Spain, a regulation of the criteria which determine the minimum qualifications for a professional to work in the area of education, training, support and management of sport activities, remains necessary. The health of the sport users and students should be protected and guaranteed by legislation in order to avoid any risks that might damage their health. The Catalan model in Spain, where there is law which formally regulates the careers in Sport. There is a will on the rest of the Spanish state to regulate in the same/ or in similar way the sports careers and we believe that this model can also be very valid for many other European countries, mainly those which follow a more interventionist approach in sports, such as France, Italy, Portugal, Greece, etc. We are also convinced that this law can also serve as a model for several Latin-American countries. The law of Sport Careers in Catalonia is the FIRST EXAMPLE of the implementation of the Bologna model in the context of professional careers' regulation. Justification The primary objective of the law is to protect the health of citizens with special emphasis on those who may be at greater risk as children, the elderly, those with some kind of disease, those who work in sports activities that entail a clear risk, etc. The law is constitutional justification of the law eradicates on the obligation of the government to preserve and protect the health of its citizens. On one hand there is the right to the free market and the free exercise of professions, however on the other hand there is another constitutional right with even greater need to be guaranteed, and this the right to health and the protection of minors This new law eliminates the monopolistic practices of sports federations and the private sector of sport. Actually the limitations imposed by this law have a positive effect on the opening of the market. According to the law, the professional practice consists of the provision of paid services in the field of sport The law contains four professional careers: a- Physical Education Teacher. b- Animator or professional sports instructor. c- Professional Sports Coach. d- Sport Director. The system of access to professional careers is based on the European model of Bologna which grant access to employment according to professional skills and competences rather than exclusively on academic qualifications. A specific profession can be accessed by a variety of skills accreditation models and a single academic degree grants access to various career paths.

### PS-PL02 Emerging Trends in Team Sports Science sponsored by Aspetar

#### USING TEAM SPORTS TO ENHANCE HEALTH AND WELL-BEING IN YOUNG PEOPLE

Duda, J.L.

*University of Birmingham*

Past research has indicated that participation in team sports facilitates the realising of recommended moderate-to-vigorous physical activity levels in young people. Engagement in team-based sports can also result in a number of psychological and physical benefits and contribute to children's overall psychosocial development. However, sustained engagement in such activities is often curtailed as dropout rates in youth sport tend to be high. As evidenced via heightened anxiety, diminished self esteem, and/or burnout, participation in team sports can also compromise the well-being of young athletes. Providing insight into the determinants of such discrepant consequences of team sport engagement, contemporary theoretical frameworks (such as Self Determination Theory; Deci & Ryan, 2000) and related research point to the implications of variability in the motivational climates created by significant others and the role of ensuing differential motivational processes in sport participants. Grounded in this literature, the European-wide 'PAPA' Project (Promoting Adolescent Physical Activity) centred on the delivery and evaluation of a theory-based coach education programme (Empowering Coaching™) in the context of youth football. This training programme aimed to work with coaches so that they could develop and implement strategies which would make the youth football environment more 'empowering' for young people (Duda, in press). In this presentation, preliminary findings emanating from the PAPA project will be highlighted. Suggestions will be provided for how we can create team sport settings that are more health-conducive for children. Deci, E. L., & Ryan, R. M. (2000). The 'what' and 'why' of goal pursuits: Human needs and the self-determination of behavior. *Psychological Inquiry*, 11(4), 227-268. Duda, J.L. (in press). The conceptual and empirical foundations of Empowering Coaching™: Setting the stage for the PAPA project. Special issue of the *International Journal of Sport and Exercise Psychology* focused on the PAPA Project.

**ECOLOGICAL DYNAMICS IN ANALYSIS OF PERFORMANCE IN TEAM SPORT**

Davids, K.

*Queensland University of Technology*

Many theoretical attempts to understand performance in team sports have an implicit basis in enrichment theories, which focus on the role of psychological processes, such as perception, anticipation and decision-making, without appropriate consideration of participant actions. This is a critical issue since research has revealed differences in decision-making behaviours when participants are allowed to regulate their action patterns in situ, compared to when they are asked to verbally report their decisions or use small micro-movements, such as stepping or pointing in a specific direction (left or right). Alternatively, an ecological dynamics perspective construes the continuous and dynamic physical interactions between cooperating and competing individuals in team sports and their performance environments as emanating from the same psychological processes. Ecological dynamics research on team sport performance has demonstrated how spatio-temporal measures of behaviour, such as angles and distances capturing interrelations between competing and cooperating performers, and their rates of change, relative to key objects and other individuals in the performance environment (e.g., goal areas, ball, opponent locations), constrain decision-making. This presentation discusses how psychological measures of decision-making behaviour do not necessarily have to be construed as internally-located measures in each individual performer. Rather, theory and research in ecological dynamics suggest that the processes of cognition, perception and action are immutably intertwined and mutually co-influential in decision-making during team sports performance. This consideration has implications for understanding performance in team sports suggesting how decision making for action may be enhanced by by: (i) focusing on the ongoing spatial-temporal interactions of performers and their performance environments; and (ii), on the information which is used continuously to guide players' goal-directed behaviours.

**14:00 - 15:00****Mini-Orals****PP-PM68 Training and Testing [TT] 3****WELLNESS FACTORS THAT DISTINGUISH RESPONDERS AND NON-RESPONDERS TO TRAINING IN ROWING**

Tran, J.1, Main, L.C.1, Rice, A.J.2, Gastin, P.B.1

*1: Deakin University; 2: Australian Institute of Sport*

**Introduction** Unravelling the training-adaptation-performance phenomena is a long-standing problem in sports science. However, research to date has tended to focus on the relationships between training and athlete wellness, with relatively little exploration of how wellness subsequently impacts performance. The purpose of this study was to investigate whether self-reported symptoms of training distress, motivation, and burnout could distinguish between responders and non-responders to training in rowing. **Methods** Nineteen sub-elite rowers (11 males, 8 females) were monitored across a 12-week training block. Participants were grouped as Responders or Non-Responders if their rowing ergometer performance improved or did not improve. Athletes completed the Multidimensional Training Distress Scale (MTDS; Main et al., 2009) and training logs (Session-Rating of Perceived Exertion (S-RPE; Foster et al., 2001)) weekly. The Sport Motivation Scale (SMS; Pelletier et al., 1995) and Athlete Burnout Questionnaire (ABQ; Raedeke et al., 2001) were completed monthly. Data were collapsed into 3-week periods to represent the early, early/mid, mid/late, and late periods of the block. **Results** Significant main effects of Group were observed for the subscales "physical signs and symptoms", "identified regulation" (of motivation), "external regulation", and "reduced sense of accomplishment". A significant interaction effect was observed for "introjected regulation". In all cases, Responders rated themselves more highly on these subscales than Non-Responders. Moderate to very strong positive correlations were observed between Group and "sleep disturbances", "depressed moods", "physical signs and symptoms", "amotivation", "introjected regulation", "devaluation", and "reduced sense of accomplishment" (rho range = 0.49 to 0.89). No independent variables were predictive of athletes being Responders or Non-Responders. **Discussion** Responders provided higher ratings for several undesirable wellness factors than Non-Responders, despite no differences in training loads between groups. These unexpected results illustrate the complexities of interpreting athlete wellness data, and may suggest that Responders felt more invested in their performance outcomes, or were more sensitive to their biopsychosocial responses than Non-Responders. **References** Foster C, Florhaug J, Franklin J, Gottschall L, et al. **VALIDATION OF A KAYAK ERGOMETER POWER OUTPUT**

Gullstrand, L.1,3, Lindberg, T.2, Cardinale, D.2, Tarassova, O.3, Bjerkefors, A.3

*1: Dept. Physiology and Pharmacology, Karolinska Institutet. 2: Elite Sports Centre, Bosön, Swedish Sports Confederation. Stockholm, 3. The Swedish School of Sport and Health Sciences*

**Introduction** It is of a significant interest that ergometers used for evaluating elite athletes are valid and reliable. In this study the aim was to investigate how well displayed power output on a widely used kayak ergometer, DS, (Dansprint ApS, DK) related to a validation setup. Previously Gore et al. (2013) described the accuracy of 12 of the same ergometer using a motor driven calibration rig simulating power between 50 up to 450 W. They found that the ergometers underestimated true mean power with 21-23%. The reference rig simulated a 1 dimensional (1D) movement; this study however, is based on 3D analysis, which was hypothesized to better describe real paddling movement's and allow more precise power calculations. **Methods** Two male national team kayakers took part in the study performing workloads from 70 up to 500 W (+30 W/stage) two times with 3 days between the measurement sessions. They were instructed to target the desired workloads displayed during 35 s bouts. The reference method included a ProReflex optoelectronic system (Qualisys AB, Gothenburg, Sweden) and force transducers (LCM 200, Futek Inc, Ca, US). The force transducers were connected with the rope from ergometer flywheel close to each end of the ergometer paddle to continuously measure force during the bouts of work. The kinematic set-up included eight cameras placed around the ergometer and two reflective markers were attached close to each force transducer. **Results** The reference method used here showed that the validated ergometer underestimated power with 37.7 % over the whole meas-

ured range compared to the reference method. The difference was systematic ( $r^2=0.989$ ) and the linear regression model could be applied (DS power =  $-2.362+0.628*x$ ). When applying a 1D analysis of the collected data, it coincided with the results from Gore et al. (2013). Discussion The data suggest that 1. The measurement solution and/or calculation for describing power output in the DS have limitations. 2. The testing rig referred to in the Introduction (Gore et al. 2013) do not fully estimate true power and 3. The reference method used here is suggested to more exactly represent true paddling power as it includes a 3D movement analysis and close to original paddling simulation set-up. Both reference methods (1D and 3D analysis) show linear differences vs. the DS ergometer, giving an option to adjust the displayed power to a true power produced by elite-athletes.

### **TIME TO EXHAUSTION AT MAXIMAL LACTATE STEADY STATE IN CONTINUOUS AND INTERMITTENT PROTOCOL IN TRAINED RUNNERS**

Guglielmo, L.G.A., Dittrich, N., Diefenthaler, F., de Lucas, R.D.

*Federal University of Santa Catarina*

**Introduction** The maximal lactate steady state intensity (MLSS) can be defined as the highest running velocity at which blood lactate remains stable during the last 20 min of constant load exercise (Beneke, 2003). The determination of the time to exhaustion (TTE), cardiorespiratory and metabolic responses at MLSS seems to be important for a better understanding of the mechanisms related to fatigue during long duration exercises (30 min or more), both continuously and intermittently, contributing to training prescription at this intensity. Hence, the aim of the present study was to determine and compare the TTE and physiological responses at continuous and intermittent (ratio 5:1) MLSS in trained runners. **Methods** Eleven male runners ( $32.7\pm 6.9$  years;  $75.3\pm 5.3$  kg;  $176.8\pm 5.7$  cm) performed the following tests: 1) maximal treadmill incremental test; 2) 3-5 submaximal tests (30 min) to determine the MLSS continuous (MLSScon) and intermittent (MLSSint); 3) 2 randomized TTE tests, in both protocols. Due to differences between tests duration, VO<sub>2</sub>, VE, and HR were expressed and analysed as percentage of each TTE (t10%, t20%, t40%, t60%, t80%, and t100%). In addition, blood lactate was analysed at 10th, 20th, 30th min and at the end of exercise on TTEcon, and at 11th, 23rd, 35th min and at the end of exercise on TTEint (t10, t20, t30, and tend). Two-way ANOVA with repeated measures was used to compare the changes in physiological variables over time at TTE and between continuous and intermittent exercise. Multiple comparisons were made with the Bonferroni post-hoc test. The significance level was set at 0.05 for all analyses. **Results** The velocity at MLSSint and lactate concentration ( $15.26\pm 0.97$  km.h<sup>-1</sup>;  $4.63\pm 1.78$  mM) were higher than in MLSScon ( $14.53\pm 0.93$  km.h<sup>-1</sup>;  $3.90\pm 1.21$  mM), while the TTE at MLSScon was longer than in MLSSint ( $67.9\pm 11$  min vs.  $57.8\pm 15$  min). Regarding the cardiorespiratory parameters (HR, VO<sub>2</sub>, and VE) during TTE, no differences were found between the two exercise protocols at the same percentages. **Discussion** The main finding of the present study was that the time to exhaustion at MLSScon was longer than TTE at MLSSint in trained runners. This could be explained by the higher velocity in MLSSint, which requires a higher metabolic demand and, consequently, greater substrate depletion, higher stress hormones release and higher metabolic acidosis. Moreover, the training volume of an interval session designed at MLSS should take into consideration this higher speed at MLSS and also the lower TTE, when compared with continuous exercise. **References** Beneke R. Maximal lactate steady state concentration (MLSS): experimental and modeling approaches. *Eur J Appl Physiol* 2003; 88:361–369.

### **MUSCLE OXYGENATION IN ELITE ICE SPEED SKATERS DURING INCREMENTAL TESTING – ADAPTATION OR ACUTE METABOLIC DEMAND?**

Born, D.P., Lindner, N., Hoppe, M.W., Sperlich, B.

*University of Wuppertal*

**Introduction** Elite long-track ice speed skaters were shown to have a remarkable oxygenation asymmetry between right and left legs quadriceps femoris muscle during cornering as well as the straight sections of the track (Born et al. 2012). Therefore, it can be questioned if chronic adaptations to the constant travelling anti-clockwise rather than the acute metabolic demand leads to the remarkable oxygenation asymmetry between right and left legs quadriceps femoris muscle. **Methods** 5 female elite German ice speed skaters ( $60.1\pm 8.1$ kg,  $167\pm 6$ cm,  $20.7\pm 2.6\%$ ,  $VO_{2max}$   $57.8\pm 5.9$  ml/min/kg) performed a 3000m on-ice race simulation on a 400m outdoor track matching the standards for international competitions. Additionally, in a laboratory test all participants cycled at two submaximal workloads (1.6 and 2.0W/kg) for 3min each followed by a ramp test until voluntary exhaustion. During both tests ventilation (VE), oxygen uptake (VO<sub>2</sub>), and heart rate (HR) were measured continuously with a portable gas analyzer (Cortex Metamax & Polar). Tissue saturation index and blood volume were determined by the concentrations of oxy-, deoxy- and total haemoglobin measured with wireless near-infrared spectroscopy devices (NIRS, Portamon) at both right and left vastus lateralis muscles. Mid-thigh skinfold thickness was determined using a Harpenden caliper (British Indicators Ltd) and body composition using a four-electrode bio-impedance analysis (Tanita Corp.). **Results** ANOVA revealed significant lower tissue saturation index in right compared to the left quadriceps femoris muscle ( $p<0.01$ ) during the 3000m on-ice race simulation when comparing 1st, 3rd and last minute. Interestingly, as well, this oxygenation asymmetry was evident during the ergometer test while cycling at submaximal and maximal workloads ( $p<0.01$ ). In contrast, changes in blood volume revealed no differences between right and left legs quadriceps femoris muscle throughout the 3000m on-ice race simulation ( $p=0.74$ ) as well as during the cycle ergometer test ( $p=0.94$ ). Mid-thigh skin fold thickness ( $p=0.17$ ) and leg muscle mass ( $p=0.30$ ) revealed no difference between the right and left leg. **Discussion & Conclusion** During the on-ice race simulation female elite ice speed skaters showed a more pronounced muscle deoxygenation in the right compared to the left legs quadriceps femoris muscle. Since this phenomenon was evident during submaximal and maximal cycling, it can be concluded that the oxygenation asymmetry is more likely due to chronic adaptation rather than the acute metabolic demand of elite ice speed skating.

### **ELECTROMYOGRAPHIC ACTIVITY DURING SLING-BASED PUSH-UP EXERCISE**

Maeo, S., Chou, T., Yamamoto, M., Kanehisa, H.

*National Institute of Fitness and Sports in Kanoya*

**Introduction** Sling-based exercise is an effective training modality for improving throwing velocity and/or strength capability of upper extremity in both untrained individuals and athletes (Saeterbakken et al. 2011). However, no information concerning muscular activities during an exercise performed with sling device is available from previous reports. This study aimed to examine the effect of using sling device on muscular activities during push-up exercise by comparing it with those during the same exercise performed on the floor. **Methods** Thirteen healthy young adult men performed two types of push-up exercise (static: maintaining the posture with the elbow joint angle at 90 deg, dynamic: repeating push-up movements at 45 beats-per-minute) on a sling and on the floor conditions. The shapes of

grips for both conditions were matched by using a grip attachment and a push-up-bar for the sling and floor conditions, respectively. Surface electromyogram (EMG) activities of the pectoralis major (PM), latissimus dorsi (LD), triceps brachii (TB), biceps brachii (BB), rectus abdominis (RA), external oblique (EO), internal oblique (IO), and erector spinae (ES) muscles were recorded during exercise. The EMG data were normalized to those obtained during maximal voluntary contraction of each muscle (% EMGmax). Results In the static exercise, the sling condition showed significantly higher % EMGmax value than the floor condition in BB muscle (sling:  $11 \pm 2\%$  vs. floor:  $6 \pm 1\%$ ; means  $\pm$  SE;  $P < 0.05$ ). In dynamic exercise, % EMGmax values for PM (sling:  $96 \pm 12\%$  vs. floor:  $78 \pm 11\%$ ), BB ( $17 \pm 3\%$  vs.  $8 \pm 1\%$ ), RA ( $40 \pm 3\%$  vs.  $31 \pm 3\%$ ), EO ( $35 \pm 3\%$  vs.  $29 \pm 3\%$ ), and IO muscles ( $33 \pm 3\%$  vs.  $28 \pm 3\%$ ) were significantly higher in the sling condition than in the floor condition. Discussion Increased activity in BB under the sling condition may be attributed to the exercise-specificity of push-ups (i.e., elbow flexion on the sling is needed to control the position of unstable grip). It has been shown that the practice of lifting task on an unstable surface cause an increase in the activation levels of the core (trunk) muscles to maintain body balance (Behm and Colado 2012). In the current results, too, the activities of the trunk muscles were higher in the sling than in the floor condition. However, the increased activity of the trunk muscles in the sling condition was more prominent in the dynamic than static condition. This result indicates that the influence of using sling on the muscular activities of the trunk muscles may depend on the difficulty of the task or the severity of the unstable condition. References Behm D, Colado JC (2012). *Int J Sports Phys Ther* 7: 226-241 Saeterbakken AH, van den Tillaar R, Seiler S (2011). *J strength Cond Res* 25: 712-718

## JUMP SQUAT VARIABLES FOR COMPETITIVE SURFING ATHLETES

Lundgren, L.1,2, Tran, T.1,2, Sheppard, J.1,2

*Computing, Health and Science*

1: ECU (Joondalup, Australia), 2: Hurley Surfing Australia HPC (Casuarina beach, Australia) Introduction Performance testing for surfing athletes should include lower extremity strength and power, because of the need for the athlete to produce and arrest force, primarily through the lower body, to execute manoeuvres. The jump squat and isometric mid-thigh pull tests (IMTP) have been validated previously as worthwhile discriminators between performance levels (Sheppard et al. In press). The aim of this study was to analyze variables that may have an effect on jump squat height (JH) in Junior to Elite surfers. Methods Twenty eight competitive surfers (11 Females and 17 Males), divided into two age groups (<16 and  $\geq$ 16, n=15 and 13), performed three jump tests and IMTPs where the maximum score was used for analysis (JH and Peak Force (PF) respectively). The jump test was a countermovement jump on a unidirectional force plate (Fitness Technology 400S, Adelaide Australia), with a linear encoder (IDM Instruments) attached to a wooden dowel that was held onto the back to measure height and velocity. Data was recorded simultaneously by personal computer (BMS Software, Innervations). The IMTP was performed as previously described (Haff et al., 1997), using an identical force plate. Variables extracted for correlation to JH was Peak Power (PP), Peak Force (PF), Peak Velocity (PV), Maximum Negative Velocity (MNV), Flight Time (FT), Rate of Force Development in take-off (RFDTO) and IMTP PF (normalized and relative to BW). Results The group means for JH were 0.35 m  $\pm$  0.03 for the <16 F, 0.39 m  $\pm$  0.06 for the <16 M, 0.40 m  $\pm$  0.05 for the  $\geq$ 16 F and 0.52 m  $\pm$  0.09 for the  $\geq$ 16 M. The variables that had a moderate to strong correlation with JH ( $p < 0.05$ ) for the <16 group was PP ( $r=0.60$ ), PV ( $r=0.73$ ), MNV ( $r=-0.91$ ) and FT ( $r=0.67$ ). For the group of  $\geq$ 16 the variables that had a strong correlation with JH ( $p < 0.001$ ) were: PP ( $r=0.87$ ), PF ( $r=0.95$ ), PV ( $r=0.90$ ), MNV ( $r=-0.88$ ) and RFDTO ( $r=-0.88$ ). IMTP PF normalized for BW had a moderate correlation to JH for the older group ( $r=0.66$ ,  $p < 0.05$ ). Discussion The variables that showed effect on jump height for both groups were PP, PV, MNV and FT, which is in accordance with previous results (González-Badillo and Marques, 2010). The correlation between JH and MNV shown in this study was very strong in comparison to other studies (González-Badillo and Marques, 2010), and may indicate that surfing athletes with the physical capabilities to execute a faster descendent phase during the CMJ may lead to greater JH. Also, possessing a greater isometric is likely important for JH performance for older athletes. References Haff GG, Stone MH, O'Bryant HS, et al. (1997). *J Strength Cond Res*, 11, 269-271. ## HEART RATE VARIABILITY AND PRECOMPETITIVE ANXIETY IN JUDO

Morales, J.1, Garcia, V.2, Buscà, B.1, García-Massó, X.3, Alamo, J.M.4, González, L.M.3

1: Ramon Llull University 2: Universitat de Girona, 3: Universitat de València, 4: Universitat de Barcelona

Introduction Anxiety in sports is a complex phenomenon that is related to emotional and cognitive processes that can cause physiological changes in the participating athletes (Cervantes, Rodas and Capdevila, 2009). Judo is an activity with a high level of uncertainty and high physiological and psychological demands. Heart Rate Variability (HRV) parameters are sensitive to changes in rates of anxiety as measured through CSAI-2R in pre-competitive situations (Mateo et al., 2011). The aim of the study was to examine HRV in stressful situations before judo competitions and to observe the differences among judo athletes in official and unofficial competitions. Material and Methods 24 national-standard judo athletes participated in this study. All subjects underwent measurements of pre-competitive anxiety and HRV in the official and unofficial competition days. The HRV was recorded at rest with each participant using a cardio tachometer and the RR signal (beat to beat) for 10 minutes. HRV was analysed using time, frequency and nonlinear domain variables. Afterwards, the Revised Competitive State Anxiety-2 (CSAI-2R) was administered prior to weight control. A repeated measures ANOVA was performed to assess the effects of the competition type on the dependent variables related to pre-competitive anxiety (CSAI-2R) and derived from the HRV. Results The ANOVA showed significant main effects of the type of competition in CSAI-2R, in HRV time domain, in HRV frequency domain and in HRV nonlinear analysis ( $p < 0.05$ ). Judo athletes have lower somatic anxiety, cognitive anxiety, heart rate and low-high frequency-high frequency ratio in unofficial than in official competitions ( $p < 0.05$ ). The parameters of the nonlinear analysis were significantly greater ( $P < 0.05$ ) in the unofficial competitions than in the official competitions Discussion The major findings of this study is the observation of higher levels of pre-competitive anxiety in judo athletes is related with an increase in sympathetic nervous activity and decreased parasympathetic nervous activity. The relationship between CSAI-2R and HRV show that pre-competitive anxiety scores vary depending on the importance of the competition. These results are consistent with studies that have used a psycho physiological approach, in which the two methods have similar behaviours: in comparison with hormone levels (Filaire et al., 2001) or when using HRV (Oreshnikov, Tihorov and Agafonkina, 2009). ## PACING STRATEGY DURING A 10-KM RUNNING RACE: CONTRIBUTIONS OF RPE, AND PHYSIOLOGICAL AND MUSCULAR PARAMETERS

Bertuzzi, R.1, Lima-Silva, A.E.2, Damasceno, M.1, Bueno, S.1, Tomazini, F.1, Pasqua, L.A.1, Bishop, D.J.3

1: USP (São Paulo, Brazil), 2: UFAL (Maceió, Brazil), 3: ISEAL (Melbourne, Australia).

**Introduction** It has been hypothesised that the pacing strategy adopted by endurance athletes is based on the rating of perceived exertion (RPE) in order to prevent premature exhaustion. While physiological and muscular parameters are also considered fundamental to success in endurance events, the relationship between these parameters and speed distribution during a long-distance running race remains unknown. Therefore, the aim of current study was to determine the contributions of the RPE, and physiological and muscular parameters on speed distribution during the different phases of a 10-km running race using a stepwise multiple regression model. **Methods** Twenty-five male endurance runners performed: a) a maximal incremental treadmill test to determine the maximal oxygen uptake (VO<sub>2</sub>max), respiratory compensation point (RCP) and peak treadmill velocity (PTV), b) a 6-min running test at 12 km.h<sup>-1</sup> to determine running economy, c) a maximum dynamic half-squat strength test (1RM), and d) a 10-km running time trial on an outdoor track in order to determine pacing strategy and RPE responses. During the 10-km running time trial, both speed and RPE responses were registered at each 400 m and the average speed of the start (first 400 m), middle (400 to 9600 m), and end (last 400 m) phases was calculated. **Results** During the start phase, RPE was the only variable selected by the stepwise multiple regression model and explained 64% (p=0.001) of the speed variance. PTV explained 74% (p=0.001) of the speed variance during the middle phase, while VO<sub>2</sub>max and 1RM accounted for additional 8% (p=0.002) and 12% (p=0.003), respectively. During the end phase, the RCP explained 64% (p = 0.002) of the speed variance, while PTV accounted for an additional 14% (p=0.003). **Discussion** It is well established that RPE responses during exercise are related to some physiological variables (e.g. ventilation and VO<sub>2</sub>). As the time needed for the stabilization of these variables (3-6 min) is superior to the time required to complete the first 400 m of the 10-km race (~90 s), the observed relationship between RPE and initial speed distribution may result from an efferent copy that is sent directly from the motor to the sensory areas in the brain (Marcora et al. 2009; JAP, 106:2060-2). In turn, PTV and RCP have been related with anaerobic energy production, while VO<sub>2</sub>max and maximum dynamic strength have been related with aerobic ATP resynthesis and capacity of storing and utilizing elastic energy, respectively. Thus, ATP availability and stretch-shortening cycle appears to assume a major role on setting of speed distribution after 400 m of a 10-km running race. **Financial support:** FAPESP 2011/10742-9

## EFFECTS OF DIFFERENT EXERCISE TRAINING INTENSITIES OVER HYPERTENSIVE RATS

Almeida, J.A., Petriz, B.A., Gomes, C.P.C., Pereira, R.W., Franco, O.L.

Catholic University of Brasilia

**INTRODUCTION** Spontaneously hypertensive rats (SHR) are commonly used in hypertension research. In this specific field, exercise has been viewed as a non-pharmacologic agent as treatment for high blood pressure (BP) (MacDonald, 2002). Nevertheless, the exercise intensity should be taken into consideration. Thus, this work aims to evaluate the BP response in treadmill running at different exercise intensities. **METHODS** Fifteen SHR with 174.9 ± 11.8mm.Hg-1 systolic BP (SBP) were divided into three groups: control group (CG), low intensity (LI) and high intensity (HI). After adaptation, the maximal lactate steady state (MLSS) was determined according to Almeida et al. (2012). Treadmill running was performed 5x per week for 30 min during 8 weeks. LI was trained at 20% below and HI at 15% above its MLSS. Moreover, incremental tests (IT) were also performed before and after exercise training. One-way ANOVA was used and significance level was set at p <0.05. **RESULTS** The MLSS was found at 20m.min<sup>-1</sup>. There were no significant differences in IT before training: CG 27.2 ± 2.7 x LI 26 ± 4.2 x HI 26.5 ± 2.2m.min<sup>-1</sup> (p >0.05). After eight weeks, HI and LI presented significant reductions in SBP in relation to the CG: 148.6 ± 28.2 x 160.4 ± 2.9 x 170.5 ± 11.2, respectively (p <0.05). Regarding the exercise intensity, HI showed a larger reduction in SBP compared to LI (p <0.05). In relation to performance, in IT after training, the V<sub>max</sub> for HI increased 53% and LI 20.6% (p <0.05). **DISCUSSION** Although both exercise intensities were able to effectively reduce the BP, the decrease was higher in HI group (p <0.05). According to Lee et al. (2009), the SBP reduction may be associated with an increase in the nitric oxide (NO) release. Furthermore, exercise intensity seems to influence the reduction of SBP and also the NO release (Santana et al., 2011). Nevertheless, other mechanisms could be associated with the SBP reduction due to exercise training (MacDonald, 2002). Therefore, the exercise at 15% above MLSS was more effective in reducing SBP as well as in increasing the performance in IT onto SHR. **REFERENCES** Almeida JA, Petriz BA, Gomes CPC, Pereira RW and Franco OL. ## REGULAR VOLUNTARY RUNNING IMPROVES COGNITIVE FUNCTIONS IN AN ANIMAL MODEL OF ATTENTION – DEFICIT/HYPERACTIVITY DISORDER

Felszeghy, K.1, Posa, A.2, Varga, C.2, Nyakas, C.1

1: Semmelweis University, 2: University of Szeged

**Introduction** Attention deficit hyperactivity disorder (ADHD) is a behaviorally defined psychiatric abnormality with unknown etiology and pathology. The dysregulation of dopaminergic transmission is in the background of the symptoms. Although hyperactivity shows remission over ageing, cognitive impairment still persist at adulthood. The neonatal dopamine (DA) depletion in rats is one of the most frequently used animal model for studying the disorder. In recent study we aimed at examining the cognitive performance of dopamine depleted animals (Luthman et al, 1997) following regular voluntary training at adult age. **Methods** At neonatal age (postnatal day 4) animals were DA-depleted by intraventricular injection of 20•g 6-hydroxydopamine. This intervention resulted in 70-90% decrement of extracellular DA content in dopaminergic brain areas. Control animals were sham operated. The half of adult depleted and control rats were placed into special cages containing a running wheel at the age of 3 months. The other half of each groups remained in normal cages by four animals per cage. Following 3 months of voluntary running animals were tested for hyperactivity and impulsivity in an open field. Attention and memory functions were assayed in novel object recognition paradigm (Wappler et al, 2009), spatial learning and memory were evaluated in a Morris water maze. **Results** Dopamine-depletion resulted in hyperactivity in open field. Depleted animals showed impaired attention and memory function both in novel object recognition and in spatial learning task. Regular voluntary running decreased hyperactivity of depleted rats. In the novel object recognition test trained animals showed significant improvement in attention as compared to controls. In spatial learning task voluntary running resulted in better working memory function, but could not influence the impaired reference memory of the dopamine-depleted rats. **Discussion** Our results indicate that 3 months of regular voluntary train-

ing decreased hypermotility and impulsivity of ADHD rats. Moreover, the regular exercise improved attention and memory function of DA-depleted animals comparing to those of untrained DA-depleted rats. These results strongly suggest that long-term and regular exercise can induce remarkable improvement in the symptoms of ADHD providing alternative or complementary therapy in the treatment of adult ADHD. ### MONITORING INTERNAL LOAD PARAMETERS DURING COMPETITIVE SYNCHRONIZED SWIMMING DUET ROUTINES IN ELITE ATHLETES

Iglesias, X., Rodríguez-Zamora, L., Barrero, A., Torres, L., Chaverri, D., Rodríguez, F.A.

*Institut Nacional d'Educació Física de Catalunya, Universitat de Barcelona (Barcelona, Spain)*

**Introduction** Although recent research provided detailed information about the physiological responses elicited during synchronized swimming (SS) competition (Rodríguez-Zamora et al., 2013), monitoring the internal load also during training is critical to the success of each conditioning program, particularly considering that vigorous exercise combines with more than 60% of time spent underwater (Rodríguez-Zamora et al., 2013). This study aimed to compare the heart rate (HR) and perceived exertion (RPE) responses as internal load indicators while performing duet routines during training and competition. **Methods** Participants were 10 SS Olympic medallists (age: 17.4 ± 3.0 years, height: 164.0 ± 6.1 cm, body mass: 52.0 ± 6.4 kg, training: 36.3 ± 6.2 h/wk, experience: 9.2 ± 2.6 years). They were monitored while performing the same technical (TD) or free duet (FD) routines during a training session (T), and during an official competition (C). HR was measured from RR intervals (CardioSwim, Freelap, Switzerland). RPE was assessed using the Borg's category-ratio CR-10 scale after each performance. Results HR responses during T and C were almost identical: pre-exercise mean (±SD) HR was 131 ± 14 (T) and 134 ± 8 (C) beats/min, and quickly increased up to peak values of 185 ± 6 (T) and 185 ± 7 (C), with interspersed bradycardic events down to 87 ± 4 (T) and 86 ± 5 (C). Routines were perceived as "hard" to "very, very hard" by the swimmers in both conditions, and mean RPE scores (0-10+) were equally high in C (7.9 ± 1.2) and T (7.5 ± 1.2) (P=0.22). RPE inversely correlated with minimum (R=-0.55; P=0.008) and mean HR (R=-0.45; P=0.026), and positively correlated with HR range (R=0.52; P=0.011). **Discussion** The internal load imposed by SS duets routines can be monitored using objective (HR) and subjective (RPE) assessments, and is virtually identical during competition and training. This can be explained by the effects of automaticity, embodied through the replication of the same movement sequence during practice, and by the swimmers' long-term adaptations to specific routine exercises and apnoea. Practicing competitive routines is suitable for developing and maintaining the cardiovascular fitness necessary for specific conditioning in elite synchronized swimmers, with the added value of favouring exercise automaticity, inter-individual coordination, and artistic expression simultaneously. **References** Rodríguez-Zamora L, Iglesias X, Barrero A, Chaverri D, Erola P, Rodríguez, FA. ### EVALUATION OF THE UNDERWATER BUTTERFLY START AFTER SENSORY-PERCEPTIVE TRAINING

Ciapparelli, C., Scurati, R., Michielon, G., Longo, S., Invernizzi, P.L.

*Università degli Studi di Milano*

**Introduction** The swimming speed depends on drag reduction and on the improvement of the propulsive actions [1]. A specific training addressed to the development of the sensory-perceptive skills and coordination might enhance the technical action and affect the previous parameters [2]. The effect of a sensory-perceptive training on the underwater kicking during the butterfly start phase of elite swimmers has been studied through a new software, which considers the data output of two common devices used for swimmers' evaluation. **Methods** Twenty-four elite butterfly male swimmers (Intervention group = IG: #12, 21.1±1.2 years, 72.1±4.9 kg, 180.8±3.5 cm, 22.0±1.0 kg·m<sup>-2</sup>; Control group = CON: #12, 20.6±1.8 years, 73.8±2.9 kg, 181.6±3.2 cm, 21.4±1.5 kg·m<sup>-2</sup>) volunteered to be included in the study. IG underwent 12 weeks of specific training based on sensory-perceptive exercises aimed to improve the dolphin underwater kicking. Before and after training, passive drag (Ben Hur, APLab, Rome, Italy) and speed variations (Speed RT, APLab, Rome, Italy) during underwater kicking without pushing-off the wall were measured. The peak power output was calculated with a new software (Underwater, CC, Busto Arsizio, Italy) which combines the measurements of Ben Hur and Speed RT devices. The performance of the start phase after diving was also measured in the 15 m. Results CON did not show difference between pre- and post- training. After sensory-perceptive exercise, IG lowered their passive drag (75.49±5.77 vs. 66.96±4.33 W, pre- vs. post-, p<0.001). During the underwater kicking, peak and mean power raised from 3375±299.9 to 4691±604.3 W, p<0.001 and from 1011±111.0 to 1468±208.4 W, p<0.001, respectively. The performance in the start phase lowered from 7.73±0.61 to 6.72±0.62 s, p<0.001. **Discussion** The analysis of the data with the new Underwater software allowed to verify the improvement of the performance of the IG underwater kicking. The lower passive drag after the sensory-perceptive training might originate from the better hydrodynamic position swimmer assumes, which would reduce the drag components [1]. The improvement of the propulsive actions might depend on the new motor pattern induced by sensory-perceptive training that would lead to a higher peak and mean power output. Altogether, in IG swimmers the hydrodynamics and the propulsive actions resulted in a better start phase compared to CON swimmers. **References** [1] Vorontsov AR, Rumyantsev VA (2000) Resistive forces in swimming. ### THE ROLE OF RATE OF FORCE DEVELOPMENT OF THE PLANTAR FLEXORS IN SPRINT PERFORMANCE

Yáñez-García, J.M., Rodríguez-Rosell, D., Pareja-Blanco, F., Mora-Custodio, R., González-Badillo, J.J.

*Universidad Pablo de Olavide*

**Introduction** Rate of force development (RFD) is considered a very important characteristic in vertical jump and sprints [1]. However, the most research suggests a moderate or insignificant relationship between performance in different actions and RFD [2-3]. The aim of this study was analyze the relationship between RFD of plantar flexor (Pflex) muscles assessed dynamically and sprint and CMJ performance. **Method** Nineteen healthy men took part in this study (age 23.8±2.9 years, height 1.79±0.07m, body weight [BW] 78.8±9.0kg). The subjects performed Pflex test with the 30%, 50% and 70%BW, acceleration test in 30m (T10, T10-20, T20, T20-30 y T30) and CMJ test. Pflex test consisted heel rise from a vertical position. RFD in Pflex was measured as the average slope of the force-time curve over time intervals of 0-25 (RFD25), 0-50 (RFD50), 0-75 (RFD75) and 0-100ms (RFD100) relative to the onset of contraction [1], and the time interval between achieving 10% and 90% of maximum force (RFD-T10-90%). Results Neither correlation was found between RFD and CMJ or between RFD for 30%BW and sprint performance. However, significant negative correlations were found between all measures of RFD for 50%BW and

T10 and T20, except for RFD-T10-90%, that was significant positive correlations. Also were obtained significant negative correlation between all measures of RFD for 70%BW and T10. Moreover, RFD-T10-90% showed significant positive correlation with T20, T30 and T10-20, and between RFD100 and T20. Discussion To our knowledge, only two works have analyzed the relationship between RFD and sprint performance (2-3), but in neither of them was observed any correlation. In both studies, the RFD was measured in an isometric half squat. The discrepancy with our results may be due to the different way of measuring the RFD. We have not found correlations between RFD of Pflx muscles and CMJ. These results suggest that probably Pflx muscles are not determinants of vertical jump, since these muscles are involved fundamentally just before takeoff, when velocity is very high, decreasing the possibility of applying force by these muscles. In conclusion, RFD assessed dynamically in plantar flexors muscles explains a moderate variance of acceleration, but no present relationship with CMJ height. References 1. ### POSTURAL ADAPTATIONS IN PREADOLESCENT KARATE ATHLETES DUE TO A ONE WEEK KARATE TRAINING CAMP

Vando, S.1, Foti, C.1, Maurino, L.2, Salernitano, G.3, Bramani, S.4, Padulo, J.1

1: University of "Tor Vergata", Rome (Italy), 2: University of "Federico II", Napoli (Italy), 3: ISPG, Caserta (Italy), 4: Rehab. Institute, Como (Italy).

Introduction There are few studies dealing with the effect karate practice on body balance. However, only one study has addressed the effect of karate training in young population (Violan et al., 1997). In view of the fact that karate become increasingly popular among children, this investigation involved sectional design to evaluate the effect of one-week: intensive karate training (14-h) vs. moderate training (3-h) on preadolescent karateka's postural sway. Methods Seventy-four karatekas were randomly assigned to Karate Group: (KG=37, age 10.29±1.68 yrs); or Control Group: (CG= 37, age 10.06±1.77 yrs). KG performed two 60 minute training sessions per day (morning – afternoon) during the Summer Camp (7 days). They performed specific exercises during the training sessions: coordinative trunk, arms and legs exercises in different body planes; flexions, lunges and extra-rotations exercises followed by static-dynamic stretching and 35-minutes of Karate kicks exercises. CG received three days for week (total time four hours) in agree with the exercise of KG. All participants, before and after the week investigation, underwent a battery of postural stability on Nintendo™ Wii Balance Board (WBB) (Clack et al., 2010). Result Pre-Camp results showed that both center-of-pressure length (COPL) and velocity (COPV) in two conditions: eyes open (EO), eyes closed (EC), were found not to be significantly different between the two groups. In Post-Camp results, the analysis revealed significant differences between groups: in COPL  $F(1,72)=27.878$ ,  $p<0.0001$  ( $\eta^2=0.279$ ); interaction training type×time  $F(1,72)=5.789$ ,  $p=0.019$  ( $\eta^2=0.074$ ); COPV  $F(1,72)=25.862$ ,  $p<0.0001$  ( $\eta^2=0.264$ ) and the interaction training type×time  $F(1,72)=5.640$ ,  $p=0.020$  ( $\eta^2= 0.072$ ). KG revealed an improvement of COPL respect to baseline in EO -37.26% ( $p<0.0001$ ), EC -31.72% ( $p<0.0001$ ), while CG revealed small adaptations in EO 3.16%, EC 0.93%. Moreover, KG revealed a COPV improvement from baseline in EO -37.92% ( $p<0.0001$ ), EC -32.52% ( $p<0.0001$ ), while CG give out small variation in EO 1.79%, EC 5.73%. Discussion One-week of high intensity karate training induced significant improvement of static body balance in karate practitioners. As top-level karate performance require both high-level of both static and dynamic balance, further researches dealing with the effect of karate practice on dynamic body balance in young practitioners are required. #### ROS MAY HAVE SUPPRESSIVE EFFECT ON ENDURANCE TRAINING-INDUCED IMPROVEMENT OF GLUCOSE METABOLISM

Matoba, H.1, Nii, A.2, Sun, Y.Y.1, Obara, S.1

1: The University of Tokushima (Tokushima, Japan), 2: Shikoku University (Tokushima, Japan)

Introduction The role of reactive oxygen species (ROS) in endurance training-induced improvement of glucose metabolism has not been fully elucidated (Listow et al., 2009; Yfanti et al., 2011). To gain insight into the role of ROS, the present study investigated whether or not vitamin C supplementation prevented the training-induced improvement of insulin sensitivity in rats. Methods Thirty two male rats aged 4 weeks were assigned to one of the four groups: sedentary (S, n=8), sedentary with vitamin C supplementation (SVC, n=8), trained (T, n=8) and trained with vitamin C supplementation (TVC, n=8). The rats of vitamin C supplemented groups were administered 500mg of vitamin C per kg body weight per day from 11 days before the start of the training until a sacrifice of the animals. The rats of the trained groups swam 6 hour per day with two 3 hour sessions separated by 45 min of rest. The training lasted for 10 days. After the training period, fasting blood sample was obtained and plasma isolated. Plasma glucose and insulin concentration was measured and insulin resistance evaluated using homeostasis model assessment (HOMA-R). Results and Discussion The training significantly decreased fasting plasma glucose and insulin concentration. The training also significantly lowered HOMA-R value. These favorable training effects were more prominent with vitamin C supplementation than without vitamin C supplementation. This finding is novel and do not accord with the previous studies (Listow et al., 2009; Yfanti et al., 2010). The vitamin C supplementation alone induced no significant changes in fasting plasma glucose and insulin concentration and HOMA-R. Conclusion This study indicates that more prominent training-induced improvement of glucose metabolism is induced with vitamin C supplementation. The finding suggests that ROS produced during training session has suppressive effect on training-induced improvement of glucose metabolism. References M. Ristow, K. Zarse, A. Oberbach, N. ## PROTEIN SUPPLEMENTATION DOES NOT FURTHER INCREASE STRENGTH AND HYPERTROPHIC MUSCLE RESPONSE TO RESISTANCE TRAINING IN HEALTHY ACTIVE YOUNG SUBJECTS.

Paoli, A.1, Pacelli, F.Q.1, Cancellara, P.1, Toniolo, L.1, Moro, T.1, Canato, M.1, Miotti, D.2, Neri, M.3, Morra, A.4, Quadrelli, M.4, Reggiani, C.1

1: Dept. of Biomedical Sciences – University of Padova, Italy; 2: Salvatore Maugeri Foundation, Pavia, Italy; 3: ALFeM – Ravenna, Italy. 4: Euganea Medica, Diagnostic Centre, Albignasego (PD), Italy

**Introduction** It is well known that regular resistance training (RT) increase muscle mass through several and complex mechanisms that involve also nutritional factors. Even if protein supplementation is widely used by athletes involved in strength based sports and by body builders the researches on the effects of this practice on muscle hypertrophy are somewhat contradictory<sup>1,2</sup>. The aim of our study was to compare the effects of normal protein diet (NP=0.85 g·kg<sup>-1</sup>·day<sup>-1</sup>) or high protein diet (HP=1.8 g·kg<sup>-1</sup>·day<sup>-1</sup>) on strength, total muscle CSA and single muscle fiber CSA. **Methods** Eighteen undergraduate students underwent to a resistance training for 2 months. Subjects were randomly assigned to NP or HP diet protocol. Strength dynamic (lat pulldown) and isometric (isometric pullgrip) tests were performed before and after the training period. Moreover latissimus dorsi muscle samples were obtained via fine needle muscle biopsy to investigate muscle fibers CSA. Magnetic Resonance (MRI) was also performed to measure whole muscle CSA. Results Our results showed that training induced a significant gain in strength in all subjects both in dynamic (+ 17%; p<0.001) and isometric (+6%; p<0.05) tests. The increase in muscle strength was accompanied by a significant (p<0.05) hypertrophic response detectable in whole muscle (from 45.13±3.3 cm<sup>2</sup> to 47.94 ±4.4 cm<sup>2</sup>) and single muscle fibres (CSA measurements, from 4787±2810 μm<sup>2</sup> to 5846±3780 μm<sup>2</sup>). No significant differences were been detected between diet groups. **Discussion** Our data suggests that, in young healthy subjects, RT elicits an upper limbs hypertrophic muscle response comparable to those reported for lower limbs, whilst protein supplementation seems to does not further increase muscle response to RT. ## EFFECT OF LEUCINE SUPPLEMENTATION ON BODY COMPOSITION IN DETRAINED RATS SUBJECTED TO CALORIC RESTRICTION

Nishimura, L.S., Pedroso, J.A.B., Matos-Neto, E.M., Moreira, R.L.L., Pires, I.S.O., Tirapegui, J.  
University of São Paulo

**Introduction** Physical detraining (PD) is associated with increased fat mass, body weight gain and changes in protein metabolism, accelerating muscle catabolism. One of the nutritional strategies used to minimize the increase in adipose mass is caloric restriction (CR). However, this strategy may potentiate the loss of muscle mass, as observed in PD. To mitigate these changes, there is supplementation with essential amino acids, particularly leucine. This seems to act effectively to promote protein balance and body fat reduction. Thus, this study aimed to evaluate the effect of leucine supplementation on body composition in detrained rats subjected to CR. **Methods** 48 adult male Sprague-Dawley rats were distributed into 2 groups: Sedentary (SED, n = 8) and Trained (TRAIN, n = 40); the animals of the latter group underwent training on a treadmill for 8 weeks. TRAIN animals were then re-distributed into four groups: Trained (TRAIN, n = 8): which continued following the physical training protocol; Detrained (DT, n = 8): consisting of animals who stopped training and had access to food ad libitum; Detrained + Caloric restriction (CR + DT): consisting of animals who stopped training and consumed 70% of DT caloric intake; Detrained + Leucine + Caloric restriction (CR + DT + LEU): composed of animals who stopped training and consumed 70% of DT caloric intake, and had 5% leucine supplementation. After 14 weeks the animals were euthanized and body composition was assessed using chemical carcass analysis. Throughout the experiment, body weight and food consumption were assessed weekly. Values are expressed as mean ± standard deviation. ANOVA was used for comparison between groups, along with Scheffé test, considering a 5% significance level. **Results** After 6 weeks of PD, a statistically significant difference was observed in the final body weight between groups TRAIN and DT (p <0.05). Regarding body composition, a statistically significant difference was observed between groups DT and CR+DT in fat-free mass (DT: 541,7g; CR+DT: 463,1g). A statistically significant difference was also observed in fat in groups CR+DT (16,08g) and CR+DT+LEU (15,98g) compared to other groups (SED: 61,46g; TRAIN: 39,98g; DT: 56,16g; DT + LEU: 44,87g). No statistical difference was observed in fat-free mass (g) and absolute protein (g) in the group supplemented with leucine. **Conclusion** Leucine supplementation was not effective to minimize the loss of lean body mass in the detrained animals subjected to caloric restriction.

## ACUTE EFFECT OF HMB SUPPLEMENT OF BONE MODULATING CYTOKINES AND DOWNSTREAM PROTEIN EXPRESSION: A PILOT STUDY

Hung, W.1, Li, S.H.2, Lin, C.L.2, Fang, S.H.1, Chang, C.K.1

1: National Taiwan University of Physical Education and Sport. 2: Chung Shan Medical University

**Introduction** Dietary supplement of β-hydroxy-β-methylbutyrate(HMB) had been proven to increase total bone mass, bone mineral density and bone strength in animal studies. In our previous study, HMB supplement not only increase bone formation but also inhibit bone resorption. The balance between osteoclast and osteoblast activity is central for maintaining the integrity of bone homeostasis. Result of our previous study indicates that HMB supplement regulates bone homeostasis in an un-coupled manner while the molecule transduction mechanism remains unknown. Therefore we designed presented to investigate the acute effect of HMB supplement within a week on noble bone modulating cytokines osteoprotegerin (OPG), RANKL and downstream protein DC-STAMP expression. **Methods** Young college male aged 20-24 who previous inexperience with ergogenic aids usage were recruited as subject of present study. All subjects ingest 3g of HMB supplement per day as previous described[1]. Blood sample were collected through venopuncture at 1, 2, 3, 6, 9, 12hours after first HMB supplement and early morning fasting blood sample were collected in the following 7 days. Circulating OPG and RANKL level were determined by ELISA. DC-STAMP and RANK protein expression were analyzed by Flow cytometry. **Results** RANKL level increased for nearly 2.5-5 fold within 2 hours after first HMB supplement and return to previous level 11 hours after supplement while OPG level remain stable during the same period. RANK expression increased within 2 hours after first supplement and remains higher than baseline level until 6th day. DC-STAMP expression was decreased 24hours after supplement. **Discussion** HMB increase osteoclastogenetic cytokine RANKL level within hours after supplement but downstream DC-STAMP protein expression were blocked. DC-STAMP has been proven to be essential for cell-cell fusion and maturation of osteoclast progenitors[2]. Decreased DC-STAMP expression also indicates decreased osteoclastogenesis and bone resorption. HMB supplement decreased bone resorption in a cellular manner while mechanisms of blocking DC-STAMP expression require further investigation. References 1. Vukovich, M.D., et al., beta-hydroxy-

beta-methylbutyrate (HMB) kinetics and the influence of glucose ingestion in humans. *J Nutr Biochem*, 2001. 12(11): p. 631-639. 2. Yagi, M., et al., DC-STAMP is essential for cell-cell fusion in osteoclasts and foreign body giant cells. *J Exp Med*, 2005. 202(3): p. 345-51.

### **FISH OIL ENHANCES MUSCLE STRENGTH AND FUNCTIONAL ABILITIES AFTER RESISTANCE TRAINING IN ELDERLY WOMEN: A PRELIMINARY STUDY**

Kamolrat, T., Thies, F., Gray, S.R.

*University of Aberdeen*

**Introduction** Anabolic resistance of muscle protein synthesis to resistance training (Greig et al., 2011) and nutrition (Guillet et al., 2004) has been proposed as a potential cause of sarcopenia. Fish oil supplementation has been found to increase muscle protein synthesis in response to insulin and amino acids in older adults (Smith et al., 2011) and may improve adaptations to resistance training in older women. However, this needs to be confirmed by results obtained from placebo controlled trials (Rodacki et al., 2012). The aim of the current study was to determine whether fish oil can enhance adaptations in skeletal muscle function after resistance training in elderly women. **Methods** A double-blind randomized placebo-controlled study design was used in this pilot study. Thirteen participants were randomly assigned to receive either 4 g fish oil (containing 1.7 g EPA and 0.4 g DHA) or 4 g control oil (olive oil) daily for 12 weeks. Participants also carried out resistance training twice a week for this period. Plasma profiles (i.e., phospholipid fatty acid composition, glucose, triglycerides, insulin and IL-6), a short performance battery test (Guralnik et al., 2000), and isometric and isokinetic quadriceps muscle strength were determined pre- and post-intervention. Results All baseline measures were similar between groups. Plasma EPA and DPA concentrations significantly increased in the fish oil group, compared with the control (P = 0.01 and P = 0.03 respectively), while insulin resistance, as measured by HOMA-IR, significantly decreased (P = 0.03). Post-intervention, the fish oil group showed a higher isometric muscle strength (change from baseline (N.m): 31.8 ± 8.7 vs. 15 ± 9.6 in fish oil and control group, respectively; P = 0.001) and a greater gait speed (change from baseline (m/s): 0.24 ± 0.12 vs. 0.09 ± 0.11 in fish oil and control group, respectively; P = 0.03) compared with the control group. However, post-intervention, there were no differences in isokinetic muscle strength, balance, chair rise time, or plasma IL-6 and triglycerides concentrations. **Discussion** We have demonstrated that 12 weeks supplementation with 4 g fish oil daily enhance the adaptive responses to resistance exercise and reduce markers of insulin resistance in elderly women. Combined with the data of Smith et al (2011) and Rodacki et al (2012) the present result suggests that fish oil may be beneficial to attenuate age-related loss of muscle mass, strength and function. **References** Greig CA, Gray C, Rankin D, Young A, Mann V, et al. ### **OKARA SUPPLEMENTATION RELIEVES FATIGUE AND MUSCLE DAMAGE THAT OCCUR DURING EXERCISE TRAINING**

Tso, T.K.1, Yang, H.F.1, Huang, C.C.2, Huang, W.N.3

*1National Chiayi University (Taiwan), 2WuFeng University (Taiwan), 3Taichung Veterans General Hospital (Taiwan)*

**Introduction:** Okara, the soybean residue from soy milk production, contains nutrients and functional components such as isoflavones and phytosterols. Previous studies have found that okara has properties beneficial to health, but few studies have conducted human trials in relation to okara. To our knowledge, no research has been conducted on the possibility of okara as a functional ingredient with health-promoting attributes in the field of sports nutrition and medicine. Therefore, the objective of this study was to investigate the effect of okara supplementation on fatigue and muscle damage in university athletes over an exercise training season. **Methods:** A total of 23 male university baseball players aged 18-23 years attending a summer intensive exercise training program completed an 8-week exercise training-okara intervention study. The supervised exercise training program consisted of physical and technical training including warm-up exercises, physical and skill practice, and pre-game competition practice. Okara supplementation in this study was a randomized, double-blind and crossover dietary intervention in which subjects consumed 2 cookies/day containing 10 g of soybean or black soybean okara for a period of 6 weeks with a one-week washout period. Blood was drawn 4 times within an 8-week intervention period for measurements of biomarkers for fatigue and muscle damage. **Results:** The results demonstrated significant differences in blood levels of ammonia, free fatty acids, creatine kinase, myoglobin, and aspartate transferase between baseline and exercise training, indicating that fatigue and muscle damage occurred during exercise training. However, those increased markers of fatigue and muscle damage were significantly decreased after the okara supplementation regardless of whether soybean okara or black soybean okara cookies were consumed. **Conclusion:** This is the first study to demonstrate that okara supplementation is beneficial to university baseball players who experience exercise training-related fatigue and muscle damage. During the eight-week exercise training period in this study, creatine kinase, myoglobin, ammonia, aspartate transferase, and free fatty acids were significantly reduced in all the athletes after okara supplementation. Fatigue and muscle damage occurring during exercise training were both relieved, indicating that okara cookies are feasible sports nutrition supplements.

### **EFFECT OF B-ALANINE SUPPLEMENTATION ON INTERMITTENT HIGH-INTENSITY CYCLING SPRINT PERFORMANCE**

Cheng, C.F.1, Hung, C.H.1, Hsu, W.C.2, Chen, P.H.1

*1: National Taiwan Normal University (Taipei, Taiwan), 2: Taipei Physical Education College (Taipei, Taiwan)*

**Introduction** Carnosine, increased by β-alanine (BA) supplement, may act as a hydrogen ions (H<sup>+</sup>) buffer in skeletal muscle [1]. The heavy accumulation of H<sup>+</sup> naturally incurred during intermittent high-intensity sprint (IHIS) may interfere with muscle contraction and decrease power production [2, 5]. Therefore, this study examines the effect of BA supplement on pH buffer and IHIS performance. **Methods** Twenty-two athletes were recruited in the pre-season period, and randomly assigned to BA (n = 11, age 19 ± 1 years, height 176 ± 4 cm, weight 68 ± 5 kg) or placebo (n = 11, age 19 ± 2 years, height 176 ± 4 cm, weight 70 ± 6 kg) group. Before and after a 4 weeks supplement (6.4 g/day of BA or cellulose), participants performed the IHIS test (10 × 10-s sprint, 60-s rest interval) with a given load derived from body mass (BM) on a cycling ergometer to determine the effects of BA on peak (POpeak) and mean (POmean) power, and performance decrements (% fatigue). The blood samples were obtained before and after IHIS test to measure the blood lactate (La) and pH levels. **Results** No significant changes in BM were found in both groups. No significant time × group interactions were observed in total work, % fatigue, and average POpeak and POmean. There were significant main effects in average POpeak (pre vs. post, 863 ± 19 W vs. 928 ± 21 W) and average POmean (pre vs. post, 712 ± 14 W vs. 732 ± 14 W) by time in both groups. From the start to the end of the IHIS test, the La concentrations increased from ~1.1 to ~13.9 mmol/L (P < 0.05), whereas pH dropped from ~7.40 to ~7.18 (P < 0.05). However, La and pH values

were identical between groups, either in the pre-testing or in the post-testing. Discussion The ergogenic effects of BA supplement are evident in activities that elicit a strong intramuscular acidotic condition [1]; however, Sale et al. [4] found that BA supplement could not attenuate the decreased pH levels during high-intensity cycling exercise. The present study could not provide support for the improvements in IHL performance after BA supplement, which is in line with other studies [3, 5]. The training effects, increases in power output after supplement, may mask the ergogenic potential of BA. The BA supplement could neither offer protection against the fall in pH values nor improve the IHL performance. Further research on the effect of BA supplement on the intermittent-based exercise is necessary. Supported by grants from National Science Council, Taiwan (NSC 101-2410-H-003 -133). References 1. ### COMBINATION OF $\alpha$ -GLYCEROPHOSPHOCHOLINE ( $\alpha$ -GPC) INTAKE AND AEROBIC EXERCISE ENHANCES GROWTH HORMONE SECRETION AND FAT METABOLISM IN YOUNG ADULTS

Sato, K., Fujie, S., Fujita, S., Okubo, T., Hamaoka, T., Iemitsu, M.

*Ritsumeikan University*

**BACKGROUND:** Choline is an important nutrient, which relates to cholinergic neuronal action as well as fat and cholesterol metabolism. Since choline is not synthesized in vivo, it needs to be ingested from food, such as beans and eggs. Recently, we demonstrated that a single dose of  $\alpha$ -Glycerophosphocholine ( $\alpha$ -GPC) enhances growth hormone (GH) secretion and hepatic fat oxidation, with concomitant increases in choline levels, in young adults (Kawamura, et al. *Nutrition* 2012). Additionally, a single bout of exercise increases fat metabolism with GH secretion. However, the effect of  $\alpha$ -GPC administration and exercise combination on growth hormone secretion and fat metabolism in young adults remains unclear. **PURPOSE:** The purpose of this study was to clarify whether the combination of  $\alpha$ -GPC administration and exercise enhances growth hormone secretion and fat metabolism in healthy young men. **METHODS:** Nine healthy young men (23 $\pm$ 1 years) performed treadmill walking exercise for 30 min at a speed of 95m/min after 30 min  $\alpha$ -GPC 1000 mg or a placebo administrations in a double-blind randomized crossover study. Respiratory quotient (RQ) and fasting blood samples were obtained before the administration of  $\alpha$ -GPC and 30 (before exercise), 60 (immediately after exercise), 90 (30 min after exercise), 120 (60 min after exercise) and 180 (120 min after exercise) min after administration. All subjects repeated the identical protocol using the placebo. **RESULTS:** Plasma total choline levels significantly increased at 60 and 180 min after  $\alpha$ -GPC administration. Area under the curve (AUC) of plasma GH level for 180 min after  $\alpha$ -GPC administration was increased significantly as compared with the placebo intake. Furthermore, AUCs of serum FFA, glycerol, acetoacetate and 3-hydroxybutyrate levels for 180 min after  $\alpha$ -GPC administration were increased significantly as compared with the placebo intake. Additionally, RQ for 90-180 min after  $\alpha$ -GPC administration, i.e., 30-120 min after exercise, were significantly decreased compared with the placebo intake. No significant change in plasma glucose level was observed in either group. **CONCLUSION:** These findings suggest that the combination of  $\alpha$ -GPC administration and walking exercise may be effective in enhancing GH secretion and fat metabolism in healthy young men rather than a single bout of exercise or  $\alpha$ -GPC administration. **REFERENCES:** Kawamura T et al. *Nutrition* 28, 1122-1126, 2012. **GRANTS:** Supported by KAKENHI of the Japan Ministry of Education, Culture, Sports, Science and Technology (MI and KS).

### THE EFFECTS OF CREATINE SUPPLEMENTATION DURING RESISTANCE TRAINING ON STRENGTH AND BODY COMPOSITION IN OLDER ADULTS - A META-ANALYSIS

Devries, M.C., Phillips, S.M.

*McMaster University*

**Introduction** Age-related sarcopenia has negative effects on muscle strength and the ability to perform activities of daily living, thus affecting quality of life. Regimes that retain or increase muscle mass and strength are of importance to the aging population. Resistance training (RT) increases muscle mass and strength in older adults and various supplements may augment this effect. However, whether the addition of creatine (Cr) supplementation enhances the gains in muscle mass and strength in this population is controversial. We aimed to determine whether the addition of Cr to a RT regime increased gains in muscle mass and strength in older adults over RT alone by conducting a systematic review and meta-analysis. **Methods** Pubmed and OVID Healthstar databases were searched. Randomized, placebo (PL) controlled trials that involved older adults supplemented with Cr and included RT regimes of at least 6 wk were included. Eight qualifying studies were identified. Anthropometric measures were reported in 4 - 6 trials. Changes in single repetition maximum (1RM) for leg press, chest press and knee extension were reported in 4 trials. Changes in isokinetic and isometric strength were reported in 3 and 4 trials, respectively. Data were analyzed using random effects meta-analysis and tested for publication bias (funnel plot) and heterogeneity (Cochrane's Q, I<sup>2</sup>). **Results** The meta-analysis comprised 234 subjects (Cr: age 62.1 $\pm$ 4.3; PL: age 62.8 $\pm$ 4.7 years) with 13.7 $\pm$ 0.7 wk of RT. There was no effect of Cr+RT over RT alone on any measure of body composition. Overall the Cr+RT vs RT alone increased leg press, chest press and leg extension 1 RM by 23.1 $\pm$ 3.7% vs. 21.6 $\pm$ 2.8; 25.6 $\pm$ 4.4% vs. 21.6 $\pm$ 3.6% and 34.2 $\pm$ 5.8% vs. 30.5 $\pm$ 5.5% respectively. There was no effect of Cr+RT over RT alone on leg press, chest press or leg extension 1RM (standard difference in means  $\pm$  SE: 0.247 $\pm$ 0.199, P = 0.215; 0.287 $\pm$ 0.208, P = 0.168; and 0.248 $\pm$ 0.209, P = 0.235, respectively). There was no effect of Cr+RT over RT alone on isokinetic (0.140 $\pm$ 0.172, P = 0.415) or isometric (0.200 $\pm$ 0.160, P = 0.211) strength. **Discussion** Overall there was no added effect of the addition of Cr to a RT regime on body composition or strength measures in older adults. While this meta-analysis includes data from 234 subjects, not all trials reported on all outcomes of interest. In fact, changes in 1 RM were based on data from only 4 qualifying trials that included 102 subjects. As retention of muscle mass is integral to healthy aging, further work investigating nutritional and exercise strategies, including Cr, to maintain or increase muscle mass during the lifespan are needed before Cr supplementation could be recommended for older adults engaging in RT.

### INFLUENCE OF CAFFEINE AND SODIUM CITRATE INGESTION ON 1500 M WHEELCHAIR PERFORMANCE

Flueck, J.L.1,3, Mettler, S.2, Perret, C.3

1: *Institute of Human Movement Sciences and Sport, ETH Zurich*, 2: *Swiss Federal Institute of Sports Magglingen* 3: *Swiss Paraplegic Centre, Institute of Sports Medicine, Nottwil*

**Introduction:** The influence of sodium citrate (SC) and caffeine (CA) ingestion on high-intensity exercise performance is well-documented in able-bodied athletes (Burke, 2008; Requena et al., 2005). However, there are no data available from wheelchair athletes. As spinal cord

injured subjects often suffer from gastrointestinal deceleration influencing absorption and effect of supplementation, data from able-bodied subjects can't be transferred to wheelchair athletes one-to-one. The aim of this study was to investigate whether a supplementation with CA, SC or the combination of CA and SC (COM) has an ergogenic effect on 1500 m time trial performance in elite wheelchair athletes. Methods: Nine healthy, elite (6 men and 3 women) wheelchair racing athletes (median [min, max]: age: 28 y [23; 54]; height: 173 cm [165; 188]; weight: 62.9 kg [48.9; 68.4]), including several Paralympic Games, World and European Championships medalists, participated in this study. A placebo-controlled, randomized, crossover and double-blind study design was employed. Subjects completed four 1500 m time trials (placebo, CA, SC or COM) on a wheelchair training roller. Time to complete 1500 m, pH, plasma bicarbonate, sodium and lactate concentrations were measured. Results: Time to complete the 1500 m time trial was not significantly different between the four treatments (median for placebo: 170.57 s [141.69; 231.95]; CA: 179.53 s [134.77; 239.61]; SC: 178.32 s [136.40; 247.04]; COM: 177.58 s [136.14; 256.18]). Plasma bicarbonate concentration and pH significantly increased after SC and COM trials compared to placebo and CA. Maximal lactate concentrations were significantly higher in CA and COM compared to placebo. Five of nine subjects suffered from gastrointestinal side effects after SC or COM supplementation. Discussion: In contrast to data from able-bodied athletes, supplementation with SC and/or CA did not show ergogenic properties on 1500 m time trial performance in elite wheelchair athletes. Although SC was absorbed and increased prestart blood bicarbonate concentration, this did not result in improved performance. As data showed some individual variability in response (enhanced performance vs. gastrointestinal side effects), we suggest individual practical considerations (compatible supplement, dosage, intake time) for every athlete. ### THE EFFECT OF BETA ALANINE SUPPLEMENTATION ON REPEATED BOUTS OF HIGH INTENSITY EXERCISE PERFORMANCE IN BOTH NORMOXIC AND HYPOXIC CONDITIONS

Hodkinson, R., Brickley, G.

*UNIVERSITY OF BRIGHTON*

Introduction  $\beta$ -alanine supplementation is a relatively new intervention in sport with few studies published on its effect on high intensity exercise (Hobson et al., 2012) and less on its effect on exercise in hypoxia.  $\beta$ -alanine supplementation has been shown to increase muscle carnosine which has been found to be an effective intracellular buffer during exercise (Harris et al, 2012). The aim of this study was to determine the effect on performance during repeated bouts of high intensity exercise in both normoxia and hypoxia following  $\beta$ -alanine supplementation. Methods Following baseline testing, 14 active participants (Mean  $\pm$ SD; age: 22  $\pm$ 2 yr, height: 179  $\pm$ 8cm, body mass: 79.2  $\pm$ 12.9kg) completed four weeks of supplementation of 5g.d-1 of either beta-alanine (treatment) or L-alanine (placebo). A randomised double blind trial was performed in which participants completed a high intensity exercise protocol (HIT) in normoxic and hypoxic (0.14) oxygen conditions before and after supplementation. HIT consisted of three isokinetic sprints of 6, 30 and 180 seconds on a SRM cycle ergometer interspersed with bouts of three and five minutes of active recovery at 50W. Peak and mean power outputs were calculated for each sprint in every trial, as well as the mean end power (last 30s) of the 180s effort. Heart rate, arterial oxygen saturation and blood lactate concentration were also recorded. Results In the treatment group mean power and end power of the 180s in hypoxia increased ( $p < 0.05$ ) 5.7% and 14.2% respectively after supplementation, from 240.6  $\pm$ 24W to 254 $\pm$ 29.4W and from 172.9  $\pm$ 17.9 W to 197.4 $\pm$ 30.8W. The peak power of the 180s effort in normoxic conditions in the treatment group increased 9.8% from 789.1 $\pm$ 146.1W to 866.1 $\pm$ 179.9W ( $p < 0.05$ ). There were no differences observed in power output after supplementation in the placebo group ( $p > 0.05$ ). There was no differences found in heart rate, arterial oxygen saturation or blood lactate concentration after supplementation in either treatment or placebo groups ( $p > 0.05$ ). Discussion The increase in mean power and end power of the 180s effort after  $\beta$ -alanine supplementation in hypoxia and not normoxia, may be explained by the increase in oxidative stress. The elevated carnosine content in skeletal muscle through supplementation may have improved performance by improving intracellular buffering capacity, increased Ca<sup>2+</sup> sensitivity and interacting with free oxygen species formed during exercise (Harris and Sale, 2013). Future research should consider changes in muscle metabolism following  $\beta$ -alanine supplementation and the addition of hypoxic exposure as a training stimulus. References Harris, R C, Sale, C. (2013). Acute Topics in Sport Nutrition, p1-17. Harris, R C, Wise, J A, Price, K A, Kim, H J, Kim, C K, Sale C. (2012). Amino Acids, 43 (1) p5-12. ### THE EFFECT OF DIETARY NITRATE SUPPLEMENTATION ON PHYSICAL PERFORMANCE IN HYPOBARIC HYPOXIA

Limmer, M., Platen, P.

*Ruhr-University Bochum*

Introduction Exercise under hypoxic conditions is associated with impaired exercise tolerance. Dietary nitrate intake has been shown to improve or at least restore exercise tolerance in normobaric hypoxia. The present field study examined the effects of dietary nitrate supplementation in hypobaric hypoxia during a typical sojourn at high altitude on exercise performance and exercise related blood and urine parameters. Methods 18 healthy, moderately trained subjects (n=12 males; n=6 females) were exposed to hypobaric hypoxia (HH) during a climb of Mt Kilimanjaro (Tanzania) up to 5739 m above sea level for 7 days. Subjects were randomly selected into two groups according to their individual  $\dot{V}O_{2max}$  and consumed daily either 0.07 L of nitrate-rich concentrated beetroot juice (6.2 mmol of NO<sub>3</sub><sup>-</sup>; BR) or 0.07 L of nitrate-depleted concentrated beetroot juice as placebo (0.0047 mmol of NO<sub>3</sub><sup>-</sup>; PL) starting two days before HH. Uric acid (UA) and urea (U) were analyzed to determine metabolic stress and creatine kinase (CK) for muscle stress in blood serum at the 4th and 7th day of HH and post HH. Urinary urea (UU) was measured daily in 24hr urine samples. Anaerobic performance was assessed by the skipped frequency (SF) and the maximal lactate production rate ( $\dot{V}L_{max}$ ) when performing 15-seconds skipping tests to maximal exertion pre, during (2nd and 5th day of HH) and post HH. Maximum hand grip strength (GS) and hand grip endurance (GE) were measured pre, during (4th day of HH) and post HH. The Lake Louise Score (LLS) was used to indicate symptoms of acute mountain sickness (AMS). Data was analyzed using repeated measured ANOVA, Students t-test, Friedman- and Mann-Whitney-test. Results Values of UA, U and UU were within the reference range for all test days whereas CK was above the reference range in PL (m: 565  $\pm$  344, 406  $\pm$  283, 291  $\pm$  155 U/L; f: 219  $\pm$  104, 201  $\pm$  89, 198  $\pm$  71 U/L) but not in BR. Furthermore, CK decreased continuously during the test period (m: 426  $\pm$  279, 339  $\pm$  227, 254  $\pm$  119 U/L; f: 212  $\pm$  75, 170  $\pm$  77, 165  $\pm$  74 U/L). There were no differences between BR and PL for SF,  $\dot{V}L_{max}$ , GS and GE. PL showed slightly higher values in LLS compared to BR. Discussion and Conclusion Dietary nitrate intake during a typical mountain climb to high altitude did not influence exercise performance or metabolic stress. Muscle stress, however, seemed to be reduced by dietary nitrate during long-lasting trekking exercise at high altitude. This was accompanied by a slightly higher perceived rate of symptoms of AMS. Conclusively, we could not find a direct improvement of anaerobic exercise performance and muscle strength but indications for an improved muscular tolerance of long-lasting exercise at hypobaric hypoxia under dietary nitrate intake.

## CARBOHYDRATE-LOWERING EXERCISE REDUCES ANAEROBIC CONTRIBUTION AND IMPAIRS CYCLING TIME-TRIAL PERFORMANCE

Cavalcante, M.

*University of Sao Paulo*

**Introduction** Some studies (Miura et al., 2000; Langfort et al., 1997) have shown that performance during high-intensity exercise is impaired after a carbohydrate (CHO)-lowering protocol due to a lower overall anaerobic contribution (AC). However, the influence of CHO-lowering exercise on time trial (TT) performance has not been verified. This would be important since TT appears to be more reliable and to have greater external validity (Atkinson et al., 2007) compared to constant-workload tests until exhaustion. Therefore, the purpose of this study was to examine the effect of CHO-lowering exercise on AC and performance during a 4-km cycling TT. **Methods** Eight amateur cyclists performed two 4-km cycling TT using a cycling simulator. The trials were performed either after a CHO availability-lowering exercise protocol (DEP) or no previous exercise (CON). Time, mean power output (PO), RPE and plasma lactate were compared between treatments using a paired t-test. ANOVA (treatment x distance) followed by a Bonferroni adjustment was used to examine differences in PO and AC. Post-hoc comparisons were made using a paired Student's t-test. **Results** The time and PO were impaired (2.5 and 8.4%, respectively) in DEP compared with CON ( $P < 0.05$ ). The PO was less at 400, 2800 and 3200m in DEP than in CON ( $P < 0.05$ ). When PO values were analysed for each 1-km interval, it was verified a reduction in DEP just in the first 1 km, compared to CON ( $P = 0.04$ ). Overall AC was reduced (16.9%) in DEP compared with CON ( $P = 0.027$ ). The AC was lower in DEP than CON at 400m ( $P = 0.041$ ), and there was a tendency ( $P = 0.065$ ) at first 1 km. There was no significant difference in RPE and plasma lactate between treatments ( $P > 0.05$ ). **Discussion** The reduction in the PO at the first 1 km suggests that athletes adopted a more conservative starting pacing strategy after a CHO-lowering exercise. Furthermore, overall AC and performance were impaired in DEP. These results are consistent with those reported previously by Langfort et al. (1997), who showed that after three days of a low-CHO diet (~ 5% CHO) the mean PO during a 30-s Wingate test was reduced, compared with a normal diet (~ 50% CHO). Similarly, Miura et al. (31) found a reduction in the overall AC when exercise was performed after a muscle glycogen-depletion-protocol. Thus, our results suggest that CHO-lowering protocol impairs TT performance due to a reduction in the AC. **References** Atkinson G, Peacock O, Gibson AS, Tucker R. ##### ACUTE EFFECTS OF CYCLING EXERCISE ON BRACHIAL ARTERY SHEAR RATE PATTERNS IN HEART FAILURE PATIENTS

Benda, N.M.M.1, Seeger, J.P.H.1,2, Hopman, M.T.E.1, Thijssen, D.H.J.1,2

*1. Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands 2. Liverpool John Moores University, Liverpool, United Kingdom*

**Introduction** Exercise training plays a central role in the treatment of heart failure (HF) patients, at least partly through improvements in vascular function. Exercise-induced shear rate patterns are a potent stimulus for vascular adaptations. However, the presence of endothelial dysfunction as well as impaired thermoregulation may alter the shear rate stimulus during exercise in HF. Therefore, we examined the effect of cycling exercise on vascular shear rate in HF patients and healthy controls. **Methods** Brachial artery shear rate was continuously measured using echo-Doppler during a bout of continuous moderate-intensity cycling exercise at 65% of maximal load in HF patients ( $n=9$ ,  $61 \pm 9$ yr) and healthy controls ( $n=9$ ,  $22 \pm 1$ yr). As cycling exercise-induced changes in brachial artery shear rate may relate to thermoregulatory changes, we continuously measured forearm skin temperature using portable thermistors. **Results** Leg exercise immediately increased antegrade shear rate in both groups, but more rapid and more pronounced in controls than in HF patients ( $P=0.006$ ). Brachial artery retrograde shear rate initially increased in both groups. Subsequently, retrograde shear rate returned towards baseline levels in controls within 20 minutes, whilst increased retrograde shear persisted in HF patients ( $P<0.001$ ). Forearm skin temperature increased in controls during exercise, which coincided with the normalization of retrograde shear, whilst HF patients showed no change in forearm skin temperature ( $P<0.001$ ). **Discussion** Compared with healthy controls, HF patients have a persistent increased retrograde shear rate during moderate-intensity cycling exercise, combined with an absent skin vasodilation. The prolonged presence of the pro-atherosclerotic retrograde shear, but also the distinct thermoregulatory responses, may alter the immediate impact of exercise training on the vasculature.

##### HEART RATE OF A PROFESSIONAL BULLFIGHTER DURING HIS PERFORMANCE IN TRAININGS AND REAL BULLFIGHT

Zafrilla, V.M.1, Terrados, N.2, Tejero-González, C.M.1

*(1) Facultad de formación de profesorado y educación-Universidad Autónoma de Madrid, (2) Unidad Regional de Medicina Deportiva del Principado de Asturias-Universidad de Oviedo (Oviedo, Spain).*

**Introduction** The bullfighter professional activity involves many hours of physical activity in either training or real bullfights. In fact, the professional standards of bullfighting entail the need for adequate physical preparation. In this regard, bullfighting has been considered as a sport or an artistic activity. However, research on the physiological demands of bullfighters activity is very limited. The aim of this study was to analyze the heart rate (HR) of a professional bullfighter during three characteristics stimuli of his professional work, to know the cardiac demand of this professional activity. **Methods** A professional bullfighter volunteered to participate in this study. We recorded HR, in 24 situations with fierce animals divided equally into 3 types of activity: training with wild cows, training with wild bulls and bullfights with public presence. HR was recorded by means of Polar Team2Pro® from the first contact with the animal until the last action. Descriptive statistics were analyzed with IBM SPSS Statistics 20. Previously, the bullfighter underwent a maximal exercise test on a treadmill, to get maximum heart rate (MaxHR), aerobic threshold (AeT) and anaerobic threshold (AT). **Results** The mean HR in trainings with

cows was 136bpm (74% MaxHR) being 35% of bpm above the AeT and 5% above the AT. In trainings with bulls, the mean HR was 157 bpm (85% MaxHR) being 73% of bpm above the AeT and 36% above the AT, while in real bullfighting the mean HR was 164 bpm (89% MaxHR) where the 79% of bpm were above the AeT and 61% of AT. Discussion This is the first study about the cardiac demand during real bullfighting. Emotional factors related to the presence of public, like anxiety and stage fright are inherent to the professional activity of bullfighters for regarding the real physical load in this activity(1). We have observed that this bullfighter present a heightened HR while he acts in bullfighting and in training with bulls, much greater than in trainings with cows, corresponding to heavy work, or very heavy in bullfight (2). ### **BRADYCARDIA DURING COLD FACE TEST AND CARDIOVASCULAR DISEASE RISK FACTORS IN SWIMMERS AND CONTROLS**

Konishi, M.1, Kawano, H.1, Gando, Y.1, Matsuda, M.2, Sakamoto, S.1, Higuchi, M.1

1: Waseda University, 2: Waseda University

**Introduction** Cold face test is a non-invasive challenge maneuver of the autonomic nervous system used to assess vagal activity (Heath et al., 1990). Although physical training improved vagal activity measured by heart rate variability (Amano et al., 2001), previous study has shown that physical training did not affect bradycardia during the cold face test (Schagatay et al., 2000). However, that study has limitations that the training term was short and that the participants were not athletes. Therefore, we compared bradycardia during the cold face test and cardiovascular disease risk factors between swimmers and controls. **Methods** Twenty two males participated in this study. The control group consisted of 12 male participants, 18-27 years of age, selected from university students, physically active, but non-athletes and non-swimmers. The swimmer group was composed by ten male swim-athletes, 20-21 years of age, who trained more than six years. The cold face test was performed in all participants in the sitting position with face immersion in cold water (3-5 degree) and apnea for 30 seconds. R-R intervals were recorded before and during the cold face test. Maximal oxygen consumption was assessed during an incremental cycle ergometer test, and pulse wave velocity (PWV) was examined at rest as cardiovascular disease risk factors. **Results** Both the swimmers and controls showed a heart rate reduction during the cold face test from baseline (swimmers:  $35.6 \pm 9.4\%$ , controls:  $22.8 \pm 8.1\%$ , mean  $\pm$  standard error,  $P < 0.01$ ). However, the rate of heart rate reduction and maximal R-R interval during the cold face test did not differ between groups. Maximal oxygen consumption was significantly higher ( $P < 0.05$ ) and PWV was significantly lower in the swimmers than in the controls ( $P < 0.01$ ). **Discussion** We found that the chronic physical training is negatively associated with arterial stiffness in young males, which is consistent with previous study (Otsuki et al., 2007). However, we did not observe the difference of bradycardia during the cold face test between the swimmers and controls. Therefore, the present study suggests that the swimming training may attenuate arterial stiffening but not affect bradycardia during the cold face test. **References** Amano M, Kanda T, Ue H, Moritani T. ### **PHYSICAL DEMANDS OF FOOTBALL ASSISTANT REFEREES IN UNIVERSITY-LEVEL MATCHES**

Ishihara, Y., Naito, H., Yoshimura, M.

*Juntendo university*

**Introduction** A number of studies have revealed physical and physiological demands of football field and assistant referees in professional matches (Krustrup et al., 2009; Mallo et al., 2009). These variables such as movement distance and speed, heart rate (HR) and rate of perceived exertion (RPE) imposed on football referring at lower match levels have yet to be thoroughly examined. We previously reported the physical demands of field referees in Japanese University-level matches. This study is an extension of our previous effort and aimed to investigate physical demands of assistant referees using the same matches observed. **Methods** Eleven male football assistant referees, who were accredited by Japan Football Association with the 2nd-class licence, were studied during Kanto region University football league in 2011. The observed variables representing their physical demands included movement distance and speed (GPS, Gpsports, Australia), HR (Polar T31, Polar, Finland) and RPE. Based on the recorded speed, their movements were classified into the following categories in conformity with the literature i) walking:  $\leq 6$  km/h, ii) jogging: 6-8 km/h, iii) low speed: 8-12 km/h, iv) moderate speed: 12-15 km/h, v) high speed: 15-18 km/h, and vi) sprinting:  $\geq 18$  km/s. The high-intensity running (HIR) was defined as the speed greater than 15 km/h (v and vi). The distance was calculated for each movement category, and the number of running bouts above HIR also counted. RPE was assessed after the completion of each match. **Results** The mean total distance covered throughout the match was  $6.65 \pm 0.53$  km, with walking accounting for the largest percentage (40 %), while HIR covering 20 % of it. The number of HIR bouts was  $29 \pm 10$  times throughout the match with no significant difference in number between halves. Mean HR and end-match RPE were  $140 \pm 16$  bpm ( $73 \pm 7.6\%$  HRmax) and  $13 \pm 2$ , respectively. **Discussion** Physical demands imposed on the assistant referees in Japanese University-level matches resembled those of FIFA top-level assistant referees (Krustrup et al., 2009; Mallo et al., 2009). The main movement pattern of assistant referees can be described as repeated brief high-intensity running (each lasting for 3-4 s) interspersed with 1-3 min of walking or low activity. However, as compared with the field referees that we examined previously, the assistant referees were required low physical demands, which well supports the earlier findings employing FIFA top-level field and assistant referees. To summarize, physical demands of assistant referees in Japanese University-level matches are similar to those in international matches, and exhibit need for intermittent anaerobic efforts and agility to keep up with play. **References** Krustrup et al. (2009). *J Sports Sci*, 27 (11): 1167-1176. Mallo et al. (2009). *Int J Sports Med*, 30: 331-336.

### THE EFFECT OF 16 WEEKS OF ENDURANCE TRAINING ON HEART RATE VARIABILITY IN OBESITY AND TYPE 2 DIABETES: A PILOT STUDY.

O'Hagan, C., Rodrigues-Krause, J., Medlow, P., Krause, M., Boreham, C., Davison, G., Collieran, G., Newsholme, P., Murphy, C., De Vito, G.

*Sheffield Hallam University*

**Introduction** Cardiovascular autonomic neuropathy (CAN) is a consequence of Type 2 Diabetes (T2D) which increases risk of mortality (1). Reduced heart rate variability (HRV) can be used as a marker of CAN (2), and reduced HRV has been observed in patients with T2D (3). Exercise training may improve HRV, but studies in T2D are lacking (4). The aim of this study was to investigate the effect of 16 weeks of walking training on HRV in obese patients with and without T2D, and to compare the effects of different training intensities. **Methods** Five obese males with Type 2 Diabetes (T2D; age  $47.6 \pm 5.2$  years, BMI  $33.8 \pm 3.7$  kg.m<sup>-2</sup>) and 18 matched controls (CON, age  $48.6 \pm 5.3$  years, BMI  $31.7 \pm 3.9$  kg.m<sup>-2</sup>) participated in this study. Time-domain parameters of HRV were obtained from ECGs recorded before and after completion of 16 weeks of endurance training (walking, 90 minutes per week) at either low-moderate (LO) or moderate-high (HI) intensity. Data are presented as mean  $\pm$  SD. Results Mean RR Interval (MRR), standard deviation of RR intervals (SDRR) and the root mean square of successive differences in RR (RMSSD) were all lower at baseline in T2D compared to CON; the difference was significant for SDRR and RMSDD (MRR:  $895 \pm 133$  ms vs.  $989 \pm 155$  ms,  $p = 0.219$ ; SDRR:  $2.73 \pm 0.99$  ms vs.  $4.08 \pm 2.3$  ms,  $p = 0.005$ ; RMSSD:  $21.93 \pm 3.92$  ms vs.  $38.20 \pm 20.29$  ms,  $p = 0.005$ ). Post-training data was available for only 13 participants. There was a non-significant increase in MRR from pre- to post-training ( $973 \pm 164$  ms vs  $1017 \pm 150$  ms,  $p = 0.09$ ), with no differences in the responses of CON and T2D. When results for T2D and CON were pooled to allow comparison of the effects of LO and HI training intensities there was a non-significant difference in the change in RMSDD (LO:  $+5.9 \pm 10.6$  ms vs HI:  $-8.06 \pm 13.4$  ms,  $p = 0.058$ ). Interestingly, the number of 'responders' (individuals who recorded increases in measures of HRV post-training) was higher in LO (5 of 6 participants) than HI (2 of 7). **Discussion** The sample sizes for this study were small and data displayed large inter-individual variability, as has been reported previously (5). Nevertheless, the trend for baseline differences between T2D and CON resembles previous observations, supporting a potential role for HRV as a marker of autonomic neuropathy in T2D. The effect of training on HRV in T2D and obesity cannot be determined from these data, and indeed previous research is inconclusive (6). However, as the importance of exercise training in treating other aspects of metabolic and cardiovascular disturbance in T2D and obesity increases, the effect of exercise training on CAN warrants further investigation. **References** 1. ### CROSS-ANALYSIS OF VARIABILITY OF HEART RATE AND DURATION OF BREATHING CYCLE IN ATHLETES

Sukhov, S.

*National Research and Practical Centre of Physical Culture*

**Introduction** One of the most informative methods of study of vegetative nervous system is the spectral analysis of variability of heart rhythm (VHR). Simultaneous recording of breathing cycles (BC) at registering the ECG provides the opportunity for cross-analysis of VHR and variability of duration of breathing cycle (VDBC) to make the assessment of synchronization of these two systems. Goal of the study was to compare the findings of cross-analysis of elite athletes and young male non-athletes. **Methods** Twenty-five elite judoists (experimental group) and fifteen healthy young male non-athletes (control group) have been examined. VHR and VDBC parameters were studied with use of hard- and software complex VNS-Spectrum. Protocol of examination included a 5-minute synchronous registration of ECG and BC with use a respiration sensor. The pneumogram was used for building a histogram of BC duration, which graphically was applied on the spectrogram of VHR. Determination of spectral power of each frequency range of spectrum of heart rhythm was performed in accordance with the International Standard. Assessment of VDBC indicators included the count of histogram columns, determination of position of the mode of histogram, position of the mode of histogram in relation to the spectrogram peak in the area high frequency (HF) component ("D" is a distance between the mode of histogram and peak of HF-component). **Results** The athletes demonstrated 1-2 peaks on BC histogram, while the control group had 2-3 peaks, which evidenced to a better cardiorespiratory synchronization in athletes. In athletes, the distance D did not exceed 0.05 Hz. A slight disorder of cardiorespiratory synchronization was noted in one athlete. While four representatives of the control group demonstrated expressed disorder of synchronization that might be assessed as a deadaptation status. There were registered 4-5 peaks on the BC histogram or a noted divergence between the peak histogram of breathing and peak HF-component of VHR. Loss of coordination of cardiovascular and respiratory systems, impairment of synchronization and decoupling of correlation links are the objective signs of stress and depletion of regulatory systems of the body. Detection of the impaired breathing pattern serves as a ground for respiratory training. **Conclusion** Cross – analysis of VHR and VDBC provides for collecting the information of functional status of athletes, and detecting the fatigue.

### THE HEART RATE DURING SLEEP IS LOWER IN THE NIGHTS AFTER EXERCISE THAN WITHOUT EXERCISE

Ganeko, M.1, Kazama, S.2, Ito, S.2, Inagaki, Y.2, Uchida, S.3

*1&3: Waseda University, 2: Aisin Seiki Co., LTD.*

**Introduction** Recently there have been studies to investigate the effect of exercise on physiological parameters such as EEG, heart rate (HR) and core temperature during sleep. Some studies have showed exercise increased HR during sleep, but these studies mostly examine the effect of one-bout exercise on HR. In this study, we examined the effect of habitual one-year regular exercise on HR during sleep using non-contact sheet type sleep monitor. **Methods** Twenty-three healthy office workers, who hadn't had regular exercise habit participated in the study. They were instructed to do cycling ergometer exercise at home with a goal of 65~73%HRmax(220-age), over 20 minutes a day, more than 4 times per week. They filled out a daily diary of their exercise. A Sheet-type sleep sensor under the bed mattress of each subject was used to monitor HR and respiratory rate during sleep throughout the study period. In addition, we measured subjective sleep quality, mood and physical fitness regularly. **Results** The annual average exercise rate was 3.4 times per week. There was no significant difference in the number of monthly-averaged exercise day. The average HR during sleep was significantly lower in the 6th month than 1st and 9th month. The average HR during sleep was significantly lower in the nights after exercise than without exercise. **Discussion** Although there were significant differences in monthly-average HR during sleep, exercise less than 4 times per week did not have a long-term impact on HR during sleep. But HR during sleep was lower in the nights after exercise than without exercise.

This result indicates that one-bout public health level exercise may decrease HR during sleep. Further studies are needed to examine how different intensity and timing exercise affect following night sleep.

### MAXIMAL HEART RATE DOES NOT LIMIT VO<sub>2</sub>MAX IN HEALTHY PHYSICALLY ACTIVE MEN

Losa-Reyna, J.I, Ponce-González, J.G.I, Torres-Peralta, R.I, Morales-Alamo, D.I, Perez-Suarez, I.I, Calle-Herrero, J.I, Rodríguez-García, L.I, Lundby, C.2, Calbet, J.A.1

1University of Las Palmas, 2University of Zürich

**Introduction** Beta-blockers reduce maximal heart rate (HR<sub>max</sub>) and VO<sub>2</sub>peak because they also reduce contractility and peak cardiac output. In the present experiments we show that healthy humans can reach their VO<sub>2</sub>max despite reducing their maximal heart rate by as much as 9 beats/min. **Methods** Ten healthy young men (age = 21.4 ± 2.1 yr, VO<sub>2</sub>peak = 3.6 ± 0.3 L/min; mean ± SD) performed six incremental exercise test to exhaustion (20W/min). The first two test were performed in random order in normoxia or hypoxia (inspiratory PO<sub>2</sub> (PIO<sub>2</sub>)=74 mmHg) and femoral venous and arterial blood gases were determined. The next four incremental exercise tests were composed of an initial incremental phase in severe hypoxia (PIO<sub>2</sub>=74 mmHg) (HYP1) until exhaustion (Exh1). At Exh1, subjects were strongly encouraged to continue the exercise (HYP2) when at the same time PIO<sub>2</sub> was changed swiftly to either 74 (placebo), 82, 91 or 99 mmHg. After 2 min the load was increased by 20 W/min until exhaustion (Exh2). At Exh2, the PIO<sub>2</sub> was increased to 142 mmHg (normoxia; NX3) and after 2 min of additional exercise, the load was increased by 20 w/min until exhaustion (Exh3). **Results** VO<sub>2</sub>peak was reduced in Exh1 in all tests (-33%, P<0.05) when compared to normoxia. Peak cardiac output (Q<sub>max</sub>) and arterial pressure was similar at exhaustion in Nx, hypoxia (PIO=74 mmHg), and Nx after hypoxia (PIO=74 mmHg) (21.4±2.3, 21.4±2.8, 21.5±1.7 L/min). Peak HR at Exh1 was similarly reduced in all conditions, and remained at this level when changing PIO<sub>2</sub> to 74 (placebo), 82, 92 and 99 mmHg in the HYP2 phases. However, at Exh2 and Exh3 in normoxia the HRpeak was 5-9 beats/min lower than the HR<sub>max</sub> (193±7 beats/min) (P<0.001). Despite this reduction VO<sub>2</sub>max was still reached at Exh3. Consequently, the oxygen pulse was 7% higher at Exh3 than in the control test in normoxia (P<0.05). **Conclusions** Since the reduction in maximal heart rate was without an effect on VO<sub>2</sub>max, Q<sub>max</sub> and systemic O<sub>2</sub> extraction, our results can be only explained if the lower HRpeak was compensated by a larger stroke volume. A greater sympathetic activation of the heart is unlikely at exhaustion with oxygenation since this should have increased heart rate, which remained unaltered with oxygenation. With a similar inotropic state and afterload, the most plausible explanation for our findings is that the slightly greater filling times with a lower HRpeak at Exh3 must have allowed attaining a 10-15 ml greater end-diastolic volume in each ventricle. Thus, it seems that in young healthy humans peak cardiac output is not limited by the achievement of maximal end-diastolic volume implying that peak cardiac output in healthy physical active young humans is unlikely limited by a pericardial constrain. *Granted by DEP2009-11638*

### CARDIOVASCULAR TIME COURSES DURING PROLONGED DRY APNEA IN EXERCISING DIVERS

Sivieri, A.I, Capogrosso, M.I, Donati, S.I, Perini, R.I, Ferretti, G.I,2

1-University of Brescia, Brescia, Italy 2-University of Geneva, Geneva, Switzerland

In static apnea, cardiovascular readjustments are such that, after an initial decrease in heart rate (HR) and increase in blood pressure (BP) (ph I, ~30 s duration), there are ~2 min of steady values (phII). Then HR decreases and BP increases again, up to the end of apnea (ph III), possibly due to chemoreflex activation. We hypothesize that the end of ph II corresponds to physiological apnea breaking point. This being so, in case of increased metabolic rate (M'), duration of phII would be shorter. **METHODS** 8 divers (age 36±7 yrs) performed voluntary maximal apnea: A) sitting at rest; B) pedaling at 30 W on a cycle ergometer. BP (finger photo-plethysmography) and arterial O<sub>2</sub> saturation (SaO<sub>2</sub>; infrared spectroscopy) were continuously recorded before, during and after apnea. M' was measured before and after apnea by a metabolic cart. Beat to beat HR, systolic (Ps) and diastolic (Pd) pressures were obtained. **RESULTS:** A): apnea lasted 227±62 s. In ph I (29±3 s), HR decreased from 98±11 b/min to 82±13 b/min, returning to control values (ctrl), Ps remained equal to ctrl (140±11 mmHg), Pd increased by 14 mmHg above ctrl (70±8 mmHg, p<0.05). In ph II (102±32 s), all parameters were stable, then HR fell to 57±5 b/min, while Ps and Pd increased, respectively, to 215±23 mmHg and 105±16 mmHg after 110±35 s (ph III). SaO<sub>2</sub> was 91±5 % at the end of ph II (p<0.05) and 75±13% at the end of apnea. B): apnea lasted 88±21 s, M' was twice as at rest. During the first 24±7 s (ph a), cardiovascular parameters remained unchanged. HR (112±9 b/min) was 15±10 b/min above exercise steady state values. Ps was 167±15 mmHg and Pd 81±15 mmHg. In the following 64±22 s (ph b), a continuous fall of HR and increase in Ps and Pd occurred. At the end of apnea, HR was 55±10 b/min, Ps 244±24 mmHg and Pd 112±13 mmHg. SaO<sub>2</sub> started to drop after ~30 s of apnea to 76±11% at the end. **CONCLUSIONS:** Apnea at exercise, with higher M', showed different cardiovascular trends from static apnea. The lack of stable cardiovascular values after the first phase a and the steep decrease in SaO<sub>2</sub> suggest early chemoreflex activation, inducing progressive bradycardia and hypertension. The absence of initial HR drop indicates that the level of autonomic activity affects the cardiac response to breath-holding.

### IMPACT OF DIFFERENT ENDURANCE RACES ON THE HEART: THE POINT OF VIEW OF THE BIOLOGIST

Le Goff, C., Melon, P., Thebault, J., Kaux, J.F., Cavalier, E., Chapelle, J.P.

University Hospital of Liège

**Objective** The aim of this study was to investigate the impact of intense exercise, represented by different endurance races, in relationship with oxidative stress and cardiac markers. In a second time, we tried to demonstrate if oxidative stress induced by physical activity is a physiological or pathological process, and to establish some issues to diagnose the risk of sudden death in athletes. **Methods** Four populations were compared, a control group of 16 participants "sedentary" (37 ± 4,39 years old), a group of 24 semi-marathon runners (41 years ± 8,76 years old), a group of 28 marathon runners (44,1 ± 8,37 years old) and a group of 33 ultra-trail runners (45,8 ± 8,7 years old). Three blood tests were done, one just before, one just after, and the last three hours after the end of the race. Different oxidative and stress and cardiac biomarkers were measured. The ultra-trail runners will be subject to an echocardiography and an ECG pre- and post-race. For statistical analysis, STATISTICA 10 software was used. We performed a non-parametric test of Kruskal-Wallis for independent sample and a Friedman ANOVA for paired samples. **Results** Myeloperoxidase increased during exercise, but the release is less important according to the level of training of the runners. GSH/GSSG ratio seems to remain stable during the race but it could increase during the 24 hours post-race. There is a decrease in lipidic peroxidation during exercise. But, we note an increase of creatine kinase, isoform MB, myoglobin and C-reactive protein during the race. We observe an increase of troponin T and natriuretic peptide but with a different kinetic than the kinetic obtained for a myocardial infarction. Medical imaging in ultra-trail runners present cardiac adaptations to endurance training, as left ventricular hypertrophy (LVH) and incomplete right bundle branch block (IRBBB). A decrease of systolic and

diastolic volumes of the left ventricle and a decrease of longitudinal strain were observed by echocardiography at the end of the race. Conclusion Endurance races induce the increase of oxidative stress objectified by different biomarkers increase, but a cell necrosis is not specially observed. In fact, the increase of the cardiac markers during endurance races but may be explained by a transient modification of myocyte permeability, with a release of pool cytosolic. These races may induce micro-muscle damages causing the appearance of an inflammatory process explaining our observations of markers of inflammation. For the medical imaging, it was observed a myocardial adaptation to training and a transient impairment of ventricular function due to dehydration.

### **CARDIAC SYSTOLIC AND DIASTOLIC FUNCTION FOLLOWING A SIMULATED 5KM RACE IN SPORTS-TRAINED ADOLESCENTS**

Unnithan, V.1, Rowland, T.2, George, K.3, Lindley, M.R.4, Roche, D.M.5

*Staffordshire University*

1: Centre for Sport, Health and Exercise Research, Staffordshire University, Stoke-on-Trent, UK, 2: Department of Pediatrics, Baystate Medical Center, Springfield, MA, 3: Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, 4: School of Sport, Exercise and Health Sciences, Loughborough University, Loughborough, United Kingdom, 5: Sport and Exercise Physiology Research Team, Liverpool Hope University, Liverpool, United Kingdom Introduction Transient impairments of left ventricular (LV) systolic and diastolic function have been demonstrated in adult athletes following prolonged endurance exercise. The effects of a short, high-intensity bout of exercise, on cardiac systolic and diastolic function are less well understood in adolescent athletes. Consequently, the aims of the study were to: 1) evaluate global LV systolic function as well as segmental wall motion responses (cardiac strain), and 2) determine global LV diastolic function using Doppler and tissue Doppler imaging, both prior to and following a simulated 5 km cross-country race. Methods Twenty trained, male adolescents (age: 15.2 ± 0.7 years) volunteered for exercise testing. Cardiac systolic and diastolic measurements were taken prior to as well as 45 min and 3 hr 45 min following a simulated 5 km race. Measurements of resting LV dimensions obtained by M-mode echocardiography facilitate the measurement of LV systolic fractional shortening, a global measure of systolic function. Longitudinal myocardial strain and systolic strain rate of the LV septum were estimated using semi-automated speckle tracking software. Data was calculated for 3 septal wall segments (base, mid and apex) and then averaged. Global LV diastolic function was represented by peak blood flow velocities across the mitral valve during early (E) and late (A) diastole determined using pulsed-wave Doppler interrogation of transmitral blood flow. Tissue Doppler imaging was employed to determine peak longitudinal mitral annular septal tissue velocities. Results LV fractional shortening was significantly ( $P < 0.05$ ) higher 3 hr 45 min post-race ( $37.6 \pm 5.8\%$ ) compared to pre-race ( $34.5 \pm 4.7\%$ ) and 45 min post-race ( $34.9 \pm 5.4\%$ ). Despite this there was no alteration in segmental strain or strain rate measurements. There was a significant ( $P < 0.05$ ) decrease in the E:A ratio both 45 min ( $2.04 \pm 0.57$ ) and 3 hr 45 min post-race ( $2.20 \pm 0.66$ ) compared to the pre-race value ( $2.80 \pm 0.68$ ) but no alterations in tissue Doppler velocities were identified. Discussion The evidence suggests that a 5 km race does not lead to any significant post-exercise attenuation in regional LV systolic and diastolic function in trained adolescents. Minor changes in global LV systolic and diastolic indices were likely related to changes in heart rate during recovery.

### **TRAINING-INDUCED LEFT VENTRICULAR HYPERTROPHY AND RUNNING PERFORMANCE ARE NOT**

Rasmussen, T., Cress, M., Lindsey, B., Lonsdorf, B., Peterson, M., Wichern, C., Wolff, A., Stayton, M., Thomas, D.

*University of Wyoming*

Introduction Previous findings from removal of the pericardium (pericardiectomy) in both pigs<sup>1</sup> and dogs<sup>2</sup> have indicated a higher maximal cardiac output and  $\text{VO}_2\text{max}$  in both species. However, whether training carried out post-pericardiectomy leads to greater left ventricular hypertrophy or enhanced running performance has not been evaluated. Methods Young adult C57B6 mice were divided into pericardiectomized (P) or control (C) groups, and further subdivided into treadmill trained (P-T, C-T) or sedentary (P-S, C-S) groups. Pericardiectomized mice underwent sterile surgery under general anesthesia (ketamine/xylazine) also involving positive pressure ventilation (Harvard small animal ventilator). Both P-T and C-T groups ran on a treadmill at increasing speeds and duration up to 22 m/min, 60 min/day for 10 wk<sup>3</sup>. All mice underwent a final run-to-exhaustion test to evaluate running performance. Echocardiography was used to measure LVH, ventricular wall/chamber dimensions, and fractional shortening (%FS) as a measure of left ventricular (LV) function, as performed by us previously on mice<sup>4</sup>. Results Compared to combined S groups, both T groups documented a significant training effect by a 26% increase in run time-to-exhaustion ( $P < 0.05$ ) and body weight-normalized LVH ( $P < 0.05$ ) with no significant difference between the two T groups. There was also a trend ( $P < 0.09$ ) towards a thicker LV septum in T compared to S mice. However, there was also a trend for LV/BW in combined pericardiectomized groups (T, S) to be heavier ( $P < 0.08$ ) than in combined control groups indicating that pericardiectomy alone can increase LV mass. Pericardiectomy also resulted in significantly increased LV internal chamber diameters during both systole and diastole (LVIDs, LVIDd;  $P < 0.05$  and  $P < 0.01$  respectively) regardless of training status. LV function as assessed by %FS was unaffected by pericardiectomy or training, and normal in all 4 groups. Discussion Training does not result in additional LVH in pericardiectomized mice, even though there was a trend for pericardiectomy to increase LV/BW. However pericardiectomy does alter LV geometry without affecting exercise performance or resting LV function (%FS) as measured by echocardiography. References 1. **EFFECTS OF LOWER BODY NEGATIVE PRESSURE ON PHASE I CARDIOPULMONARY RESPONSES AT EXERCISE ONSET IN HUMANS**

Fagoni, N., Bringard, A., Adami, A., Capelli, C., Lador, F., Moia, C., Morel, D.R., Tam, E., Ferretti, G.

*University of Brescia, Italy*

**Introduction** The kinetics of cardiac output (CO) at the onset of exercise is characterized by two phases. The first rapid phase (phase I) is generally attributed to the sudden withdrawal of vagal tone (Fagraeus & Linnarsson, 1976). Yet, in acute hypoxia, with reduced vagal activity, the phase I amplitude (A1) for CO was still positive (Lador et al, 2008). Moreover, although vagal activation was greater supine than upright, the phase I of CO and stroke volume (SV) was not evident (Wieling et al, 1996). Thus, it was postulated that the phase I CO increase might also be due to the sudden increase in venous return and its effects on SV via the Frank-Starling mechanism (Sheriff et al, 1993). If this was the case, application of increasing levels of lower body negative pressure (LBNP) would generate a progressively greater increase in A1 of SV at exercise start. **Methods** To test this hypothesis, 8 subjects repeated 3 transitions of 5-min 50-W pedaling exercise supine, with 0 (control), -15, -30 and -45 mmHg of LBNP. LBNP was used as a tool to vary the amount of blood displaced in the lower limbs at rest. Heart rate (HR), SV, mean arterial pressure (MAP) and CO were continuously recorded using Portapres device and determined on a beat-by-beat basis using Modelflow method (Wesseling, 1993). After superposition of the 3 transitions, kinetics of CO, SV and HR were fitted using bi-exponential model, and model parameters were compared among the 4 conditions using repeated ANOVA (Tukey post-hoc test). Results LBNP significantly increased A1 of SV from  $7.5 \pm 3.7$  control to  $16.7 \pm 12.4$  and  $21.4 \pm 7.9$  ml, for -30 and -45 mmHg of LBNP respectively; A1 of HR decreased during -45 mmHg LBNP ( $14.1 \pm 8.5$ ) respect to -15 mmHg LBNP ( $22.4 \pm 3.2$ ). Thus, A1 of CO exhibited only a trend to increase. The time constant of phase I ranged between 1.5 and 3.5 s and was unaffected by LBNP exposure, for SV, HR or CO. At exercise start, there was a linear relation between HR and MAP, to attain a minimum MAP value, after which both parameters increased toward the range of exercise steady state values. **Conclusion** The tested hypothesis, namely that the phase I of SV is controlled by mechanical factors, was supported by these results. If HR kinetics was under neural control, then the phase I kinetics of CO would be under dual control: neural (vagal withdrawal) and mechanical. Moreover, the trends of the HR versus MAP relationship indicate that baroreflex resetting occurred after phase I, suggesting a role of sympathetic activation in it. **References** Fagraeus & Linnarsson, 1976. *J Appl Physiol* 40, 679-82 Lador et al, 2008. *Am J Physiol Regul Integr Comp Physiol* 295, R624-32 Sheriff et al, 1993. *Am J Physiol* 265, H1227-34 Wieling et al, 1996. *J Physiol* 494, 601-11 Wesseling, 1993. *J Appl Physiol* 74, 2566-73

**THE INFLUENCE OF PRIOR STEP EXERCISE ON THE AEROBIC CAPACITY DURING INCREASING RAMP RUNNING TEST IN YOUNG WOMEN**

Zaicenkoviene, K., Stasiulis, A.

*Lithuanian Sports University*

**Introduction.** After unusual physical activities (like bench stepping) including eccentric and concentric muscle contractions we might observe delayed onset muscle soreness (DOMS) which is mostly felt 24-72 hours after physical loads (Yanagisawa et al., 2010). There is some evidence how prior exercise affects lactate and ventilatory thresholds (Davies et al., 2011). There are no data about the effect of eccentric prior exercise on aerobic capacity changes during increasing ramp running test (IRT). Therefore, the aim of this study was to evaluate the effect of prior stepping on the indices of aerobic capacity during increasing ramp running test in young women. **Methods.** The subjects were healthy aerobics and dance specializations females students (n = 14) with an average age of 24.7 (6.4) years, height 168.0 (3.5) cm, weight 58.6 (6.4) kg, VO<sub>2</sub> max 2.475 (0.344) l/min. The studies were conducted in the Laboratory of Department of Applied Biology and Rehabilitation. The subjects performed three IRT on a treadmill (LE 200 CE, HP Cosmos) - a control one, 1 hour and 24 hours after stepping prior load (SPL). Maximal Oxygen Uptake (VO<sub>2</sub>max) („Oxycon Mobile“ (Germany) was determined according the dependence of average VO<sub>2</sub> during 15 s on the work intensity. The first (VeT1) and the second (VeT2) ventilatory thresholds were established according to the dependence of pulmonary ventilation. The highest value of VO<sub>2</sub> during 15 s of increasing running test was considered as VO<sub>2</sub> peak. At 5th and 20th min after IRT capillary blood samples of 0.1 ml from the subjects' fingers were taken using special one time devices using „Accutrend Lactate“ (Germany) analyzer. **Results.** We established that 1 h after SPL VeT2 (p = 0.024), VO<sub>2</sub>max (p = 0.049), maximal aerobic and maximal IRT speed (p = 0.036) and [La] 5 min. (p = 0.007) were decreased one hour after SPL. The majority of indices (VO<sub>2</sub>max (p = 0.030), the highest test speed (p = 0.036) and power (p = 0.014) were increased again 24 h after SPL, only VeT2 remained lower though the difference was not statistically significant (p = 0.898). Running economy at moderate and heavy intensities, the values of VEmax, HRmax and other indices did not change after SPL. **Conclusion.** The second ventilatory threshold and VO<sub>2</sub>max were decreased only 1h after stepping in young women. Other parameters of aerobic capacity were not changed at this moment of recovery and no significant changes of aerobic capacity were observed 24 h after stepping. **References.** Yanagisawa, O., Kurihara, T., Okumura, K., Fukubayashi, T. **CARDIORESPIRATORY AND METABOLIC RESPONSES TO AN ACUTE BOUT OF HIGH RESISTANCE CIRCUIT TRAINING VS TRADITIONAL STRENGTH TRAINING IN SOCCER PLAYERS.**

Marín-Pagán, C., Romero-Arenas, S., Alcaraz, P.E.

*Catholic University San Antonio*

**Cardiorespiratory and Metabolic Responses to an Acute Bout of High Resistance Circuit Training vs Traditional Strength Training in Soccer Players.** **Introduction** Maximal strength training is essential to optimize the power levels in soccer players (1). Circuit weight training could be a good tool for strength training in this population because improve strength and power (2) and minimizes training time(3). To date

only one research has studied (3) the acute responses of high resistance circuit (HRC) training on mechanical power and heart rate (HR), however no studies have been found regarding cardiorespiratory and metabolic responses. Therefore, the aim of this study was to compare cardiorespiratory and metabolic responses during HRC protocol vs. traditional strength training (TS) in soccer players. Methods 10 semiprofessionals soccer players performed 4 sessions: familiarization, maximal test in a treadmill, HRC and TS training. Maximal oxygen consumption normalizes to body weight (VO<sub>2</sub>maxR) and maximal HR (HRmax) were obtained in the maximal test. The order of training sessions was randomly and cross-over. The difference between protocols was the time of rest between exercises: TS=3' and HRC=35". Local muscular rest was the same (31) in both protocols. During training sessions, VO<sub>2</sub>R and HR were measured using a portable gas analyzer. Blood lactate (Lac) concentration was measured after exercise (1.5', 5', 7'). Results Significant differences (p<0.001) were obtained for VO<sub>2</sub>R, HR and Lac between groups. VO<sub>2</sub>R during HRC was 75% higher than TS (HRC=30.9±3.0; TS=17.7±2.5% of VO<sub>2</sub>maxR). During HRC training HR was higher by 39%. After training session, Lac in HRC was higher in circuit training in the 3 measures (HRC=9.4±2.2; 8.7±1.7; 8.4±1.7, TS=4.4 ± 1.1; 3.9 ± 1.2; 3.2 ± 1.2 mmol•l<sup>-1</sup>). Discussion During HRC, cardiorespiratory and metabolic responses were significantly higher than when the subjects were training with TS protocol. Respect VO<sub>2</sub>R (4) the authors reported similar results (~32% of VO<sub>2</sub>maxR) in circuit weight training with lower resistances. With the same protocols, Alcaraz et al. (3), have been reported similar values for HR (HRC=~71; TS=~62% of HRmax). Metabolic responses, measured by Lac, show that HRC was significantly more intensive than TS protocol. A recent study (5) found values of Lac slightly higher (10.5±2.1 mmol•l<sup>-1</sup>) after 5' of high-intensity interval training which performed with 6RM loads. Therefore HRC could be considered as a good tool for achieve improvements in soccer players, as this may improve strength and endurance jointly and also reducing training time. ### N-ACETYLCYSTEINE ALTERS SUBSTRATE METABOLISM DURING HIGH-INTENSITY CYCLING EXERCISE IN WELL-TRAINED HUMANS

Trewin, A.1, Petersen, A.C.1,2, Billaut, F.3, McQuade, L.4, McInerney, B.V.4, Stepto, N.K.1,2

1: SES and 2: ISEAL, Victoria University, Melbourne, Australia; 3: Institut National du Sport du Québec, Canada; 4: APAF, Macquarie University, Sydney, Australia

**Introduction** The generation of exercise induced reactive oxygen species (ROS) is a pertinent physiological event in order to facilitate optimal cellular signalling and function. Antioxidants balance ROS to provide a spatial-temporal equilibrium termed redox homeostasis. Disturbances in redox homeostasis may lead to suboptimal metabolic responses and alter exercise performance. This study investigated the effects of the antioxidant N-acetylcysteine (NAC) on metabolism during fixed work rate high-intensity interval exercise (HIIE) and self-paced 10 min time trial (TT10) performance. **Methods** Nine well-trained (mean ± SD; VO<sub>2</sub>peak 69.4 ± 5.8 ml.kg<sup>-1</sup>.min<sup>-1</sup>, peak power output (PPO) 385 ± 43 W) male cyclists participated in a double-blind, repeated measures, randomised crossover trial. Following maximal aerobic capacity testing and familiarisation, two separate trials (NAC/placebo supplementation) were performed on a cycle ergometer (Lode, Groningen, Netherlands) 7 days apart consisting of 6 × 5 min HIIE bouts at 82 % PPO (mean ± SD; 316 ± 40 W) separated by 1 min at 100 W. Then after 2 min recovery at 100 W, TT10 was performed. Oral NAC (100mg.kg<sup>-1</sup> per dose) supplementation was mixed with sports drink and consumed twice daily for 2 days, and 1h pre-trial. Expired gases for indirect calorimetry, electromyographic (EMG) data and venous bloods were collected. Results Respiratory exchange ratio (RER) was 2.9 ± 1.7% and 2.0 ± 1.4% lower with NAC in HIIE bouts 1 and 5, respectively (P<0.05). Fat oxidation was elevated with NAC compared to placebo during HIIE bouts 5 and 6 (9.9 ± 8.9 vs. 3.9 ± 4.8 μmol.kg<sup>-1</sup>.min<sup>-1</sup>; P<0.05), as was blood glucose throughout HIIE (4.3 ± 0.6 vs. 3.8 ± 0.6 mmol.L<sup>-1</sup>; P<0.05). Blood lactate was lower with NAC after TT10 and recovery (3.3 ± 1.3 vs. 4.2 ± 1.3 mmol.L<sup>-1</sup>; P<0.05). Blood glutathione was not significantly affected by NAC (P>0.05). Median EMG frequency of the Vastus lateralis was lower with NAC during HIIE (79 ± 10 vs. 85 ± 10 Hz; P<0.05), but not TT10 (82 ± 10 vs. 83 ± 12 Hz; P=0.32). Finally, NAC decreased mean power output 4.9 ± 6.6 % (effect size -0.29 ± 0.37, mean ± 90% CI) during TT10 (305.4 ± 57.4 W vs 319.1 ± 45.5 W). **Discussion** Our findings indicate that NAC altered glycolytic metabolism as shown by the reduced blood lactate concentration and RER during HIIE, along with a relative increase in fat oxidation. Furthermore, EMG frequency shifts were indicative of an attenuation of fast twitch glycolytic muscle fibre recruitment. In summary, these data suggest that NAC alters substrate metabolism and muscle fibre-type recruitment during HIIE and is detrimental to subsequent TT10 performance.

### LIPID PEROXIDATION AND ANTIOXIDANT ADAPTATION IN REGULAR TRAINING

Mitić, N.1, Popovic, L.1, Radic, I.1, Miric, D.2, Djokic, T.1

Medical Faculty, Kosovska Mitrovica

**Introduction** Exercise induces a multitude of physiological and biochemical changes capable to rise free radical production which trigger a chain of damaging reactions known as lipid peroxidation and oxidative stress. On the other hand continued presence of low concentration of RONS can serve as a stimulants for expression of antioxidant enzymes, indicating that regular exercise can decrease the incidence of wide range of RONS associated diseases. The aim of this work was to examine the effect of regular exercise on lipid peroxidation and antioxidant adaptation. **Methods** Lipid peroxidation markers (malondialdehyde-MDA, % ind MDA) and antioxidant status (ascorbic acid-Asc, ascorbat-A, dehydroascorbat-DHA and ratio DHA/A, GSH and CAT) were estimated at 30 sportsmen (regular training group) and 30 sedentary students (control group) at rest. Results Sportsmen under regular training showed increased level of MDA and %indMDA compared to control (4,26 vs. 3,04 μM/L, p<0,0001; 41,77% vs. 35%, p=0,045). Plasma antioxidant capacity was higher in sportsmen (Asc: 62,27 vs. 55,4 μM/L; DHA/A: 2,16 vs. 1,62 p=0,022; GSH: 25,8 vs. 22,4 μM/L p=0,0018). Only activity of CAT didn't show significant change (2,91 vs. 3,50 mK/L p=0,88). **Discussion** Our results are consistent with findings of other researchers (Brites et al., 1999). The potential role of RONS in exercise induced adaptation has been recognized and it seems that effects are systemic. They include increased antioxidant damage-repair enzyme activity, lower oxidative damage and increased resistance to oxidative stress. Antioxidant supplementation in regular exercise should be performed carefully since it can prevent useful adaptation effect (Radak et al., 2008). **Conclusions** Sportsmen under regular training showed increased lipid peroxidation but also an improved plasma antioxidant status compared to sedentary students. Training induced antioxidant adaptation reduces the risk of cellular injury during exercise. References Brites FD, Evelson PA, Christiansen MG, Nicol MF, Basilio MJ, Wikinski RW and Lesuy SF. (1999). Soccer players under regular training show oxidative stress but an improved plasma antioxidant status. Clinical Science, 96, 381-385. Radak Z, Chung HY and Goto S. (2008). ### OXIDATIVE STRESS STATUS IN ELITE ATHLETES OF DIFFERENT SPORT DISCIPLINES

Hadzovic-Dzuvo, A.1, Valjavec, A.1, Hadzimiratovic, A.1, Mekić, A.2, Lepara, O.1

1:Faculty of Medicine, University Sarajevo (Sarajevo, Bosnia and Herzegovina) 2:Faculty of Sport and Physical Education, University of Sarajevo (Sarajevo, Bosnia and Herzegovina)

**Introduction** Exercise training may increase production of free radicals and reactive oxygen species (ROS) in different ways. The training type and intensity may influence free radicals generation, which leads to differences in oxidative stress status between athletes, but the results of the previous studies are inconsistent. The aim of this study was to estimate oxidative stress status in elite athletes of different sport disciplines. **Methods** The study included 40 male elite athletes divided in three groups according to the sport type: 15 wrestlers, 12 soccer players and 13 basketball players. All the athletes were highly skilled professional competitors with international experience (2 Olympic players). Blood samples were taken from 8-10 a.m. after 12 overnight fast. Serum total antioxidative capacity (ImAnOX) and advanced oxidation protein products (AOPP), as markers of oxidative stress status, were determined by photometric tests (Immun Diagnostik). The results were presented as mean±SD. The variables were tested by ANOVA. **Results** The mean ImAnOX concentration was 344.8±35.6 µmol/L in soccer players, 342.5±36.2 µmol/L in wrestlers and 345.0±31.3 µmol/L in basketball players ( $p=0.133$ ; NS). The mean AOPP concentration in soccer players was 60.0±23.0 µmol/L, in wrestlers 68.5±30.8 µmol/L and 69.9±29.1 µmol/L in basketball players, but the difference was not significant ( $p=0.424$ , NS). There was no significant correlation between ImAnOX and AOPP concentration in soccer players ( $r=0.13$ ), wrestlers ( $r=0.325$ ) nor in basketball players ( $r=-0.119$ ). **Discussion** Our results showed no significant differences in the levels of oxidative stress status markers among various elite sports athletes. In spite of this fact, average concentrations (tests instructions proposed values) indicated high level of oxidative stress accompanied with increased antioxidative response in all groups. In accordance to the previous studies (Marin DP et al., 2011; Djordjevic et al., 2012) our results indicate that elite sports engagement is a potent stimulus of oxidative stress that leads to the large recruitment of antioxidative defense. Oxidative stress status monitoring and intervention in consumption of antioxidants is recommended as a part of training regime. **References** Martinovic J, Dopsaj V, Kotur-Stevuljevic J, Dopsaj M, Stefanovic A, Kasum G, Vujovic A. ### MUSCLE ISCHEMIC PRECONDITIONING DOES NOT IMPROVE EXERCISE PERFORMANCE DURING 5000 M RUNNING SELF PACED EXERCISE

Crisafulli, A.1, Marongiu, E.1, Ghiani, G.1, Sanna, I.1, Palazzolo, G.1, Olla, S.1, Pusceddu, M.1, Sanna, P.1, Corona, F.2, Concu, A.1, Tocco, F.1

university of cagliari

**Introduction** Classically, the ischemic preconditioning (IP) refers to a protective phenomenon against cell injury induced by infarction (Crisafulli et al. 2004). Moreover, muscle IP has been found capable of improving exercise performance in laboratory testing (Crisafulli et al. 2011, de Groot et al. 2010). This investigation aimed at verifying the hypothesis that IP improved performance during self-paced exercise (SPE) in the field. **Methods** Eleven healthy male well trained runners performed three randomly assigned 5000 m self-paced running tests in a outdoor athletic track. One was the reference (RT) test, while the others were performed after muscle IP (IPT) and a control sham test (ST). Average speed was measured during each test. Mean values of heart rate (HR), oxygen uptake (VO<sub>2</sub>), aerobic energy cost (AEC), and blood lactate (BLa) after race were also gathered. **Results** It was found that none of the studied variables were affected neither by IPT nor by ST with respect to the RT test. In detail, speed was on average 4.32±0.31, 4.79±0.29, and 4.45±0.32 m·s<sup>-1</sup> for the RT, the ST, and the IPT test respectively. HR was 176.4±8.8, 173.8±5.4, and 175.4±5.8 bpm. VO<sub>2</sub> was 3.5±0.69, 3.74±0.85, and 3.62±1.19 l·min<sup>-1</sup>. AEC was 1.04±0.15, 1.08±0.1, and 1.09±0.15 kcal·kg<sup>-1</sup>·km<sup>-1</sup>. Finally, BLa after races reached a level of 12.85±3.54, 11.88±4.74, and 12.82±3.6 mmol·l<sup>-1</sup>. **Discussion** Findings of the present investigation indicate that ischemic preconditioning is not capable to ameliorate performance during self paced exercise in the field. These results are in contrast to what previously found in the laboratory setting. Possible reasons for this outcome are: i) the different fitness level of the subjects enrolled in the present investigation with respect to that of other studies, as the present study was conducted in highly trained athletes; ii) the different setting between laboratory fixed-work output and SPE testing, since, apart from classical physiological and metabolic feed-backs, during SPE fatigue is the consequence of other factors such as athlete' experience, motivation, expected effort duration etc., which all may affect performance outcome. **References** Crisafulli A, Melis F, Tocco F et al (2004). *Am J Physiol (heart circ physiol)* 87, H235-H242. ### INFLUENCE OF STRENUOUS EXERCISE ON LIPID PEROXIDATION AND NEUTROPHIL INFLAMMATORY RESPONSE IN SEDENTARY PEOPLE

Popovic, L.1, Mitic, N.1, Radic, I.1, Miric, D.2, Djokic, T.1

Medical Faculty, Kosovska Mitrovica

**Introduction** Beside the fact that sources of free radical production during exercise continue to be debated it is undoubtedly that intense exercise can result in oxidative modification of lipids and proteins. This process also leads to acute inflammation and diminished muscle force production. Inflammatory response is followed by infiltration of the affected areas by neutrophils, their degranulation, and increased metabolic activity associated with additional free radical formation. That process has been indicated by the increased concentration of myeloperoxidase (MPO) in circulation following an exercise bout. The purpose of this study was to examine influence of strenuous exercise on oxidative stress generation and neutrophil inflammatory response in sedentary students. **Methods** Experiment was conducted on 30 male sedentary students. Strenuous exercise was performed using Bruce treadmill protocol (Wilmore et al, 2005). Markers of lipid peroxidation (malondialdehyde MDA, indMDA, % indMDA) and myeloperoxidase activity (MPO) were estimated at rest and after exercise test. **Results** It was found that after the treadmill test the level of MDA in plasma increased from 3,04 to 4,39 µM/L,  $p<0,0001$ ; the same as indMDA (4,60 vs. 5,71 µM/L  $p=0,0006$ ). After the exercise protocol % indMDA significantly decreased (35% vs. 24,71%,  $p=0,0003$ ). MPO in plasma was also found to be higher after treadmill test comparing to rest level (45,8 vs. 62,5 U/L,  $p<0,0001$ ). **Discussion** Significantly increased concentration of MDA, indMDA and decrease of % indMDA after performed test demonstrate increased lipid peroxidation process and oxidative stress induced by strenuous exercise. Increased activity of MPO in plasma after exercise test pointed the role of acute inflammation and neutrophil degranulation in oxidative stress induced by strenuous exercise. Our results are consistent with findings of other researchers (Morzov et al, 2003). **Conclusions** This results clearly show that strenuous exercise performed by sed-

entary people induce oxidative stress generation pointing the role of neutrophil inflammatory response in that process. References Wilmore JH & Costill DL. (2005). *Physiology of Sport and Exercise: 3rd Edition*. Champaign, IL: Human Kinetics Morozov V, Pryatkin S, Kalinski M & Rogozkin V. (2003). ### **INFLUENCE OF STRENUOUS EXERCISE ON OXIDATIVE STRESS AND ANTIOXIDANT DEFENSE IN SEDENTARY PEOPLE**

Popovic, L.1, Mitic, N.1, Radic, I.1, Miric, D.2, Djokic, T.1

*Medical Faculty, Kosovska Mitrovica*

Introduction It is well known that strenuous exercise, especially then sporadic, causes structural damage or inflammatory reaction within the muscle. Muscle cells are susceptible to oxidative stress and numerous mechanism have been postulated to explain the progressive cell and tissue damage produced by RONS. As a result of lipid peroxidation, cell membrane fluidity decrease leading to inhibition maintain of ionic gradient. Malondialdehyde (MDA) is consistent marker of exercise induced oxidative stress and lipid peroxidation. The blood antioxidant defense is a complex system consisting of various molecules capable to prevent, limitate and repair damages induced by RONS. The aim of this work was to examine the occurrence of oxidative stress during strenuous exercise and to determinate consequent antioxidant response. Methods Experiment was conducted on 30 male sedentary students. Strenuous exercise was performed using Bruce treadmill protocol (Wilmore et al, 2005). Markers of lipid peroxidation (MDA) and antioxidant status (ascorbic acid Asc, dehydroascorbate / ascorbate rate DHA/A, catalase CAT, glutathione GSH) were estimated at rest and after exercise test. Results MDA level in plasma significantly increased after exercise compared with the rest level (from 3,04 to 4,40  $\mu\text{M/L}$ ,  $p < 0,0001$ ). Increased levels of Asc (from 55,4 to 67,37  $\mu\text{M/L}$   $p < 0,0001$ ) and DHA/A rate (1,62 to 2,05  $p = 0,0014$ ) were also obtained in plasma after performed test. There was no significant change in GSH level (21,4 vs. 23,37  $\mu\text{M/L}$   $p = 0,19$ ) and activity of catalase significantly decreased (3,50 vs. 2,75  $\text{mK/L}$ ) after exercise. Discussion Increased concentration of MDA, after performed test demonstrate increased lipid peroxidation process and oxidative stress induced by strenuous exercise. Increased concentration of ascorbic acid and DHA/A rate in plasma after exercise suggest activation of antioxidant defense system and ascorbic acid mobilization from tissues (dominantly adrenal gland). Our results are consistent with findings of other researchers (Fisher-Wellman et al, 2009). Conclusions Strenuous exercise induces oxidative stress generation, increased lipid peroxidation and subsequently activation of antioxidant defense system. References Wilmore JH & Costill DL. (2005). *Physiology of Sport and Exercise: 3rd Edition*. Champaign, IL: Human Kinetics Fisher-Wellman K & Bloomer R. (2009). Introduction Patients with chronic kidney disease (CKD) suffer from a variety of co-morbid diseases creating a vicious circle that leads to gradually inactivity (Painter et al. 2005). Inactivity contributes, in turn, to reduced physical functioning and increases mortality. Cardiovascular (CV) diseases are recognized as the major cause of mortality in this population (Foley et al. 1998). However, the traditional CV risk factors cannot completely explain this increased CV risk. Chronic oxidant stress (OS) and inflammation state have been proposed as nontraditional CV risk factors in CKD (Himmelfarb et al. 2000). If it is well known that regular physical activity may improve OS and inflammation in healthy subjects, no study have investigated together, these 2 nontraditional CV risk factors in CKD. Therefore, the aim of this study was to determine whether an intradialytic aerobic training program 1)- reduce OS and inflammation markers and 2)- improve aerobic fitness and lipid profile in CKD patients. Methods Eighteen haemodialysis patients (66.5 $\pm$ 11,5yrs) were randomly assigned to either intradialytic physical training (30min of cycling, 60% VO<sub>2</sub>peak, 2x/week) group (EX; n=9) or a non-exercising control group (CON; n=9). At baseline and 3 months later, body composition (total body mass, fat free mass, fat mass), aerobic fitness ( , 6-min walk test) markers of pro/antioxidant status (plasma isoprostanes; erythrocytes SOD, GPX activities and GSH/GSSG ratio), inflammation (CRP) and lipid profile (TG, total cholesterol, HDL, LDL) were determined. Results Intradialytic aerobic training protocol did not alter body composition and inflammatory markers but had some beneficial effects on aerobic fitness, lipid profile and OS markers. Indeed, performance on the 6-min walk test significantly increased by 14.7% in EX, but did not change in CON. Plasma TG were significantly reduced by 23% in EX without no change in CON. After the 3 month period, the EX group exhibited lower isoprostanes level compared to CON (28.8 $\pm$ 9.5 vs 44.8 $\pm$  13.7 respectively,  $p < 0.001$ ). Conclusion These results demonstrate that intradialytic aerobic training protocol may improve OS, cardiorespiratory and lipid profiles in CKD patients leading to a decrease of CV risk factors. ### **ECONOMY OF CHILDREN'S MOVEMENTS TO TREADMILL SPEEDS AND PHYSICAL ACTIVITY LEVELS**

Matta, H., Moghaddaszadeh, A.1, Hicks, E.2, Morrison, K.2, Belcastro, A.N.1,2,3

*York University*

Introduction Oxygen cost and metabolic/gross economy (GE) of movement to exercise (increasing speed (TS)) vary with increases in body stature/growth. Whether stature/growth profiles and/or body composition and fitness factors have a similar impact on children's GE when indexed to physical activity (PA) levels (quantified by accelerometry) is unclear. Is the relationship between GE for PA comparable to GE for TS? The purpose of this study was to determine the GE of children's participation to varying levels of physical activity and assess their relationships to stature, body dimensions and body composition. Procedures Children (9.8 $\pm$ 0.9 yrs) were assessed for VO<sub>2</sub>, HR, VCO<sub>2</sub>, and RER over treadmill speeds (66.6, 99.6 and 132.6m/min for 3 min each at 0% grade). Accelerometers (ActiGraph GT1X - hip) were used to quantify physical activity (PA) levels in counts/min (3sec epochs). Gross economy (GE) for treadmill speed (TS) was expressed as relative VO<sub>2</sub>/m/min from 66.6 and 132.6 m/min; and GE for physical activity (PA) was expressed relative VO<sub>2</sub>/cnt/min from 2000-6000 cnts/min. ANOVA and statistical comparisons were assessed at a  $p = 0.05$ . Results The GE-TS (VO<sub>2</sub>/m/min) for children (height 155.0 $\pm$ 5.6cm; weight 64.6 $\pm$ 11.3kg) increased from 0.170 $\pm$ 0.017 to 0.213 $\pm$ 0.018 over speeds of 66.6 and 132.6 metres/min ( $p < 0.05$ ). The relationships ( $r^2$ ) between GE-TS and height and leg length (LL) were -0.92 and -0.88, respectively ( $p < 0.05$ ). The PA levels varied from 2071 $\pm$ 308 to 5465 $\pm$ 1424 counts/min ( $p < 0.05$ ). The GE-PA (VO<sub>2</sub>/cnt/min) values ranged from 0.0056 $\pm$ 0.001 and 0.0057 $\pm$ 0.001, respective-

ly ( $p > 0.05$ ). The relationships ( $r^2$ ) between GE-PA and height and leg length (LL) were -0.13 and -0.31, respectively ( $p > 0.05$ ). BMI, body fatness and aerobic power were related to GE-PA but not GE-TS. Minimal relationship was observed for GE-TS and GE-PA ( $r^2 = 0.01$ ). Discussion The primary finding was that metabolic/gross economy for children participating over a range of treadmill speeds and physical activity levels are impacted differently by stature/growth. As predicted GE-TS was highly related to stature/growth; in contrast minimal impact was observed for GE-PA and stature/growth. The GE-PA was related to BMI and aerobic power over the range of PA assessed. Therefore, the GE differences observed for TS and PA needs to be considered when estimating children's oxygen consumption from ACC-derived PA linear regression during laboratory (i.e., TM), active play and/or activities of daily living. ### **ELECTROMYOGRAPHIC THRESHOLD OCCURS AFTER ATTENUATION OF MUSCLE DEOXYGENATION DURING INCREMENTAL KNEE-EXTENSION EXERCISE**

Kohei, K.I., Shinsuke, N.I., Yuko, K.I., Masako, F.I., Tetsuya, K.I., Takafumi, H.I.

*Ritsumeikan University*

**BACKGROUND** Muscle deoxygenation follows an S-shaped profile and the response displays a slow down or plateau point (the attenuation point of muscle deoxygenation (APMD)) at high intensity despite further increase in pulmonary oxygen uptake during incremental whole body exercise, which mechanism is still unclear. However, previous studies suggested the mechanism might be a change in muscle fiber type recruitment where EMGT occurs incidentally to APMD, a change in muscle oxidative metabolism balance or a commencement of the other muscle deoxygenation (Osawa et al. 2012). However, no study has ever examined whether EMGT occurs after APMD during incremental small-muscle-mass exercise. **PURPOSE** To clarify whether EMGT occurs after APMD during incremental knee extension exercise in the rectus femoris (RF). **METHODS** Five subjects performed incremental knee extension exercise (20 Nm increment per a stage, every two minutes from 20 Nm until exhaustion) on the dominant leg using isokinetic ergometer (Biodex, BDX-4, Sakai Medicine). The exhaustion was defined as the point when the subjects were unable to achieve their target muscle power three repetitions in a row. The subjects were instructed not to eat foods and not to play hard exercise three hours prior to this test. Muscle deoxygenation using near-infrared spectroscopy (NIRS) and electromyography (EMG) activity using surface EMG in the RF were simultaneously measured during incremental knee extension exercise. The values of muscle deoxygenation and EMG were continuously plotted every 10 s. The error sum of squares of each regression line was calculated, and when the sum of the error sum of squares of the two lines was minimal, the intersection between the two lines was determined as APMD and EMGT. **RESULTS** During the incremental knee extension exercise, APMD occurred ( $462.0 \pm 78.5$  s) significantly earlier than EMGT ( $586.0 \pm 37.1$  s) ( $P < 0.05$ ). The subjects became exhaustive at  $618.0 \pm 44.4$  s. The power output at APMD ( $88.0 \pm 10.9$  Nm) was significantly lower than EMGT ( $116.0 \pm 8.9$  Nm) ( $P < 0.01$ ). There was no significant correlation between APMD and EMGT. **CONCLUSION** This study suggested that EMGT occurs after APMD in the RF and the possibility of the change in muscle fiber type recruitment could be excluded from the mechanism for the occurrence of APMD during incremental knee extension exercise. **REFERENCES** Osawa et al. Journal of Japanese College of Angiology 2012; 52: 103-107

### **ARTERIO-VEINUS OXYGEN DIFFERENCE AS A MEASURE OF RECOVERY KINETICS FOLLOWING CONCENTRIC-ECCENTRIC ISOKINETIC ARM AND LEG EXERCISE**

Mookerjee, S., Knicker, A., Drescher, U., Koop, S., Hoffmann, U.

*Bloomsburg University*

**Introduction** Assessments of dynamic changes in recovery respiratory kinetics following resistance exercise can provide information on the control and regulation of O<sub>2</sub> transport and utilization. An important parameter in this context is the arterio-venous difference in O<sub>2</sub> concentration (avDO<sub>2</sub>). The avDO<sub>2</sub> measured by respiratory oxygen uptake (V'O<sub>2</sub>) and cardiac output (CO) may be used as an indicator of the synchronization of muscle perfusion and muscular O<sub>2</sub> demands. Moreover, the delay between offset in exercise and changes in the avDO<sub>2</sub> can be used as an indicator of transport delays between muscle and lungs. **Methods** Thirteen healthy male subjects aged  $26.9 \pm 3.1$  years, performed a 20-repetition isokinetic (combined, concentric and eccentric) arm or leg exercise protocol at 60 deg/s, 150 deg/s, and 240 deg/s, in randomized order. Recovery (150 seconds) breath-by-breath V'O<sub>2</sub> and beat-to-beat CO by impedance cardiography were recorded to determine post-exercise avDO<sub>2</sub>. Statistical analysis for the peaks of avDO<sub>2</sub> (see below) were analyzed for amplitude and maximum time via a two-way (factors: 'limb' × 'speed') ANOVA for repeated measurements. **Results** The first peak was identified in 76 of 78 cases. Amplitudes of the first peak (mL/L) ranged from 186 (SD 52) at 60 deg/s to 174 (SD 32) at 240 deg/s for the arms; 174 (SD 32) at 60 deg/s to 179 (SD 42) for the leg exercise. Time to attain the first peak ranged from 7.2s at 60 deg/s to 6.8s at 240 deg/s for the arms; 8.2s at 60 deg/s to 5.6s at 240 deg/s for the legs. There were no significant between factors differences for the first amplitude of the avDO<sub>2</sub> curves. These first peaks were significantly influenced ( $P = 0.032$ ) by muscle mass (i.e. arm versus leg) involved. A second avDO<sub>2</sub> peak was identified in 45 of 78 cases. Since there was no systematic pattern of distribution of these second waveforms across the testing conditions, no further analyses were conducted. **Discussion** It can be assumed that the restriction of muscle blood flow during sets of concentric-eccentric contractions inhibits aerobic metabolism at the end of this phase. At the onset of recovery, the first avDO<sub>2</sub> wave is caused by the arrival of O<sub>2</sub> desaturated blood from the muscle to the lungs. This delay results from the occlusion of venous volume and blood flow within the active musculature. Therefore, the second avDO<sub>2</sub> 'wave' represents this imbalance in perfusion during recovery. This delay between the offset in exercise and changes in the avDO<sub>2</sub> can be used to gauge transport delays between the muscular and pulmonary sites. **References** Cunningham D, St Croix, C, Paterson D., Özyener F, Whipp B. **THE INFLUENCE OF MOTORCYCLE CLOTHING ON HUMAN BODY**

Zwolińska, M.

*Central Institute for Labour Protection - National Research Institute*

**Introduction** Since 20th century motorcycles alongside being a very popular sport, have also become a very popular means of transport. However, riding a motorcycle involves greater risk of accidents than car driving. A motorcyclist is not protected by any security cage. In fact, the only protection motorcyclists have is specialized motorcycle clothing. It is specifically designed to protect not only against the weather conditions, but also against burns from hot parts of a motorcycle and hits by small stones. But first of all, motorcycle apparel is the only protection at the time of the fall or collision with other vehicles or objects. This abstract presents the role of motorcycle clothing and its influence on a human body. **Methods** To verify the influence of motorcycle clothing on the human body, the experiments with the participation of 6 volunteers were conducted. Selected physiological parameters, e.g. core body temperature, skin temperature, humidity between underwear and a human body were measured. Tests were performed *inter alia* in a climate chamber. A single test of motorcycle clothing was divided into several stages, including: measurement of the above mentioned parameters at rest time (21-22°C laboratory and climatic chamber 28°C), during exercise (climatic chamber), and recovery time (climatic chamber). **Results** Based on the obtained results, it has been found out that the motorcycle clothing combined with moderate exercises (30min-75W) and a high temperature affects the human thermoregulatory system. In all testing sets of motorcycle clothing, volunteers obtained a high core temperature ( $t_{core} > 38^{\circ}\text{C}$ ). Moderate exercise resulted in an increase of the value by about  $1^{\circ}\text{C}$ . Even a physiological parameter, such as a skin temperature, exceeds the calculated value of the comfort temperature (at a rest phase). After the test the skin temperature remained within the range of  $35.4 \pm 0.2^{\circ}\text{C}$ . During the tests, in the space between clothing and a body, high values of relative humidity (90%) were noted (on the chest). Volunteers' subjective assessment revealed that thermal comfort was maintained only for leather clothing and it lasted 20min from the moment of putting the clothes on. **Discussion** The obtained results of this study showed that motorcycle clothing affects the human thermoregulatory system. According to the ISO 7933 the recommended threshold safe value of  $t_{core}$  is  $38^{\circ}\text{C}$ . It is inadvisable to exceed that value. The high relative humidity ( $>70\%$ ) in the space between a body and clothing can cause sensation of steaming, dyspnoea and severe discomfort, additional increased by the presence of liquid sweat on the skin (Bartkowiak 2010). Therefore, one should be aware of the impact of motorcycle clothing and climatic conditions on the thermal load of the body. **References** Bartkowiak G. (2010). FTEE 4(81) 82-86. **ANTHROPOMETRICAL CHARACTERISTICS AND AEROBIC CAPACITY AS SUCCESS PREDICTORS IN DANCESPORT**

Liiv, H.1, Wyon, M.2, Jürimäe, T.1, Mäestu, J.1, Jürimäe, J.1

*1 Faculty of Exercise and Sport Sciences, University of Tartu, Estonia 2 Research Centre for Sport, Exercise and Performance, University of Wolverhampton, UK.*

**Introduction** Ballroom dancing has become a worldwide popular sport aspiring Olympic status. In competitions, dancers are judged both on technical skill and on expressiveness. The aim of the current study was to investigate international level dancesport participants' anthropometrical characteristics and aerobic capacity in relation to the gender, dance style and international ranking. It was hypothesized that dancers with better aerobic capacity are having higher places in international ranking and that anthropometrical characteristics are influencing international ranking result. **Methods** Thirty competitive dancesport couples served as subjects for this study. Twelve couples competed in Standard competitions, 7 Latin and 11 in Ten Dance. Their mean training experience was  $14.9 \pm 5.1$  yrs and training volume was  $11.8 \pm 6.3$  hours per week.  $\text{VO}_2 \text{ max}$  was measured during an incremental treadmill test and anthropometrical parameters followed ISAK guidelines (Norton and Olds, 1996). The Carter and Heath (1990) anthropometric somatotyping method was used to calculate participants body type. International ranking results were collected on testing day from DancesportInfo Rating System (<http://dancesportinfo.net/DisplayTopCouples.aspx>). **Results** Male and female dancers had mean  $\text{VO}_2 \text{ max}$  of  $60.0 \pm 5.2$  and  $51.5 \pm 6.0$   $\text{ml} \cdot \text{min}^{-1} \cdot \text{kg}^{-1}$ , respectively and no correlation with international ranking was evident. Standard dancers tend to be more ectomorphic with greater stature, arm span and sitting height compared with Latin American dancers. Although Standard dancers were ectomorphic, those dancers who had higher mesomorphic scores had higher international ranking. **Discussion** The results of present investigation demonstrated that international level dancesport participants of different styles have relatively high aerobic capacity values compared to dancers from other genres. However anthropometrical characteristics did influence international rating; in Standard dance participants with higher muscularity had a higher international ranking. **References** Carter, J E L, Heath, B H, (1990). **BRAIN CORTICAL ACTIVITY DURING PRONE BRIDGING**

Verschuere, J., De Pauw, K., Tellez, H.F., Roelands, B., Berckmans, B., Meeusen, R.

*Vrije Universiteit Brussel*

**Introduction** Prone bridging (PB) is described as a timed isometric test to evaluate core endurance in which stability is regulated by supraspinal control mechanisms (Slobounov et al., 2005). The aims of this study are to examine brain functioning during PB until volitional exhaustion and to localize exercise induced changes in brain activity using spectral analysis. We hypothesize that cortical activation will increase during PB and that less core trained individuals will show a more pronounced shift towards higher brain oscillations during PB. **Methods** Forty university students ( $22.1 \pm 0.97$  years;  $\text{BMI}: 22.9 \pm 2.0$ ) participated in this study. Continuous EEG data (sampling rate: 500Hz, impedance  $< 5\Omega$ ) were derived from 32 active Ag/AgCl electrodes while participants performed a PB until volitional exhaustion. Subjects were divided in better (BCT) and less core trained (LCT) according to the duration of the PB, using percentile 25 for LCT and percentile 75 for BCT. Seven BCT and ten LCT were included for data analysis. Dorsolateral prefrontal, fronto-central and central brain areas were

selected for data analysis. EEGLab was used to clean and process the datasets. For each four seconds datasets (frequency bins: 0.25Hz) the discrete Fourier transform was calculated ( $\mu V^2$ ) to calculate the power spectrum. Kolmogorov-Smirnov tests and ANOVA repeated measures were conducted. Level of statistical significance was set at 0.05. Results Cortical activity decreases across the power spectrum at the beginning of PB compared to baseline, whereas cortical activity gradually increases during PB with highest values at the end of the PB. Time until volitional exhaustion was  $336 \pm 97$ s in BCT and  $129 \pm 30$ s in LCT ( $p < 0.05$ ). The most pronounced changes in the power spectrum were observed within  $\beta$ -2 and  $\gamma$  frequency bands, especially localized in FP1 and FP2. Although a shift to these higher frequencies and higher absolute power values during exercise was noticed earlier for LCT compared to BCT, no significant differences were found. Discussion Cortical activation increases during isometric postural control exercises until volitional fatigue. Furthermore, the LCT group showed a tendency toward higher activation of faster brain oscillations towards the end of the PB. Moraes et al (2007) suggest that an increased power in the  $\beta$  frequency band is in association with increased arousal, attention and stress. Further research is needed to determine if cortical activation can change using core stability training. References Slobounov et al. Clin. Neurophys 2005;116:315-323 Moraes, et al. Arq Neuropsiquiatr 2007;65(3-A):637-641

## EFFECTS OF COMPRESSION GARMENT FOR 10 HOURS BEFORE AND DURING WARM-UP ON SUBSEQUENT CYCLING AND RUNNING PERFORMANCE

Lee, D.C.W.

*The Chinese University of Hong Kong*

Compression garments (CG) have historically been used to treat circulatory illness, such as venous thromboembolism and leg ulcers (Dascombe, Hoare, Sear, Reaburn, & Scanlan, 2011). More recently, CG have been widely adopted by both competitive and recreational athletes before, during and after exercise and competitions (Sperlich et al., 2010). There are studies confirmed the ergogenic effects of CG on sport performance, such as attenuation of muscle oscillation (Bringard, Perrey, & Belluye, 2006), increased arterial perfusion (Bochmann et al., 2005), improved peripheral circulation and venous return (Agu, Baker, & Seifalian, 2004). The trend of effects of CG is more positive on the recovery process after exercise, but does not always shown significant effects during exercise from previous studies. Triathlon is one of the fastest developing sports in last decade. Athletes need to get their muscles warmed up to its optimal condition and be ready for the mass-start of swimming. At the same time, there are often limited time and space for athletes to warm-up on site before competition. It will be useful information for coaches and athletes to plan their warm-up strategies if CG can accelerate the warm-up process and enhance the readiness of muscle for the aggressive start of competition. There are also controversial results from previous studies of CG, and lack of scientific evidence on confirming those assertions in a triathlon setting. Therefore, the aim of this study is to investigate the effects of CG for 10 hours before and during warm-up on subsequent cycling and running performance. ## PHYSIOLOGICAL CHARACTERISTICS OF ELITE FEMALE GYMNASTS

Moustogiannis, A., Theos, A., Ioannidi, V., Maridaki, M.

*National and Kapodistrian University of Athens*

Introduction Sporting performance is influenced by physical strength, body weight and body height (Latt et al. 2009). Especially in gymnastics age, height and strength of the upper and lower limbs seem to affect performance (Baxter et al. 2002). The purpose of the present study was to investigate the anthropometric and physiological characteristics of elite female gymnasts. Method Twelve elite female gymnasts (age:  $10.3 \pm 1.3$  yrs, body weight:  $31.3 \pm 5.8$  kg, body height:  $135.0 \pm 7.5$  cm and BMI  $17.1 \pm 1.3$  kg/m<sup>2</sup>) ranked first in the Greek national championship participated in this study. Upper limbs strength (handgrip), lower limbs strength (squat jump), flexibility (sit and reach test) and agility (agility T-test) were measured. Results are presented as mean  $\pm$  SD. Results Arm strength did not differ significantly between dominant and non dominant hand ( $12.3 \pm 4.7$  vs.  $11.9 \pm 5.5$  kg respectively,  $p = 0.43$ ). Participants also performed in high standards in squat jump ( $39.3 \pm 8.1$  cm), sit & reach test ( $34.7 \pm 3.5$  cm) and agility T-test ( $12.7 \pm 1.1$  sec). Discussion Results of the present study suggest that gymnastics training promotes symmetrical development of upper limbs strength along with lower limbs strength, agility and flexibility. ## FUNCTIONAL ASYMMETRY OF MOTOR SYSTEM IN ELITE BOWLERS

Okorokov, M.1, Fomin, R.2

*1: MGIMO (Moscow, Russia), 2: Omegawave (Espoo, Finland)*

Introduction At the present time, there is limited literature that provides information about the assessment of elite bowlers' performance. Bowlers' motor activity during training and competing directly affects the athletes' entire motor system. However, the existing sources do not have any quantitative data characterizing the elite bowlers' motor system; this information is only available for cricket players (Kaminski et al, 2000; Kountouris et al, 2013). Bowlers' long-term muscular activity is associated with specific adaptational changes in their nervous and muscular systems. The goal of this study was to explore the specifics of functional asymmetry in the professional bowlers' motor system. Methods Subjects: 5 male elite bowlers taking part in European competitions (22 yrs, 177 cm high, and weighing 74 kg on the average). A Multi-Joint System Pro-4 and a Balance System SD (Biodex, USA) were used. In the first session, the athletes performed an isokinetic test by flexing and extending the left and right arm shoulder joints at various rates (90, 150, and 210 deg/sec), with 21 repetitions for both arms at each rate and 3 min pauses between sets. During the second session, the athletes performed static and dynamic balance tests; 3 attempts for both legs on a stable platform and 3 triesattempts on a dynamic platform; followed by 3 attempts for each leg on a dynamic platform. The next step was a single-leg stability test; 3 attempts for 30 seconds for each leg on a dynamic platform. The

final test was fall risk assessment; 3 attempts for 45 seconds for both legs separately on a dynamic platform. Results The tests showed some functional asymmetry between the subjects' left and right legs and shoulders. The right shoulder had more peak and average torque at different rates (both during flexing and extension) and was more stable at every rate. The right shoulder also had the best overall stability, workout during extension, power, and fatigue performance. The right leg demonstrated considerably better stability than the left leg in all tests. Discussion It is possible that the functional asymmetry of the bowlers' motor system is associated with specific neuromuscular adaptation (Fomin & Seliæv, 2011) to long-term training. In our opinion, bowlers should pay special attention to the functional asymmetry of the motor system and include exercises for reducing the asymmetry in their training programs. ### **FAR INFRARED EMITTING FABRIC PROMOTES BETTER PERFORMANCE IN RUNNING**

Gaspari, A., Souza, T.M.F., Guimarães, P.S., Felipe, T.I., Rodrigues, G.F.C., Souza, G.V., Chacon-Mikahil, M.P.T., Moraes, A.C.

*University of Campinas - Brazil - Sponsor: Rhodia Solvay*

Introduction The fabric made from polyamide yarn far infrared emitting (FIRE) absorbs heat from the human body to return it in the form of far infrared rays. The infrared emission promotes an increase in mobility of body fluids promoting improvement of the circulation. This can delay fatigue and enhance performance by increasing the supply of oxygen and substrates, as well as the removal of metabolic waste. Thus, we believe that the use of FIRE(Emana®) garment promotes improvement running performance. The aim of the study was to assess the effect of FIRE garment on running performance of individuals undergoing cardiopulmonary test. Methods We analyzed 17 volunteers, 13 men (24.6 ± 3.1 years and 75.2 ± 9.5 kg) and four women (23.7 ± 4.3 years and 60.8 ± 8.4 kg), which performed two exercise tests on a treadmill until exhaustion, using FIRE and placebo garments in a cross-over, double blind and placebo control study. We measured the oxygen consumption (VO<sub>2</sub>) each breath, heart rate (HR), speed (S) and total time (TT) of running. To evaluate the efficiency of FIRE garment were compared (Student t-test) the results obtained in the peak oxygen consumption (VO<sub>2</sub>peak) and in the speeds achieved during the percentages of 60, 70, 80 and 90% of the VO<sub>2</sub>peak (ANOVA two-way). Results In the tests with FIRE garment were achieved significantly higher speeds in 70% (placebo = 9.2 ± 1.4 km/h; FIRE = 9.7 ± 1.4 km/h, p = 0.021), 80% (placebo = 10.3 ± 1.7 km/h; FIRE = 11.0 ± 1.7 km/h, p = 0.001) and 90% (placebo = 11.9 ± 1.8 km/h; FIRE = 12.6 ± 2.1 km/h, p = 0.001) of the VO<sub>2</sub>peak. However, no significant differences were found between the speeds achieved in 60% of the VO<sub>2</sub>peak, as well as in the variables VO<sub>2</sub>, HR, S and TT at the time of VO<sub>2</sub>peak. Discussion Similar results with the use of sportswear were found in the study of Youn et al. (2001) showed 3.2% increase in the performance between 75 and 80% of VO<sub>2</sub>peak with far infrared emitting garment and Kemmler et al. (2009) showed increase in performance from 1.5 to 2.2% at submaximal intensities with compressive garment. The present study found increases of 5.8%, 6.5% and 5.8% in the speed of running with FIRE garment in the percentages of 70, 80 and 90% of VO<sub>2</sub>peak respectively, two times higher than results reported in the literature. This effect may be related to the larger emitting area of the FIRE garment that covered the entire body, compared to the Youn et al. (2001) garment that consists of shorts and a shirt. Conclusion The garment made with FIRE fabric promotes an increase in the submaximal running speeds relative to peak oxygen consumption when compared to placebo garment. References Youn et al. *IJASS*, v.13, n.1, p.77-94, 2001. Kemmler et al. *J Strength Cond Res*, v.23, n.1, p.101-5, 2009.

### **A NOVEL APPROACH TO DETERMINE THE APPROPRIATE WORK RATE TO NORMALISE THE INTENSITY OF INTERVAL TRAINING TO THE MODERATE-INTENSITY DOMAIN IN POST-MENOPAUSAL WOMEN**

Birk, G.K., Lyall, G., Harris, E., Ferguson, C., Birch, K.M.

*University of Leeds*

Introduction: Interval Training (IT) promotes greater cardiovascular health benefits compared to traditional continuous training. However, determining the mechanistic benefit of IT requires delineation of the relative impact of work rate, work:recovery ratios and the resulting metabolic stress on the benefits attained. Conventional methods used to determine IT work rates (WR) such as % maximal oxygen uptake (VO<sub>2</sub>max) can lead to some participants training above and others below the lactate threshold (LT). Thus the exercise intensity of IT will be different between individuals, likely influencing the health benefits attained. The aim of this study was to investigate a novel method of determining the appropriate WR for IT which normalises all individuals to the moderate-intensity domain when using a work:recovery ratio of 10:10s. Methods: 9 post-menopausal women (55±4yr) completed a ramp-incremental test (RIT 15W/min) to exhaustion on a cycle ergometer. Breath-by-breath (BxB) gas exchange was used to determine VO<sub>2</sub>max and obtain a non-invasive estimate of LT. Participants then completed 2 IT sessions with a work:recovery ratio of 10:10s. Session 1: Cycling for 5 consecutive 6min blocks. WR for block 1 was set at 50% of the difference between WR at LT and VO<sub>2</sub>max from the RIT. WR for each subsequent block increased by 10W, with BxB data used to determine the highest WR at which participants remained within the moderate-intensity domain (0.05). These data confirm all individuals were exercising below the LT (1.17±0.17 l/min) and in the moderate-intensity domain. Discussion: Traditional methods used to determine WR do not account for the different influences that can affect the overall intensity of IT. The novel method proposed herein effectively determines the exact WR which will ensure IT is performed in the moderate-intensity domain.

### **CYCLING TIME TRIAL POSITION: TORSO ANGLE AFFECTS METABOLIC AND PHYSIOLOGICAL VARIABLES**

Fintelman, D., Highton, P., Adams, T., Sterling, M., Hemida, H., Li, F.X.

*University of Birmingham*

Introduction During the cycling time trial (TT), nearly 90% of the power output is used to overcome air resistance (Debraux et al. 2011). To minimize aerodynamic drag, cyclists adopt a TT position by lowering the torso. Previous studies showed that TT position reduces peak power output (PPO) compared to an upright position. However, torso angle was not systematically controlled or only a small number of positions were tested at sub maximal intensity. Therefore the aim of this study was to determine the effect of torso angle on metabolic and physiological variables in the complete range of TT positions. We hypothesised that lowering torso angle will affect these variables in a non-linear manner, with the effect decreasing as torso angle is increasing. Methods 19 trained male time trialists, performed 3-min stage incremental tests on a cycle ergometer at their preferred torso angle and at 0, 8, 16 and 24° relative to the ground. Heart rate (HR), PPO, cadence, O<sub>2</sub> uptake (VO<sub>2</sub>), CO<sub>2</sub> exhale, breathing frequency, ventilation (VE) and gross efficiency (GE) were measured throughout

the session. Results were analysed with a one-way rm ANOVA. Results All maximal values of the recorded variables increased with increasing torso angles ( $p < .001$ ). A reduction of 16% PPO was recorded between the most upright ( $24^\circ$ ) and flat ( $0^\circ$ ) position. Post hoc tests revealed the flat position limited the  $VO_2$  ( $p < .015$ ), HR ( $p < .007$ ), cadence ( $p < .041$ ) and VE ( $p < .017$ ) compared with all other torso angles. The  $VO_2$  of the preferred position fits perfectly in line with the other torso angles and consequently the mean GE was not different. Discussion The present study demonstrates that extreme torso angles limit cycling performance. These results are in contrast with previous research showing no significant difference in HR and  $VO_2$  between torso positions at maximal intensity (e.g. Origenes et al. 1993). However, previous studies have compared upright and TT positions and lack information about torso angles. The decrease in  $VO_2$  and VE in the flat position could be explained by the abdominal compression, which hinders the work of the diaphragm and limits lung volume. Another explanation could be that muscles are not working in their optimal range and therefore maximum force applied is progressively limited as torso angle is reduced. These results demonstrate that changes of torso angle produce a non-linear reduction in all metabolic and physiological variables measured. It is suggested that for non-elite cyclists, torso angles lower than  $8^\circ$  should be avoided. References Debraux P, Grappe F, Manolova AV, Bertucci W (2011). ### THE EFFECT OF HIGH INTENSITY INTERVAL EXERCISE ON POSTPRANDIAL TRIACYLGLYCEROL AND LEUKOCYTE ACTIVATION

Gabriel, B.1, Gray, P.1, Pruneta-Deloché, V.2, Moulin, P.2, Ratkevicius, A.1, Gray, S.R.1

<sup>1</sup>Institute of Medical Sciences, University of Aberdeen, Aberdeen, UK <sup>2</sup>INSA de Lyon, Lyon, France

Introduction Atherogenesis is thought to be a postprandial phenomenon associated with immune activation [1]. A single bout of high intensity interval exercise (HIIE) can attenuate postprandial triacylglycerol (TG) [2], although the longevity and mechanisms underlying this observation remain to be elucidated. The aim of this study was to determine whether this attenuation in postprandial TG remained 2 days after a bout of HIIE and to monitor markers of leukocyte activation. A secondary aim was to determine the mechanisms underlying the reduction in postprandial TG observed after HIIE. Methods Eight young men each completed two three day trials. On day 1: subjects rested (Control) or performed 5 x 30 sec maximal sprints (HIIE). On day 2 and 3 subjects consumed high fat meals for breakfast and 3h later for lunch. Blood samples were taken at various times and analysed for TG, glucose and TG-rich lipoprotein (TRL)-bound LPL-dependent TRL-TG hydrolysis (LTTH). Flow cytometry was used to evaluate granulocyte, monocyte and lymphocyte CD11b (indicates early leukocyte-endothelium adhesion) and CD36 (regulator of oxLDL uptake by monocytes) expression. Results On day 2 of HIIE TG area under the curve was lower ( $P < 0.05$ ) (7.46 [1.53] mmol/l/7h) compared to the control trial (9.47 [3.04] mmol/l/7h) with no differences during day 3 of the trial. LTTH activity was higher ( $P > 0.05$ ) in HIIE, at 2 hours of day 2, compared to control. Granulocyte, monocyte and lymphocyte CD11b expression increased with time over day 2 and 3 of the study ( $P < 0.0001$ ). Lymphocyte and monocyte CD36 expression decreased with time over day 2 and 3 ( $P < 0.05$ ), with no change within granulocytes. There were no differences between trials in CD11b and CD36 expression on any leukocytes. Discussion As previously shown [2], HIIE attenuated postprandial TG on day 2 of the study, with this effect abolished by day 3. This suggests that to benefit from HIIE, with respect to postprandial TG, HIIE will have to be performed on an almost daily basis. The reduction in postprandial TG was associated with an increase in LTTH (an indicator of LPL activity [3]). HIIE had no effect on postprandial responses of CD11b or CD36. ### EMG FREQUENCY COMPONENTS OF LOWER LIMB MUSCLE ACTIVATION DURING CYCLING TO FATIGUE.

Priego, J.I.1, Bini, R.R.2, Diefenthaler, F.3, Carpes, F.P.4

<sup>1</sup>GIBD (Valencia, Spain), <sup>2</sup>UFRGS (Porto Alegre, Brazil), <sup>3</sup>CDS-UFCS (Santa Catarina, Brazil), <sup>4</sup>CHS-UNIPAMPA (Uruguiana, Brazil)

Introduction It is uncertain whether fatigue and workload would affect muscle recruitment during cycling. Therefore, this study assessed the combined effects of changing workload and fatigue state on frequency components of lower limb muscle activation during cycling. Methods Twelve male well-trained cyclists underwent an incremental cycling test to exhaustion while muscle activation was recorded from the right and left vastus lateralis (VL), biceps femoris (BF) and gastrocnemius – medial head (GM). Muscle recruitment was assessed via frequency band analyses of muscle activation signals. Effects from workload/fatigue and differences between muscles were assessed using effect sizes. Large effect sizes have been chosen for discussion of results. Results Muscle activation increased with workload/fatigue due to greater contribution from low (BF only – 12%) but not from high frequency components and due to an overall increase in muscle activation (~64%). Greater overall low frequency activation were observed for VL (~6%) and BF (13%) compared to the GM. High frequency activation for GM was greater than observed for VL (~20%) and BF (~10%). Discussion Diefenthaler et al. (2012) showed no substantial changes in low frequency components followed by large decreases in high frequency components of muscle activation during cycling at constant load to exhaustion. However, in our results we found increases in low frequency contents of BF activation without changes in high frequency components of lower limb muscles. That could be due to its lower percentage of type I fibers and small motor units compared to VL. Only BF and VL were affected by fatigue and workload increment, which potentially was due to their role as motor drivers in trained cyclists. Diefenthaler et al. (2012) found similar results while others described changes for VL in non-cyclists (Von Tscherner, 2009). High and low-frequency components of GM did not change, different of reported in Von Tscherner (2009) assessing non-cyclists. We also observed that the high-frequency component of this muscle is greater than VL and BF. It suggests that GM could present a greater proportion of larger motor units, compared to BF and VL. In conclusion, this study demonstrated that workload/fatigue affected BF and VL without changes in GM and the different muscle activation may be attributed to a muscle fibers proportion. ### RELATIONSHIP BETWEEN ANAEROBIC THRESHOLD AND RATE OF PERCEIVED EXERCION IN HIGH LEVEL ATHLETES OF ANTIOQUIA, COLOMBIA

Valbuena Ruiz, L.H., Jimenez Garces, J.M., Mestra Palomino, L.

INDEPORTES ANTIOQUIA - UNIVERSIDAD PONTIFICIA BOLIVARIANA UPB

Introduction The anaerobic threshold is the change from aerobic to anaerobic metabolism when sport action is executing with incremental characteristics. It is marked by multiple measurable parameters both quantitative and qualitative and determined by different meth-

ods. Rate of perceived exertion (RPE) as a qualitative and quantitative method has been used in training monitoring in high level athletes. This method has historically correlated with direct measurement methods and established a clear relationship between physiological parameters with incremental exercise test and RPE. Most studies show that RPE or Borg scale, in connection with anaerobic threshold values (12-13 on 6 to 20 scale value). Objective: RPE correlate with Ventilatory Anaerobic Threshold by ergospirometry. Methods: The study included 45 cycling, finswimming, hockey and triathlon athletes which had undergone a stress test with the RPE. Correlation was obtained between the Ventilatory Anaerobic Threshold (VT<sub>2</sub>), RPE and VO<sub>2</sub> in threshold point. We used a cycle ergometer and spirometer Oxicon Delta Jaeger, and Borg scale, ranging from 6 to 20, to determine RPE in all the subjects. For data analysis we used SPSS 15.0 software. Was carrying out a simple linear correlation in order to establish relation between oxygen consumption and RPE and calculated Pearson Correlation Coefficient. Results: It was observed that RPE in subjects analyzed was higher average to report in other studies. Furthermore, it was found that higher trainability and higher oxygen consumption, greater RPE. Conclusions The study established that analyzed variables have difference with those of previously reported studies. This is very different from findings of this study to establish a value of 16 for the threshold. It is also interesting to note that in subject available literature, correlation of VO<sub>2</sub> and RPE is similar and is given by high level training of these athletes. RPE determined by BORG scale could be a proper control method which reduces training costs and have permanent control in high level athletes. It also, could establish or correlate with other quantifiable methods such as the use of lactate to obtain a more valid criteria. References 1.Borg G. ### THE INFLUENCE OF SLEEP ON RECOVERY FROM CENTRAL AND PERIPHERAL FATIGUE

Shioda, K., Suzuki, T., Kinugasa, R.

*Kanagawa University*

Introduction Sleep is crucial for restoring the physiological processes that maintain the body and brain properly functioning. However, it is unclear that mechanism of recovery in relation to central or peripheral fatigue resulting from muscle contraction. The interpolated twitch technique is generally used to assess voluntary activation of skeletal muscles (Kooistra et al., 2007). Additionally, the decline of voluntary activation in maximal efforts is the sign of central fatigue (Gandevia, 2001). This study, therefore, investigated the influence of sleep on recovery from sustained fatigue task using interpolated twitch technique. Methods Healthy young adults, who did not have sleep problem, underwent the 2 experimental conditions (sleep condition, control condition) in a counter-balanced order. In the sleep condition, subjects took a short sleep (about 2-hour), whereas in the control condition, subjects were instructed to maintain resting state without sleep. Subjects performed a set of six sustained (22-second) maximum voluntary contraction (MVC) of the elbow flexor muscles before and after each condition. After each sustained MVC, brief contractions were performed at 30, 60 and 100% MVC with superimposed electrical stimulation to biceps brachii muscle. During sleep, we recorded polysomnogram (PSG) including electroencephalogram (EEG), electro-oculogram (EOG), electromyogram (EMG), and heart rate (HR). Results MVC gradually decreased each set in sleep and control condition. Especially, there were quite differences between conditions with respect to rate of change of MVC and voluntary activation. Discussion The present study indicated that short sleep has a positive effect on recovery from fatigue of elbow flexor muscles assessed by interpolated twitch technique. Also, it is conceivable that sleep is essential for recovery from both central and peripheral fatigue. References Kooistra RD, de Ruyter CJ, de Haan A. (2007). *Eur J Appl Physiol*, 100(3), 309-320. ### PSYCHOPHYSIOLOGICAL EFFECTS OF AN ONSIGHT LEAD CLIMB FOR LOWER GRADE CLIMBERS

Draper, N.

*University of Canterbury*

Introduction Anecdotally rock climbers and their coaches have described elite climbers having a "no fall mindset" that perhaps set them apart from climbers of lower ability (Dickson et al.; Fryer et al. 2012). Regardless of whether climbing on a top rope or as a lead climb there are few differences in psychological of physiological makers. Although found to hold for elite climbers, the findings of recent studies in the field suggest that this ability to lock down the mind and focus on climbing without anxiety induced changes in physiological responses extends to advanced and intermediate level climbers (Dickson et al.; Draper et al. 2011; Fryer et al. 2012). Therefore the aim of this study was to examine whether the "no fall mindset" also held true for low-grade or novice climbers. Methods Twenty (12 male, 8 female) low grade rock climbers volunteered to take part in the study. Participants took part in three testing sessions, a VO<sub>2</sub>max test, a familiarisation sessions and the final test climb. Participants were randomly assigned to an on-sight top-rope or lead climb ascent of the test route. A range of physiological and psychological measure were taken during the testing sessions including VO<sub>2</sub> and HR during climb, lactate and cortisol concentrations as well as Profile of Mood State, Revised Competitive State Anxiety Inventory-2 and the National Aeronautics and Space Administration Task Load Index. Results There were though significant differences found between the groups for lactate and cortisol concentrations, concentrations, climb time, heart rate and VO<sub>2</sub>. Discussion The aim of this study was to examine if the no fall mindset, attributed to elite climbers and now found to extend to advanced and intermediate climbers also extended to novice climbers. Results indicate that there were significant differences between the psychological and physiological responses of climbers undertaking an on-sight top-rope climb when compared to an on-sight lead climb. It is possible that experience plays a key role in understanding the differences in safety protocols and impacts upon the physiological and psychological responses of climbers as well as differences in climbing ability. ## A MULTIDISCIPLINARY COMPARATIVE APPROACH TO TALENT IDENTIFICATION IN TENNIS

Fett, J., Ulbricht, A., Fernandez-Fernandez, J., Ferrauti, A.

*Ruhr-University Bochum*

Introduction Tennis is a complex sport requiring a mixture of physical, technical/tactical and psychological skills. Due to this complexity, the relationship between physical/technical parameters and performance is scarce. Therefore, the aim of the present study was to compare the influence of selected technical and physical factors on tennis performance (i.e., ranking) in a group of elite young tennis players in relation to different age groups. Methods 267 nationally ranked young tennis players (male U12+U14 n=81, U16+U18 n=77; female U12+U14 n=70, U16+U18 n=39) were tested for strength, upper body power, speed, agility, jumping ability and tennis specific endurance (German Tennis Test). Moreover, 179 of these subjects (male U12+U14 n=50, U16+U18 n=56; female U12+U14 n=40, U16+U18 n=33) were evaluated by the national coaching staff through a questionnaire, including technical (i.e., serve, slice, volley), tactical (i.e., match strategy) and coordinative (i.e., timing) items. Multiple regression analysis was used to assess the relation between physical tests, questionnaire items and performance (i.e., national ranking). Results Results showed that in younger players (U12+U14) tennis performance is mainly explained by technical, coordinative and tactical factors (male:  $R^2(\text{technique}) = .68$ ,  $p < .05$ ;  $R^2(\text{tactic}) = .51$ ,  $p < .05$ ;  $R^2(\text{coordination}) = .57$ ,  $p < .05$ ;  $R^2(\text{condition}) = .22$ ,  $p > .05$ ; female:  $R^2(\text{technique}) = .45$ ,  $p > .05$ ;  $R^2(\text{tactic}) = .28$ ,  $p > .05$ ;  $R^2(\text{coordination}) = .55$ ,  $p > .05$ ;  $R^2(\text{condition}) = .33$ ,  $p > .05$ ). In older players (U16+U18) performance can be primarily attributed to their physical performance, while technique, tactics and coordination were found to be weak predictors (male:  $R^2(\text{technique}) = .17$ ,  $p > .05$ ;  $R^2(\text{tactic}) = .17$ ,  $p > .05$ ;  $R^2(\text{coordination}) = .33$ ,  $p > .05$ ;  $R^2(\text{condition}) = .42$ ,  $p < .05$ ; female:  $R^2(\text{technique}) = .58$ ,  $p > .05$ ;  $R^2(\text{tactic}) = .17$ ,  $p > .05$ ;  $R^2(\text{coordination}) = .58$ ,  $p > .05$ ;  $R^2(\text{condition}) = .64$ ,  $p < .05$ ). Discussion Our findings reinforce the idea that performance in tennis is multifaceted. Depending on the age group, the influencing factors (e.g., physical or technical/tactical) are different. While in young players technique and tactical skills seem to be strong predictors of tennis performance, physical qualities are more important in older players. This might be due to the effects of maturation, training experience and talent selection. According to the present results coaches should give more importance to the technical/tactical skills in early years (with an appropriate development of basic physical qualities (i.e., coordination)), while the physical training would have more importance in the puberty. ## PERFORMANCE DIFFERENCES BETWEEN ANAEROBIC POWER TEST LABORATORY AND FIELD IN YOUNG BRAZILIAN SOCCER PLAYERS

Sousa, S., Rogrigues, E.Q., Cintra Filho, D.A.

*Londrina State University*

Anaerobic power is an important variable for soccer, because those actions such as kicking techniques require good levels of power. Thus, it is essential to investigate this variable, but most indicated that the evaluation of field or laboratory? The aim of this study was to investigate the differences between anaerobic power test laboratory and field in young Brazilian soccer players. Methods: 12 young soccer players (age  $13,5 \pm 0,5$ ; body mass  $58,5 \pm 17,7$  kg;  $1,70 \pm 0,1$  cm). They were evaluated by two power ratings, one field test (Rast - Running Based Anaerobic Sprint Test) first day and laboratory test (Wingate) on the second day. In the Rast protocol (Zacharogiannis et al., 2004), they performed warmup a 5-minute, a 5-minute rest interval, after 6 x 35 meters sprint separated by 10 seconds passive recovery. We used two photocells Electronic Sun Pack (China) arranged to 35m away, to capture the times of the sprints and calculated the variables, peak absolute power (PAP), relative peak power (RPP), mean absolute power (MAP), relative mean power (RMP) and fatigue indices (FI). Wingate test protocol (Mastrangelo et al., 2004) consisted 5-minute warmup, a 5-minute rest interval. Resistance to pedaling was based on body mass (BM) by (0,075 kg of resistance per kilogram of BM). Wingate test consisted 30-second sprint and the variables were calculated by software Ergometric 6.0 the same RAST (PAP, RPP, MAP, RMP, FI). Statistical analysis was performed by the Shapiro-Wilk test for normality, and the performance differences between laboratory and field tests were assessed using the Student t test for independent samples. SPSS 17.0 was used. Results: Differences were found between PAP x PAP  $p < 0,01$ , RPP x RPP  $p < 0,00$ , MAP x MAP  $p < 0,03$ , RMP x RMP  $p < 0,01$ . Discussion: The differences found show that it is necessary to be careful when choosing an assessment, regardless of the sport. Likewise, the limitations of the study should be considered, because the errors in the application of the protocol can influence the results. On field and laboratory tests, as well Wingate RAST can be reproducible and valid for measuring performance in anaerobic power (Zagato; Heck; Gobatto 2009; Hachana et al., 2012) but protocols must be in accordance with the characteristics of research participants. ## TEST-RETEST RELIABILITY OF 3-MIN ALL-OUT TEST FOR RUNNING

Kuo, Y.H.1, Hsu, W.C.2, Chen, P.Y.1, Cheng, C.F.3

1: National Taiwan Normal University (Taipei, Taiwan), 2: Taipei Physical Education College (Taipei, Taiwan), 3: National Taiwan Normal University (Taipei, Taiwan)

Introduction Critical power (CP) and anaerobic work capacity (W') could be successfully estimated from a single test, called 3-min all-out test (3MT), for cycling [5] and rowing [3]. Recently, the CP and W', defined as the critical velocity (CV) and maximal capacity for work above CP (D'), can be determined from 3-min all-out running test (3MRT) using the global positioning sensor (GPS) [4] and accelerometer [1]. Good reproducibility of CP and W' estimated from 3MT for cycling [2] and rowing [3] has been reported, however, the repeatability of 3MRT is unknown. Previous studies [2, 3] also found that VO<sub>2</sub>max was significantly related with VO<sub>2</sub>peak measured from the 3MT. There-

fore, this study examines the test-retest reliabilities of 3MRT, and investigates the relationship between  $VO_{2peak}$  and  $VO_{2max}$ . Methods Twelve collegiate male sprinters were recruited and performed an incremental exercise test on a treadmill at laboratory and two 3MRTs on a level outdoor track, separated by at least 48 hours. In the 3MRT trials, the portable Cortex metabolic analysis system (Metamax 3B) with GPS module was continuously used to measure the oxygen uptake, heart rate (HR), and running speed. The CV and D' derived from the 3MRT were analyzed according to the study of Pettitt et al. [4]. The blood samples were obtained before and after 3MRT to measure the blood lactate concentrations (La). Results There were significant test-retest reliabilities in CV (intraclass correlation coefficient [ICC] = 0.74, 95% confidence interval [CI] = 0.32 to 0.92 m/s,  $P < 0.05$ ) and D' (ICC = 0.70, 95% CI = 0.09 to 0.87 m,  $P < 0.05$ ) between the two 3MRT trials. No significant differences in La were found either before (~1.0 mmol/L) or after (~12.1 mmol/L) 3MRT. No significant differences in CV, D', % $VO_{2max}$  at CV, peak HR, and temperature were found between the two 3MRT trials. However, the peak HRs (~178 bpm) and  $VO_{2peak}$  (~49.4 ml/kg/min) in both 3MRT trials were significantly lower than maximal HR (~191 bpm) and  $VO_{2max}$  (~55.0 ml/kg/min) during incremental exercise test. Discussion These results, which are consistent with other studies [2, 3], indicate that 3MRT has moderate test-retest reproducibility in CV and D'. Our study failed to provide support for the relationships between  $VO_{2peak}$  and  $VO_{2max}$ . It can be partly explained by the differences in temperatures between indoor (22.0 ± 0.5 °C) and outdoor (34.5 ± 0.8 °C) environment. Nevertheless, 3MRT has appropriate test-retest reliability even at high temperature environment. References 1. Broxterman RM, Ade CJ, Poole DC, Harms CA, Barstow TJ. ## AEROBIC AND ANAEROBIC POWER DURING ERGOMETER AND TRACK-CYCLING IN ADOLESCENT CYCLISTS

Nimmerichter, A.1, Williams, C.A.

1: University of Applied Sciences, Wr. Neustadt, Austria; 2: University of Exeter, Exeter, UK

Introduction Incremental exercise tests utilising cycle ergometers have long been used to prescribe exercise intensities for both outdoor training and to predict cycling performance. The use of ergometry tests is also endorsed by organisations like British Cycling for talent identification. In a recent study, the validity of the air-braked Wattbike ergometer (WB) showed acceptable accuracy when compared to the SRM mobile power-meter (Hopker et al., 2010). The aim of this study was to compare power outputs measured during performance tests on the WB compared to track-cycling in young cyclists. Methods Fourteen trained adolescent cyclists (age: 14.8 ± 1.1 y;  $VO_{2max}$ : 63.5 ± 5.6 mL/min/kg) randomly completed three performance tests of 10 s, 1 min and 3 min on either, a WB ergometer or on a wooden track using their own bikes mounted with SRM mobile power-meters. The participants were asked to produce the highest possible power output during all trials, which were separated by at least 30 min. During the 10-s performance test maximal ( $P_{max10s}$ ) and mean ( $P_{mean10s}$ ) power output, as well as, the optimal cadence (Cadopt) and the corresponding power output (Popt) was analysed. For the 1-min and 3-min performance tests, mean power output ( $P_{mean1min}$ ,  $P_{mean3min}$ ) and mean cadence (Cadmean1min, Cadmean3min) was determined. Results During the 10-s performance test  $P_{max10s}$  and  $P_{mean10s}$  were significantly higher on the WB compared to SRM (16.7 ± 1.9 W/kg vs 15.2 ± 1.5 W/kg and 14.8 ± 1.5 W/kg vs 13.2 ± 1.3 W/kg;  $p < 0.005$ ). The bias ± 95% limits of agreement were 9.1 ± 18.9% for  $P_{max10s}$  and 11.3 ± 15.5% for  $P_{mean10s}$ . No significant differences between WB and SRM were observed for Popt (15.2 ± 1.9 W/kg vs 14.6 ± 1.8 W/kg;  $p = 0.22$ ) and Cadopt (102 ± 9 rpm vs 97 ± 8 rpm;  $p = 0.06$ ).  $P_{mean1min}$  was 8.2 ± 0.5 W/kg and 6.8 ± 0.7 W/kg on the WB and SRM, respectively ( $p < 0.001$ ). The bias ± 95% limit of agreement was 18.0 ± 13.9%. Mean cadence was significantly different between WB and SRM (103 ± 5 rpm vs 114 ± 7 rpm;  $p < 0.001$ ). Likewise,  $P_{mean3min}$  was 5.5 ± 0.5 W/kg and 5.0 ± 0.7 W/kg on the WB and SRM, respectively ( $p < 0.001$ ) with a bias ± 95% limit of agreement of 9.3 ± 12.0%. Mean cadence was 97 ± 3 rpm on the WB and 104 ± 5 rpm during track-cycling ( $p < 0.001$ ). Discussion Trained adolescent cyclists were able to produce significantly higher power outputs during ergometer-cycling compared to track-cycling. The agreement between WB and track-cycling-derived power output is limited and therefore, talent identification based on ergometer-cycling should be used with caution. Young cyclists probably need more experience to develop the technical skills required for track-cycling to reach their potential assessed during ergometer-cycling. Hopker, J., Myers, S., Jobson, S. A., Bruce, W., & Passfield, L. (2010). Validity and reliability of the Wattbike cycle ergometer. *Int J Sports Med*, 31(10), 731-736.

## AEROBIC EXERCISE PRIOR TO RESISTANCE EXERCISE COMPROMISES FUNCTIONAL ADAPTATIONS, YET BOOSTS INCREASES IN MUSCLE SIZE

Lundberg, T.R.1, Fernandez-Gonzalo, R.2, Carlsson, D.2, Tesch, P.A.1,2

(1) Mid Sweden University, Östersund, Sweden (2) Karolinska Institutet, Stockholm, Sweden

INTRODUCTION Aerobic exercise (AE) may compromise resistance exercise (RE) induced muscle adaptations. However, 5 wks concurrent AE and RE interspersed by 6 h recovery, showed greater increase in muscle size with similar improvements in muscle strength and power, compared with RE only (Lundberg et al. 2013). We hypothesized that performing consecutive AE and RE, not allowing for recovery, would hamper increases in muscle size and function resulting from RE. METHODS Ten moderately trained men (26±5 yrs) were subjected to 5 wks unilateral (both legs) knee extensor RE 2-3 d/wk. In addition, one randomly assigned limb completed AE 15 min prior to onset of RE. Any AE session comprised ~45 min exhaustive concentric one-legged cycle ergometry. RE consisted of 4 x 7 maximal concentric-eccentric flywheel knee extensions. Peak power was measured during each RE session, and maximal isokinetic and flywheel torque and power were assessed before and after training. Likewise, volume and signal intensity of m. quadriceps were determined by means of magnetic resonance imaging (MRI). RESULTS Day by day peak power performance during RE sessions was 19% lower ( $p < 0.05$ ) for the leg subjected to AE. In the rested state before and after training, average concentric-eccentric torque (~10%) and power (~17%) improved similarly across legs. However, the increase in flywheel concentric peak torque was greater ( $p < 0.05$ ) after RE (10%) than AE+RE (4%). Similarly, isokinetic peak torque at 210 and 240°/s, tended to be reduced (-9%,  $p < 0.1$ ) after AE+RE but unchanged after RE. Both legs showed increased muscle volume after training, yet the increase was more prominent (interaction  $p < 0.05$ ) after AE+RE (6%) than RE (3%). Signal intensity of MRI scans increased ( $p < 0.05$ ) by 7% after AE+RE, with no change in RE. DISCUSSION There were less work and force produced when AE preceded RE than with RE alone. Increases in flywheel peak concentric torque was compromised by AE+RE, and performance at higher angular velocities was reduced, compared with RE. Notwithstanding, RE-induced increases in muscle size were exaggerated by concurrent AE. These results infer that performing consecutive bouts of AE and RE, alters aspects of muscle size and, in vivo muscle function, noted with RE alone. Some of these divergent responses may be counterproductive for athletes aiming at developing explosive strength, speed or power. ### ANTIOXIDANT STATUS AFTER INTENSIVE EXERCISE REALIZED AT 1850 METERS IN NON-ACCLIMATED ENDURANCE TRAINED ATHLETES

Durand, F., Durand, F.1, Hapkova, I.1, Gaston, A.F.1, Estripeau, P.1, Pincemail, J.2, Vela, C.1

1; LPSA (Perpignan, France), 2; CHU (Liège, Belgique)

**Introduction** Endurance-trained athletes exhibit higher antioxidant capacities due to beneficial effects of training whereas intensive exercise leads to oxidative stress at sea-level (SL). Altitude can aggravate exercise-induced oxidative stress. Many studies were interested in exercise-induced oxidative stress and decreased in antioxidant status of athletes at altitude. However the most studies reported effect of altitude upper to 3000 meters and/or in the context of 'live high-train low' (Pialoux et al., 2009, 2010). This is not really the altitude for the majority of sporting events in which lowlanders athletes are the main actors on a half-day or a day nor for altitude training camp which interest more modest altitude. Therefore this study investigated the effect of 1850 meters altitude on a single bout exercise-induced changes in redox status in lowlanders endurance-trained athletes. **Methods** All athletes (n=9) performed an incremental exercise test VO<sub>2</sub>max at SL. A first cycle exercise at 85% VO<sub>2</sub>maxSL for one hour was realized at SL. One week later, the same exercise at 1850 meters (ALT, Font-Romeu) was performed without acclimatization. Athletes rose at altitude very early in the morning of the test and performed after an overnight fasting. Blood samples were collected before and after exercise. Results VO<sub>2</sub>max SL equal to 58.22 ± 0.96 ml.min<sup>-1</sup>.kg<sup>-1</sup>. During SL exercise, SpO<sub>2</sub> (hemoglobin O<sub>2</sub> saturation) was in mean 99 %. No difference occurred at SL before and after exercise in GPx (respectively 55.11 ± 3.77 vs 52 ± 4 U.l.g-1Hb) nor in SOD (983.7 ± 34.8 vs 946.7 ± 44.98 U.l.g-1Hb). No one was also observed before and after ALT exercise. No difference in both enzymes occurred between SL and ALT condition while SpO<sub>2</sub> was however decreased during ALT exercise (92 %). Ascorbic acid increased after exercise at SL and ALT, whereas no significant interaction occurred between exercise and condition. **Discussion** Endurance-trained athletes have antioxidant capacity to counterbalance an exercise-induced free radical production at SL. 1850 meters do not seem to be a level of hypoxia being enough for oxidative stress generation and so decrease of antioxidant capacity with out and with intense exercise. This study report the absence of effect of an acute exposure at 1850 meters on redox status of endurance athletes who would come to realize a unique event at this altitude and/or come to begin an altitude training camp. **References** Pialoux V, Mounier R, Rock E, Mazur A, Schmitt L, Richalet JP, Robach P, Coudert J, Fellmann N. ### PSYCHO-PHYSIOLOGICAL STRESS RESPONSES DURING PRACTICE AND COMPETITION IN YOUNG FEMALE COMPETITIVE TENNIS PLAYERS

Fernandez-Fernandez, J.1, Sanz-Rivas, D.2, Boulosa, D.A.3, Mendez-Villanueva, A.4

1 Ruhr-University Bochum, Germany; 2 University Camilo Jose Cela, Spain; 3 Catholic University of Brasilia, Brazil; 4 ASPIRE Academy for Sports Excellence, Qatar

**Introduction** Tennis induces important physical and psychological stress, which might play an important role during competition, as it requires steadiness, precision, motivation and motor control for effective shot making over the whole match. Salivary cortisol (SC) has been recommended as an index of training and competitive stress, although studies reported controversial results. Thus, the aims of this study were to compare the psycho-physiological responses to practice sessions (i.e., simulated tennis match play) and competitive games in high-level young tennis players and determine the possible differences in these responses between winners and losers. **Methods** Twelve young female elite tennis players (Age: 13.0 ± 0.3 years; weight: 51.4 ± 1.3 kg; height: 1.68 ± 0.3 m), participated in this study. Players were monitored during one match (MD) and a practice session (i.e., simulated match play; TD), separated by 2 weeks. Measurements included salivary collections for cortisol (SC) analyse (collected at 8 h; 10 min pre- and post-game, and 20 h); psychological variables using the revised Competitive Sport Anxiety Inventory (CSAI-2R), which was completed each time salivary samples were collected (i.e., 10 min pre and 10 min post-practice and competition), and physiological responses, by monitoring heart rate (HR) and rate of perceived exertion (RPE) at selected changeover breaks in play (that occurred at the end of the first, third and every subsequent odd game of each set) throughout the match/practice. **Results** Physiological responses (i.e., HR and RPE) were significantly higher for losers only during MD (HR: 158.9 ± 8.3 vs. 168 ± 6.7 beats•min<sup>-1</sup>; RPE: 12.9 ± 1.2 vs. 15 ± 0.8, for losers and winners respectively; p < 0.05). MD elicited higher SC values for losers at awakening (15.2 ± 0.7 vs. 14.0 ± 1.3 nmol•l<sup>-1</sup>; p < 0.05) and evening (38.9 ± 1.0 vs. 25.4 ± 1.4 nmol•l<sup>-1</sup>; p < 0.05) when compared to winners, as well as higher SC levels in all-time points during MD (p < 0.05). Both winners and losers showed significantly lower SC levels in TD when compared to MD at all-time points (p < 0.05). CSAI-2R results showed that winners on MD and TD situations had significantly higher Self-confidence and lower Cognitive Anxiety and Somatic Anxiety scores than losers (p < 0.01). **Discussion** Results indicate that both the independent variables of condition (match vs. practice) and status (winner vs. loser) influenced the psycho-physiological responses for these young athletes. The simultaneous measurement of cortisol and self-reported psychological indicators would provide an approach to examine changes in anxiety, and its relationship to performance. **References** Filaire, E., Alix, D., Ferrand, C. & Verger, M. ### PORTIMÃO RHYTHMIC GYMNASTICS WORLD CUP SCORES ANALYSIS. GROUP AND INDIVIDUAL HOOP ROUTINES

Ávila Carvalho, L., Leandro, C., Lebre, E.

Porto University

The first time rhythmic gymnastics (RG) groups have participated in the Olympic Games, was in 1996 in Atlanta, the first individual participation was in 1984 in Los Angeles. Since that time the level of RG performance has continuously improved. These improvements were also determined by the new guidelines of International Federation of Gymnastics. In order to understand some immediate consequences of the RG code of points implementations we analyzed some key aspects of the hoops routines scores in the 2009 Portimão RG World Cup Series. We focused on the Difficulty scores analysis (body and apparatus difficulties) and on the Artistic and Execution scores in groups and individual routines. For this we analyzed all composition forms submitted by the groups and individual gymnasts competing in the World Cup competition. We divided the sample in 3 ranking groups categories: 1st, 2nd and 3rd part of the final ranking for hoops routines. SPSS version 17.0 was used to carry out the data statistical analysis. The significance level used was α=0.05. **Results:** a) In Difficulty scores: (1) Group routines had a higher departure score than individual gymnasts routines. However, individual routines actually achieved a higher final score in the 1st and in 2nd part of the final ranking; (2) The maximum departure scores for both individual and

group routines are 10 points or close to 10. When we analysed the maximum values achieved in the final scores we found significant differences between the departure score and the final score in the two types of routines (groups and individuals). b) In Execution and Artistic scores: (1) The artistic scores were higher than the execution scores both in groups and individual routines for all categories (1st, 2nd and 3rd part of the final ranking for hoops routines); (2) The execution scores were higher in individual routines when compared with all categories of groups routines; (3) The artistic scores were higher in group routines in the 2nd and 3rd part of the final ranking when compared to the individual gymnasts; (4) The execution and the artistic scores are almost similar in individual and in group routines; (5) There was a moderate positive correlation between the group's execution and artistic scores whereas in the individuals gymnasts there was a strong positive correlation between those scores. Conclusions: a) The individual gymnasts achieved a higher final score in Difficulty scores when compared to groups, the last with the same demand in the five gymnasts; b) We observed a substantial difference between the scores proposed by the coaches in the competition forms and the scores attributed by the judges; c) The lower the ranking position of the gymnast or the group, the higher is the difference between the departure and final scores in Difficulty evaluation. The lower performance level of the gymnasts or group, higher was the overvalued composition by the coaches.

### HEART RATE PROFILE IN SPRINT ON VARIOUS SLOPES

Trecroci, A., Cavaggioni, L., Formenti, D., Arcelli, E., Alberti, G.

*University of Milan*

**Introduction** The running uphill is an intense activity, which can be performed in several training programs as an alternative way to work at high intensity, stressing the cardiovascular system. Precisely, sprinting on incline requires a considerable muscle activation of the lower limb, which affects central aerobic responses, as changes in heart rate (HR) (1,2). Therefore, the aim of the study was to investigate the HR variation during individuals sprint on different inclinations, based on two assumptions: I. HRs rise faster when sprinting on high slopes compared to the level. II. HR reaches higher peaks with increasing slope. **Methods** Ten amateur soccer players carried out three "all-out" sprint lasting 6 seconds for each slope: level-7%-14%-18%. Every bout was separated by a complete recovery. Heart rate monitors (beat to beat) were used to record the time (milliseconds) among heartbeats before, during and after any sprint. **Results** Unlike what has been found during the sprints, heart rate assumed a different profile right after the effort between gradients. I. On slope of 18% heartbeats rose faster than what happened on the level reaching the peak value almost two second before ( $8368 \pm 451$ ms vs.  $10291 \pm 462.2$ ms;  $p < 0.05$ ). II. Statistical differences were not highlighted between heart rate peaks in all of the gradients: level= $154$ bpm, 7%= $159$ bpm; 14%= $155$ bpm, 18%= $157$ bpm ( $p > 0.05$ ). **Discussion** In accordance with the first assumptions, results suggest that running on high slopes (>14%) produces a marked rising of the heartbeats which stress the cardiac system. A possible explanation could regard the fact that intense activity, such as sprinting uphill, increases the ratio of concentric to eccentric muscle activation involving a great metabolic expenditure (3). Although heart's stroke volume is the parameter that mainly limits the aerobic performance (4), high rates of volume stroke (via the increase of heartbeats) are required to cover those demands of oxygen from the muscles, paying for any anaerobic debt. In conclusion, it is reasonable to assume that sprinting uphill is one of the best ways of training due to its significant impact on the central cardiovascular system. **References** 1) Yokozawa T., Fujii N., Ae Michiyoshi. ### INTENSITY PACING STRATEGY AND DOWNHILL STRATEGY DURING A CROSS COUNTRY SKI RACE

Formenti, D.1, Rossi, A.1, Thomassen, T.O.2, Weydahl, A.2

*1: Università degli Studi di Milano, Italy. 2: HIF, Norway.*

**INTRODUCTION** During a cross country ski race the intensity pacing strategy could be affected by different variables. It's not easy to choose the winner strategy. In a previous analysis we found no correlation between the mean heart rate (HR) during the race and the time of the race (RT). In a downhill, the HR normally decreases until the beginning of next flat or uphill. The HR-trend during downhill can be influenced by the payment of oxygen debt and different downhill strategy (Mognoni et al., 2001). The aim of this study was to investigate which intensity pacing strategy would give the best race time during a cross country ski race. **METHODS** During a 10 km interval start skating race, HR of 9 male cross country skiers (Category U-23) was recorded by Polar RS400® (Hz.5sec). We found that all the racers had a clear decrease in HR at about 7 km, in correspondence with a long downhill. We considered the percentage of HR max given by the subjects (%HRmax) pre and post the downhill ( $\% \Delta HR = \% HR_{pre} - \% HR_{post}$ ). In order to study the influence of downhill strategies on the RT, we calculated the correlation index between  $\% \Delta HR$  and RT for all the skiers. As indicator of intensity pacing strategy, we used the angular coefficient of the linear regression for all the HR profiles. HR data were analyzed by Polar Pro Trainer® and Microsoft Excel 2003®. **RESULTS** From angular coefficients, we noticed that all the subjects incremented their HR from the start to the end. There were no correlation between the angular coefficient and RT ( $R^2 = 0.013$ ), and between  $\% \Delta HR$  and the RT for all the skiers ( $R^2 = 0.005$ ), showing that the capacity of recovery during the downhill did not influence RT. The decrease in HR changes from subject to subject. **DISCUSSION** The increment of HR from the start to the end, as the angular coefficients show, has not a linear relationship with RT. This is in opposition with which was found by Lima-Silva (2010) in 10-km running race. The decrease in HR during the downhill, changing for each subject strategy, did not influence RT. The skiers could push faster to increase speed or let the ski flow to recover (Bilodeau et al., 1991).  $\% \Delta HR$  could be influenced by individual technique, ski wax, athletic condition and the kind of work during the downhill. The final part of the race reflects higher intensity as compared to the initial, even if each skier chose his preferred strategy both during the whole race and the downhill. We hypothesise that the skiers used different pacing and downhill strategies during this downhill, a new study is prepared to focus upon this. **REFERENCES** Bilodeau B. et al. (1991). *Int. J. ### BLOOD ALKALOSIS AFFECTED CARDIO-DYNAMIC AND OXYGEN UPTAKE RESPONSES DURING ALL-OUT SUPRA-MAXIMAL CYCLING EXERCISE

Leprêtre, P.M., Hanon, C., Delfour-Peyrethon, R., Thomas, C., Perrey, S., Dorel, S., Bishop, D.

*UFR-STAPS Université de Picardie Jules Verne*

**Introduction** The greater long sprint performance observed in trained compared to recreational subjects is partly attributable to greater oxygen uptake (VO<sub>2</sub>) (Bosquet et al. 2007). Hanon et al. (2010) noticed a VO<sub>2</sub> decrease before the all-out running exercise exhaustion. Previously, Berger et al. (2006) reported that metabolic alkalosis altered VO<sub>2</sub> adaptation especially in the second part of exercise, without

described the responses of its peripheral (a-vO<sub>2</sub>diff) and central (Qc) factors. Objective To investigate whether acid-base balance status affected the Qc - VO<sub>2</sub> relationships, 11 well-trained male cyclists performed on a cycle ergometer a progressive exercise to determine the peak of oxygen uptake (VO<sub>2</sub>peak) and two all-out supra-maximal events in random iso-kinetic conditions with (BICA) or without (PLAC) bicarbonate oral ingestion. Results The highest VO<sub>2</sub> values measured during PLAC and BICA trials were equal to  $92.2 \pm 6.3$  and  $96.6 \pm 8.2\%$  of VO<sub>2</sub>peak, respectively. At the end of all-out trials, VO<sub>2</sub> decrease was related to Qc drop in BICA ( $r = 0.67$ ,  $P < 0.05$ ) but not in PLAC conditions ( $r = 0.51$ ,  $P = \text{NS}$ ). Alkalosis moreover induced a higher heart rate at rest, a lower high stroke volume value and a significant drop of Qc during exercise ( $P < 0.01$ ). Finally, the decrease in mechanical power was not correlated with cardiorespiratory responses. Discussion Mortensen et al. (2008) already reported that Qc and VO<sub>2</sub> reached peak values after 60s and levelled off at values similar to 6% below maximal cycling. High intramuscular forces would affect the time course of the stroke volume (Nassis and Geladas 2002) and then cardiac output in our PLAC condition but not after BICA ingestion that induced a modified contribution of heart rate and stroke volume in Qc responses at rest and during exercise. Conclusion Suppressed acidosis by oral bicarbonate ingestion did not significantly change mean power output but induced different contribution of stroke volume in Qc responses during a long sprint event. ### **BODY BALANCE AND PROPRIOCEPTION AMONG DIFFERENT SPORT-SKILLS**

Cavaggioni, L., Boccolini, G., Bonfanti, L., Trecroci, A., Alberti, G.

*University of Milan*

INTRODUCTION Balance is important not only to improve athletes' performance, but also to guarantee an efficient lifestyle in daily activities for normal people(1). There are many clinical measure of balance abilities both in a static or dynamic way, but exist a simple test called "Y Balance Test" which requires proprioception, flexibility, strength and stability. This evaluation system is predictive of lower extremity injuries(2), and discriminating between athletes based on age and sport (3). The aim of this study was to compare balance abilities among 4 different categories of sport-skills: team sports(TS), water sports(WS), individual sport(IS) and sedentary(S). METHODS 137 male volunteers who participated in agonistic competitions were recruited: TS (n=30), WS (n=24), IS (n=54), S (n=29). To assess dynamic balance, participants performed multidirectional maximal single-leg reaches in 3 directions with both legs: anterior, posteromedial and posterolateral. This procedure was replicate for 3 times and for each limb was measured the Composite Score with the following formula:  $(AD+PLD+PMD)/(3 \times \text{limb length}) \times 100$ . RESULTS Observing the mean Composite Score with Right Leg, TS had an higher balance compared to WS(104.8% vs. 83.4%)( $p < 0.05$ ). IS was elevated with significant differences compared with other groups and S had a higher values from WS(102% vs. 83.4%), but lower from S(102% vs. 109%)( $p < 0.05$ ). Considering Left Leg, TS had an higher mean value only with WS(106.4% vs. 83.4%) but not with other groups. WS was significantly different from all sports with the lowest mean Composite percentage(83.4%). In terms of dynamic balance, individual sports (IS) reached the maximum mean value, whereas water sports (WS) obtained the lowest one, owing to their cyclic movements; although S and TS express good proprioception abilities, team sports have a greater control, due to their opens-skill actions. Surprisingly the right leg had a better Composite Score among groups rather the left one, and it could be attributed to a different cross dominance between limbs. Probably the dominant leg is more stable and strength, so it produces an effective major balance control. REFERENCES (1) Judge JO. ### **IS THE ABILITY TO CHANGE DIRECTION INFLUENCED BY HIP STRENGTH AND FLEXIBILITY IN YOUTH SOCCER PLAYERS?**

Paul, D.1, Nassis, G.1, Marques, J.1, Kenneally, D.1, Chalabi, H.1

*ASPETAR-Qatar Orthopaedic and Sports Medicine Hospital*

Introduction The ability to change direction is an important characteristic of soccer. However, current understanding regarding factors important for change of direction (CoD) performance remain unclear. Therefore, the aim of the present study was to determine the relationship between measures of hip strength and flexibility and CoD performance. Method Sixteen trained youth team soccer players (mean  $\pm$  SD age:  $16.3 \pm 0.3$ y, weight:  $58.6 \pm 4.9$ kg, height:  $174.8 \pm 5.9$ cm) participated in the study. Hip strength (adduction and abduction) was measured using a hand held dynamometer and adductor flexibility (bent knee fall out test-the lower the value the better the flexibility) by the distance of the most distal part of the fibula and surface using an inflexible tape measure. Participants also performed a modified 20m L run test with timing gates placed at 2m before (8m) and 2m (12m) after the CoD in order to determine actual turn time. Data were normally distributed. Pearson's correlation between CoD and physical measures was performed. Results Average total times were 4.05s ( $\pm 0.16$ ) and 4.12s ( $\pm 0.16$ ) for the right and left side and mean CoD turn times were 0.91s ( $\pm 0.18$ ) and 0.97s ( $\pm 0.15$ ) for right and left side, respectively. A significant relationship ( $p < 0.05$ ) was observed between right flexibility and right (-0.50) and left (-0.58) CoD total time. No other correlations were found. Conclusion The main findings of the present study were 1) greater hip flexibility is associated with slower total CoD time 2) there was no relationship found between hip abduction and adduction strength and the ability to change direction. We speculate that greater flexibility may decrease the stiffness and elongate the durations of the eccentric and concentric action phase (Knudson et al., 2001). Although no relationship was observed between hip strength and CoD performance, other indices of strength and power e.g. rate of force development are worth investigating. In conclusion, a player's hip flexibility may be related to direction change ability and can possibly be considered as another facet to the complex paradigm of CoD performance. ### **EFFECT OF A PERIODIZED PRE-SEASON TRAINING PLAN ON INTERNAL TRAINING LOAD AND MEASURES OF STRESS, HORMONES, IMMUNITY AND PHYSICAL PERFORMANCE IN YOUNG TENNIS PLAYERS**

Gomes, R.V.1, Moreira, A.1, Crewther, B.T.2, Nosaka, K.3, Aoki, M.S.1

1 - University of São Paulo, São Paulo, Brazil; 2 - Imperial College, London, United Kingdom; 3 - Edith Cowan University, Western Australia, Australia

Introduction To date, relatively few reports have examined the training stressors imposed on young elite tennis players during pre-season and there is no previous investigation examining the subsequent impact on physical performance capacity. Therefore, the study aim was

to investigate the effect of a periodized pre-season training plan on internal training load and subsequent stress tolerance, hormones, mucosal immunity and physical performance in tennis players. Methods Well-trained young tennis players (n=10) were monitored across the pre-season tennis period, which was divided into 4 weeks of overload training and a 1 week tapering period. Weekly measures of internal training load, training monotony, stress tolerance (sources and symptoms of stress) were taken, along with salivary testosterone, cortisol and immunoglobulin A (IgA). Maximum strength, running endurance, jump height and agility were assessed pre- and post-training. Results The periodized training plan led to significant weekly changes in training load (i.e. increasing in weeks 3 and 4, decreasing in week 5) and post-training improvements in strength, endurance and agility ( $P < 0.05$ ). Cortisol concentration and the symptoms of stress also increased in weeks 3 and/or 4, before returning to baseline in week 5 ( $P < 0.05$ ). Conversely, the testosterone to cortisol ratio decreased in weeks 3 and 4, before returning to baseline in week 5 ( $P < 0.05$ ). Discussion The periodized pre-season training plan evoked similar weekly changes in external and internal training load in young tennis players. The training plan also produced adaptive changes in stress tolerance, cortisol and the testosterone to cortisol ratio, which may have mediated the improvements in performance capacity. The results of the present study confirm the effectiveness of a simple periodized training plan (initial overloading and then tapering) for improving the performance capacity of young tennis players pre-competition. The presented findings support the use of the session-RPE and DALDA as practical tools for monitoring training in the field setting. In addition, hormonal responses could also be useful physiological measures of training responses. When used as part of a multi-factorial monitoring program, these psychometric and physiological measures may assist coaches making decisions regarding how a group or individual are responding to training.

### VARIABILITY EFFECTS OF THROWING WITH „OVERSIZE-BALL“ AND „SHOOTING-RING“ IN BASKETBALL

Mueller, H., Maurer, L.K., Maurer, H.

*Justus Liebig University*

Introduction In Basketball two training devices are used to improve hit rate: an oversized ball with regulation weight (OS) and a shooting ring to be mounted on top of the regulation rim to reduce its diameter (SR). Both devices have the goal to enhance the pressure of throwing with higher accuracy (i.e. with less variability of ball trajectories at the rim level). There is no empirical evidence of positive effects of OS or SR. Moreover, negative effects cannot be excluded since altered size and moment of inertia of OS as well as a varied perception caused by SR can influence the throwing movement. We therefore analyzed acute effects on performance and kinematics with focus on variability measures in this study. Methods 29 Junior Basketball players (national level; Mage = 15.5; SDage = 1.9) performed 100 throws with OS and SR each and 200 throws with regulation ball and rim in the laboratory. The sequence of conditions was balanced. Ball flight and movement execution was recorded with a marker-based 16 camera VICON-MX system. Hit rate, variability/dispersion of ball trajectories at the rim level as well as release angle and velocity were compared between conditions (OS, SR, regulation). Results The hit rate decreased in throws with OS ( $t(28) = 7.0, p < .001, d = 1.3$ ) and SR ( $t(28) = 7.6, p < .001, d = 1.4$ ). Preliminary kinematic results of 15 participants showed no differences in variability/dispersion of ball-flight curves at the rim level between conditions. However, with OS, release angle as well as release velocity were higher compared to the regulation condition (angle:  $t(14) = 5.96, p < .001, d = 1.6$ ; velocity:  $t(14) = 2.51, p = .02, d = 0.8$ ). Discussion Throws with OS and SR lead to lower hit rates, which is a consequence of the reduced hit area. The training devices do not seem to cause negative effects on stability or variability of the throws. In fact, players temporarily adapted their throwing movement at least with OS. They released the ball with higher angle and faster velocity, which might be a form of a more error-tolerant movement execution. Whether training with OS or SR can transfer the more beneficial throwing execution/strategy to the regulation condition, is currently tested.

### TRAINING ADAPTATION DOES NOT CORRELATE WITH SONOANATOMIC CHANGES IN QUADRICEPS MUSCLE IN AN ELDERLY HEALTHY GROUP

Delicado, M.C.1, Guillamó, E.1, Oviedo, G.R.2, Frauzino, F.C.1, Álamo, J.1, Roca, A.1, Miguel, M.1, Ventura, J.L.1, Javierre, C.1

*University of Barcelona. Medical School*

Introduction The aim of this study was to assess: the functional capacity, the quadriceps muscle size and the walking speed after a physical activity plan (PAP) in an elderly group. Methods Participants were 30 healthy volunteers  $\geq 64$  years, 24 were subjected to an activity program (AG) and 5 were the control group (CG). The program included 4 weekly sessions (focusing on strength, endurance, balance and proprioception) for 20 weeks. Two of these weekly sessions took place in the laboratory, while the other two were conducted at the patients' home. At the beginning and at the end of the program, we carried out a graded treadmill stress test until exhaustion with cardioventilatory monitoring, an ultrasound measurement of the anteroposterior diameter of the quadriceps, the thigh perimeter measurement and a test of walking speed along 10 meters (modified from JAMA 2011). Results The values at the start and at the end of the program, showed significant changes in both groups in:  $VO_2$  peak, ventilation and heart rate. We found significant differences in the 10 meters walking speed test ( $p = 0.002$ ) and the maximal heart rate ( $p = 0.005$ ) during the maximal stress test when comparing the two groups. There were no changes in: the quadriceps diameter, the thigh perimeter and the other ventilatory variables. Significant correlations were observed between the diameters of the quadriceps and the respiratory equivalent for  $O_2$  and  $CO_2$  ( $p < 0.003$ ), the fractional exhaled  $O_2$  and  $CO_2$  ( $p < 0.001$ ) and the heart rate ( $p < 0.05$ ); also between the thighs perimeters and the respiratory equivalent for  $O_2$  and  $CO_2$  ( $p < 0.05$ ), fractional exhaled  $O_2$  and  $CO_2$  ( $p < 0.03$ ) and  $O_2$  consumption/weight ( $p < 0.04$ ) both before and after PAP. Discussion The participants in the program of physical activity referred an improvement in carrying out daily living activities of the participants but without changes neither in the ultrasound measurements of quadriceps diameter nor in thigh perimeter. Other factors, such a decrease in fatty infiltration of the muscle, could compensate the possible increase in the lean muscle size. The walking speed along 10 meters seem to correlate with the increase in  $VO_2$  max. References Perula LA, et al. (2012) Arch Phys Med Rehabil. 93(10):1677-84. Raj IS, Bird SR, Shield AJ. ### COMPARISON BETWEEN OBESITY AND METABOLIC SYNDROME IN THE CARDIOMETABOLIC RESPONSE TO INCREMENTAL EXERCISE

Milia, R.1, Velluzzi, F.1, Roberto, S.1, Lai, D.1, Contis, M.1, Chighini, G.P.2, Milia, N.3, Sebis, L.1, Sainas, G.1, Concu, A.1, Loviselli, A.1

*University of Cagliari*

**Introduction.** It was recently observed that higher fitness should be considered a characteristic of metabolically healthy but obese phenotype by converse obesity is often associated with metabolic syndrome (MS) that is a condition of accumulated risk factors of metabolic origin including central obesity, hypertension, insulin resistance, impaired glucose tolerance and dyslipidaemia. This study was devised to assess the difference on cardiometabolic response to incremental exercise between female subjects affected by obesity and metabolic syndrome. **Methods.** One group consisted of 36 sedentary obese woman were selected according to be (18 subjects, OB group) or not to be affected by Metabolic Syndrome (18 subjects, MS group) matched for age and body mass index. A normal-weight group (NW) matched for age, consisting in 16 female subjects has been also recruited. Each participant underwent an incremental exercise test on a cycle-ergometer up to exhaustion. Maximal oxygen uptake (VO<sub>2</sub>max), carbon dioxide production (VCO<sub>2</sub>), heart rate (HR) and oxygen pulse, were measured by using a gas analyzer. Blood arterial pressure was also assessed. **Results.** The main results was that there were no significantly differences between OB group and MS group respectively on average (mean ± standard deviation) in VO<sub>2</sub>max 17.3±2.9 mL•Kg•min<sup>-1</sup> vs. 17.2±2.8 mL•Kg•min<sup>-1</sup> (NW value was 21.9±5.7 mL•Kg•min<sup>-1</sup> p<0,005); VCO<sub>2</sub> 1841.1±415.9 mL•min<sup>-1</sup> vs. 1647.9±307.2 mL•min<sup>-1</sup>; oxygen pulse 9.6±1.8 mL•min<sup>-1</sup> vs. 10.4±2 mL•min<sup>-1</sup>. However the OB group reached a significantly higher maximal heart rate value that was on average 162.4±11.4 bpm while that of the MS group was on average 150.7±20 bpm, although both group have reached similar maximal workload (OB 122.2±25.5 watt•min<sup>-1</sup> vs. MS 107±22.2 watt•min<sup>-1</sup>). As regards the blood pressure level reached at maximal workload there were no significantly differences between two groups. **Discussion.** In our study OB and MS group showed a significantly lower fitness with respect to NW, without any differences between patients groups, suggesting the main role of obesity per se. **References.** Ortega F.B. et al (2013) *Eur. ### EVALUATION OF THE PARAMETER Tlim IN COPD PATIENTS

Simi, H., Wallner, D., Hofmann, P., Wurzinger, G.

*FH JOANNEUM Sport Science Laboratory, Institut of Sport Science University of Graz, LKH Hoergas-Enzenbach*

**1**Sport Science Laboratory FH JOANNEUM, **2**Institut of Sport Science, University of Graz **3**LKH Hörgas-Enzenbach **Introduction** A multitude of studies have shown that respiratory muscle training has positive effects on inspiratory muscle strength and endurance [1]. The measurement of inspiratory muscle strength has been well established. Questions about the determination of inspiratory muscle endurance are still open. **Aim** Aim of the study was to evaluate the parameter Tlim in COPD patients, to investigate the value of inspiratory muscle strength as a predictor for inspiratory muscle endurance. **Methods** 24 COPD patients (GOLD B-D: 8 Patients B, 10 Patients C, 6 Patients D), 68±7.8 years of age, participated in this study. Patients P<sub>max</sub> was defined as the maximal inspiratory mouth pressure, during ten completed manoeuvres with a break of 10 seconds. The mean value of the best three measurements was taken. Tlim was determined as the time span in seconds until exhaustion, while breathing against a resistive load of 60% P<sub>max</sub>. Measurement stopped when four breaths were not completed successively. All measurements were performed with RespiFit S (E. Biegler GmbH, Mauerbach, Austria). A bodyplethysmography to define forced expired volume in the first second (FEV<sub>1</sub>), forced vital capacity (FVC), FEV<sub>1</sub>%FVC ratio, residual volume (RV), total lung capacity (TLC) and RV%TLC ratio was initially conducted in all patients. Correlation analysis was performed accordingly. **Results** Mean Tlim reached from 149±135 sec., mean P<sub>max</sub> from 62±18,54 mbar (e.g. mean value in COPD B-D: 75,51±27,45 mbar, [2]) No significant correlation was found between the Tlim and P<sub>max</sub>, Tlim and height, weight and lung function parameter, except a negative correlation between Tlim and FEV<sub>1</sub> (-0,474; p=0,019). **Conclusion** Inspiratory muscle endurance has to be determined in addition to inspiratory muscle strength when evaluating inspiratory muscle function in COPD patients. The results confirm studies completed with healthy subjects [3]. A reason for the negative correlation between Tlim and FEV<sub>1</sub> could be justified by completing the bodyplethysmographie a few days before testing P<sub>max</sub> and Tlim. **References** [1] Loetters F., van Tol B., Kwakkel G. & Gosselink R (2002). *Eur Respir J* (20), 570-576. ### FUNCTIONAL CLASSIFICATION OF LOWER BACK DISORDERS IN ATHLETES

Kaneoka, K.

*Waseda University*

**Introduction:** The pathomechanism of low back pain (LBP) among young athletes is not clear owing to the lack of radiological findings. We classified lower back disorders of collegiate athletes according to the functional findings. **Methods:** In total, 115 collegiate athletes who had LBP visited the orthopaedic clinic in our university during 2008 to 2012. They were examined by an orthopaedic surgeon, and the spinal findings, tenderness points, and neurological findings were recorded. The subjects were classified into 4 pathomechanism categories according to the findings of clinical examinations: intervertebral disc pain (IVD), zygapophysial joint pain (facet), sacroiliac joint pain (Sij), and non-specific LBP (NS). The athletes whose LBP exaggerated with lumbar flexion motion, as evident on magnetic resonance images, were determined as having IVD pain. The athletes whose LBP exaggerated with lumbar extension motion, particularly with posterior oblique extension, were determined as having facet pain. The athletes with LBP localized at the posterior sacroiliac spine and tenderness at the Sij, which exaggerated after Sij stress tests, were determined as having Sij pain. **Results:** Fifty-nine (39%) athletes had IVD pain; of these, 24 (16%) showed positive neurological and MRI findings and were diagnosed with IVD herniation, and the other 35 (23%) were diagnosed with discogenic LBP. Fifty-six (37%) athletes had facet pain and 18 (12%) had Sij pain. Ten athletes did not show exaggerated LBP during both flexion and extension and were classified in the NS category. Several athletes were categorized into 2 or more pathomechanism categories. **Discussion:** Identification of the pathomechanism of lower back disorders is important for their prevention. Therefore, we estimated the pathomechanism of LBP on the basis of the functional and clinical findings; among collegiate athletes, the prevalence of discogenic pain was 39%; facet pain, 37%; Sij pain, 12%; and non-specific LBP, 9%.

**THE EXAMINATION OF THE EFFECT OF ORAL-DENTAL HEALTH STATUS ON FEMALE ATHLETES' PERFORMANCE**

Ayan, S., Baglar, S., Yapici, H., Memiş, U.

*Kirikkale University, Kirikkale University, Kirikkale University, Bulent Ecevit University*

Introduction Researches has shown that insufficient oral health has negative effects on general health status (Cameron et al, 2006; Matilla et al, 1995; Tenevuo et al, 1990). Training programmes on solving that incompetence of athletes which should be carefully designed by exercise physiologists, sports medicine specialists and trainers can also increase the effect of itself and minimize the time spending on reaching the goal. The aim of this research was to examine the relationship between female athletes' (basketball, handball, soccer) oral-dental health status  $DMFT \geq 4.00$ - $DMFT < 4.00$  and their speed, agility and Bosco Test results. Methods 52 female athletes participated in this research. Bosco Test, different agility tests, and 10,20,30 m sprint tests (Meckel et al, 2009) were conducted. Oral-dental examination of the sample group was done in the clinics of Faculty of Dentistry and performance tests were done in the sports hall of Kirikkale University. To determine oral-dental health status decayed, missing, filled tooth (DMFT) index suggested by World Health Organization (World Health Organization, 2010) was used. After gaining approval from the ethics committee of Faculty of Medicine, performance tests were conducted and dental examinations were made and finally statistical analysis were done. Results The mean age of participants were  $19,3 \pm 1$ (yr), mean weight was  $57,6 \pm 8$ (kg), mean height was  $164,4 \pm 0,5$ (cm), and mean sport age was  $4,5 \pm 2$ (yr). Results revealed that there was a significant difference between performance test results of female athletes who have less than 4 DMFT values and those who have equal or over 4 DMFT values ( $p < 0.01$ ). On the contrary, Bosco test results of athletes whose DMFT values were equal or over 4 were significantly better than the other group. Discussion Recently, many studies have urged that athletes have insufficient oral-dental health which can affect their performance. Insufficient health status of oral-dental region can cause pneumonia by means of increased number of gram negative bacteria and decreased level of saliva (Marik and Zalaga, 2001; Ostajic, 2004). In this research, athletes who had worse oral-dental health status also had worse performance test results. Similar results were also found other studies (Gay-Escoda et al, 2001; Jason et al, 2009; Tenevuo et al, 1990). References MARIK PE., ZALAGA GP. (2001). **ENDURANCE TRAINING IMPROVES METABOLIC PARAMETERS IN CACHECTIC CANCER PATIENTS.**

Matos-Neto, E.M., Camargo, R.G., Neves, R.X., Ribeiro, H.Q., Enju, L.M., Capel, F., Figuerêdo, R.G., Alcantara, P.S., Pinhata, J., Maximiano, L., Seelaender, M.

*University of São Paulo*

Introduction – Cachectic patients usually show lower cardiorespiratory fitness, profound wasting, endocrine disorders, fatigue and decreased quality of life. On the other hand, endurance exercise training is considered a strategy to reduce these symptoms (Fong et al. 2012). Therefore, the goal of the study was to test the effectiveness of a protocol of endurance training in reducing cachexia effects. Methods – Both group of patients with gastric carcinoma – non-cachectic cancer (NcC, n = 15), cachectic cancer (cC, n = 7) – Cancer group, and the group of patients with umbilical hernia. Control group (N, n = 22), were submitted to an endurance training protocol (Dimeo et al. 1997, adapted), consisting of 6 weeks of walking on a treadmill with increasing volume and intensity, assessed individually after a submaximal test (Kline et al., 1987), to estimate each volunteer's  $VO_{2max}$ . The submaximal test and plasma lactate evaluates were carried out at the first, third and sixth week of the experimental protocol to ensure the maintenance training intensity. None of the patients received anticancer drugs. Results – Volunteers had significant difference in the body mass (N:  $78.52 \pm 3.46$  Kg, NcC:  $76.43 \pm 4.96$  Kg and cC:  $54.32 \pm 6.71$  Kg) ( $p = 0.01$ ). Significant differences were found to serum glucose levels (N:  $98.0 \pm 4.33$  mg/dL, NcC:  $101.5 \pm 4.85$  mg/dL and cC:  $167.5 \pm 1.5$  mg/dL) ( $p = 0.001$ ). The significant difference at the end of the sixth week (N:  $23.7 \pm 3.55$  ml.kg.min and Cancer group:  $23.38$  ml.kg.min  $\pm 3.91$ ) compared with the first week (Control group:  $11.43 \pm 3.98$  ml.kg.min and Cancer group:  $5.52 \pm 2.59$  mL.kg. min) ( $p = 0.001$ ), proved the protocol to be effective in increasing estimated  $VO_{2max}$  in the groups. Plasma lactate decreased at the end of the sixth week as a result of training (Control group:  $0.88 \pm 0.06$  mmol/L and Cancer groups:  $0.35 \pm 0.91$  mmol/L) compared to the first week (Control group:  $1.03 \pm 0.21$  mmol/L and Cancer groups:  $1.31 \pm 0.13$  mmol/L) ( $p = 0.004$ ). Discussion – Patients with cancer often show reduction of cardiorespiratory fitness and increased fatigue. Physical training improves physical fitness and quality of life of patients (Pekmezi and Demark-Wahnefried, 2011). Our results show that cachectic patients may benefit from the practice of regular exercise. References Dimeo FC, Tilmann MH, Bertz H et al. *Cancer* 1997; 79: 1717-1722. **THE TEST-RETEST RELIABILITY OF EUCAPNIC VOLUNTARY HYPERVENTILATION AND PULMONARY FUNCTION IN DIAGNOSING EXERCISE INDUCED BRONCHOCONSTRICTION**

Williams, N.C., Hunter, K., Johnson, M.A., Sharpe, G.R.

*Nottingham Trent University*

Introduction EVH is commonly used to diagnose EIB and can reveal the condition in previously undiagnosed athletes (Dickinson et al., 2011). The within-subject test-retest reliability of EVH responses have not been reported but are of interest to those using EVH as an outcome measure in intervention-based studies. The aim of the study was to assess the within-subject test-retest reliability of pulmonary function before and after EVH, and subsequent EIB diagnosis over four, weekly sessions in both non-EIB controls (CTRL) and EIB sufferers. Methods Eight recreationally active EIB positive ( $\geq -10\% \Delta FEV_1$  after EVH) males and 8 (age and activity matched) non-EIB males volunteered for the study. Following familiarisation all participants performed 4 EVH tests each separated by 5-7 days. During EVH participants breathed a dry (<5% RH) gas mixture (5%  $CO_2$ , 21%  $O_2$ , balance  $N_2$ ) and maintained a minute ventilation of  $30 \times$  baseline  $FEV_1$  for 6 min. FVC and FEV1 were measured before and 3, 6, and 16 min after EVH. Reproducibility of pulmonary function parameters pre and post EVH was assessed, intraclass correlation coefficient (ICC)  $> 0.70$  was considered a minimum acceptable reliability (Baumgartner & Chung, 2001). Within-subject coefficient of variations for raw pulmonary function data were calculated to assess the within-participant reproducibility in response to EVH. Independent samples t-tests compared pulmonary function differences between EIB and CTRLs. Results Excellent (ICCs  $\geq 0.70$ ) test-retest reliability was observed over the four weeks for FVC, FEV1,  $\% \Delta FEV_1$  and absolute change in FEV1 at each time point for both CTRL and EIB groups. Mean within-subject CVs for FVC were  $\leq 0.02 \pm 0.01$  for CTRLs and  $\leq 0.09 \pm 0.08$  for EIBs over the four weeks

for all time points. Mean within-subject CVs for FEV1 over the four weeks at all time points for CTRL and EIB were  $\leq 0.02 \pm 0.01$  and  $\leq 0.1 \pm 0.12$  respectively. Importantly the diagnostic outcome measure of  $\% \Delta FEV1$  showed excellent relative reliability over the four weeks with high ICC values of  $\geq 0.95$  for each time point. Pre EVH values of FEV1 were significantly lower in the EIB group when compared to CTRLs ( $p < 0.05$ ).  $\% \Delta FEV1$  was greater for the EIB group (3min  $26 \pm 16\%$ ; 6min  $28 \pm 19\%$ ; 16min  $22 \pm 16\%$ ) compared to CTRLs (3min  $3.3 \pm 2.1\%$ ; 6min  $2.2 \pm 2.0\%$ ; 16min  $1.5 \pm 1.4\%$ ) at all post EVH time points ( $p < 0.05$ ). Conclusion The within-subject response to EVH, assessed by changes in pulmonary function, was highly reliable in this small sample of both CTRL and EIB participants. This supports the use of EVH to assess EIB intervention-based research. References Dickinson J, McConnell A, Whyte G. (2011). *Br J Sports Med*, 45(14):1126-1131 Baumgartner TA, Chung H. ### PHYSICAL INACTIVITY AND OTHER LIFESTYLE RISK FACTORS FROM CATALAN PHYSICIANS

Pardo, A.1, McKenna, J.2, Mijangas, A.3, Camps, B.4, García, J.5, Aranda, S.6, Violán, M.1

*National Institute of Sport Science (INEFC), 1: PAFES Group (Barcelona, Spain)*

Introduction Previous literature has shown that physicians with poor personal habits such as physical inactivity or overweight are less likely to counsel patient about healthy lifestyle (Reilly, 2007; Frank et al., 2010). The present study identifies lifestyle risk factors (LRF) such as physical inactivity, overweight and smoking habit and their combination in a sample of physicians from the Catalan Medical Council. Methods 2,400 physicians (30 to 55 years) were randomly selected; each received a self-administered mailed questionnaire identifying medical specialization, work setting, health self-perception, body mass index (BMI), physical activity (PA) and smoking habits. Results 762 physicians responded (52% female). Half of physicians (49.7%) were under-exercisers (do not exercise enough to meet current PA guidelines (WHO, 2010)), nearly all self-perceived good health, while 80.5% were non-smokers. Almost 6 in 10 males reported overweight or obesity (56.9%) versus 18.2% of females. 72.6% presented one or more LRF from under-exercising, BMI  $\geq 25 \text{ kg/m}^2$  and a current smoking habit. Physical inactivity was the commonest of the LRFs (24.1%), while the most common combination paired under-exercising with BMI  $\geq 25 \text{ kg/m}^2$  (17.5%). Males were three times more likely than females to present the combination of under-exercising and a BMI  $\geq 25 \text{ kg/m}^2$  (OR=3.38; 95% CI=2.31-4.95,  $p < .01$ ). Those who perceived 'Poor' health status were three times more likely to report both LRFs (OR=3.61; 95% CI=1.88-6.94) than those who perceived positive health status ( $p < .01$ ). Conclusions Our findings suggest that females physicians support the most optimal lifestyles, yet almost one of four physicians in the current study presented one or more LRFs, with under-exercising or/and overweight/obesity being the most prevalent. Being male physician and having poor health were the strongest predictors for both under-exercise and obesity. Low compliance with PA recommendations could adversely influence the PA promotion that, in turn, influences patients' health. References Reilly JM. (2007). *Am Fam Physician*.1;75(5):738, 741. ### SELF-REPORTED EXERCISE LIMITATIONS IN ASTHMATIC ADOLESCENTS

Westergren, T.1, Lødrup Carlsen, K.C.2,3, Carlsen, K.H.2,3,4, Fegran, L.1, Berntsen, S.1

*1 University of Agder, 2 Oslo University Hospital, 3 University of Oslo, 4 Norwegian School of Sport Sciences.*

Introduction Physical activity (PA) is associated with several health benefits. Optimal use of asthma medications in asthmatic adolescents may enable a physically active lifestyle.(1) However, children and guardians perceiving asthma medication as potentially harmful may accept a lower level of PA.(2) The aim of the present study was to determine whether use of medications, asthma exacerbations, self-reported exercise induced asthma (EIA) symptoms and lung function is associated with self-reported exercise limitations (EL) in adolescents with asthma. Methods From the birth cohort, Environment and Childhood Asthma study in Oslo, Norway,(3,4) 95 13-years old adolescents with asthma participated in a structured interview concerning asthma symptoms and exacerbations, use of medication and provoking factors during the last 14 days. Lung function was measured by maximum forced expiratory flow-volume curves. Data were analyzed using logistic regression analysis. Results Exercise limitation due to asthma was reported by 22% of the adolescents. Use of inhaled corticosteroids (ICS) and  $\beta_2$ -agonists were reported by 32% and 37%, respectively. Subjects reporting EL significantly more often than those who did not, reported asthma exacerbations (24% vs 8%  $p=0.047$ ), EIA symptoms (57% vs 30%  $p=0.021$ ), use of ICS (71% vs 20%  $p < 0.001$ ) and  $\beta_2$ -agonists (67% vs 29%  $p=0.002$ ). Forced Expiratory Volume in 1 second (% of predicted) was not significantly reduced in adolescents with EL. In multivariate analysis only use of ICS ( $p < 0.001$ ) was associated with EL and explained 28% of the variance in self-reported EL. Discussion The use of ICS may indicate greater severity of asthma and and/or the importance of perceived asthma severity, whereas no use of  $\beta_2$ -agonists in 33% of adolescents with EL may indicate non-adherence or limited knowledge of therapeutic options for preventing EIA symptoms. Further analysis on associations between EL, self-reported disease and symptom perception, and objectively measured EIA is needed. References 1. Berntsen S. ### SAFETY OF HIGH-INTENSITY INTERVAL TRAINING IN PATIENTS WITH TYPE 2 DIABETES TREATED WITH ORAL HYPOLYCEMIC AGENTS: DIABETES EM MOVIMENTO® PILOT STUDY

Mendes, R., Sousa, N., Garrido, N., Rocha, P., Themudo Barata, J., Reis, V.

*University of Trás-os-Montes e Alto Douro*

Introduction High-intensity interval training (HIIT) is characterized by brief periods of high-intensity aerobic exercise separated by recovery periods of lower-intensity aerobic exercise or rest and has been recently recognized to improve health outcomes in non-athletes population. However, studies about its effects in type 2 diabetic patients are still lacking. This study aims to analyze the metabolic and cardiovascular safety of high-intensity interval training in patients with type 2 treated with oral hypoglycemic agents. Methods Twelve individuals with type 2 diabetes (diagnosed at  $5.83 \pm 3.13$  years; 6 men and 6 women; age  $58.67 \pm 5.35$  years; glycated hemoglobin  $7.08 \pm 1.18\%$ ; body mass index  $30.07 \pm 5.64 \text{ kg/m}^2$ ) treated with oral hypoglycemic agents (metformin, N = 5; metformin + sitagliptin, N = 4; metformin + vildagliptin, N = 3) underwent a single exercise session of HIIT on treadmill. After a 5-min warm-up, subjects performed 5 sets of 3 min brisk walking at 70% of heart rate reserve, interspersed with 3 min at 30% of heart rate reserve. In the end a 5-min cool-down was carried, totaling a 40-min exercise session. Treadmill speed and grade were adjusted to induce the defined intensity. Training zones were calculated with Karvonen heart rate reserve method. Exercise sessions were held in the morning period during standardized break-

fast postprandial state. Capillary blood glucose was measured at baseline, during exercise and during 50 min recovery. Blood pressure was measured at baseline and during 50 min recovery. Capillary blood glucose and blood pressure were assessed in 10-min periods. Results No acute adverse events occurred during exercise or recovery: no symptomatic hypoglycemia, hyperglycemia, hypotension, hypertensive crises, no symptoms of myocardial ischemia or stroke and no musculoskeletal injuries. Both blood glucose and blood pressure decreased with exercise. Minimum capillary blood glucose values were registered at the end of exercise ( $91.17 \pm 38.71$  mg/dl) and minimum systolic blood pressure values were registered at 40 min of recovery ( $108.67 \pm 9.65$  mmHg). Conclusions HIIT appears to be a safe exercise strategy to control glycemia and cardiovascular risk in patients with type 2 diabetes treated with metformin or with a combination of metformin and DPP-4 inhibitors sitagliptin and vildagliptin. Trial funding and registration Diabetes em Movimento® is funded by Portuguese Foundation for Science and Technology with reference SFRH/BD/47733/2008 and is registered in Current Controlled Trials with reference ISRCTN09240628.

### **BENEFITS OF INTEGRATIVE TRAINING TO BREAST CANCER PATIENTS' HEALTH. A PILOT STUDY.**

Casla Barrio, S.

*INEF (Universidad Politécnica de Madrid)*

Introduction Breast Cancer is the most common cancer in occidental women (SEOM). It presents a very high survival (SEOM) with a lot of side effect produced by the treatments such as chemotherapy, which decreases patient lean mass (Demark-Wahnefried, 2001). Research has showed important decrease in specific-cancer mortality in active patients (Irwin, 2008). Our goal is to know the effect of a guide exercise program on global strength of women with breast cancer. Methods: The design of the project was one arm, pre-post test. This program consisted in 24 classes of combined exercise (strength and aerobic activities), guided by a qualified, developed in Universidad Politécnica de Madrid. The intensity was monitored by Polar FT7 heart rate monitors. 31 women were studied. Global strength was assessed by Grip T.K.K.5401, functional capacity was assessed by 6 minutes walking test, quality of life was assessed by FACT-B questionnaire and depression was assessed by CES-D test. Results: A positive change was observed in the global strength ( $p=0.009$ ) and in the functional capacity ( $p=0.005$ ). Also they showed an increase in their quality of life ( $p=0.034$ ), and in different psychological aspects as depression ( $p=0.029$  y  $p=0.003$ ) Discussion: Related to our primary outcome, the results showed an improvement in global strength. Strength is an important factor to improve in this target population because of the existent relationship between strength improvements and lean mass increase (Demark-Wahnefried, 2001). Demark-Wahnefried et al. (Demark-Wahnefried, 2008) assessed the effect of combined exercise in this population and results showed that lean mass was preserved in intervention group. Women presented better functional capacity at the end of the program agree with previous interventions (Eyigor, 2010) what showed a survival increasing in this population (Kasymjanova, 2009). Study conclusions suggest that this kind of global intervention could improve global strength and functional capacity, important to increase the survival. ### **EFFECTS OF PHYSICAL EXERCISE IN PATIENTS WITH ACUTE LEUKEMIA UNDERGOING INDUCTION CHEMOTHERAPY**

Wehrle, A.1, Kneis, S.2, Bertz, H.2, Dickhuth, H.H.1, Gollhofer, A.3

*University of Freiburg (Germany)*

Introduction In recent years some clinical trials have demonstrated, that physical activity is feasible and has positive physical and psychological effects on patients with haematological malignancies undergoing chemotherapy. Little is known about the contributions of resistance and endurance training to the results found and data in acute leukemia are limited anyway. First cycles of chemotherapy for acute leukemia (induction chemotherapy) are one of the most intense chemotherapy. The medical therapy as well as extended hospitalisation causes a lot of side effects including physical deconditioning which are affecting quality of life. Therefore the aim of this ongoing study is to investigate and compare the effects of two exercise varieties – resistance and endurance training with patients diagnosed with acute leukemia. Methods Twenty-nine patients, diagnosed with acute leukemia were included in the study. Prior to induction-chemotherapy the patients were randomly assigned to one of three training groups: endurance, resistance or stretching/ mobilisation (control condition) and will perform a 30-minute program (3x/week) for the duration of their hospitalisation (4-6 weeks). Endurance capacity (incremental bicycle exercise test, blood lactate measurement), maximum strength (isokinetic strength test; knee extension/flexion), body composition (bioelectrical impedance analysis) and quality of life (EORTC QLQ-C30) were compared pre and post exercise intervention. Results So far we were able to recruit 29 patients in 2,5 years. Seven patients dropped out, due to insufficient physical and/ or mental condition. On an average, 65% (endurance: 64%, resistance: 78%, stretching/mobilisation: 58%) of the planned training sessions could be carried out and no adverse events due to physical exercise (i.e. bleeding, fracture) occurred. On the basis of mean differences, the stretching/ mobilisation group show the largest decline in physical capacity compared to both training groups. Further there is a weak superiority of resistance over endurance exercise training. Discussion Up to now the results give an indication that these patients benefit from our exercise programs, especially from resistance training. However, a larger sample size is needed to confirm this existing trend. The results provide a basis for further investigations to learn more about the impact of exercise and the mechanisms in that special clinical context.

### **ACUTE CENTRAL AND PERIPHERAL EFFECTS OF MAXIMAL EXERCISE IN HYPOXIA AND COLD IN PEOPLE WITH SPINAL CORD INJURY.**

Frauzino, F.C.1, Miguel, M.2, Delicado, M.C.1, Vidal, J.3, Soto, C.1, Barbany, J.R.1, Medina, J.3, Ventura, J.L.1, Javierre, C.1

*University of Barcelona*

Introduction We have studied the differences in respiratory adaptation and peripheral vascular response after maximum exertion in environmental conditions similar to those practiced in winter sports, in people with spinal cord injury (SCI) and in able-bodied subjects (AB) physically active. Methods Twenty-four healthy volunteers have participated: 12 had a history of clinical SCI (the degree of the injury lesion following ASIA scale were: A 62%, B 23%, C 8% and 8% D) and 12 were AB subjects. Each subject performed three maximal exer-

cise testing with ventilatory monitoring but changing environmental circumstances: at sea level and 22-24 °C, at 3000 m of simulated altitude in a hypobaric chamber and 22-24 °C and at 3000 m of simulated altitude and 5-6 °C. Diameters were measured in: brachial artery, radial artery and posterior tibial artery by ultrasound means at rest and after active hyperemia. Results Comparing the values of simulated altitude tests in respect to sea level, we detected significant decreases in the VO<sub>2</sub> uptake accompanied by changes in ventilation, respiratory rate and tidal volume. In parallel, exhaled O<sub>2</sub> and CO<sub>2</sub>, the respiratory equivalent for O<sub>2</sub> and CO<sub>2</sub> and end-tidal O<sub>2</sub> and CO<sub>2</sub> showed statistically significant changes. The ultrasound measures did not show significant changes, neither between SCI and AB subjects nor between sea level and simulated altitude or between cold and 22-24° C. Discussion The acute response to physical exertion in SCI, compared with AB subjects, does not present significant differences in the peripheral vascular response, but significant ventilatory changes in hypoxia for the two groups and without substantial changes in the cold environment References Phillips AA, Krassioukov AV, Ainslie PN, Warburton DE (2012). *J Neurotrauma* Oct 10;29(15):2431-2445. ##### MUSCLE POWER, STRENGTH AND PHYSICAL PERFORMANCE ARE ASSOCIATED WITH VENTILATORY FUNCTION IN HEALTHY OLDER PEOPLE

Sillanpää, E.1, Stenroth, L.1, Bijlsma, A.Y.2, Rantanen, T.1, McPhee, J.S.3, Jones, D.A.3, Narici, M.V.3, Gapeyeva, H.4, Pääsuke, M.4, Barnouin, Y.5, Hogrel, J.Y.5, Butler-Browne, G.5, Maier, A.B.2

1University of Jyväskylä, FI; 2VU University Medical Center, NL; 3Manchester Metropolitan University, UK; 5University of Tartu, EE; 6Institute of Myology, GH Pitié-Salpêtrière, FR

Introduction: Several physiological performance tests have been used to describe the associations between ventilatory function and functional capacity in patients suffering chronic obstructive lung diseases, while few studies have been conducted in healthy older adults. Methods: 135 healthy 69 to 82-yr-old men and women participated in the study, which was performed as a part of European research co-operation (Myoage). Associations between lung function (forced vital capacity (FVC), forced expiratory volume in 1s (FEV1), flow rate in the middle of exhalation (FEF50), FEV1/FVC) and functional capacity (quadriceps and grip strength, muscle power in jumping action, 6-min walking, timed up and go test (TUG)) were tested by partial correlations and stepwise linear regression models adjusted with body size and composition. In addition functional capacity in participants with normal ventilatory capacity and COPD stage I (GOLD definition, FEV1/FVC below 0.70) were compared with Student's T-test. Results: 6-min walking and grip strength were independently associated with FVC ( $r_{2adj}=0.68$ ,  $p<0.001$ ) and muscle power with FEV1 ( $r_{2adj}=0.52$ ,  $p<0.001$ ), FEF50 ( $r_{2adj}=0.16$ ,  $p=0.001$ ) and FEV1/FVC ( $r_{2adj}=0.094$ ,  $p=0.004$ ). Time taken in TUG test was significantly longer in COPD stage I participants compared to counterparts with normal ventilatory function ( $p=0.023$ ). Discussion: Muscle power production is stronger predictor of ventilatory variables that are related to rapid expiration, than other commonly used performance measurements. In contrast, variance in FVC was explained by muscle strength and aerobic components of functional capacity. Muscle power related performance is better in participants with normal ventilatory function compared to those with early stage COPD. The results suggest that age-related decreases in muscle strength and power are related to lung function also during healthy aging.

##### REPRODUCIBILITY AND VALIDITY OF THE PORTUGUESE VERSION OF THE PREGNANCY PHYSICAL ACTIVITY QUESTIONNAIRE

Santos, P.C.1,2, Maciel, P.1, Moreira, C.2, Abreu, S.2, Santos, R.2,4, Silva, P.2,3, Mota, J.2

Escola Superior de Tecnologia da Saúde do Porto

1 ESTSP (Porto, Portugal); 2 FADEUP (Porto, Portugal); 3 ISMAI (Maia, Portugal) Introduction Physical activity (PA) during pregnancy has been encouraged by several national and international entities aiming health promotion. However, there are few specific questionnaires for the assessment of PA in this condition. Aim was to adapt the cultural and linguistic Pregnancy Physical Activity Questionnaire (PPAQ) into Portuguese, and analyze its reliability and validity. Methods The translation and cultural adaptation followed three steps. 1) double independent forward translation was carried out and analyzed by a translation expert panel that achieved the reconciliation form. 2) back translation of the reconciled version was made to ensure the conceptual equivalence. 3) cognitive equivalence was tested with a panel consisted in six pregnancy women, native speakers of Portuguese, and a key nursing. A sample of 116 pregnant women in different trimesters of pregnancy completed the self-administered PPAQ and wore the accelerometer - ActiGraph for the following seven days to determine the validity of the questionnaire. Reproducibility was assessed at the end of the seven days period, when the questionnaires were repeated. Results Intra class correlation coefficients used to measure reproducibility of the PPAQ were 0.86 for total activity, 0.91 for sedentary, 0.84 for light activity, 0.85 for moderate activity, 0.81 for vigorous activity, and ranged from 0.85 for household/caregiving to 0.99 for occupational activity. Overall, Pearson correlations between the PPAQ and the Actigraph measures using the three previously published cut points were positive but poor, with data ranged from 0.077 to 0.107 for total activity (all trimesters vs 1st and 2nd trimester), 0.054 to 0.238 for vigorous activity (all trimesters vs 1st and 2nd trimester), 0.002 to 0.083 for moderate activity (all trimesters vs 1st and 2nd trimester) and 0.023 to 0.069 for light-intensity activity (all trimesters vs 1st and 2nd trimester). Discussion/Conclusion Analyses of current study showed moderate to high values of reproducibility what confirmed PPAQ as an accurate measure of a broad range of physical activities during pregnancy. However, concerning validation, the comparison with results obtained by Atigraph did not show adequate degrees of agreement. This suggests that PPAQ may be valid for ranking individuals' behavior, but limited to quantify PA. Its difficult to obtain a valid estimation of a highly variable behavior such as free-living physical activity by self-report. However, the questionnaire allows us to know the type of activities which makes PPAQ a good addition to biophysical measures. References ACSM. (2006). *Exerc Sport Sci Rev*, 28(2), 93-96. ### WORKPLACE HEALTH PROMOTION AND ITS IMPACT ON THE WORK ABILITY OF YOUNGER AND OLDER EMPLOYEES IN A MEDIUM-SIZED BUSINESS

Wilke, C., Weber, C., Biallas, B., Froböse, I.

*German Sport University Cologne*

**Introduction** Demographic change, an extended work life and the employee's health show growing importance in today's professional world. Thus, employers face the challenge of finding qualified trainees. In addition, older employees need more time to convalesce. Promoting the health of older employees strongly is crucial in order to employ them until retirement. **Methods** 157 younger (< 45 years) and older workers (≥ 45 years) (102 men, 55 women) in a medium-sized business took part in a two-year project regarding workplace health promotion. All employees were tested at the beginning (T1) and at the end of the project (T2) towards their work ability and physiologic parameters (body mass index, lipoproteins). The physiologic parameters were measured through diagnostic methods, work ability was assessed through the work ability index (WAI). An intervention focused on both condition oriented (i.e. physical activity, nutrition) and behaviour oriented prevention (i.e. job-analysis, ergonomics). **Results** Work ability ( $p > .05$ ) and physiologic parameters ( $p > .05$ ) showed no age-related difference. Age was not associated with work ability. Age was positive associated with body mass before ( $r = .31^{**}$ ;  $p \leq .01$ ) and after the intervention ( $r = .30^{**}$ ;  $p \leq .01$ ). Age was also positive associated with LDL-cholesterol before ( $r = .35^{**}$ ;  $p \leq .001$ ) and after the project ( $r = .30^{**}$ ;  $p \leq .01$ ). **Discussion** We could not find any association between age and work ability. This is in accordance to other studies (Berg et al., 2009; Freude et al., 2000). Younger employees were less likely to be overweight than older employees. This positive association is consistent with findings from further research (Reas et al., 2007). Also, older workers showed a higher LDL-cholesterol than younger workers. This finding was expected, since it is assumed that the LDL-cholesterol level rises with increasing age (Parhofer et al., 2007). The results indicate the importance of work place health promotion for the health status of employees, especially older workers. **References** BERG, E. van den, Zwart, B. de, Burdorf, A. ### ASSOCIATION BETWEEN INTRA-ABDOMINAL PRESSURE AND MUSCLE ACTIVITY LEVELS OF TRUNK MUSCLES

Tayashiki, K., Takai, Y., Maeo, S., Yamamoto, M., Kanehisa, H.

*National Institute of Fitness and Sports in Kanoya*

**Introduction** Increasing intra-abdominal pressure (IAP) plays an important role in acquiring stability and stiffness of the spine (Cholewicki et al. 2002). IAP is increased during various tasks, e.g. lifting and jumping. However, how IAP varies among tasks remains question. Furthermore, it is also unknown whether IAP measurement has good repeatability inter- and intra-day. We examined 1) the repeatability of IAP measurement over repeated trial inter- and intra-day, and 2) the exercise-related difference in the increase of IAP with relation to the activity level of trunk muscles during various tasks. **Methods** Six young males performed bracing, drawing, isometric trunk flexion and extension tasks with maximal voluntary effort. During these task, IAP with a pressure transducer placed in the rectum and surface electromyography (EMG) activities from rectus abdominis (RA), oblique external (OE) and internal (OI) muscles, and erector spine muscle (ES) were determined. All subjects performed each task twice in inter- and intra-day. **Results** There was no significant difference in IAP during each of the task in either the inter- or intra-day comparisons. Intra-class correlation coefficient for IAP measurement was 0.987 for inter-day and 0.779 for intra-day. To examine the association between IAP and EMG amplitude, the data were averaged across trials and days in each task. The maximal IAP value obtained in each task was  $86.4 \pm 13.0$  mmHg for bracing,  $74.4 \pm 14.4$  mmHg for trunk extension,  $55.9 \pm 12.4$  mmHg for trunk flexion, and  $9.5 \pm 4.5$  mmHg for drawing. The IAP in drawing was significantly lower than those in the other tasks. For all tasks except for drawing, IAP linearly increased with increases in the exerted force ( $r = 0.711 - 0.943$ ) and EMG amplitude ( $r = 0.297 - 0.704$ ). The slope of the regression line in the relationship between IAP and muscle activity levels for each muscle differed among the tasks. **Discussion** The findings obtained here were 1) IAP measurement has good inter- and intra-day repeatability, satisfying the standard value of repeatability ( $\geq 0.75$ ) (Vincent, 1995), and 2) increase of IAP differs among the tasks although IAP increases in proportion to exerted force and muscle activity levels of trunk muscles in each task. The current findings on the association between IAP and muscle activity levels of trunk muscles are consistent with earlier findings (Cresswell et al. 1992; Cholewicki et al., 2002). On the other hand, the task-related difference observed in the association between IAP and muscle activity levels indicates that the contribution of trunk muscle activation to IAP depends on exercise modality. In general, drawing maneuver has been considered to elevate IAP, but the current result did not support this. This may be derived from the posture-dependent difference (standing vs. prone). **References** Cholewicki J, Ivancic P.C, Radebold A (2002) *Eur J Appl Physiol* 87:127-133. ### 1RM BENCH PRESS PERFORMANCE: A NEW METHOD OF EVALUATION IN RECREATIONAL MALE AND FEMALE

Thomas, E.1, Filingeri, D.2, Paoli, A.3, Bellafiore, M.1, Bianco, A.1, Palma, A.1

1. *University of Palermo*; 2. *Loughborough University*; 3. *University of Padua*

**Introduction** It is widely recognized that the bench press test is the most valid in determining upper body maximal strength in both athletes and sedentary. Various approaches are used for its evaluation, both through prediction equations or practical attempts. The aim of this study is to use a new method for the evaluation of the bench press test (BP) using combined previous validated theoretical and practical procedures. **Methods** Fifteen participants (8 male Age=23,5±2,3 FM%=17,3±9,2 and 7 female Age=27,9±10 FM%=25,6±6,9) with no specific training history were tested. Physiological parameters were recorded before, during and after each attempt. In first instance, the participants had to perform repetitions to fatigue (RTF) with 1/3 of their body mass (BM) for a maximum of 25 repetitions. After a 5-minute rest, RTF were assessed with 1/2 of BM and the number of repetitions performed was then used on the theoretical Mayhew's equation. Subsequently the participants were invited to attempt the Mayhew 1-RM for a maximum of three attempts. RPE scale was used during

experimentation. Results  $\frac{1}{2}$  BM workload was significantly (.001) gender related with RTF showing higher performance values for male ( $25 \pm 6,6$  repetitions) compared to female ( $11 \pm 10,6$  repetitions). Moreover, compared to 1RM performance the Meyhew's equation showed a percentage accuracy of 01,7% in female and an underestimation of 18,3% in male. No significant difference between genders were found on Blood Lactate (BL) and RPE recorded immediately post 1RM performance. Oxygen uptake (VO<sub>2</sub>) and Heart rate (HR) showed some significant differences. Conclusions Despite the study at this stage is still a pilot it leads to consider this new method effective for recreational male and female. High accuracy percentage suggests low time consuming testing sessions and easiness in estimating 1RM on the bench press. At this stage the study confirms the safety and feasibility of the BP test and the accurateness of Meyhew's equation in particular in female.

## EVALUATION OF CHRONOTYPES IN YOUNG ITALIAN PHYSICALLY ACTIVE ADULTS

Vitale, J., Roveda, E., Montaruli, A., Carandente, F.

*University of Milan*

**INTRODUCTION** The expression of circadian rhythms can be different in people and this trait can be defined as "circadian typology" or "chronotype". There are three different chronotypes: Evening-type (E-type), Morning-type (M-type) and Neither-type (N-type). Morning-types show an early sleep-wake cycle and have their best performances in the morning, on the contrary evening-types show a late sleep-wake cycle and they have the best performances in the evening. The circadian typology emerges especially during adolescence and it is influenced by individual factors, like age and sex, and by environmental factors. The chronotype is typically defined by a validated questionnaire, the Morningness-Eveningness Questionnaire (MEQ). **METHODS** 500 subjects, Italian students of Sports Sciences from University of Milan, 345 males and 155 females, mean age:  $21,9 \pm 2,24$  have been recruited. They compiled voluntarily the MEQ to determine their chronotype. The MEQ has been related with age, sex and photoperiod at birth for each subject. None of the participant was a shift worker. Ten subjects for each category of chronotype (10 M-types, 10 E-types and 10 N-types) wore an actigraph to evaluate the sleep-wake cycle and the level of physical activity across the day. **RESULTS** MEQ scores showed that the subjects were 334 N-types, 117 E-types (105 Moderate E-types and 12 Extreme E-types) and 49 M-types (48 Moderate M-types and 1 Extreme M-type). The mean score of MEQ was  $48.18 \pm 8.66$  but, as we expected, women totalized a higher mean score ( $49.54 \pm 8.57$ ) if compared to men's mean score ( $46.82 \pm 8.69$ ). The data collected by the actigraphs showed that E-types were more physically active starting from the late afternoon until night and the M-types were more active in the morning. **DISCUSSION** We observed that individual factors, age and sex, influenced the chronotype: being our sample composed by young students, there were, as expected, more E-types (23,4%) than M-types (9,8%) and girls showed greater scores of the MEQ with a predisposition toward morningness compared to men. E-types had the predisposition to be active and to practice physical activity in the late afternoon/evening and M-types had the predisposition to be active and to practice physical activity in the morning. Training programs should be scheduled according with the individual's chronotype. **REFERENCES** 1. Horne, J.A., Brass, C.G. & Peititt A.N. (1980). *Ergonomics* 23: 29-36. 2. ## EFFECTS OF SOCIAL AND ENVIRONMENTAL DETERMINANTS ON OVERWEIGHT AND OBESITY AMONG BRAZILIAN SCHOOLCHILDREN

Guedes, D., Martins, D.J.Q., Martins, L.H.S., Roman, E.R.

*State of Parana' Secretariat of Sport, Brazil*

**Introduction** Current evidence suggests that the development and execution of intervention programs related to prevention and management of overweight and obesity require the identification of obesogenic social and environmental determinants [1]. Studies available in literature have shown the complex association between social and environmental determinants and obesity [2,3]. The aim of this study was to identify the social and environmental determinants that are most strongly associated with the prevalence of overweight and obesity in a representative sample of Brazilian schoolchildren assisted by Parana Health Program. **Methods** The Parana Healthy Program is an action of the State of Parana' Secretariat of Sport serving approximately 2 million of schoolchildren. Its activities are focused on the prevention and weight management through nutrition education and physical activity. The study used multistage sampling to obtain representative estimates of the schoolchildren population from the State of Parana, Brazil. A total of 5460 subjects (2946 girls and 2514 boys) aged 4 to 20 years were included in the study. Overweight and obesity were defined by body mass index, based on sex-and-age-specific cut-off recommended by the IOTF. Social and environmental determinants were collected using a structured questionnaire. The impact of social and environmental determinants on the prevalence of overweight and obesity were analyzed using odds ratios (OR), established by binary logistic regression adjusted for the remaining independent variables included in the regression models. **Results** In girls, prevalence of overweight and obesity were 18.9% and 8.2%, respectively, whereas the corresponding numbers in boys were 18.6% and 9.5%. The chance of overweight was higher in schoolchildren that engaged in 2 hours or more of daily screen time (OR = 2.41; 95% CI 1.52-3.48), whose parents had higher educational levels (OR = 1.82; 95% CI 1.42-2.37),  $\leq 2$  siblings (OR = 1.92; 95% CI 1.39-2.67) and high economic class (OR = 2.07; 95% CI 1.47-2.75). Schoolchildren who traveled by car to school (OR = 1.60; 95% CI 1.24-1.97), lived within a radius of  $\leq 5$  km from school (OR = 1.56; 95% CI 1.17-2.11) and consumed foods sold in the school cafeteria (OR = 1.88; 95% CI 1.49-2.34) presented a high odds of overweight. **Conclusions** The background from a particular region of a country should be considered when implementing preventive measures regarding overweight and obesity. Measures taken should consider a multi-level intervention that includes the family, school and physical environment. **References** [1] Swinburn B, Egger G, Raza F. *Prev Med.* 1999; 29:563-570. ## SPEED OF TREADMILL WALKING AND SURVIVAL IN PATIENTS WITH CARDIOVASCULAR DISEASE. A 10-YEAR FOLLOW UP STUDY

Bernardi, E.1, Myers, J.2, Mazzoni, G.1, Terranova, F.1, Grossi, G.1, Codecà, L.1, Cogo, A.1, Conconi, F.1, Grazi, G.1

*post graduate student in sport medicine*

**Introduction:** Walking speed has been shown to be associated with survival in older adults [1]. In this study the association between the speed maintained in a 1 Km walking test and all-cause mortality in patients with cardiovascular disease has been determined. **Methods:** 1255 male patients, aged 25-85 years at baseline, completed 1 km treadmill walking test [2] at moderate intensity corresponding to a

perceived exertion of 11-13 on the 6-20 Borg scale. Subjects were followed for all-cause mortality for up to 10 years. Cox proportional hazard models were employed to determine variables associated with mortality. Based on the average speed (AWS) maintained during the test the subjects were subdivided into quartiles and mortality risks were calculated across quartiles. To assess the discriminatory accuracy of walking speed in estimating survival, receiver-operating-characteristics curves were constructed. Results: During a median 8.2 years of follow-up, a total of 141 deaths from any cause occurred, with an average annual mortality of 1.4 percent. The best predictor of increased risk of death was AWS (95% CI 0.45-0.75,  $P < 0.0001$ ). Mortality increased in a graded fashion from the highest to the lowest AWS quartile. Compared to the first quartile, the relative mortality risk for the second, third, and fourth quartiles were progressively reduced with hazard ratio (HR) of 0.77 (95%CI 0.52-1.13,  $P = 0.18$ ) for the second; of 0.41 (95%CI 0.24-0.70,  $P = 0.01$ ) for the third; and of 0.36 (95%CI 0.19-0.68,  $P = 0.002$ ) for the fourth quartile ( $P$  for trend  $< 0.0001$ ). A further reduction in mortality risk was observed among subjects in the fittest quartile who improved their AWS relative to the subjects of the same quartile who did not improve. Conclusions: The AWS determined by 1-km treadmill walking test is a useful tool for predicting survival and guiding rehabilitation in subjects with stable cardiovascular disease. References: 1. ## IMPLEMENTING HEALTH PROMOTION PROJECTS IN SPORTS CLUBS – SUPPORTING AND LIMITING FACTORS

Zillmann, N., Mairinger, F., Tschirk, B.

*University of Vienna*

Implementing health promotion projects in sports clubs – supporting and limiting factors Zillmann, N., Mairinger, F. & Tschirk, B. University of Vienna (Vienna, Austria) Introduction For some time now sports clubs provide a setting for the initiation of educational and developmental processes through physical activity in various target groups and as a result attract public attention (Breuer & Feiler, 2012). Furthermore, in recent years a trend emerged showing that sports organisations engage increasingly in health promotion initiatives to meet expectations of public and private entities alike. At the same time, with initiating such projects, sports clubs face a variety of challenges that quickly lead them to experience both personal and structural limits (Bette, 2009). As part of the evaluation of the Austrian health promotion initiative UGOTCHI limiting and supporting factors for sports club project participation were investigated. Methods Both quantitative and qualitative methods were applied in the two-year UGOTCHI evaluation. Representatives of participating sports clubs were invited to partake in an online survey (2011,  $n=137$ ; 2012,  $n=125$ ) investigating their appraisal and effects of the project. In addition, in 2012 all non-participating sports clubs were asked to participate in an online questionnaire covering amongst others aspects of reasons for their non-participation ( $n=1098$ ). Furthermore, focus group discussions were initiated with representatives from participating and non-participating sports clubs to identify influencing factors that determine the involvement in the health promotion initiative UGOTCHI. Results Through the evaluation various supporting and limiting factors for project participation could be identified. For example the major restraining factor for both participating and non-participating sports clubs were deficient resources (material, spacial and personal) to implement additional (health promotion) projects that are not core competence of sports clubs. Supportive elements are the organizational support through the sports association and the financial aids provided. Overall, the results of the qualitative and the quantitative examinations were comparatively similar. Discussion The results will be discussed in the light of the increasing challenges for sports clubs and their club work. Similarities and dissimilarities between participating and non-participating sports clubs will be demonstrated. In addition, some aspects not directly linked to the project emerged, that seem to impact the everyday work of a sports club. References Bette, K.-H. (2009). ## CARDIORESPIRATORY FITNESS AND NUTRITIONAL STATUS OF STUDENTS: EVOLUTION IN 30 YEARS

Araujo, T., Ferrari, G., Matsudo, S., Oliveira, L.C., Matsudo, V.K.R.

*CELAFISCS*

Introduction Longitudinal projects seem to be the most appropriate approach to understand development of aerobic power (AP). The objective of this study was to compare the changes of AP according to the decade and nutritional status among schoolchildren in a period of 30 years Methods Data were selected from a longitudinal cohort study with more than 16.000 evaluations from 1978 to 2010. Sample consisted 1.212 students that should have performed a complete physical evaluation and be in pre puberty between 10 and 11 years. The evolution of 30 years was analyzed in the years 1978/1980, 1988/1990, 1998/2000, 2008/2010. They were classified according to the age and sex according to the parameters of the growth curves of body mass index. It was considered overweight those with z-score above 1 and below a normal weight. AP was evaluated by a sub-maximal progressive protocol on a bicycle ergometer with a mechanical load calculated from the weight. To calculate the  $VO_{2max}$  used the nomogram Astrand. MANOVA analysis was performed followed by Bonferroni and percent delta to determine the percentage difference in values between groups and between decades. Results The AP values were significantly higher in the normal weight (14.29 to 24.71%) than the overweight. Regarding the evolution of the AP analyzed every decade, the results showed that  $VO_{2max}$  ( $ml \cdot kg^{-1} \cdot min^{-1}$  and  $l \cdot min^{-1}$ ) decreased significantly in the three decades analyzed in both normal ( $46.50 \pm 12.0$  to  $35.43 \pm 11.7$  and  $1.56 \pm 0.3$  to  $1.17 \pm 0.3$ ) and in overweight ( $37.70 \pm 9.6$  to  $30.33 \pm 10.33$  and  $1.72 \pm 0.3$  to  $1.35 \pm 0.4$ ) groups. The normal weight group has decreased AP either absolutely or relative (25% and 23.8%) and overweight has decreased absolute and relative in 21.5% and 19.5% in three decades. Discussion In a period of 45 years there was a decline per year of AP (Tomkinson, Olds, 2007). These changes have been very consistent according to gender and nutritional status (Craggs et al, 2011). Conclusion Nutritional status particularly overweight affects negatively the AP pre-pubescent school. Changes in environmental, socioeconomic, nutritional and physical activity of recent decades seemed to have a negative effect on AP of school regardless of nutritional status. The impact could be even more deleterious among children with overweight and obesity as they have the same values up to 25% less than AP. ## IS KNOWLEDGE OF PHYSICAL ACTIVITY GUIDELINES MOTIVATIONAL BENEFICIAL FOR BEHAVIOUR CHANGE? RESULTS FROM A NATIONAL SURVEY

Knox, E., Eslinger, D.W., Biddle, S.J.H., Sherar, L.B.

*Loughborough University; The NIHR Leicester-Loughborough Diet, Lifestyle and Physical Activity Biomedical Research Unit*

**Introduction** The publishing of global recommendations for physical activity (PA) and health (WHO, 2010) marked a concerted effort to raise the profile of PA for health and place it on the health agenda of policy-makers. Despite this, no plan has yet been formed to promote and disseminate the information in these guidelines. The guidelines key messages are: aim for 150 minutes of moderate-to-vigorous PA a week; PA can be accumulated in bouts of 10 minutes or more; PA should raise the heart rate and breathing rate; lifestyle activities can be made more active; and more health benefits result from more PA. National campaigns all over the world have taken the lead in promoting these messages e.g. 'Swap 4 wheels for me own two feet to get going for 150 minutes a week' (Change4Life, UK); 'Find thirty, find a better you! It's not a big exercise' (Find30, WA). The following research examined whether knowledge of the key messages of the PA guidelines could contribute towards a greater intention to engage in more PA. **Methods** The 2007 Health Survey for England provides data on 14,385 individuals from the UK. Individuals were excluded if they were <18 years old and if they had illnesses/disorders likely to restrict PA, leaving a sample of 4,691 (88% white, 55% female, 50% under 45 years old and 62% non-manual workers). Ordinal logistic regression examined the degree to which intentions (agree/disagree with statement; 'Would like to engage in more PA') could be predicted by agreement with the following statements: 'PA can be accumulated in daily life' (N=3,392); 'PA is good if only 10 minutes' (N=3,413); 'physical activity is good even if it is moderate' (N=3,414); 'PA is better for health if at least 30 minutes' (N=3,384); and 'PA is better for health if I get out of breath' (N=3,369). **Results** Agreement that sufficient PA can be achieved in daily life (OR=.75), PA is good even if only 10 minutes (OR=.14), and PA is good even if it is moderate (OR=.59) significantly contributed to greater intentions to become more active ( $p > .001$ ). Agreement that PA is better for health if at least 30 minutes (OR=-.35) and PA is better for health if you get out of breath (OR=-.42) significantly predicted lower intentions to become more active ( $p < .05$ ). All models showed good fit ( $p < .001$ ). **Discussion** Knowledge of three of the key messages of the PA guidelines (i.e. 10 minute bouts and moderate PA is beneficial, and physical activity can be accumulated in daily life) significantly predicted greater intentions to become more physically active. Future efforts which focus on the convenience of PA appear preferable to those which emphasise greater durations and intensity. Research is needed to determine the best way to educate the general population about PA guidelines and motivate increased engagement. **References** Change4Life. 'Get Going Everyday'. 2011. ## THE EVALUATION OF PHYSICAL FITNESS PARAMETERS OF TURKISH JUNIOR GOLFERS

Odabas, I.1, Bulgan, C.1, Ulug, M.2

*1: HU (Istanbul, Turkey); 2:OzU (Istanbul, Turkey)*

**Introduction:** Golf is a very popular sports in the world and more than 50 millions players in all ages and levels around the world (Lephard et al., 2007). Physical conditioning is one of the most important parameter in golf performance and proper swing movement (Lephard et al., 2007; Tsang and Hui-Chan, 2004). Strength, power, flexibility, balance, core stability, endurance, body awareness they are all physical traits that every consistent golfer must possess. In order to improve performance in golf, training must be specific to the demands of the game involved. It is important to recognize how physical attributes relate to the swing, pata so the aim of this study was to determine to physical fitness parameters of junior golfers in Turkish National Golf Team. **Method:** In study, 14 males and 13 females (mean ages  $14.6 \pm 1.07$  and sport ages 1.5-5.5 years) in total 27 golfers joined as subjects voluntarily. Physical tests were consisted measurement of height, weight, height of sitting, arm span, subcutaneous fat thickness from the 6 body areas. Also body composition was calculated by using Yuhaz's formula. In physical fitness parameters, muscular endurance, muscular strength, left and right swing body flexibility and static balance were measured. All golfers' data collection were taken in the same day. All data results were analysed by using SPSS program (version 18.0; SPSS, Inc., Chicago, IL). **Results:** In results there were no significant differences between all parameters and sport ages of the golfers. Male golfers had more results in parameters of height, height of sitting, right foot balance, 30s body flexion, right swing flexibility, hand grip mean values and push up values rather than female golfers. However, female golfers had more results in parameters of average values of body fat, average values of shuttle run, left swing flexibility and body flexibilities. **Discussion:** As a conclusion, it can be say that there were no any differences according to the gender-specific in age group. So in future researches might be determining the specific relationships between physical characteristics and launch characteristics by gender and also creating golf-specific training program for fitness parameters can also improve flexibility, strength and balance abilities for junior golfers. **References:** Lephart, M.S.; Smoliga, J.M.; Myers, J. B.; Sell, T.C.; Tsai, Y-S. (2007) *Jour. of Strength and Conditioning Resrch*, 21(3), 860–869. Tsang, W.W., and C.W. Hui-Chan. (2004). *Med. Sci. Sports Exerc.* 36: 658–667.

## MAXIMAL AEROBIC PERFORMANCE AND HEART RATE VARIABILITY DURING EARLY RECOVERY AFTER REPEATED SPRINT TEST IN SMOKING FEMALE

Lee, C.L.1, Lee, M.C.2

*1National Sun Yat-sen University, Taiwan; 2Yu Da University, Taiwan*

**Introduction:** Smoking is an important risk factor for cardiovascular disease. Many individuals engage in a physical activity to reduce their cardiovascular risk associated with smoking, but heart rate variability (HRV) during the early phase of the recovery after a repeated sprint test (RST) has barely been studied. Therefore, the purpose of this study was to investigate the effects of cigarette smoking on a maximal aerobic capacity, anaerobic capacity, and HRV in college female students. **Methods:** 8 smokers (S) and 27 non-smokers (NS) randomly completed the experimental design. All of the participants performed a 20 meter shuttle run test for measuring the maximal aerobic capacity, and a repeated sprint test for estimating anaerobic capacity. RST consists of 6x10-s sprints with 60-s active recovery between every single sprint. HRV was recorded in a supine position for 30-min following RST. A power-spectral analysis of R-R intervals was performed to obtain the low-frequency (LF), and high-frequency (HF) components. **Results:** Peak power, mean power, and the heart rate were observed no significantly difference between S and NS groups during the RST ( $p > 0.05$ ), but fatigue index was significantly higher in the S group than in the NS group during the RST ( $34.2 \pm 13.5$  vs.  $26.2 \pm 13.2$  %,  $p < 0.05$ ). Maximal oxygen uptake was significantly higher in the NS group than in the S group ( $p < 0.05$ ). The SDNN (standard deviation of the NN interval), and the RMSSD (root mean square successive difference) were not significantly different between the S and NS groups; however, NS group has a significantly higher HF % relative to S group (95 % CI = 12.1-16.5 vs. 3.8-11.8,  $p < 0.05$ ). **Discussion:** Smoking may increase exercise fatigue during the RST, and decrease the

maximal aerobic capacity in college female students. Smoking also reduces parasympathetic nerve activities, but smoking as previous hypothesized does not activate the sympathetic cardiac control. We suggested that the possible reasons for the higher fatigue index, and the lower cardiovascular fitness in smoking females may derive from either, an aerobic metabolism restriction (Spencer et al., 2005), or the muscle O<sub>2</sub> uptake limitation (King et al., 1987). A smoker should receive more encouragement, and educational information about suitable smoking cessation strategies, in order to improve cardiac autonomic function. ### ATTEMPT TO DEVELOP A SIMPLE AND LESS DEMANDING GLUCOSE TOLERANCE TEST

Nii, A.1, Matoba, H.2, Obara, S.2

1: *Shikoku University (Tokushima, Japan)*, 2: *The University of Tokushima (Tokushima, Japan)*

**Introduction** Evaluating blood glucose regulation is important in preventing type II diabetes. In current oral glucose tolerance tests (OGTT), plasma glucose concentration is measured before and 2 hours after ingestion of a solution containing 75 g glucose. On the day prior to testing, efforts should be made to control confounding factors, such as exercise and carbohydrate content of meals (Kaneko et al., 1998). Thus, the OGTT is rather demanding, restricted its use primarily to diagnosis in medical settings. This study was performed to develop a simpler, less demanding type of OGTT that can be used in exercise and sports instruction settings. **Methods** Subjects were healthy males and females aged 20–74 years, with serum HbA<sub>1c</sub> concentrations <6.1%, randomized to 60 min rest OGTT (n=69) or 60 min exercise OGTT (n=32). The 60 min rest OGTT consisted of ingesting 1 ml/kg body weight of glucose solution (75g/225ml) and drawing blood samples in resting condition at 0, 15, 30, 45 and 60 min after ingestion for measurement of glucose concentration. The protocol for the 60 min exercise OGTT was identical, except that subjects performed step exercises from 30 to 45 min after glucose injection. The step exercise period consisted of 3 sets of 4 min of exercise and 1 min of rest. An index of blood glucose regulation capacity was determined by calculating the area under the time-glucose curve using the trapezoidal method and dividing by 100. **Results** The mean index of blood glucose regulation capacity for the 60 min rest OGTT was 76.4 (SD: 12.4) (range, 56.1-118.6), with three subjects having index values >100. The mean index for the 60 min exercise OGTT was almost identical 76.6 (SD: 11.8) (range, 60.2 and 110.9). The index was significantly related to body mass index (BMI) for the 60 min rest, but not for the 60 min exercise, OGTT (p<0.05). **Discussion** Although we expected that the index would be lower for exercise than for rest OGTT, because step exercises consume glucose (Larose et al. 2010), we found that the mean values of the index for both tests were almost the same. This finding indicates that subjects with normal blood glucose regulation capacity are able to maintain normal glucose concentrations during both rest and exercise OGTTs. Small amounts of glucose solution (1 ml/kg-wt) and a 60 min OGTT may be valuable in screening for glucose regulation, but not for a diagnosis of type II diabetes. **References** Kaneko T, Wang PY, Tawata M, et al. (1998). *Lancet*, 352, 289. Larose J, Sigal RJ, Boule NG, et al. (2010). *Med Sci Sports Exerc*, 42, 1439-1447.

### HIGH IMPACT EXERCISE INCREASED CORTICAL THICKNESS AT THE SUPERIOR FEMORAL NECK IN OLDER MEN: A 12-MONTH RANDOMISED BLINDED TRIAL USING MULTI-SLICE COMPUTED TOMOGRAPHY

Allison, S.J.1, Folland, J.P.1, Rennie, W.J.2, Summers, G.D.3, Poole, K.E.S.4, Brooke-Wavell, K.1

1: *Loughborough University (UK)*, 2: *University Hospitals of Leicester (UK)*, 3: *Derby Hospitals NHS Trust (UK)*, 4: *University of Cambridge (UK)*

**Introduction** Hip fractures in older adults are a major public health problem leading to loss of independence and large health-care expenses. Hip fractures in old age are associated with cortical thinning in the superior femoral neck. Interventions that increase cortical thickness at this region would be beneficial in fracture prevention. This study evaluated the influence of high impact exercise on regional cortical thickness at the femoral neck in older men. **Methods** Fifty, healthy community-dwelling older men were prescribed a 12-month high impact unilateral exercise intervention, which progressed to 50 multidirectional hops performed daily on one randomly allocated leg. Multi-slice computed tomography (CT) scans of the hips were performed at baseline and after 12-months of exercise by observers blind to the leg allocation. Regional CT analysis of the mid femoral neck was used to examine cortical thickness in anatomical quadrants. Cortical thicknesses were square root transformed to achieve normal distribution prior to statistical analysis. Two-way repeated measures ANOVA was used to identify leg (exercise leg [EL] vs. control leg [CL]) x time (pre vs. post) interactions. **Results** Thirty-four men (mean±SD, age 70.0±3.9 yrs) exercised for 12-months, attending 92±9% of prescribed sessions. Fourteen men did not complete the 12-month exercise intervention due to: medical conditions or injuries unrelated to the intervention (n=9), time commitments (n=2), or discomfort during exercise (n=3), whilst two participants' data were excluded due to image artefacts. Cortical thickness in the superoposterior quadrant increased more in the EL compared to the CL (EL from 0.29 [95%CI: 0.19-0.41] to 0.44 [0.29-0.61] mm; CL from 0.34 [0.22-0.47] to 0.40 [0.26-0.57] mm; ANOVA interaction, P=0.001) as did superoanterior quadrant cortical thickness (EL from 0.81 [0.61-1.00] to 0.93 [0.72-1.17] mm; CL from 0.81 [0.65-1.0] to 0.85 [0.66-1.00] mm; ANOVA interaction, P=0.016). Inferoposterior quadrant cortical thickness also increased in the EL relative to the CL (EL from 2.94 [2.74-3.15] to 3.08 [2.87-3.30] mm; CL 2.91 [2.66-3.17] to 2.90 [2.67-3.14] mm; ANOVA interaction, P=0.014), although inferoanterior quadrant response did not differ between legs (ANOVA interaction, P=0.090). **Discussion** Brief high impact exercise substantially increased cortical thickness (up to 52%) at regions considered critical in terms of hip fragility. Although high impact exercise may not be feasible for all older people, carefully targeted high impact exercise may significantly reduce the risk of hip fracture.

**AGE AND GENDER DIFFERENCES IN THE CORRELATION BETWEEN MUSCLE MASS AND PHYSICAL PERFORMANCE AMONG OLDER JAPANESE ADULTS.**

Kitano, N., Tsunoda, K., Mitsuishi, Y., Tsuji, T., Jindo, T., Saghazadeh, M., Soma, Y., Okura, T.

*University of Tsukuba*

**Introduction** It is well-known that muscle mass correlates with physical performance (Visser et al., 2002); however, the correlation between muscle mass and physical performance may differ by age because individual differences, e.g. shape of body, cognitive function and muscle mass are extended with aging. We determined whether age and gender differences affected the relationship between muscle mass and physical performance. **Methods** We randomly selected 1,700 community-dwelling older adults aged 65–85 years from Kasama city, Japan and obtained 336 eligible subjects (169 men, 167 women; average age  $73.2 \pm 5.0$  years). We assessed whole-body and lower-limb muscle mass using a bioelectrical impedance method (MC-980A, TANITA, Japan). To evaluate physical function, we used 7 physical performance tests: 1) grip strength, 2) one-leg balance, 3) standing time from a long sitting position, 4) sit-to-stand, 5) habitual walk, 6) timed-up-and-go and 7) choice stepping reaction time. Participants were divided into 4 groups by age and gender: 1) young-old ( $\leq 74$  years) men, 2) old-old ( $\geq 75$  years) men, 3) young-old women and 4) old-old women. To reveal the correlation between muscle mass and physical performance, a partial correlation analysis was performed controlling for body mass index and clinical history pertaining to heart disease, stroke, knee pain, and low back pain. **Result** We confirmed significant correlations between whole-body muscle mass and grip strength in every group ( $|r| = 0.27\text{--}0.52$ ). In young-old women, 3 other performance tests ( $|r| = 0.20\text{--}0.29$ ) also correlated with whole-body muscle mass, whereas, there were no significant correlations between these pairs in old-old women. Lower-limb muscle mass correlated with grip strength in young-old men ( $|r| = 0.31$ ) and was associated with 4 performance tests in young-old women ( $|r| = 0.23\text{--}0.39$ ), although no significant relationships were found among these pairs in old-old adults. **Discussion** A previous study reported that appendicular skeletal muscle mass is significantly related to a comprehensive score which considered balance, sit-to-stand test and habitual walk (Kim et al., 2012). Our study revealed that young-old women, in particular, had a significant correlation between muscle mass and physical performance. This new finding suggests that, not only sufficient muscle mass, but other factors such as nerve function and skilled movements might be necessary to maintain a high level of physical function in both old-old men and old-old women. **References** Visser M., Kritchevsky SB., Goodpaster BH., et al. **WALKING PROGRAM IMPACT ON DIABETIC ELDERLY POPULATION**

Cruz, J., Esperança, A., Leitão, C.

*Escola Superior de Educacao e Ciencias Sociais/Research Center for Human Movement Sciences - Instituto Politecnico de Leiria*

**Introduction** In 2011, 366 million adults had Diabetes Mellitus, leading to 4.6 million deaths all over the world. In 2010, the prevalence among Portuguese population ranging 20-79 years-old was 12.4% (991,000 individuals), one fourth of which, were 60-79 years-old. Physical activity benefits are well documented on the literature, and include improvements on body composition, fitness, HbA1c and blood pressure. The aim of this study was to analyze the impact on Diabetes Mellitus control through a walking program at VO<sub>2</sub>R60% in elderly people. **Methods** 13 diabetic subjects (Hb1Ac  $\geq 6.5\%$ ) aged 60-72 years-old volunteered to participate in this program. Program consisted of 2 non-consecutive walking sessions a week at VO<sub>2</sub>R60% for 10 weeks. VO<sub>2</sub>Max was assessed with the Rockport One-Mile Fitness Walking Test. Body fat and visceral adiposity were assessed with a Tanita monitor (BC-420MA) and waist circumference taken at the iliac crest. Blood pressure was assessed with a Rappaport Premium sphygmomanometer. A Roche Unimate 5 kit was used for HbA1c data. All analyses were conducted in SPSS software V.20 for Windows. **Results** Weight ( $80.4 \text{ kg} \pm 14.01$  vs.  $79.4 \text{ kg} \pm 13.94$ ;  $p=0.017$ ), visceral adiposity ( $13.1 \pm 3.54$  vs.  $11.8 \pm 3.33$ ;  $p=0.010$ ), body fat ( $35.9\% \pm 8.75$  vs.  $32.5\% \pm 8.21$ ;  $p=0.005$ ), waist circumference ( $102 \text{ cm} \pm 10.82$  vs.  $99 \text{ cm} \pm 10.24$ ;  $p=0.011$ ), SBP ( $134.6 \text{ mmHg} \pm 7.92$  vs.  $129.2 \text{ mmHg} \pm 5.41$ ;  $p=0.031$ ), HbA1c ( $6.9\% \pm 0.95$  vs.  $6.2\% \pm 0.51$ ;  $p=0.005$ ) and VO<sub>2</sub>Max ( $18.2 \text{ ml.kg.min} \pm 7.45$  vs.  $23.1 \text{ ml.kg.min} \pm 6.62$ ;  $p=0.005$ ) improved significantly over the 10 week program. **Discussion** This study shows that a 10 week long VO<sub>2</sub>R60% walk, performed twice a week, has a positive impact on the diabetic and body composition profile of elderly people, in line with previous researches (Gan et al., 2003; Westoff et al., 2007; Umpierre et al., 2011). **References** Boulè, NG., Haddad, E., Kenny, GP., Wells, GA. & Sigal, RJ.(2001). **ELDERLY PERFORMANCE ASSESSMENT IN STEP TEST USING OPTOJUMP. 'ACT ON AGEING': A PILOT STUDY**

Brustio, P.R.1, Magistro, D.2, Liubicich, M.E.1

*1:University of Turin - Italy 2:Tohoku University - Japan*

**Introduction** During the aging process physical function declines and an important locomotion change can be seen (Chodzko-Zajko et al., 2009). This decline is an important indicator of impaired mobility in elderly and seen during daily activities such as climbing stairs (Spiriduso & Cronin, 2001). The aim of this cross sectional pilot study on elderly people, is to observe the changes of Step Number (SN), Contact Time (CT) and Execution Time (ET) during a Step Test protocol and also to determinate gender differences. **Methods** The pilot study included 38 sedentary elderly subjects (M:F ratio of 1:1,  $73.11 \text{ yrs} \pm 5.13$ ) living in Piemonte, Italy. Data were collected using the 3 minutes

Step Test (3ST), the Six-Minute Walk Test (6MW) and the Chair Rise Stand Test (CR). OptoJump © instruments and software were used to assess changes in CT and ET during 3ST performances. We analyzed the relationship among 3ST, 6MW and CR data and we used Mann Whitney's test to determine gender differences. The significance level was  $p < .05$ . Results Descriptive 3ST analyses showed that SN decreased during the test, while ST and SP increased. Significant correlations were found among 3ST and 6MW ( $p < .001$ ) and CR ( $p < .05$ ). A Significant gender difference was found in SN ( $U=102$   $Z=-2.280$   $p < .05$ ), and in SP ( $U=109$   $Z=-2.087$   $p < .05$ ) and in 3ST ( $U=110$   $Z=-2.058$   $p < .05$ ). In particular, a significant gender difference was found after the second ( $U=113.5$   $Z=-2.255$   $p < .05$ ) and third minute ( $U=96$   $Z=-2.473$   $p < .05$ ) in SN and after the third minute of CT ( $U=91$   $Z=-2.655$   $p < .05$ ) and ET ( $U=98$   $Z=-2.409$   $p < .05$ ). A significant gender difference was observed in 6MW ( $U=104.5$   $Z=-2.219$   $p < .05$ ), but not in CR ( $U=165.5$   $Z=-.169$   $p=.869$ ). Discussion This pilot study showed that 3ST parameters changed during performance. However the data showed significant differences between women and men in the third minute. Probably this difference was due to the significant differences of aerobic endurance. In fact the level of aerobic endurance could affect performance of 3ST results. These results suggest the need of a different gender-specific cut off in 3ST assessment in elderly. References Chodzko-Zajko, W. J., Proctor, D. N., Fiatarone Singh, M. A., Minson, C. T., Nigg, C. ## EFFECTS OF SQUARE-STEPPING EXERCISE ON PHYSICAL FITNESS AND COGNITIVE FUNCTION IN HEALTHY OLDER ADULTS

Shimura, Y.1, Nakagaichi, M.2, Shigematsu, R.3, Okura, T.4, Tanaka, K.4

1: Osaka International University (Osaka, Japan), 2: Nagasaki University (Nagasaki, Japan), 3: Mie University (Mie, Japan), 4: University of Tsukuba (Ibaraki, Japan)

Introduction: Older adults generally have not only reduced muscle mass and reduced functional fitness, but also less cognitive function than younger adults. Numerous studies have found that exercise habituation including resistance training, aerobic exercise and balance training might offer many significant health benefits for older adults. However there are few reports about the cognitive benefits associated with exercise for older adults. This study was to undertaken investigate the intervention effects of square-stepping exercise (SSE) on physical fitness and cognitive function in healthy older adults. Methods: Participants were thirteen healthy older adults (age  $72.4 \pm 3.5$  years). Six participants performed SSE program for 90 min, 2 days a week, for 12 weeks. Seven participants completed a resistance training program for 90 min, 2 days a week, for 12 weeks. SSE was performed using a thin-felt mat that was partitioned into 40 squares (Shigematsu et al., 2006). Additionally, we advised them to perform their respective training programs in their daily life. Physical fitness (hand-grip strength, 10-m walking, timed up & go, 8-foot up & go, functional reach, single limb stance with eyes open, single limb stance with eyes closed, sit & reach, 30-sec chair stand, 30-sec arm curl, and stand-up from lying position), muscle mass in forearms, upper arms, lower legs, thighs and trunk, and cognitive function (Five-Cog. Test: Yatomi et al., 2005) were measured 2 times (first day session, 3 months after the initial session) of all participants. Results: Regarding physical fitness, SSE group had significant improvement in the 8-foot up & go (pre:  $25.0 \pm 4.8$  sec, post:  $21.5 \pm 4.2$  sec,  $P < 0.05$ ), timed up & go (Pre:  $5.5 \pm 1.0$  sec, Post:  $4.8 \pm 1.2$  sec,  $P < 0.05$ ), and 30-sec chair stand (Pre:  $18.6 \pm 5.0$  times, Post:  $22.7 \pm 5.8$  times,  $P < 0.05$ ). Furthermore, there were significant changes in the cognitive function including motor task (Pre:  $34.5 \pm 7.1$ , Post:  $44.7 \pm 9.7$ ,  $P < 0.05$ ), position judgment task (Pre:  $46.5 \pm 6.7$ , Post:  $50.8 \pm 9.5$ ,  $P < 0.05$ ), word memory task (Pre:  $54.2 \pm 12.5$ , Post:  $60.3 \pm 9.5$ ,  $P < 0.05$ ), animal name imagination task (Pre:  $47.7 \pm 9.8$ , Post:  $51.0 \pm 7.6$ ,  $P < 0.05$ ), and common word task (Pre:  $46.0 \pm 8.1$ , Post:  $57.0 \pm 13.6$ ,  $P < 0.05$ ). Discussion: This study suggests that square-stepping exercise has some beneficial effects to maintain or improve the mobility including lower muscle strength and endurance, agility and dynamic balance, and the cognitive function in healthy older adults. ## PRACTICING SPORTS AT ADOLESCENCE: IS IT BETTER AT PROMOTING HEALTHY LIFESTYLES THAN DOING REGULAR PHYSICAL ACTIVITY?

Arumi Prat, I., Puig-Ribera, A., Wasley, D., Martori, J.C.

Universitat de Vic. Cardiff Metropolitan

Introduction: A high percentage of 17-years-old boys (61%) in Europe play sports regularly (European Comission, 2010). However, it is not clear if sports participation in adolescence is better at promoting healthy lifestyles than regular physical activity (PA) (i.e. walk to school) (Peretti-Watel et al., 2001). Therefore the main aim of this study is to investigate the differences between practicing sports and doing regular PA on the adoption of healthy behaviors (smoking, alcohol, fruit and vegetable consumption) among 16-17 years old Spanish boys. Methods: A survey was conducted with 317 boys (92 % response rate) from 12 secondary schools in Osona (Barcelona) that agreed to participate in the study (75%). Participants completed measures of PA (adolescent version of the IPAQ), smoking, alcohol, fruit and vegetable consumption (STEPS Instrument) and sports participation (Maurice Pieron Questionnaire). Chi Square tests, t-test, and one way ANOVA were used to analyze the data. Results: Seventy-one percent of boys participated in sport, 17% engaged in regular PA and 11% were sedentary. Alcohol consumption was significantly more frequent among boys who practiced team sports than individual sports ( $p=0.001$ ). Twenty-two percent of team sport players drank alcohol 1 to 4 times a week while 19% of physically active reported consumption at this level. Individual sports players and sedentary boys significantly reported less alcohol consumption ( $p < 0.001$ ) than sport players (13.7% and 13.8% respectively). Smoking behavior was greater among boys practicing team sports compared to those physically active or sedentary but differences were not significant ( $p=0.15$ ) (44.5% vs. 29% individual sport, 33% sedentary and 37% active). Fruit and vegetable consumption was similar across all groups except for the sedentary who were less likely (17%) to meet the healthy recommendations (5 pieces per day). However, approximately only 1 in 3 met the guidelines in the sporty and active groups. Discussion: Practicing sports at adolescence is not associated to the adoption of healthier lifestyles in boys. Participating in sports -particularly team sports- was associated to a higher alcohol consumption and smoking than being regularly active or even sedentary. Thus, promoting regular PA among male adolescents could be an effective way to adopt healthy lifestyles. Furthermore, sport promotion programs should include the promotion of other healthy habits. **ALPINE SKIING WITH UNILATERAL TOTAL KNEE ARTHROPLASTY**

Kristensen, M.1, Pötzelsberger, B.2, Scheiber, P.2, Müller, E.2, Dela, F.1

*(1) University of Copenhagen, (2) University of Salzburg, Austria*

**Introduction** With a growing aged population in Europe the prevalence of e.g. rheumatic diseases will increase and with this the incidence of total joint replacements. Until now studies investigating sports participation following Total Knee Arthroplasty (TKA) are limited. Alpine skiing stimulates leg muscle strength and cardiovascular fitness and can be practiced until old age. Studies on the feasibility, benefits and risks associated with alpine skiing after TKA are warranted. In this study we focused on muscle growth and metabolism after practice of alpine skiing following TKA. **Methods** 26 patients with TKA were divided into an intervention group (IG, n=16; 11 males) and a control group (CG, n=10; 3 males) which were matched for age, BMI and time since TKA ( $69.8 \pm 1.1$  (mean  $\pm$  SE) and  $71.5 \pm 1.2$  yrs.;  $29.6 \pm 1.2$  and  $29.0 \pm 1.1$  kg/m<sup>2</sup>;  $2.7 \pm 0.3$  and  $3.3 \pm 0.2$  yrs., respectively). IG underwent 12 wk skiing training with an instructor with 2-3 skiing days/wk of 3-4h pr. session. Fasting blood samples and muscle biopsies (v. lateralis) on both legs were obtained before and after (6-9 days) the intervention. The data was tested for statistical significance by t-tests. **Results** No difference between the operated leg and the non-operated leg in fiber type composition (FT), cross-sectional area (CSA) and capillary density (CD) before or after the intervention was seen, and the data are shown as pooled data. FT, CSA and CD did not change with skiing (data not shown). Before training CD was higher ( $P < 0.05$ ) in IG ( $3.98 \pm 0.2$  cap/fiber) vs. CG ( $2.69 \pm 0.2$  cap/fiber) and a similar difference was found after skiing ( $4.06 \pm 0.2$  and  $2.61 \pm 0.1$ , respectively). Plasma insulin concentrations decreased ( $P < 0.05$ ) with skiing in IG ( $44 \pm 6.4$  to  $36 \pm 5.8$  pM) but not in CG ( $55.5 \pm 12.9$  to  $49.1 \pm 8.2$  pM). Plasma glucose concentrations tended ( $P < 0.1$ ) to decrease in IG but not in CG (data not shown). HOMA2 (index of insulin sensitivity) improved ( $P < 0.05$ ) from  $0.86 \pm 0.12$  to  $0.70 \pm 0.11$  with skiing in IG, while it did not change in CG ( $1.08 \pm 0.26$  and  $0.95 \pm 0.17$ ). No effect of skiing on blood lipids was observed (data not shown). No adverse events occurred. **Discussion** and **conclusions** In contrast to the prevailing view, practice of alpine skiing is indeed possible after TKA. There were only modest effects on the muscle parameters, while glucose metabolism was improved with skiing. The effect size is similar to what has been found in healthy elderly after a similar training program (1). It could be speculated that increased training intensity would have shown a higher response on CSA and CD. 1. Dela F, et al. Glucose homeostasis and cardiovascular disease biomarkers in older alpine skiers. *Scand J Med Sci Sports* 2011 (21) Suppl 1:56-61.

**DANCE AS A FACTOR IN ELDERLY QUALITY OF LIFE**

De Brito, A.P.F.1, Carvalho, R.2

*(1) CESPU - COOPERATIVA DE ENSINO SUPERIOR, POLITÉCNICO E UNIVERSITÁRIO; (2) ISMAI, MAIA, PORTUGAL*

**Introduction:** Quality of life is related to self-esteem and well-being covering variety of factors such as health condition, socioeconomic level, emotional state, socialization, intellectual activity, self care, family support, cultural and ethical values, life style, satisfaction with daily activities and the environment (Flangan, 1982). Several authors have reported connexion between seniors and biological aspects, the decline of physical and psychological conditions, loss of will to perform usual tasks and memory (Flangan, 1982; Spirduso et al., 2005). The activities practice related dance makes everyday life healthier, because develops areas such as socio-affective, psychomotor and perceptual-cognitive; it's also considered pleasurable activity for elderly (Cress et al., 2005; Federici et al., 2005; Rikli & Jones, 1998). **Objective:** determine the importance of dance in elderly physical activity level, taking into account their initial physical/ psychological conditions. **Methodology:** Quantitative, hypothetical-deductive, quasi-experimental longitudinal study was used and based on questionnaire adapted from Quality of Life Scale, Flanagan EQVF (Santos et al., 2002), WHO Quality of Life-Bref (2004), and Functional Fitness Test Battery (Rikli & Jones, 1998). Was applied on two occasions (beginning and after 2 months). A not random sample was used, consisting 29 elderly (7 males and 22 females) with age of  $78.6 \pm 5.5$  years from two retirement homes in Porto. Data processing was performed using descriptive analysis, t-test, Factor Analysis (search for uncorrelated variables), ANOVA (test for equality means corresponding to each level of IMC). Statistics were performed using SPSS 19 with 5% significance level. **Results:** Considering loneliness in elder age as a fact, study proved that dance led to a significant increase in awareness for improvement quality of life, with significant enhancement in their physical fitness. Variables such as medication and weight had no influence on the variation of dance motivation. Women were able to improve their physical fitness level better than men. **Conclusions:** The elderly have improved their quality of life significantly with few dance classes. **References:** Cress et al. (2005). Best practices for physical activity programs and behaviour counselling in older adult populations. *Journal Aging Physical Activity*, 13(1), 61-74. Federici et al. (2005). **FUNCTIONAL LIMITATION AND ASSOCIATED FACTORS: DATA FROM BRAZILIAN ELDERLY**

Guimarães, A.V.1, Confortin, S.C.1, Marchesan, M.1, Monego, E.1, Danielewicz, A.L.1, Barbosa, A.R.1

*Universidade Federal de Santa Catarina*

**Introduction** The functional limitation assessment provide useful preliminary knowledge about healthy elderly subjects and risk or progression to disability in non-disabled older subjects. The objective of this study was to investigate the factors associated with functional limitation among elderly of a rural community in southern Brazil. **Methods** In this cross-sectional and household-based study a total of 477 elderly ( $\geq 60$  years; random sampling) were examined in 2010/2011. The study was conducted in the city of Antônio Carlos, state of Santa Catarina. Three motor performance tests verified the functional limitation: 'chair stand', 'pick up a pen' (assessed by time) and 'balance' (Barbosa et al. 2005). The score of each test ranged from 0 (unable to perform the test) to 3 (good performance). A scale, based on the sum of the scores (0 to 9) obtained in the three tests found functional limitations: with functional limitation (0 to 5) and without functional limitation (6 and more). The independent variables were sex, age group (60-74;  $\geq 75$  years), living arrangements (living alone/accompanied); education (no schooling / 1 year / 2 years or +); currently working (yes/no); cognitive function (normal/altered) and sedentary behavior ( $\leq 4$ ; 4-5;  $\geq 6$  hours/day). Poisson regression (Prevalence ratio [PR] and CI 95% [confidence interval]) was employed to analyze data. **Results** Of the 477 subjects, 207 are males ( $73.3 \pm 9.0$  years) and 270 are females ( $73.2 \pm 8.8$  years). The prevalence of functional limitation was 24.0% (CI95%: 19.9 to 28.1). Functional limitation was positively associated with older age (PR 1.70; CI95%: 1.23 to 2.36), not working (PR: 2.87; CI95%: 1.69 to 4.85) and cognitive deficit (PR 2.37; CI95%: 1.63 to 3.43). **Discussion** The association between functional limitation and older participants can be explained by greater fragility and number of chronic diseases (Kim et al., 2011). Elderly

who work at home or are retired have worse health status (Schunck & Rogge, 2010) and a greater prevalence of excess weight (Martin et al., 2008). These factors may explain the difficulty in performing motor tasks. Individuals with cognitive deficit may have decreased motivation, resulting in reduced physical activity, exercise and social activities (Raji et al., 2002), reflecting the decline in physical function / muscle. ### ACUTE EXERCISE DECREASE PTP-1B PROTEIN LEVEL AND IMPROVE INSULIN SIGNALING IN THE LIVER OF OLD RATS

Moura, L.P.1, Pauli, L.S.S.1, Cintra, D.E.1, De Souza, C.T.2, Silva, A.S.R.3, Sponton, A.C.S.1, Marinho, R.1, Ropelle, E.R.1, Pauli, J.R.1

*State University of Campinas (UNICAMP)*

1:Course of Science Sport, School of Applied Science, State University of Campinas (UNICAMP), SP – Brazil 2: University of Southern Santa Catarina, SC, Brazil 3:Course of Physical Education and Sport, State University of São Paulo (USP), SP – Brazil Introduction It is established that insulin resistance associated with a progressive decrement in insulin action occurs with aging. In the present study, we investigated whether the improvement in insulin sensitivity and insulin signaling, mediated by acute exercise, could be associated with modulation of protein-tyrosine phosphatase 1B (PTP-1B) in the liver of old rats. Methods Aging rats were subjected to swimming for two 1.5-h long bouts, separated by a 45 min rest period. Sixteen hours after the exercise, the rats were sacrificed and proteins from the insulin signaling pathway were analyzed by immunoblotting. Results Our results show that the fat mass was increased in old rats. The reduction in glucose disappearance rate (Kitt) observed in aged rats was restored 16h after exercise. Aging increased the content of PTP-1B and attenuated insulin signaling in the liver of rats, a phenomenon that was reversed by exercise. Aging rats also increased the IRbeta/PTP-1B and IRS-1/PTP-1B association in the liver when compared with young rats. Conversely, in the liver of exercised old rats, IRbeta/PTP-1B and IRS-1/PTP-1B association was markedly decreased. Moreover, in the hepatic tissue of old rats, the insulin signalling was decreased and PEPCK and G6Pase levels were increased when compared with young rats. Interestingly, 16h after acute exercise, the PEPCK and G6Pase protein level were decreased in the old exercised group. Conclusion These results provide new insights into the mechanisms by which exercise restores insulin signalling in liver during aging. Fapesp process n° 2010/12091-2, 2010/12718-5 and 2012/01750-0.

### COMPETITION RESULTS - APPROPRIATE CRITERIA FOR TALENT ION?

Wulff, J., Hoffmann, A.

*Institute for Applied Trainings Science*

Introduction To qualify for talent promotion programs in Germany a successful participation in Junior World Championships (JWCh) is required. Therefore, it is generally assumed that the most successful junior athletes will also be the most promising senior elite athletes. The aim of the study was to examine whether senior elite triathletes have already been successful in the junior age and to discuss the suitability of competitive results as selection criteria in triathlon. Methods For the world's top 20 triathletes from 2004-2011 rankings in the JWCh and the rankings of the Olympic Games and/or the Senior World Championships were assembled and analysed retrospectively by Fisher-Freeman-Halton test. From the date of birth and event date the age of the first appearance on senior elite level was calculated and compared between the JWCh participants and the Non-JWCh- participants using t-test for independent samples. Results Almost half of the international male and 62 % of the female senior elite athletes did not finish in the top 20 at JWCh. There is no association between ranking in JWCh and the rankings on senior elite level. Considering German athletes 75 % of the successful seniors had also been successful in JWCh, which is the highest value of all nations, whereas only 8 % of USA senior triathletes participated successfully in JWCh. Non-JWCh- participants (male and female) become senior elite performer at a significantly higher age. Discussion The German system of long-term athlete development, focusing strongly on international junior competitions, seems to choose the most promising junior athletes and is capable to set the base for top rankings. However, the career development of international elite athletes proves, that previous runners resp. swimmers or late bloomers can similarly be successful. Selection policy of leading triathlon nations also include performance prerequisites tests (as eg. standardised time trials in each discipline) and discretionary criteria in addition to performance criteria to comply with those typical pathways to elite performance in triathlon. Talent selection guidelines should always take the amount of sport-specific training into account and should regularly be adjusted to performance developments on senior elite level. ### CHANGES OF JUMPING SKILL IN FEMALE VOLLEYBALL PLAYERS DURING AN ANNUAL TRAINING CYCLE

Busko, K., Michalski, R., Lipinska, M.

*Josef Pilsudski University of Physical Education*

Introduction Measurements of power output and the height of jump in jumps on force plate are a routine methods used in laboratory testing (Häkkinen, 1993; Busko, 2009). Aim The aim of the study was to follow the changes of the maximal power and height of jump measured in spike jump and counter movement jump in female volleyball players during an annual training cycle. Methods Six Second Division female volleyball players took part in the study. Their mean ( $\pm$ SD) age, body height, body mass and duration of training practising amounted 21.8 $\pm$ 1.9 years, 180.6 $\pm$ 3.7 cm, 67.6 $\pm$ 4.1 kg and 7.7 $\pm$ 2.9 years, respectively. The maximal power output and the height of rise of the body mass center during vertical jumps were measured on a force plate for counter-movement jumps (CMJ) and spike jumps (SPJ). Four measurements were carried out: before (I) and after (II) the preparatory period, after the end of first (III) and second (IV) competitive season. The results were statistically processed using analysis of variance (ANOVA) with repeated measures (post-hoc Tukey test,  $p < 0.05$ ). Results The values of CMJ height of jump significant decreased from 0.394 $\pm$ 0.038 m before the preparatory period (I) to 0.371 $\pm$ 0.038 m after the end of preparatory period (II), 0.371 $\pm$ 0.031 m after the end of first competitive season and 0.368 $\pm$ 0.041 m (III) and after the end of second competitive season (IV) while the relative maximal power output were 24.72 $\pm$ 2.83 W/kg, 24.56 $\pm$ 5.9 W/kg, 24.36 $\pm$ 4.26 W/kg and 24.11 $\pm$ 5.07 W/kg, respectively. The relative maximal power output values of SPJ changed insignificantly from 37.01 $\pm$ 7.11 W/kg (I) to 36.93 $\pm$ 8.23 W/kg (II), 36.90 $\pm$ 10.21 W/kg (III) and 35.41 $\pm$ 9.29 W/kg (IV). The height of SPJ jump were 0.479 $\pm$ 0.054 m,

0.493±0.072 m and 0.495±0.080 m and 0.465±0.074 m, respectively. Discussion In our study, there were no significant changes in the power output measured in SPJ and CMJ and in the SPJ height of jump during an annual training cycle. Height of jump in CMJ significantly decreased throughout the all season. The results obtained in this study are not agreement with the results of the paper of Häkkinen (1993) and Busko (2009), who reported an increase in the power output and the height of jump during the preparatory period and then reducing the value during competitive season. ### IS AGILITY ASSOCIATED WITH CORE STRENGTH, BALANCE AND STRAIGHT SPRINTING SPEED IN HIGH-LEVEL YOUTH SOCCER PLAYERS?

Faude, O., Roth, R., Suter, K., Zahner, L., Donath, L.

*University of Basel*

**Introduction** The ability to change direction quickly and easily (i.e. agility) is considered important for successful performance in soccer (Sporis et al., 2010). Agility requires maintaining and controlling body position while quickly decelerating and accelerating. Thus, it might be assumed that balance, core strength, and sprint performance may be correlated with agility. We therefore investigated the association between agility and various measures of balance, core strength and sprint ability in high-level youth soccer players. **Methods** The under-13 to under-21 teams of a professional Swiss soccer club participated in the present study. Due to age-related differences in physical performance the under-13 to 16 (N = 39 players, age: 14.0 (SD 1.1) y, height: 1.66 (0.10) m, weight: 51.7 (11.3) kg) and the under-17 to 21 (N = 28 players, age: 17.9 (1.3) y, height: 1.77 (0.05) m, weight: 70.6 (7.5) kg) age categories were separately analyzed. After a familiarization session during regular training, all players performed the following tests in a gym: 30-m straight sprint (10-m and 20-m split times), an agility test (total distance: 32 m incl. three 180° turns), static balance on a force plate (center-of-pressure (COP) path length displacement for each leg separately), isometric peak force during back extension and trunk flexion, strength endurance in prone plank position, and a dynamic core strength test (modified Russian twist). **Results** In the older players, agility was significantly correlated with trunk flexion strength (r=0.44), balance performance (COP displacement right leg: r=0.39, left leg: r=0.49), and sprint acceleration (10-m split: r=0.46, 20-m split: r=0.43). Multiple regression analysis revealed left leg balance performance being the single best predictor of agility time (R<sup>2</sup>=0.56, P=0.01, SEE=2.4%). In the younger age group, agility was significantly correlated with height (r=-0.53), weight (r=-0.65), trunk flexion (r=-0.44) as well as back extension strength (r=-0.45), dynamic core strength (r=-0.38), and sprint times (10-m split: r=0.47, 20-m split: r=0.64, 30-m time: r=0.69). Multiple regression analysis revealed 30-m sprint time being the single best predictor of agility time (R<sup>2</sup>=0.59, P<0.001, SEE=3.0%). **Discussion** We conclude that in different age groups different physical abilities are predictive for agility. While mainly balance and acceleration are related to agility in older players, anthropometric characteristics, core strength and sprinting speed are more important in younger players. The current results may serve as a basis for interventional strategies to improve agility in high-level youth soccer. Sporis G, Jukic I, Milanovic L, Vucetic V. (2010). *J Strength Cond Res*, 24, 679-686.

### VALIDITY AND RELIABILITY OF A TRIGONOMETRIC METHOD TO EVALUATE RIGHT AND LEFT STRAIGHT LEG RAISE TEST AND HIP ABDUCTION TEST

Vázquez-Guerrero, J., Moras, G., Rodríguez-Jiménez, S.

*INEFC-Barcelona*

**Purpose:** The aim was to present a trigonometric method for estimating the range of movement (ROM) from field-based tests and to assess the concurrent validity and intra- and interrater reliability when this method is applied to the right and left straight leg raise test (SLR) and hip abduction test (HIP-ABD). **Methods:** Thirty trained young men (age, 22.2 ± 5.4 years; height, 176.5 ± 8.8 cm; body mass, 70.3 ± 9.1 kg) participated in this study. The gold standard used to establish the concurrent validity of the flexometer method (FM) was goniometry. Measurements were taken in two positions, corresponding to a submaximal and close to maximal ROM for the evaluated tests. All measurements were taken by two trained raters. The ROM assessed by the FM was calculated in degrees using trigonometry. Descriptive statistics were used to summarize ROM measurements in the FM and the goniometric technique (GT). Concurrent validity was evaluated using Pearson's correlation coefficient (PCC) and the interclass correlation coefficient (ICC). Inter- and intraobserver reliability was evaluated using the ICC, the standard error of measurement (SEM) and the minimal detectable change (MDC). **Results:** Both the SLR and the HIP-ABD showed high concurrent validity and good inter- and intra-rater reliability with an ICC value that was always > 0.9. The estimated errors (SEM) and the minimal detectable change (MDC) in repeated measurements appeared to be less in FM than in GM. **Conclusions:** This study indicated that the FM is a valid and reliable method for assessing hip ROM. Due to its convenience and cost-effectiveness, this new method could be widely used to measure the ROM of several joints. **References:** Boone, D. C., Azen, S. P., Lin, C. **INFLUENCE OF 30-HOURS SLEEP DEPRIVATION AND EXERCISE ON LIPID METABOLISM DURING MAXIMAL EXERCISE**

Górecka, M.1, Kozacz, A.1, Bogdan, A.2, Mikulski, T.1, Żernicka, E.1

*1 Mossakowski Medical Research Centre, PAS, Warsaw, Poland. 2 Central Institute for Labour Protection – National Research Institute, Warsaw, Poland.*

**Introduction** Popularity of ultra-endurance events is increasing. Most of the time the exercise intensity is moderate during event but ends with a sprint finish. Thus, the purpose of this study was to evaluate changes in lipid metabolism in physically active individuals prior and after prolonged exercise combined with complete sleep deprivation followed by graded maximal effort. **Methods** Graded maximal test (50 W every 3 min) to volitional exhaustion was performed on cycloergometer by 11 endurance trained men before (trial B) and immediately after (trial A) 30 hours of prolonged exercise (simulated adventure race) combined with complete sleep deprivation. Triglyceride (TG), free fatty acids (FFA), total (C) and high density lipoprotein cholesterol (HDL-C), glucose (G) and angiotensin-like protein 4 (ANGPTL4) concentrations in plasma were measured before and at the end of the maximal exercise. **Results** There were significant differences between B and A trials in rest/basal TG ( $1.30 \pm 0.21$  vs.  $0.44 \pm 0.07$  mM), C ( $4.09 \pm 0.29$  vs.  $3.61 \pm 0.30$  mM), HDL-C ( $1.35 \pm 0.12$  vs.  $1.46 \pm 0.10$  mM) and FFA ( $2.017 \pm 0.336$  vs.  $1.152 \pm 0.119$  mM) concentrations in plasma. ANGPTL4 concentration in plasma was increased by 30% in trial A at rest. No difference was found in resting G concentration between trials. After maximal exercise performed in trial B significantly higher values were found in C and HDL-C concentrations ( $4.09 \pm 0.29$  vs.  $4.63 \pm 0.27$  and  $1.35 \pm 0.12$  vs.  $1.59 \pm 0.10$  mM, respectively). Concentration of FFA was reduced after exercise from  $2.017 \pm 0.336$  to  $0.865 \pm 0.131$  mM ( $p < 0.05$ ). In trial A plasma TG concentration was significantly higher after maximal exercise than at rest ( $0.438 \pm 0.075$  vs.  $0.867 \pm 0.110$  mM, respectively) but no difference was found in FFA concentration. As in trial B plasma C and HDL-C concentrations were significantly increased ( $p < 0.001$ ). A significant decrease from  $5.73 \pm 0.32$  to  $3.63 \pm 0.24$  mM in plasma glucose after maximal exercise in trial A was noted. **Discussion** The experimental protocol of the study required that all the individuals were well trained amateurs who often take part in ultra-endurance events. Thus, their ability to use fat energy substrates should be increased by repeated aerobic endurance training. The interesting finding of the study is that the well-known healthy changes in lipid profile associated with exercise are also present in such an extreme conditions. Fall in blood glucose found after maximal exercise in trial A is a syndrome of fatigue.

**CARDIOPROTECTIVE EFFECTS OF EXERCISE TRAINING ON LEFT VENTRICULAR REMODELING AND NEUROHUMORAL ACTIVATION IN EXPERIMENTAL PULMONARY ARTERIAL HYPERTENSION**

Schmidt, C.1, Bovolini, A.1, Sousa, G.C.1, Hoffmann, M.1, Girardi, D.1, Moreira-Gonçalves, D.1, Leite-Moreira, A.2, Duarte, J.A.1, Henriques-Coelho, T.2

*1: FADEUP (Porto, Portugal), 2: FMUP, (Porto, Portugal)*

**Introduction** Pulmonary arterial hypertension (PAH) directly affects the right ventricle but left ventricle dysfunction (LVD) was recently described in PAH patients, which can be due to left ventricle (LV) cardiac atrophy and/or neurohumoral activation (Lourenço et al., 2006; Hardziyenka et al., 2011). Exercise training (ExT) was shown to prevent doxorubicin-induced cardiac atrophy (Scott et al., 2011) and neurohumoral activation in other settings of heart failure (Crimi et al., 2009). The present study analyzed the preventive effect of exercise preconditioning on LV in a rat model of PAH induced by monocrotaline (MCT). **Methods** Male Wistar rats were randomly separated in sedentary (SED; 4 weeks sedentary) and trained groups (EX; running sessions of 60 min/day, 5 days/week, at 25 m/min, during 4 weeks). After, animals were injected with MCT (60mg/kg; SED+MCT and EX+MCT) or the same volume of vehicle (SED+V and EX+V). Afterwards, all animals remained sedentary for additional 4 weeks. Next, animals were submitted to LV hemodynamic evaluation in baseline and isovolumic conditions. Samples from LV were collected for histological analysis and RT-PCR analysis. **Results** In baseline conditions, systolic (peak systolic pressure and dP/dtmax) and diastolic function (dP/dtmin and Tau) were compromised in SED+MCT but not in EX+MCT ( $P < 0.05$ ). Under isovolumic conditions, SED+MCT showed additional deterioration in the same parameters, but exercise training prevented it ( $P < 0.05$ ). This improved hemodynamic profile in EX+MCT was associated with preservation of LV mass and cardiomyocyte area, as well as reduced fibrosis ( $P < 0.05$ ). Regarding neurohumoral activation, ET-1 mRNA levels were increased in SED+MCT group and normalized in EX+MCT ( $P < 0.05$ ). **Discussion** The present work shows that ExT exerts a positive impact on LV, protecting from functional impairments in baseline and under stress conditions. These improvements were related with less cardiac atrophy and fibrosis, as well as lower ET-1 mRNA, all of which have been previously implicated with cardiac dysfunction (Lourenço et al., 2006; Hardziyenka et al., 2011). Of note, this protective effect was observed 4 weeks after the last training session, highlighting that cardioprotection could be sustained for several weeks. **References** Lourenço J, Roncon-Albuquerque R Jr, Brás-Silva C, Faria B, Wieland J, Henriques-Coelho T, Correia-Pinto, Leite-Moreira AF. **VOLUNTARY PHYSICAL EXERCISE ATTENUATES THE CARDIAC CHANGES INDUCED BY AGE IN FEMALE WISTAR RATS.**

Hoffmann, M.1, Bovolini, A.1, Schmidt, C.1, Castro e Sousa, G.1, Girardi, D.1, Moreira-Gonçalves, D.1,2, Leite-Moreira, A.2, Henriques-Coelho, T.2, Fonseca, H.1, Duarte, J.A.1

**Introduction** Aging is associated with functional and structural cardiac alterations, which compromise the organ ability to sustain stressful stimuli. Regular physical activity is known to provide a cardioprotective phenotype, preventing or delaying the deterioration of cardiac function in response to several cardiac insults. Our aim was to determine if long-term voluntary wheel running is able to attenuate the age-induced impairment of cardiac function in laboratory animal. **Methods** Female Wistar rats ( $n = 19$ ) with 5 months of age were randomly divided into three groups: Sedentary Young (SED-Y,  $n = 7$ ; immediately sacrificed); Sedentary Old (SED-O;  $n = 6$ ; standard housing for

9 months) and Active Old (ACTIVE-O; n =6; housed in cages with a running wheel for 9 months). At the end of experimental protocol, rats were prepared for hemodynamic evaluation of the left ventricle (LV) function with conductance catheters. After sacrifice LV samples were collected from all animals for histological analysis of cardiomyocytes cross-sectional area (CSA; H&E) and fibrous tissue expression (sirius red staining). Results Physical activity improved systolic (higher dP/dtmax) and diastolic function (higher dP/dtmin and faster relaxation evaluated by Tau) in the Active Old group. This functional improvement was associated with lower levels of interstitial collagen (P<0.05). Discussion Chronological age induces gradual and deleterious alterations in the heart and compromises cardiac functionality (1, 2). Our results, in agreement with others (1,3), show that the structural and functional age-related impairments can be mitigated by regular exercise providing a cardioprotective phenotype. Regular physical exercise seems to prevent or delay structural and functional alterations induced by ageing. References A. M. Bronikowsky, P. A. Carter, T. J. Morgan, T. Garland, JR., N. Ung, T. D. ### EFFECT OF WHOLE-BODY CRYOTHERAPY ON SKELETAL MUSCLE REGENERATION IN ELITE GRECO-ROMAN WRESTLERS

Zembron-Lacny, A.

*University School of Physical Education Poznan*

**Introduction** In response to intense exercise or trauma, myogenic satellite cells become activated, proliferate, and repopulate the myofiber population by fusing together or fusing with existing myofibers. This process is largely mediated through nitric oxide, pro-inflammatory cytokines and growth factors that are produced and release in response to the injury (Zembron-Lacny et al., 2012). In sports medicine, a number of post-exercise recovery strategies are used to improve satellite cells activation and muscle regeneration such as whole-body cryotherapy (WBC), often without scientific evidence of their benefits (Banfi et al., 2010). The purpose of the study was to assess the efficacy of WBC combined with intensive training on extracellular markers of satellite cells activity and their relationship with skeletal muscle damage in elite Greco-Roman wrestlers. **Methods** Blood samples were collected before a 8-day course of daily WBC sessions (-120oC, twice a day), and then before and after the last single WBC session during the conditioning camp (in-season, May). Results Creatine kinase (CK), myoglobin (Mb) and tumour necrosis factor alpha (TNFalpha) demonstrated the highest levels after 8-day training and cryotherapy but did not change following the single WBC session. By contrast, nitric oxide (NO) and interleukin IL-1beta significantly decreased after the single WBC. The C-reactive protein (hsCRP) as well as growth factors HGF, IGF-I, PDGF-BB and BDNF increased after training and WBC, and then significantly decreased after the last single WBC session. The changes in muscle damage markers as well as inflammatory mediators, growth factors IGF-I and PDGF-BB were not different compared with group participated only in the training, except for growth factors HGF and BDNF. **Discussion** We have concluded that wrestling training has significant influence on factors regulating the myogenic satellite cells whereas WBC dose not induce general or specific positive effects in muscle regeneration. WBC seems to be an ineffective recovery strategy in non-injured athletes but it requires the further studies to confirm the present observations. **References** Banfi G, Lombardi G, Colombini A, Melegati G. ### THE INFLUENCE OF LOW-MODERATE ALTITUDE TRAINING ON THE CELL-MEDIATED IMMUNITY OF ELITE SPEED SKATERS

Yu, T., Chang, Y.

*China Institute of Sport Science*

**Introduction** Altitude training has been widely applied in the athletes to improve their performance. While altitude training could enhance the oxygen-transporting ability, altitude-associated hypoxia is considered as an environmental stressor and its potential negative effects on immune system have not been well addressed. In this study, we tested the effects of altitude training on the T lymphocytes in the elite speed skaters in order to evaluate the role of altitude training on the cell-mediated immunity. **Methods** Elite speed skaters underwent low-moderate altitude training for 1 week. Peripheral whole blood samples were extracted from the athletes before, during and after the altitude training and analyzed by flow cytometry for the detection of total T cells (CD3+), helper/inducer T cells (CD4+) and suppressor/cytotoxic T cells (CD8+) using monoclonal antibodies against CD3, CD4 and CD8, respectively. T-test and ANOVA were employed to compare the difference among distinct groups using SPSS software and p < 0.05 was considered statistically significant. **Results** We found that one week low-moderate altitude training could lead to a significant decrease of the percentage of total T cells in the whole blood samples in the elite speed skaters when compared to the data at sea level one week before the altitude exposure (66.94% vs 74.01%, respectively, p=0.013). Interestingly, the declined T cell proportion during the low-moderate altitude training was recovered 8 weeks after the athletes returned to sea level. A decreasing tendency of CD4+ and CD8+ T cells was also observed during low-moderate altitude training; however, the ratio of the percentage of CD4+ T cells to CD8+ T cells kept unchanged, suggesting the balance of distinct subpopulation of T cells is not disturbed by the low-moderate altitude training. **Conclusion** Taken together, low-moderate altitude training transiently suppresses the proportion of T cells in peripheral whole blood and thus may weaken the cell-mediated immune functions in the athletes, which should be considered for the health care of the athletes and the plan-making during the altitude training to obtain better results.

### THE EFFECT OF DIFFERENT CARBOXYHEMOGLOBIN ANALYZERS ON HB-MASS ESTIMATIONS.

Voss, S.C.1,2, Achtzehn, S.3, Elzain Elgingo, M.2, Mester, J.3, Bourdon, P.2

*1 Anti-Doping Lab Qatar, Doha, Qatar 2 Aspire Academy for Sports Excellence, Doha, Qatar 3 German Sport University, Institute of Trainingscience and Sportinformatics, Cologne, Germany*

**Introduction:** The determination of Hemoglobin mass by the optimized carbon monoxide rebreathing method is an emerging technique in the field of sport science and sport medicine [1]. For the calculation of the resulting mass mainly the change of the baseline carboxyhemoglobin fraction (COHb%) from before to the COHb% after CO administration is used. The analysis of COHb% is performed by CO-Oximeters or blood gas analyzers with oximeter module. The functional principle for all analyzers used is similar; however, as athletes can be monitored by different institutions like i.e. Olympic training center, sport institute or university the question comes up how comparable the test results are. While Ulrich et al. showed differences between OSM3 and RapidLab 1245 we decided to investigate

differences between OSM3, ABL80 and Cobasb221 [2]. Methods: 9 subjects performed two times the CO-Rebreathing procedure to estimate their total HB-Mass. The blood was analyzed directly in quintuplicate for COHb% on an OSM3 CO-Oximeter (Radiometer, Copenhagen, Denmark), an ABL80 FLEX CO-OX analyzer (Radiometer, Copenhagen, Denmark) and a Cobas b221 blood gas analyzer (Roche, Mannheim, Germany). Venous blood was taken instead of capillary blood to have enough sample volume for all measurements. Results: The correlations of the HB-Mass between the analyzers were within a range of  $R^2=0.91 - 0.99$ , however the Bland Altman Plot showed depending on the analyzer type mean differences of 41 – 86g. Compared to the other two analyzers the OSM3 method seemed to have a trend to higher differences depending on the height of the HB-Mass. Discussion and Conclusion: We could demonstrate that the obtained HB-Mass determination values depend on the spectrophotometer that is used for COHb% measurement. The mean differences were comparable to those obtained by Ulrich et. al. [2]. To avoid misinterpretation of HB-Mass values by different institutions information about the applied analyzer should be always included in a report. 1. Schmidt, W. and N. Ulrich, G., et al., Dependence of hemoglobin mass estimation with the optimized CO-rebreathing method on different spectrophotometers. *Scand J Med Sci Sports*, 2012. 22(2): p. 224-31.

### PHYSICAL EXERCISE ANTAGONIZES DOXORUBICIN-INDUCED TOXICITY ON HEART AND BRAIN MITOCHONDRIA

Marques-Aleixo, I.1, Santos-Alves, E.1,2, Mariani, D.1, Coxito, P.2, Rocha-Rodrigues, S.1, Balça, M.M.1, Moreira, P.I.2,3, Oliveira, P.J.2, Magalhães, J.1, Ascensão, A.1

1: CIAFEL/FADEUP (Porto, Portugal) 2: CNC (Coimbra, Portugal) 3: Laboratory of Physiology, FMUC (Coimbra, Portugal)

**Introduction** The highly effective anticancer drug Doxorubicin(Dox) induces unwanted effects in non-target tissues, particularly cardio and neurotoxicity involving mitochondrial dysfunction (Carvalho et al. 2009). To counteract its toxic effects, physical exercise has been proposed (Ascensao et al. 2012). We here analyzed the effect of endurance training(ET) and voluntary physical activity(VPA) against heart, brain cortex and cerebellum mitochondrial dysfunction induced by sub-chronic treatment of Dox. **Methods** Sprague-Dawley rats were divided in six groups (n=6 per group): saline sedentary (Sal+Sed), saline ET (Sal+ET; 12wks of endurance treadmill running), Sal+VPA (12wks of voluntary free wheel running), Dox sedentary (Dox+Sed; 2mg.kg<sup>-1</sup> x 7wks of treatment), Dox+ET and Dox+VPA. Heart, brain cortex and cerebellum mitochondria were isolated and in vitro endpoints of oxygen consumption, membrane potential( $\Delta\Psi$ ) and susceptibility to permeability transition pore(PTP) were evaluated. Results Dox treatment affected heart, brain cortex and cerebellum mitochondrial oxygen consumption as seen by state 3 and by respiratory control ratio and  $\Delta\Psi$  endpoints as well as the susceptibility to PTP induction by calcium. Physical exercise per se, particularly ET, ameliorated heart and brain mitochondrial bioenergetics and increased mitochondrial tolerance against calcium-induced PTP opening. Dox-induced mitochondrial bioenergetics impairments was positively modulated by both ET and VPA. **Discussion** Generally, our data suggest that both types of physical exercise, characterized by distinct intensities and durations, modulate mitochondrial bioenergetics isolated from the studied tissues into a more resistant phenotype, including ATP generating capacity and the vulnerability to mitochondrial mediated apoptotic cell death. It is possible that chronic exercise stimulation may up-regulate important cellular and mitochondrial defense systems that contributed to the observed protect against Dox-related mitochondrial impairments. The study of the molecular mechanisms associated with exercise-induced cardiac and brain cortex and cerebellum mitochondrial protection is warranted. ### HIGH-INTENSITY INTERVAL TRAINING ENHANCES HIPPOCAMPAL BDNF SIGNALING: POSSIBLE NEW EFFECT OF HIT ON COGNITIVE FUNCTIONS

Daisuke, M., Lee, M., Okamoto, M., Inoue, K., Soya, H.

University of Tsukuba

**Introduction** Exercise is effective for enhancing both aerobic capacity and brain function. What type of exercises is most effective, however, is still uncertain, as most past studies have focused on endurance training (ET). Recently, low-volume high-intensity interval training (HIT) has been shown to enhance aerobic capacity as effectively as ET (Gibala et al., 2006). Furthermore, we have already demonstrated that voluntary resistance wheel running (RWR) enhances spatial memory related to hippocampal brain-derived neurotrophic factor (BDNF) (Lee et al., 2012). Voluntary RWR is intermittent exercise and produces shorter distances but higher work levels than does forced running. This allows us to postulate that HIT plays a beneficial role in hippocampal functions. To address this, we tried to establish a model of HIT for animals and to examine its effects on hippocampal plasticity. **Methods** Male Wistar rats (10 weeks old) were randomly assigned to three groups: untrained sedentary control (n=8), ET (n=9), and HIT (n=9). Exercised animals were habituated to treadmill running for 1 week before starting training, which was carried out for 4 consecutive weeks with 5 sessions per week. ET consisted of 30-min of continuous running at 20 m/min. HIT consisted of 10 bouts of 30-sec sprinting, and the sprint bouts were separated by 2.5-min recovery periods. The initial treadmill speed was 30-40 m/min in the first week and was increased gradually to 60 m/min by the final week. The ratios of HIT to ET were 1:6 in exercise time and 1:2~1:4 in exercise volume. After 4 weeks of training, we measured VO<sub>2</sub>max, and 3 days later, we sacrificed the rats and took samples. We determined CS activity of the plantaris and soleus muscles to evaluate aerobic capacity. To determine the effect of training on the brain, we evaluated the expression of hippocampal proteins, BDNF, the receptor TrkB, and the transcription factor p-CREB using a Western blot analysis. **Results and Discussion** The plantaris CS activity significantly increased in each training group. Furthermore, a tendency toward increased VO<sub>2</sub>max values was seen in the HIT group (p<0.08). Although there was no significant difference in VO<sub>2</sub>max values between groups, the relative intensity (% value of VO<sub>2</sub>max) at the same speed was significantly lower in training groups than in the control group. These results suggest that ET and HIT enhance aerobic capacity equally. Regarding BDNF signaling, HIT significantly increased hippocampal BDNF, TrkB, and p-CREB protein levels. ET enhanced only TrkB expression, although it produced a strong tendency toward increased BDNF (p<0.07) and p-CREB (p<0.08) protein levels. Taken together, our findings suggest that HIT, which is more effective for improving aerobic capacity, also increases hippocampal BDNF signaling leading to improved spatial memory. HIT would play a role in the enhancement of cognitive functions. **References** Gibala MJ et al. *J Physiol*, 575, 901-911 (2006). Lee MC et al., *J Appl Physiol*, 113, 1260-1266 (2012).

## MODELLING THE HUMAN NEUROMUSCULAR JUNCTION IN VITRO TO INVESTIGATE THE MECHANISMS OF SKELETAL MUSCLE PLASTICITY

Player, D.J., Martin, N.R.W., Ferguson, R.A., Hill, E.J., Lewis, M.P.

*Loughborough University; Aston University*

Introduction: Human in vitro models to study skeletal muscle (SkM) plasticity in response to exercise have taken the form of monolayer or tissue engineered cultures, in the absence of neuronal input. Electrical stimulation has been used to mimic the nerve. The presence of a functioning neuronal input would allow for the investigation of activated mechanisms in response to contraction (exercise) in vitro without the necessity for an electrical stimulus. Methods: Human primary muscle derived cells (MDC's) were isolated through explant culture of Vastus Lateralis biopsies. Human SkM constructs were engineered as previously described (Smith et al., 2012). At 14 days, constructs were sampled for immuno-histochemical (IHC) analysis. Neurons were generated from neuron-committed human teratocarcinoma (NT2) cells and were differentiated as described (Podrygajlo et al., 2009). NT2's were plated to form neurospheres with the addition of retinoic acid for differentiation. Experiments were also conducted to ascertain the compatibility of culturing MDC's in NT2 media. Results: Isolated MDC's displayed  $36.8 \pm 10.4\%$  Desmin positivity and fusion of  $64.9 \pm 7.6\%$  in monolayer culture ( $n = 5$  independent cell populations,  $n = 3$  donors). Matrix contraction of MDC seeded collagen constructs was observed within hours of initial preparation, confirming cell attachment and matrix remodelling. Constructs displayed a high degree of cell alignment and density, with the presence of multinucleate myotubes in multiple focal planes. Microscopy illustrated NT2 neurosphere formation and early neurite outgrowth with retinoic acid treatment. Media compatibility experiments showed that there were no differences in Desmin positivity or fusion of MDC's cultured in NT2 media or NT2 media supplemented with IGF-I, compared to control MDC media. Discussion: The data described provides a preliminary foundation for future experiments to examine the co-culture of human MDC's and human derived neurons in a bio-mimetic SkM model. Future experiments will utilise the cells and SkM model characterised herein, to investigate muscle-nerve interaction and neuromuscular junction formation in vitro. This will provide the foundation of a pre-clinical model that can be utilised for the study of potential 'exercise', pharmacologic and genetic therapies for SkM disease. ## INFLUENCE OF DIETARY NITRATE SUPPLEMENTATION ON THE POWER-DURATION RELATIONSHIP FOR HIGH-INTENSITY EXERCISE

Kelly, J., Vanhatalo, A., Wilkerson, D.P., Wylie, L., Jones, A.M.

*University of Exeter*

Introduction: Dietary nitrate supplementation has been reported to improve tolerance to constant power output, high-intensity cycling, knee-extensor exercise and running. Typically, enhanced exercise tolerance has been reported in exercise trials of 6-15 min in duration. However, it remains unknown whether nitrate supplementation may be ergogenic during shorter-duration, higher-intensity exercise. Improvements in cycling time trial (TT) performance over 4 km and 16.1 km and 10 km, with a range of maximal exercise durations of 6-30 min, have also been reported following nitrate supplementation. Collectively, these results suggest a beneficial shift in the power-duration relationship (rightwards and/or upwards) for severe-intensity exercise as a result of nitrate supplementation. The increased ratio of power output to  $Vo_2$  reported following nitrate supplementation suggests that this effect might be related to an increased critical power (CP). We tested the hypothesis that dietary nitrate supplementation would increase the CP and/or  $W'$  during cycling exercise. Methods: In a double-blind, randomized, crossover study, nine recreationally-active male subjects supplemented their diet with either nitrate-rich concentrated beetroot juice (BR; 2 x 250 ml/day,  $\sim 8.2$  mmol/day nitrate) or a nitrate-depleted beetroot juice placebo (PL; 2 x 250 ml/day,  $\sim 0.006$  mmol/day nitrate). In each condition, the subjects completed four separate severe-intensity exercise bouts to exhaustion at 60% of the difference between the gas exchange threshold and peak power attained during incremental exercise (60% $\Delta$ ), 70% $\Delta$ , 80% $\Delta$  and 100% peak power, and the results were used to establish CP and  $W'$ . Results: Nitrate supplementation improved exercise tolerance during exercise at 60% $\Delta$  (BR:  $696 \pm 120$  vs.  $593 \pm 68$  s,  $P < 0.05$ ), 70% $\Delta$  (BR:  $452 \pm 106$  vs. PL:  $390 \pm 86$  s,  $P < 0.05$ ), and 80% $\Delta$  (BR:  $294 \pm 50$  vs. PL:  $263 \pm 50$  s,  $P < 0.05$ ) but not 100% peak power (BR:  $182 \pm 37$  vs. PL:  $166 \pm 26$  s,  $P > 0.05$ ). The power-duration relationship was rightward-shifted by BR compared to PL as a consequence of small but non-significant improvements in both CP (BR:  $221 \pm 27$  vs. PL:  $218 \pm 26$  W,  $P > 0.05$ ) and  $W'$  (BR:  $19.3 \pm 4.6$  vs. PL:  $17.8 \pm 3$  kJ,  $P > 0.05$ ). Conclusion: Dietary nitrate supplementation results in a rightward-shifted power-duration relationship in recreationally-active subjects, leading to improved endurance during severe-intensity exercise ranging from 4-12 minutes. These modulations may be expected to translate into a  $\sim 2$ -3% improvement in cycling TT performance in sub-elite cyclists.

## CAFFEINE AND CARBOHYDRATE SUPPLEMENTATION WAS UNABLE TO IMPROVE INTERVAL EXERCISE PERFORMANCE AND AGILITY IN ATHLETES

Lee, C.L.1, Cheng, C.F.2, Lee, C.J.2, Huang, H.W.3, Kuo, Y.H.3, Lee, M.C.4

*1:National Sun Yat-sen University (Taiwan), 2:National Taiwan Normal University (Taiwan), 3:National Taiwan Normal University (Taiwan), 4:Yu Da University (Taiwan)*

Introduction: Caffeine (CAF) added to carbohydrate (CHO) has been suggested improve endurance performance via a central nervous system activation (Carter et al. 2004; Doherty et al. 2005); however, little is known about the acute effect of the ergogenic benefits of the CAF+CHO on high-intensity interval sprint performance (HIS), agility capacity and blood metabolic profile. Hence, the purpose of our study was to characterize the effects of CAF+CHO ingestion on the physiological performance measurements. Methods: Twelve team-sport male athletes ( $20 \pm 1$  yrs,  $179 \pm 7$  cm, and  $75 \pm 9$  kg) underwent four interventions at least one week apart in a randomized, double blind fashion experiment, and a cross-over-design. Participants ingested the placebo (PLA) or CAF (6 mg/kg BW) of 1-h before high-intensity interval sprint test and agility test, with pre-exercise PLA or CHO solution (0.8 g/kg BW) ingestion immediately before testing protocol. The HIS protocol included ten sets of 5x4-second sprints on a cycle ergometer with 20-second recovery between bouts. Two bouts of agility were performed pre-HIS and post-HIS. The statistical significance was determined using a two-factor repeated measure ANOVA with the level of significance set at  $p < 0.05$ . Results: The peak power, mean power, and agility capacity were not significantly different between trials ( $p > 0.05$ ). Related to PLA, CAF+CHO resulted in a 5.2% reduction in total work, which corresponded with a 24.7-25.7% increase in fatigue at the end stage of the HIS. CAF+CHO supplementation also resulted in an 11.1% increase in blood lactate, and elevations in higher blood glucose concentration throughout the HIS while compared with PLA ( $p < 0.05$ ). The cortisol concentration also increased with

CAF+CHO and CAF related to PLA (244.3 vs. 242.6 vs. 190.7 ng/ml), but there was no significant effect of CAF+CHO supplementation on testosterone concentration ( $p > 0.05$ ). Discussion: These findings show that caffeine co-ingested with carbohydrate did not improve high-intensity interval sprint performance, agility capacity, and fatigue in team-sport male athletes. There was a trend towards a greater catabolism in cortisol and smaller anabolic hormone in testosterone/cortisol ratio, when the participants ingested CAF+CHO or CAF. It confirms that the recommendation to ingest this in a fashion of CAF+CHO provides less benefit, nor additive effects on the magnitude of the interval intense performance (Conger et al. 2011). #### THE EFFECT OF LOCAL BIOACTIVE ANDROGEN PRODUCTION ON SKELETAL MUSCULAR HYPERTROPHY

Aizawa, K., Wada, S., Ushida, T., Akimoto, T.

*Institute of Sport*

**Introduction** Androgens such as testosterone play important roles in exercise-induced skeletal muscular adaptation (Storer et al., 2003). Testosterone is converted by 5 $\alpha$ -reductase (Srd5a1) into a dihydrotestosterone (DHT), which is the most powerful androgen. Recently, we reported that the androgen production occurs in various peripheral tissues including skeletal muscle and is activated by exercise (Aizawa et al., 2007, Aizawa et al., 2010). Although, exercise training activates local androgen production in skeletal muscle, the physiological role of the bioactive androgen production through Srd5a1 in skeletal muscle is unknown. **Methods** We generated a Srd5a1 expression vector and evaluated its protein expression by western blot. Then, the Srd5a1 expression vector was transfected into C2C12 myoblasts to evaluate DHT production. Moreover, the Srd5a1 vector was introduced into tibialis anterior muscle of mice to examine the function of Srd5a1 in vivo. **Results** The Srd5a1 protein was successfully produced by the Srd5a1 vector and it promoted an intracellular conversion of DHT from testosterone in vitro. Forced expression of Srd5a1 increased skeletal muscle mass in vivo. In addition, levels of muscular DHT concentration and phospho-p70s6k, which indicates protein synthesis, were increased with the Srd5a1 expression in skeletal muscle. **Discussion** The local bioactive androgen production through Srd5a1 activated skeletal muscle protein synthesis and increased muscle mass. We previously reported that exercise training-induced increase in muscular DHT was associated with muscular hypertrophy in rats (Aizawa et al., 2011). These data suggested that local bioactive androgen production plays an important role in skeletal muscular hypertrophy. **References** TW. Storer, L. Magliano, L. Woodhouse, ML. Lee, C. Dzekov, J. #### DOES EXERCISE INFLUENCE THE APOPTOSIS RELATED PROTEINS IN HEALTHY TRAINING SENSITIVE AND TRAINING RESISTANCE RATS' BRAIN?

Marion, O.I, Koltai, E.I, Koch, L.2, Britton, S.2, Radak, Z.1

*1. Research Institute of Sport Sciences, Faculty of Physical Education and Sport Sciences (TF), Semmelweis University, Budapest, Hungary 2. Department of Anesthesiology, University of Michigan Medical*

**Introduction** Apoptosis is well regulated form of cell death that is important to maintain the homeostasis of organisms. In the recent years numerous studies are published what are related to apoptosis after traumatic brain injury, ageing brain or diseased brain. Among these papers fewer studies are investigated apoptosis and the effect of exercise in healthy brain. Therefore we were interested whether exercise does influence the apoptosis related proteins in healthy training sensitive and training resistance rats' brain. **Methods** 27 selective breeding 11th generation for low response to training (LRT) and high response to training (HRT) rats were training for 3 months at the 70% of maximal oxygen uptake (VO<sub>2</sub>max) at 30 min/day. Animals were divided into 4 groups: low response to training control (LRTC) and exercise trained (LRTE) and high response to training control (HRTC) and exercise trained (HRTE). The brain function was evaluated by Morris-maze test and passive avoidance test. Moreover we have measured VO<sub>2</sub>max, and the content of some of the proteins that are related to or playing a key role in apoptosis. Statistical significance was assessed by non-parametric Kruskal-Wallis ANOVA and Mann-Whitney U-test for post-hoc analyses. The significance level was set at  $p < 0.05$ . **Results** In the results of Morris-maze could not see any significant changes, but in the case of long time memory we measured a significantly difference between HRTC and HRTE group. VO<sub>2</sub>max is increased significantly in both of exercised groups. Level of silent mating type information regulation 2 homolog 1 (SIRT1) is significantly higher in HRTC compare with LRTC group. Furthermore the levels of SIRT1 were lower in HRTE group compare with HRTC and LRTC. Exercised training is increased the level of the tumor suppressor protein, p53 in the LRT and HRT groups. In the case of acetylated p53 we measured lower levels in HRTE compare with HRTC and LRTE group. Bcl-2-associated X protein (Bax) is decreased in HRTE group compare with LRTE group. Level of B-cell lymphoma 2 (Bcl-2) is not changed in our investigation; however we can see decreasing tendency in HRT group by effect of exercise. **Discussion** We suggest that regular exercise training can influence the level of p53, which is a key regulator of apoptosis. The exercise training-associated decreasing tendency of Bcl-2 is HRTE group might be support our hypothesis that different trainability rats have various response to apoptosis. Data suggest that physical activity play a role in the apoptosis in the brain.

### THE EFFECT OF EICOSAPENTAENOIC AND DOCOSAHEXAENOIC ACID ON PROTEIN SYNTHESIS AND BREAKDOWN IN MURINE C2C12 MYOTUBES

Gray, S., Kamolrat, T.

*University of Aberdeen*

Introduction Eicosapentaenoic acid (EPA) and Docosahexaenoic acid (DHA) have been found to stimulate protein synthesis (Smith et al., 2010) with little information regarding the effects on protein breakdown. Furthermore whether there are distinct effects of EPA and DHA remains to be established. The aim of the current study was to determine the distinct effects of EPA and DHA on protein synthesis, protein breakdown and signalling pathways in C2C12 myotubes. Methods Fully differentiated C2C12 cells were incubated for 24 hours with 0.1% ethanol (control), 50µM EPA or 50µM DHA prior to experimentation. After serum (4h) and amino acid (1h) starvation cells were stimulated with 2mM L-leucine and protein synthesis measured using 3H-labelled phenylalanine. Protein breakdown was measured using 3H-labelled phenylalanine. Signalling pathways (Akt, mTOR, p70S6k, 4EBP1, rps6 and FOXO3a) were measured via western blots. Results Data revealed that after incubation with EPA protein synthesis was 25% greater (0.89(0.24) DPM/ng protein vs 1.12(0.14) DPM/ng protein, in control and EPA cells respectively; P<0.05) compared to the control cells, with no effect of DHA. Protein breakdown was 22% (16.7(2.9) DPM/ng protein vs 13.0(1.8) DPM/ng protein, in control and EPA cells respectively; P<0.05) lower, compared to control cells, after incubation with EPA, with no effect of DHA. Analysis of signalling pathways revealed that both EPA and DHA incubation increased (P<0.05) p70s6k phosphorylation, EPA increased (P<0.05) FOXO3a phosphorylation, with no alteration in other signalling proteins. Discussion The current study has demonstrated distinct effects of EPA and DHA on protein metabolism with EPA showing a greater likelihood to result in skeletal muscle protein accretion. These alterations to protein metabolism occurred alongside and increase in phosphorylation of p70s6k, a key regulator of protein translation (e.g. Miyazaki & Esser, 2009), and FOXO3a, a key regulator of the ubiquitin proteasome system which may account for up to 80% of proteolysis during muscle wasting (Tawa et al., 1997). ### PHYSICAL INACTIVITY AND HIGH FAT DIET SYNERGISTICALLY ENHANCE THE ACCUMULATION OF INTRAMYOCYELLULAR DIACYLGLYCEROL AND INDUCE INSULIN RESISTANCE IN MURINE SOLEUS MUSCLE.

Takechi, S., Tamura, Y., Ikeda, S., Kawamori, R., Watada, H.

*Juntendo University Graduate school of medicine*

Introduction Intramyocellular lipids, especially intramyocellular diacylglycerol (IMDG) has been reported that one of the causes of insulin resistance in skeletal muscle#1. In human, long term (~4wks) bed-rest increased intramyocellular lipid (IMCL) accumulation accompanied with muscle atrophy#2, in addition short term only 3days high fat diet (HFD) increase IMCL levels and decrease insulin sensitivity. Both physical inactivity and long-term (generally more than 4wk) high fat diet (HFD) induce insulin resistance in skeletal muscle, however, the combined effect of these factors on insulin resistance and its mechanism have not been clarified yet. Methods To elucidate them, C57BL6J mice were randomly assigned to four groups; control group, 24h hind-limb cast immobilization (HCl) group, short-term (2wk) HFD group, and 24h HCl after 2wk HFD group. Then, we evaluated ex-vivo insulin-stimulated 2-deoxy glucose uptake (2DG-uptake) and insulin signal. Results Twenty four hours HCl significantly decreased insulin-stimulated 2DG-uptake by ~40%, while 2wk HFD did not alter 2DG-uptake. On the other hand, 24h HCl after 2wk HFD dramatically decreased insulin-stimulated 2DG-uptake by ~75%. In parallel with decreased insulin-stimulated 2DG-uptake, we observed decreased insulin stimulated tyrosine phosphorylation of insulin receptor substrate (IRS)-1 after 24h HCl, which were more exacerbated in 24h HCl after 2wk HFD group, while only 2wk HFD did not change. Then, we examined intracellular fat composition and protein level of DGAT1 that mediate the formation of triacylglycerol (TG) from diacylglycerol (DG) and Acyl-CoA, thus reduce the accumulation of DG level. Intriguingly, we found that 24h HCl increased intramyocellular DG (IMDG) in soleus by ~190%, while the amount of intramyocellular TG (IMTG) was not changed. Moreover, whereas IMDG and IMTG were not changed by 2wk HFD, 24h HCl after 2wk HFD dramatically increased IMDG and IMTG by ~330% and ~140%, respectively. Associated with these IMDG accumulations, DGAT1 level was down regulated by ~50% in both 24h HCl group and 24h HCl after 2wks HFD group. Conclusion These results suggested that physical inactivity and HFD synergistically induce IMDG accumulation and insulin resistance in soleus muscle. Reduced DGAT1 expression induced by 24h HCl seems to be involved in this mechanism at least in part. reference #1.Itani SI, Ruderman NB, Schmieder F, Boden G. ### USING RADIOLABELED ATP KINASE ASSAYS TO ASCERTAIN RESISTANCE EXERCISE AND FEEDING-INDUCED CHANGES IN AMPK AND P70S6K ACTIVITY.

McGlory, C.1, Drust, B.2, Close, G.L.2, MacLaren, D.P.M.2, Campbell, I.T.2, Morton, J.P.2, Hamilton, D.L.1

*1 Health and Exercise Science Research Group University of Stirling, U.K. 2 Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, U.K.*

Introduction: Resistance exercise-induced increases in muscle growth are thought to be underpinned by activation of the mTOR-p70S6K signalling axis (Drummond et al., 2009). Conversely, endurance exercise is believed to stimulate mitochondrial biogenesis mediated by the AMPK-PGC1α pathway (Atherton et al., 2005). However, activation of these diverse signalling pathways is thought to be incompatible and performing resistance and endurance-type exercise in close proximity results in a compromised adaptation (Hawley, 2009). Contemporary methods to ascertain the activity of these pathways are semi-quantitative. However, assays of protein kinases using radiolabeled ATP are the gold standard for the assessment of kinase function offering a fully-quantitative assessment of changes in activity. The aim of this study was to identify the molecular response of human skeletal muscle to resistance exercise and feeding in well-trained males employing radiolabeled ATP kinase assays. Methods: Six, healthy, well-trained males performed a bout of resistance exercise (70% 1RM, 4\*10 repetitions of leg press and leg extension) followed by the immediate consumption of 20g of egg white powder in a 500 mL solution. Muscle biopsies were obtained pre exercise and at +1h and +3h post egg white consumption. Results: Data are expressed as pmol/min/mg (mean ± SD). AMPK activity was significantly reduced from pre at 3h post drink (24.15 ± 3.29 to 15.64 ± 2.62; p<0.05) whilst p70S6K activity significantly increased from pre at 1h (8.84 ± 1.91 to 17.18 ± 6.43; p<0.05) and 3h post drink (15.62 ± 7.64 p<0.05). Conclusion: These data suggest that resistance exercise and feeding suppress AMPK activity whilst concomitantly increasing the

activity of p70S6K. This finding lends support to the notion that the integration of resistance and endurance exercise may result in a compromised muscle adaptation. References 1. Atherton, P. ### NO ASSOCIATION OF THE ACTN3 GENOTYPE WITH THE UPPER BODY ANAEROBIC CAPACITY IN YOUNG SWIMMERS

Orysiak, J.1, Zmijewski, P.1, Sitkowski, D.1, Majorczyk, E.2, Dybek, T.2, Zembron-Lacny, A.3, Grochowska, J.1, Pokrywka, A.1  
1: IS (Warsaw, Poland), 2: OUT (Opole, Poland), 3: USPE (Poznan, Poland)

**Introduction** It was suggested, that  $\alpha$ -actinin 3 gene (ACTN3) R577X polymorphism could influence athletic performance. In previous research the frequency of allele R or RR genotype was higher in power athletes (Ma et al., 2013, Yang et al., 2009). Moreover, this genotype was associated with higher strength and shorter sprint time (Yang et al., 2009). The aim of the present study was to examine the association of the ACTN3 genotype with the upper body anaerobic capacity among young swimmers. **Methods** Ninety national-level (medallists in national championships) swimmers (46 males aged  $15,0 \pm 1,3$  and 44 females aged  $15,0 \pm 1,0$  years), and 110 (50 males and 60 females) non-athletes participated in this investigation. In swimmers, upper body anaerobic power was measured by the Wingate Anaerobic Arm Test (WAAT) on arm cycloergometer. Peak power (PP), mean power (MP) and fatigue index (FI) were determined. Genomic DNA was extracted from blood cells. Genotyping for the ACTN3 R577X polymorphism was performed based on methods described by Mills et al. 2001. Results ACTN3 genotype distributions met Hardy-Weinberg equilibrium in swimmers ( $\chi^2=0,10$ ;  $P=0,75$ ) and non-athletes ( $\chi^2=0,68$ ;  $P=0,41$ ). The frequency of the ACTN3 genotype was similar in swimmers and non-athletes (RR= 44%, RX= 43%, XX= 12% vs. 36%, 51%, 13%;  $\chi^2=1,42$ ;  $P=0,50$ ). The distribution of the R and X alleles in swimmers was similar, compared to non-athletes ( $\chi^2=1,42$ ;  $P=0,50$ ). We did not observe any effect of ACTN3 R577X polymorphism on the PP, MP, FI, even after adjustment for age and somatic features. Separately conducted analysis in men and women also did not reveal significant effect of ACTN3 genotype on WAAT results. Neither RX genotype nor homozygotes conferred an advantage on the PP, MP, FI. **Discussion** In this study, the distribution of the ACTN3 genotype was similar between nonathletic controls and national-level young swimmers as well as we found no effect of ACTN3 R577X polymorphism on anaerobic capacity (PP, MP, FI) in young, competitive swimmers, both male and female. These results could indicate that ACTN3 R577X polymorphism alone does not allow to identify individuals with predisposition for sprint performance, probably other factors i.e. ability to coordinate and properties of muscle tissue may be at least as important as single gene polymorphism. **References** Ma F, Yang Y, Li X, Zhou F, Gao C, Li M, Gao L. ### NONFUNCTIONAL OVERREACHING IS ASSOCIATED TO LOW-GRADE CHRONIC INFLAMMATION IN SWISS MICE.

Pereira, B.C.1, De Souza, C.T.2, Pauli, J.R.3, Ropelle, E.R.3, Rocha, E.M.4, Cintra, D.E.3, Freitas, E.C.1, Papoti, M.1, Da Silva, L.E.4, Lira, F.S.2, Silva, A.S.1

*School of Physical Education and Sport of Ribeirão Preto, EEFERP-USP*

**Introduction** Nonfunctional overreaching (NFOR) is characterized by a performance decrement that can be reversed after weeks or months of recovery (1). Pereira et al. (2) developed a new OT protocol that induced NFOR in 100% of mice. The innovation of this protocol was the inclusion of downhill running sessions at a -14% grade during four weeks. Davis and co-authors (3) linked the performance decrease induced by a single acute session of downhill running with high concentrations of interleukins (i.e. IL-1 $\beta$  and IL-6) in soleus muscles. Thus, we aimed to verify whether the performance decrease induced by chronic sessions of downhill running (2) is linked to high concentrations of cytokines in Swiss mice. **Methods** Swiss mice were divided into control (C), trained (TR) and overtrained (OTR). The body weight and food intake of all groups were recorded weekly. The incremental load test (ILT) and exhaustive test (ET) were used to measure performances before and after exercise protocols. 24h after ET, muscle samples (i.e. extensor digitorum longus - EDL and soleus) were removed and stored for subsequent determination of the protein contents of IL-6 and tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ) by immunoblotting. One-way ANOVA followed by Bonferroni's post hoc test was used to examine the differences between the studied parameters. Results TR and OTR groups diminished significantly their body weight compared to C group. While TR group increased the exhaustion velocity and time to exhaustion compared to C group, OTR group diminished these performance parameters compared to TR group. TR group presented significantly lower levels of IL-6 in serum, and TNF- $\alpha$  for EDL and soleus compared to C group. On the other hand, OTR group presented significantly higher levels of IL-6 and TNF- $\alpha$  for EDL and soleus compared to TR group. **Discussion** The main difference between IL-6 increase in response to physical exercise or severe infections is the behaviour of TNF- $\alpha$  (4). Generally, TNF- $\alpha$  did not increase in response to exercise (4). The high values of TNF- $\alpha$  in the OTR group indicate that the IL-6 increase is possibly linked to inflammation instead of regular response to physical exercise. In summary, Pereira's protocol (2) led to low-grade chronic inflammation marked by high values of IL-6 in serum and muscle samples, and TNF- $\alpha$  in muscle samples. **References** 1. ### VARIATION OF THE HIF1A AND MB GENES IN LITHUANIAN ATHLETES

Gineviciene, V.1, Jakaitiene, A.1, Milasius, K.2, Tubelis, L.2, Kucinskas, V.1, Utkus, A.1

1: Vilnius University, 2: Lithuanian Educational University

**Introduction** The efficiency of energy supply to human skeletal muscle in the hypoxic state is dependent on many factors. Hypoxia-inducible factor 1 (HIF-1) is a transcription factor that regulates gene expression in response to hypoxia and has been associated with athletic performance. A polymorphism (Pro582Ser) of the HIF1A gene has been shown to be associated with changes of maximal oxygen consumption ( $\dot{V}O_{2max}$ ) during training. Myoglobin plays a crucial role in energy metabolism by carrying molecular oxygen between the capillaries and the mitochondria to satisfy the requirement for sustained work. There is little information on the functional implications of MB (A79G) variation and no research related to the performance of elite athletes. As HIF1A is an essential mediator of the adaptive re-

sponse to hypoxia and myoglobin is the primary oxygen-carrying protein of muscle tissues, we hypothesized that variants of the HIF1A and MB genes might be associated with Lithuanian elite athletes' status. Methods A total of 165 Lithuanian elite athletes (78 endurance-oriented, 38 power-oriented, 49 "mixed group") and 240 healthy unrelated individuals (controls) were genotyped (PCR-RFLP). Anthropometric measurements, anaerobic muscle strength and VO<sub>2</sub>max were evaluated. Results The results revealed no significant HIF1A allele or genotype frequency differences between the athletes and the controls (Pro/Pro 77.6%; Pro/Ser 21.8%; Ser/Ser 0.6% vs. Pro/Pro 75.0%; Pro/Ser 21.3%; Ser/Ser 3.8%; P=0.134). The frequency of the HIF1A Ser allele was higher in the power-oriented (17.1%) athletes compared to endurance-oriented (11.5%), "mixed group" (7.1%) and controls (14.4%). Muscle strength phenotypic indexes did not differ between athletes depending on their HIF1A genotype (P>0.05). Interestingly, we found that athletes carrying the Pro/Ser genotype exhibited significantly higher VO<sub>2</sub>max (69.5 vs. 60.3 ml/kg/min, P<0.05) than those carrying the Pro/Pro genotype. MB genotypes in athletes group showed differences from controls (AA/AG/GG: 19.4/63.0/17.6% vs. 27.9/45.0/27.1%; P=0.002). The frequency of MB A allele was higher in endurance athletes than in controls (53.2% vs. 50.4%; P=0.001). The power-oriented athletes with the MB GG genotype were significantly higher, with larger muscle mass, grip strength and short-term explosive muscle power (vertical jump test) than AA genotyped athletes (P<0.05). Conclusions We found preliminary evidence that the HIF1A (Pro582Ser) and MB (A79G) variants may be associated with Lithuanian elite athletes status: athletes carrying the HIF1A Pro/Ser genotype associated with higher aerobic capacity; the MB GG and A/G genotypes are related to speed-power sports, and AA genotype to endurance demanding sports. We conclude that the HIF1A and MB variants may belong to a group of several genetic variations that influence top-level physical performance.

### PROTECTIVE ROLE OF 17-BETA-ESTRADIOL TOWARD IL-6 LEUKOCYTE EXPRESSION INDUCED BY INTENSE TRAINING IN YOUNG FEMALE ATHLETES

Vitale, J., Scala, L., Silvestri, I., Scurati, R., Michielon, G., Alberti, G., Venerando, B., Tringali, C.

*University of Milan*

Several experimental data demonstrated that the levels of physical activity during childhood could influence the growth and development of muscle, fat, and bone (Eliakim et al., 1996) so, setting the levels of training appears to be crucial so that physical activity could be beneficial to children growth (Cooper et al., 2004). Exercise performed at a competitive level could deeply modify the immune system and the cytokine response of athletes. In this report, we demonstrated that young elite female artistic gymnasts (n.16; age: 9-15 years), showed an increase of interleukin 6 (IL-6) and tumour necrosis factor alpha (TNF-alpha) mRNAs expression in blood mononuclear cells (PBMCs), in comparison to young girls performing the same sport at a recreational level (n.16; age: 10-15 years). The increase of IL-6 and TNF-alpha mRNAs appeared to be directly linked to the intensity and to the duration of the training. Moreover, in elite athletes engaging in artistic gymnastics and, also, in synchronized swimming (n.34; age: 9-15 years), IL-6 gene expression appeared to be modulated by the levels of circulating oestrogens: pre-pubertal athletes (n. 20; age: 11 +/- 1 years) revealed higher increases of IL-6 than pubertal athletes (n. 14; age: 14 +/- 1.6 years). In pre-pubertal athletes, body mass index (BMI) percentile was inversely correlated with both the increases of IL-6 and TNF-alpha. The consequence of these events was the shift of the cytokine profile toward a pro-inflammatory status. These modifications induced by training performed at an elite level risk to negatively affect the growth of female children athletes (Marchovecchio et al., 2012). REFERENCES 1. Abstract: We investigated the ability of testosterone (T) to restore differentiation in multiple population doubled (MPD) murine myoblasts, previously shown to have a reduced differentiation in monolayer (Sharples et al. 2011) and bioengineered skeletal muscle cultures (Sharples et al. 2012) vs. their parental controls (CON). Cells were exposed to low serum conditions in the presence or absence of T (100 nM) ± PI3K inhibitor (LY294002) for 72 hrs and 7 days (early/late muscle differentiation respectively). Morphological analyses were performed to determine myotube number, diameter (µm) and myonuclear accretion as indices of differentiation and myotube hypertrophy. Changes in gene expression for myogenin, mTOR and myostatin were also performed using real time-polymerase chain reaction (RT-PCR). Myotube diameter in CON and MPD cells increased from 17.32 ± 2.56 µm to 21.02 ± 1.89 µm and 14.58 ± 2.66 µm to 18.29 ± 3.08 µm (P≤0.05) respectively after 72 hrs of T exposure. The increase was comparable in both MPD (+25%) and CON cells (+21%) suggesting a similar intrinsic ability to respond to exogenous T administration. Addition of PI3K inhibitor (LY294002) in the presence of T attenuated these effects in myotube morphology (in both cell types) suggesting a role for this pathway in T stimulated hypertrophy. Finally, myoblasts showed reduced responsiveness to T stimulated expression of mTOR and T reduced myostatin in MPD myoblasts only. The present study demonstrated T's ability to rescue differentiation and hypertrophy in myoblasts that displayed reduced differentiation capacity vs. their parental controls, the action of testosterone in this model appeared to be mediated by PI3K/Akt signalling. ### EFFECTS OF CAFFEINE ON AEROBIC PERFORMANCE IN SELF-PACED MANNER IN THERMONEUTRAL AND HOT ENVIRONMENTS.

Matsumoto, T., Katsumata, N., Yamashita, N., Fukaya, T., Narita, T., Kashima, D., Fan, M., Matsuoka, D.

Introduction There are many reports in which caffeine supplementation increases aerobic exercise performance in thermoneutral condition, however those effects in hot environments are controversial. On the other hand, athletes competes the race in self-paced manner,

not in constant pace used in many studies. The purpose of the present study was to clarify the effects of caffeine on aerobic performance in self-paced manner both in thermoneutral and hot conditions. Methods Eight healthy recreationally active men (age: 23 years, height: 173.3 cm, mass: 65.3 kg, VO<sub>2</sub>max: 48.5 ml/min/kg) volunteered in this study. Each subject performed 4 trials of 15-min time trial in self-selected pace after a 20-min pre-exercise at 22 C using a bicycle ergometer with caffeine (CAF, 5 mg/kg) or placebo (CON), taken 60 min before in the double-blind manner and in randomized order, either in thermoneutral (WBGT 20 C) or hot (WBGT 31 C). Rectal temperature (Tre), heart rate (HR), oxygen consumption (VO<sub>2</sub>), work output and RPE were recorded. Results Mean Tre did not exceed 38C during 15-min time trial both at WBGT20 and WBGT31. Total work of CAF (170.0 kJ) was significantly higher than CON (161.6 kJ) at WBGT20, however there was no difference (CAF: 161.8 kJ, CON: 159.3 kJ) at WBGT31. There was no significant difference in the relative work (%VO<sub>2</sub>max) between CAF and CON at WBGT20, however %VO<sub>2</sub>max of CAF was significantly higher than CON at 7-9, 10-12, 13, 14 and 15 min periods (p<0.05) at WBGT31. HR of CAF was significantly higher than CON at 10-12, 13 and 14 min periods (p<0.05) at WBGT20, and at 4-6, 7-9 and 10-12 min periods (p<0.05) at WBGT31. RPE of CAF was significantly higher at 10-12, 13, 14 and 15 min periods (p<0.05) at WBGT20, and significantly lower than CON at 1-3 min period (p<0.05) at WBGT31. There was no significant difference in work output per RPE (kJ/PRE) between CAF and CON at WBGT20, however kJ/PRE of CAF was significantly higher than CON at 7-9 min period (0.73 vs 0.6 kJ/PRE, p<0.05) at WBGT31. Discussion At thermoneutrality (WBGT20), caffeine increased aerobic performance in self-selected pace manner with the increased HR and RPE. It is suggested that caffeine-induced increase in aerobic work capacity is attributed to the suppression of PRE during exercise. In the hot environment (WBGT31), caffeine did not increase total work, but increased kJ/RPE at 7-9 min period. Effects of caffeine could not deny even at hot condition. #### **CARBOHYDRATE CO-INGESTION WITH PROTEIN DELAYS DIGESTION AND ABSORPTION BUT DOES NOT MODULATE POSTPRANDIAL MUSCLE PROTEIN ACCRETION**

Gorissen, S.H.M.1,2, Burd, N.A.1,2, Hamer, H.M.1,2, Gijzen, A.P.3, van Loon, L.J.C.1,2

1: Top Institute Food & Nutrition (Wageningen, the Netherlands), 2: Department of Human Movement Sciences and 3: Human Biology, NUTRIM, MUMC+ (Maastricht, the Netherlands)

**BACKGROUND:** Sarcopenia is thought to arise from a blunted responsiveness of skeletal muscle tissue to food intake. Recent evidence suggests that this is, at least partly, attributed to senescent muscle becoming more resistant to the capacity of postprandial insulin release to enhance skeletal muscle perfusion. **OBJECTIVE:** To determine the impact of carbohydrate co-ingestion with protein on dietary protein digestion and absorption kinetics and subsequent postprandial muscle protein accretion in healthy young and older men. **DESIGN:** Twenty-four healthy young (age: 21±1 y, BMI: 21.8±0.5 kg•m<sup>-2</sup>) and 25 older (age: 75±1 y, BMI: 25.4±0.6 kg•m<sup>-2</sup>) men received a primed continuous L-<sup>15</sup>N-phenylalanine infusion and ingested 20 g intrinsically L-[1-<sup>13</sup>C]-phenylalanine-labeled protein with (Pro+CHO) or without (Pro) 60 g carbohydrate. Biopsies were collected from the vastus lateralis in a postabsorptive state and at 2 and 5 h after protein ingestion. **RESULTS:** Carbohydrate co-ingestion delayed the postprandial rise in exogenous phenylalanine appearance rate (P=0.001). Dietary protein-derived phenylalanine availability over the 5 h postprandial period was lower in the older (62±2 %) when compared with the young group (74±2 %, P=0.007), with no differences between the Pro and Pro+CHO conditions (P=0.202). Carbohydrate co-ingestion did not modulate postprandial muscle protein synthesis rates (0.035±0.003 vs 0.043±0.004 and 0.033±0.002 vs 0.035±0.003 %•h<sup>-1</sup> following Pro vs Pro+CHO in the young and older group, respectively). In accordance, no differences in muscle protein-bound L-[1-<sup>13</sup>C]-phenylalanine enrichments were observed between conditions (0.020±0.002 vs 0.020±0.002 and 0.019±0.003 vs 0.022±0.004 MPE following Pro vs Pro+CHO in the young and old, respectively). **CONCLUSION:** Carbohydrate co-ingestion with protein delays dietary protein digestion and absorption, but does not modulate postprandial muscle protein accretion in healthy young or older men.

#### **REMARKABLE REDUCTION OF FAT MASS IN OVERWEIGHT MEN IN FOUR DAYS WITH PROLONGED EXERCISE AND SEVERE CALORIC RESTRICTION**

Pérez-Suárez, I., Ponce-González, J.G., Calle-Herrero, J., Holmberg, H.C., Calbet, J.A.

University of Las Palmas de Gran Canaria

**Introduction** Obesity can be treated by reducing energy intake and/or increasing energy expenditure to achieve a negative energy balance. One of these interventions alone, either with or without pharmacological aid, produces only a moderate loss in mean weight (2-3 kg or less); while dieting in combination with exercise for 3-12 months reduces body weight by an average of 1.1 kg more than simply dieting (Shaw et al. 2009). A similar or more pronounced reduction in body mass can be achieved much more rapidly (i.e., within 3-10 days) by combining severe caloric restriction, with extensive daily exercise. It has been shown that elevating the amount the protein relative to carbohydrate in weight-loss diets lessens the loss of lean mass and promotes loss of fat mass. **Methods** To determine if fat mass can be reduced by 3-4 kg in four days of low energy intake (LE) and 9 hours of daily low-intensity exercise. Fifteen healthy overweight men were enrolled in this study divided in five experimental phases: a pre-test, walking+LE for 4 days (W+LE), control diet+reduced exercise for three days (DIET), and follow-up 4 weeks (POST1) and one year later (POST2). During W+LE, the participants were randomly assigned to consume a diet consisting solely of protein (n=8) or sucrose (n=7) (0.8 g/kg body weight each day in both cases). **Results** Whole-body fat mass was reduced by a mean of 2.3, 2.9, 4.0, and 2.1 kg following the four last phases, respectively (P<0.05). About 2/3 of the fat was loss from the trunk. After W+LE, serum levels of glucose, insulin, HOMA, total and LDL cholesterol levels, and triglycerides were reduced; FFA and cortisol were increased. Serum leptin concentration was reduced by 64, 50 and 33 % following W+LE, DIET and POST1, respectively (P<0.05). The effects were similar in both groups. **Discussion and conclusions** Prolonged walking for several hours in consecutive days combined with a very low calorie diet can be used to reduce fat mass by 0.7-0.9 kg/day in overweight adults. The main advantage of this weight loss method is that fat is mostly lost from the trunk and that the effect is achieved in a rather

short time. The intervention is accompanied by improvements in blood lipids and a fast and sustained reduction of leptin serum concentration. This indicates reduced leptin resistance after the intervention; which may help to maintain body weight. Also some lean mass is lost, this only represents less than 15% of the whole mass lost. For these reasons it would be worthy to determine if this weight loss program could be repeated periodically to achieve greater reduction of fat mass over a much shorter period of time than achieved with other weight reducing programs. References Shaw et al. (2009). Cochrane Database Syst Rev. CD003817. Granted by MEC (DEP2010-21866).

### **MATCHING ENERGY INTAKE TO EXPENDITURE OF ISOCALORIC EXERCISE AT HIGH AND MODERATE INTENSITIES**

Holliday, A., Blannin, A.

*University of Birmingham*

**Background:** Those seeking to manage their bodyweight use a variety of strategies, but the most common approaches involve attempting to exercise more and consume fewer calories (Weiss et al., 2006). A poor comprehension of the energy cost of exercise and the energy content of food may contribute to weight gain and the poor success rate of "exercise alone" weight-loss interventions. **Purpose:** To investigate individuals' ability to consciously match energy intake with energy expenditure after exercise at moderate and high intensity. **Method:** In a counterbalanced cross-over study design, 14 low- to moderately-active, lean individuals (7 male; mean age  $23 \pm 3$  years; mean BMI  $22.0 \pm 3.2$  kg·m<sup>-2</sup>) completed both a moderate-intensity (60% VO<sub>2</sub>max, MOD) and a high-intensity (90% VO<sub>2</sub>max, HIGH) exercise bout on a treadmill, matched for energy expenditure, EE, (450 kcal). Participants were blinded to the intensity and duration of each bout. Thirty minutes post exercise, participants were presented with a buffet, where they were asked to consume food in an attempt to match energy intake with the energy expended during the exercise bout. This was termed the "matching task," providing a EL<sub>match</sub> value. Upon finishing the matching task, a verbal estimate of energy expenditure (EST) was obtained before the participant was allowed to return to the buffet to consume any more food, if desired. This intake was covertly measured and added to EL<sub>match</sub> to obtain an ad libitum intake value (EL<sub>ad lib.</sub>). **Results:** A significant condition x task interaction showed that, in MOD, EST was significantly lower than EE ( $298 \pm 156$  kcal vs.  $443 \pm 22$  kcal,  $p = 0.01$ ). In the HIGH condition, EE, EL<sub>match</sub> and EST were similar. In both conditions, participants tended to over-eat to a similar degree, relative to EST, with EL<sub>match</sub> 20% and 22% greater than EST in MOD and HIGH respectively. Between condition comparisons demonstrated that EL<sub>match</sub> and EST were significantly lower in MOD, compared with HIGH ( $374 \pm 220$  kcal vs.  $530 \pm 248$  kcal,  $p = 0.002$  and  $298 \pm 156$  kcal vs.  $431 \pm 129$  kcal,  $p = 0.002$  respectively). For both conditions, EL<sub>ad lib.</sub> was approximately 2-fold greater than EE. **Discussion:** Participants exhibited a strong ability to estimate exercise energy expenditure after high-intensity exercise. Participants appeared to perceive moderate-intensity exercise to be less energetic than an isocaloric bout of high-intensity exercise. This may have implications for exercise recommendations for weight-loss strategies, especially when casual approaches to exercise and attempting to eat less are being implemented. References Weiss, E. C., Galuska, D. A., Khan, L. K., & Serdula, M. K. (2006). Weight-Control Practices Among U.S. Adults, 2001–2002. *Am J Prev Med*, 31(1), 18–24.

### **DIETARY NITRATE CO-INGESTION WITH PROTEIN DOES NOT FURTHER ENHANCE WHOLE-BODY PROTEIN SYNTHESIS RATES IN OLDER, TYPE 2 DIABETIC MEN**

Kouw, I.W.K., Cermak, N.M., Burd, N.A., Gijzen, A.P., van Kranenburg, J., van Loon, L.J.C.

*NUTRIM School for Nutrition, Toxicology and Metabolism, Maastricht University Medical Centre+, Maastricht, the Netherlands*

**INTRODUCTION:** Impairments in insulin-mediated capillary recruitment and muscle tissue perfusion have been suggested to result in a blunted postprandial muscle protein synthetic response following protein ingestion in the elderly population. Dietary nitrate supplementation may serve as an effective nutritional intervention strategy to enhance amino acid delivery to skeletal muscle tissue and thus augment postprandial muscle protein accretion. The present study investigates whether ingestion of dietary nitrate prior to the consumption of a meal-like amount of protein modulates dietary protein digestion and absorption kinetics and improves whole-body protein synthesis rates in older, type 2 diabetic patients. **METHODS:** Twenty-four older, type 2 diabetic men (age  $72 \pm 1$  y; BMI  $26.7 \pm 0.4$  m<sup>2</sup>·kg<sup>-2</sup>; HbA<sub>1c</sub>  $7.3 \pm 0.2$ %) received a primed, continuous infusion of L-[2H<sub>5</sub>]phenylalanine, L-[2H<sub>2</sub>]tyrosine, and L-[1-13C]leucine and ingested 20 g specifically produced intrinsically L-[1-13C]phenylalanine-labelled dietary protein with (PRONO3) or without (PRO) a single bolus of sodium nitrate (0.15 mmol·kg<sup>-1</sup> body weight). Muscle biopsies were taken from the vastus lateralis before and 2 and 5 h after protein ingestion. Blood samples were collected at regular intervals to assess protein digestion and absorption kinetics and whole-body protein balance. **RESULTS:** Exogenous phenylalanine appearance rates significantly increased in both groups following protein ingestion ( $P < 0.001$ ), with no differences between groups. The percentage of dietary protein-derived phenylalanine that appeared in the systemic circulation over the 5 h postprandial period was  $59 \pm 2$ % (PRO) and  $57 \pm 3$ % (PRONO3;  $P > 0.05$ ). Whole-body protein synthesis rates significantly increased ( $P < 0.001$ ), whereas breakdown rates were significantly reduced in the postprandial phase when compared with the postabsorptive phase ( $P < 0.001$ ), with no differences between groups. **DISCUSSION:** Ingestion of a meal-like amount of dietary protein stimulates whole-body protein synthesis rates and inhibits protein breakdown, resulting in a positive net protein balance. Prior ingestion of sodium nitrate does not modulate dietary protein digestion and/or absorption kinetics and subsequent whole-body protein net balance in older, type 2 diabetic patients. Further analyses are necessary to assess the specific impact of nitrate co-ingestion on postprandial muscle protein accretion.

### **CARBOHYDRATE MOUTH RINSING DOES NOT IMPROVE TIME TRIAL PERFORMANCE IN THE FASTED OR FED STATE**

Trommelen, J., Cermak, N.M., Mullers, M., Loon, L.J.C.

*Maastricht University*

**Introduction:** It has previously been reported that carbohydrate (CHO) mouth rinsing during exercise may enhance the performance of short (45–60 min), high intensity (>75% VO<sub>2</sub>peak) exercise bouts. However, not all studies investigating this phenomenon have found evidence to support this claim. The discrepancy in these findings may be due to testing subjects in the fasted (post-absorptive) or fed state when liver glycogen stores may be more or less compromised. The purpose of this study was to define the impact of a CHO mouth-rinse on ~1 h time trial performance in trained cyclists in both the fasted and fed condition. **Methods:** Using a double blind, repeated-measures crossover design, 16 trained male cyclists ( $26 \pm 2$  y;  $4.9 \pm 0.1$  W·kg<sup>-1</sup>) were selected to perform 4 time trials of ~1 h in duration (1020 ± 31 kJ) on a cycle ergometer while rinsing their mouths with a 6.4% sucrose solution (CHO) or a non-caloric sweetened placebo (PLA) for 5 s after every 12.5% of their set amount of work. Two trials were performed in an overnight fasted state (12 h), whereas two other trials were performed 2 h after consuming a standardized breakfast (36 kJ·kg<sup>-1</sup>, 65 En% carbohydrate). Power output and heart rate were recorded continuously throughout the test. **Results:** Performance time did not differ between treatments and averaged  $69.27 \pm 1.75$  vs  $68.10 \pm 1.80$

min in the CHO and PLA treatment, respectively ( $P = 0.10$ ). The lack of any ergogenic benefit from the CHO rinse was apparent in both the fasted (CHO:  $69.58 \pm 2.00$  vs PLA:  $68.57 \pm 1.93$  min) and fed state (CHO:  $68.96 \pm 1.68$  vs PLA:  $67.63 \pm 1.77$  min: treatment  $\times$  prandial state interaction:  $P = 0.84$ ). In line, mean power output and heart rate did not differ between treatments. Furthermore, after dividing the time trial into 12.5% segments, no differences in power output or RPM's were observed over time between treatments. Conclusion: Carbohydrate mouth rinsing does not improve ~1 time trial performance when performed in either the fasted or the fed state.

### EFFECTS OF SEVERE ENERGY DEFICIT ON MUSCLE MASS: INFLUENCE OF PROTEIN INGESTION AND EXERCISE VOLUME .

Maldonado Marfínez, E., Ponce-González, J., Losa-Reyna, J., Pérez-Suárez, I., De La Calle-Herrero, J., Guadalupe-Grau, A., Holmberg, H.C., Calbet, J.A.L.

**Introduction:** The signaling phosphatidylinositol-3-kinase (PI3K) signaling pathway plays a central role in the regulation of muscle mass in response to fasting, diet changes, and exercise. However, little is known on the signaling changes in this pathway in response to a severe energy deficit (SED) in combination with varying extents of low-intensity exercise and different levels of protein in the diet. The hypothesis we tested here was that down-regulation of the PI3K/AKT/mTOR/70S6K pathway caused by SED is attenuated both by such exercise (in a volume-dependent manner) and by ingestion of whey protein, thereby helping to preserve muscle mass. **Methods:** Fifteen overweight male volunteers first performed 4 days of prolonged exercise (45 min of one-arm cranking at 15% of their maximal intensity followed by 8 h walking each day) with caloric restriction (0.8 g whey protein (PRO) ( $n=8$ ) or sucrose (SU) ( $n=7$ ) per kg body weight each day) (designated as the PE+CR period). Thereafter followed 3 days of reduced exercise and resume a normal diet that was isoenergetic with their usual diet prior to PE+CR (designated CD). Muscle biopsies were taken from both the deltoid and one of the vastus lateralis muscles (135 biopsies in all) and the phosphorylation levels of SER473 and Thr308AKT, SER2448mTOR, Thr37/454EBP1, Thr642AS160 and p70S6K determined in these samples by Western blotting. **Results:** In comparison to the baseline values prior to PE+CR, the serum concentration of insulin was 48 and 31% lower, and the lean mass 1.1 and 0.5 kg less after PE+CR and CD, respectively ( $P < 0.05$ ), independent of the type of diet. Compared to PRE, the total amount of Akt protein was reduced by 24% after CD in the PRO group ( $P < 0.05$ ), but unaltered in the SU group. Phosphorylation at Ser473Akt was 32% higher in the PRO group ( $P < 0.05$ ) and this increase was more pronounced in the exercised arms and legs, with no difference between these extremities; whereas the total amount of Ser473Akt remained constant. No changes were observed in Thr308Akt and the only alteration in Thr642AS160 was a 16% increase from PE+CR to CD in the PRO group ( $P < 0.05$ ). The total levels of phosphorylated Ser2448mTOR and the mTOR protein were elevated after both PE+CR and CD, particularly in the PRO group and to a greater extent in the exercised muscles ( $P < 0.05$ ). The amount of exercise or type of diet had no influence on phosphorylation of No 70S6K or 4EBP1. **Discussion:** Although ingestion of whey protein enhanced phosphorylation of Akt/mTOR, particularly with extensive exercise, phosphorylation of the downstream components of this signaling cascade that stimulates protein synthesis remained unaltered. The observation that lean mass was reduced to the same extent with both diets indicates that during severe energy deficit, ingestion of protein neither stimulates the synthesis nor inhibits the breakdown of proteins. **Granted by CSD 028/UPB10/12**

### THE EFFECT OF A SINGLE BOLUS, 7 DAYS AND 28 DAYS DECAFFEINATED GREEN TEA EXTRACT INGESTION ON FAT OXIDATION DURING EXERCISE

Randell, R.K., Hodgson, A.B., Lotito, S.B., Jacobs, D.M., Rowson, M., Mela, D.J., Jeukendrup, A.E.

*University of Birmingham, Unilever R&D (Sharnbrook), Unilever R&D (Vlaardingen, NL)*

**Introduction:** Ingestion of a decaffeinated green tea extract (GTE) in the 24 h before a bout of steady state moderate intensity exercise has been found to increase fat oxidation rates by up to 17%, in healthy males [1]. Other studies have shown that GTE ingestion, alongside exercise training, increases fat utilisation during exercise, compared to exercise training alone [2]. However, recently no change in fat oxidation rates during exercise was observed following 1 and 7 day ingestion of a caffeinated GTE [3]. To date no study has directly compared the effects of acute, long term and chronic GTE ingestion on substrate metabolism during exercise. **Purpose:** The aim of this study was to investigate the effects of a single bolus decaffeinated GTE (dGTE) (day 1) and following 7 and 28 days ingestion (day 7 and 28,) on whole body fat oxidation rates during moderate-intensity exercise in healthy lean males. **Method:** In a cross over, placebo controlled design 19 healthy, lean males [ $\pm$  SD weight  $75.0 \pm 7.0$  kg; body mass index (BMI)  $23.2 \pm 2.2$  kg·m<sup>-2</sup>; maximal oxygen consumption (VO<sub>2</sub>max)  $55.4 \pm 4.6$  mL·kg<sup>-1</sup>·min<sup>-1</sup>] ingested dGTE or placebo for 28 days, separated by a 28-day wash-out period. Participants completed a 30-min cycle exercise bout (50% W<sub>max</sub>) at 2 h after a single bolus of dGTE or placebo (day 1), and after 7 and 28 days of ingestion. Indirect calorimetry was used to calculate rates of whole body fat and carbohydrate oxidation during exercise. Blood samples were collected at rest and during exercise for analysis of plasma fatty acids (FA), glycerol and (-)-epigallocatechin gallate. **Results:** Ingestion of dGTE did not result in statistically significant changes in fat oxidation rates during exercise after a single bolus and following 7 and 28 days supplementation, compared to placebo. In addition, plasma concentrations of FA and glycerol, at rest and during exercise, were unaltered by dGTE ingestion at any of the time points. **Conclusion:** A single bolus of dGTE and following 7 and 28 days supplementation did not alter whole body fat oxidation rates or fat metabolism-related blood metabolites during exercise in healthy males. Research investigating the mechanisms of GTE in relation to fat metabolism is needed to determine the factors generating inconsistencies in reported efficacy. 1. ### EFFECTS OF CAFFEINE CONTAINING ENERGY DRINK ON SIMULATED VOLLEYBALL PERFORMANCE

Pérez-López, A.I, Abián-Vicén, J.2, Lara, B.2, Salinero, J.J.2, Valadés, D.1, Del Coso, J.2

*1. Alcalá University, Madrid, Spain. 2. Camilo José Cela University, Madrid, Spain*

**Introduction** Consumption of caffeine or caffeine-containing products prior to competition has been reported as a frequent behavior in athletes. While the effects of caffeine on endurance sport activities have been well established (Jenkins et al., 2008), the outcomes of caffeine ingestion on team-sports performance are scarce (Del Coso et al., 2011; Schneider et al., 2006; Stuart et al., 2005). The purpose of this study was to assess the effects of caffeine containing energy drink on volleyball players' performance during a simulated match and specific testing. **Methods** A double-blind, placebo controlled and randomized experimental design was used in this study. On two different days, 15 amateur volleyball players ( $179.5 \pm 7.9$  cm and  $80.2 \pm 13.3$  kg) ingested 3 mg of caffeine per kg of body mass in the form of an energy drink (Fure®, ProEnergetics) or the same drink without caffeine (placebo). After sixty minutes for caffeine absorption, participants performed six tests: a) spike test; b) manual dynamometry; c) squat jump (SJ); d) counter-movement jump (CMJ); e) 15-s rebound jump

(15RJ); f) agility T-test. Later, a simulated volleyball match was played and recorded. Afterward time motion analysis was done. Results In comparison to the placebo drink, the ingestion of caffeinated energy drink increased the mean jump height in SJ ( $31.1 \pm 4.3$  vs.  $32.7 \pm 4.2$  cm;  $P < 0.05$ ), CMJ ( $35.9 \pm 4.6$  vs.  $37.7 \pm 4.4$  cm;  $P < 0.05$ ) and 15RJ ( $29.0 \pm 4.0$  vs.  $30.5 \pm 4.6$  cm;  $P < 0.05$ ). Manual dynamometry for right ( $41.3 \pm 9.0$  vs.  $44.7 \pm 6.8$  kg;  $P < 0.05$ ) and left hand ( $39.8 \pm 7.1$  vs.  $42.9 \pm 7.3$  kg;  $P < 0.05$ ) was also increased after the energy drink ingestion. The time to complete the T-test was significantly reduced with the energy drink ( $10.8 \pm 0.7$  vs.  $10.3 \pm 0.4$  s;  $P < 0.01$ ). In addition, spike test velocity tended to be increased with the caffeinated energy drink ( $73 \pm 9$  vs.  $75 \pm 10$  km/h;  $P = 0.07$ ). Finally, during the simulated match, actions played precisely were more frequent ( $24.6 \pm 14.3$  vs.  $34.3 \pm 16.5$  %;  $P < 0.05$ ) with the ingestion of the energy drink. Discussion The pre-exercise ingestion of a caffeine-containing energy enhanced jump height in volleyball specific tests, handgrip force, spike and displacement velocities and improved the frequency of actions with precision during a volleyball match. Thus, caffeine-containing energy drink was effective to improve specific physical performance in volleyball. References Del Coso J, Munoz G, Munoz-Guerra J. ## THE EFFECT OF BEETROOT JUICE ON MECHANICAL EFFICIENCY AND PERFORMANCE DURING ROWING

El-Chab, A., Adams, C., Simpson, C.

*Oxford Brookes University*

Introduction Previous studies with human subjects have demonstrated that ingestion of nitrate rich beetroot juice can lower resting blood pressure, reduce the sub-maximal oxygen of exercise and enhance performance (Lansley et al., 2011a, Lansley et al., 2011b). However, these results were observed during cycling and running tasks which do not substantially engage the upper body musculature. Potentially, the effects of dietary nitrate supplementation may be greater in tasks that require significant use of both lower and upper muscle mass. Therefore, this study examined the effect of beetroot juice ingestion on resting blood pressure, rowing economy and 1500-m rowing performance in moderately trained oarsmen. Methods Eight moderately trained male rowers completed the study (age  $27 \pm 5$  yrs; weight  $79.0 \pm 10.7$  kg; height  $1.81 \pm 0.09$  m). Subjects completed a progressive incremental test to determine lactate threshold (1 mmol.L<sup>-1</sup> above baseline) and VO<sub>2</sub>max (VO<sub>2</sub>max =  $4.55 \pm 0.53$  L.min<sup>-1</sup>) and then performed a 1500-m time trial for familiarisation. On two occasions, subjects arrived at 07:00 after an overnight fast and were randomly assigned to ingest either 70 ml of beetroot juice concentrate or a denitrated beetroot juice placebo (nitrate: 4.8 mmol vs <0.005 mmol; James White Drinks Ltd). Resting blood pressure was monitored during the next 150 min before subjects completed 20 min of rowing (0-10min: work rate of 10% below LT; 5 min rest; 10-20 min: work rate of 10% above LT) and then performed a 1500m time trial on a rowing ergometer (Model E, Concept 2, Nottingham, UK). All trials were separated by at least 7-days and data analysed using repeated measures ANOVA. Results Beetroot juice supplementation did not show any effect on oxygen consumption at LT-10% ( $3.30 \pm 0.26$  L/min) and at LT+10% ( $3.82 \pm 0.12$  L/min) compared with placebo ( $3.26 \pm 0.24$  and  $3.87 \pm 0.11$  L/min, respectively). Time to completion of the 1500 m was also not affected by beetroot juice ( $306.1 \pm 5.6$  s) compared with placebo ( $306.6 \pm 5.3$  s). No significant changes were observed in systolic and diastolic blood pressure after beetroot juice ingestion compared with placebo. Discussion This study suggests that the ingestion of beetroot juice containing 4.8 mmol of nitrate, 150 min before exercise does not improve oxygen economy or 1500-m time trial performance in moderately trained rowers. ## THE EFFECT INGESTION OF CARBOHYDRATE AND CAFFEINE ON ENDURANCE EXERCISE PERFORMANCE IN HYPOXIA ENVIRONMENT

Wu, C.1, Chen, C.1, Chang, C.2, Chiu, C.3

1: *NCHU (Taichung, Taiwan)*, 2: *NTUPES (Taichung, Taiwan)*, 3: *TPEC (Taipei, Taiwan)*

Introduction Ingestion of carbohydrate may significantly increase the exogenous carbohydrate oxidation rate and delay muscle glycogen depletion during exercise. Intake of caffeine, on the other hand, increases the rate of fat oxidation during exercise, and which may reduce the demand of muscle glycogen during endurance exercise, thus to delay the onset fatigue. Hypoxic environment, however, may lower the rate of fat oxidation. The current study was to examine the effect of carbohydrate and caffeine supplementation on endurance exercise performance in hypoxic environment. Methods Eight healthy young males completed 4 experimental trials: caffeine (6mg/kg)(C), glucose (1g/kg)(G), caffeine (6mg/kg) plus glucose (1g/kg)(C+G) and placebo (P) trials, in a double-blind, cross-over design. Subjects consumed the drinks 60min before exercising on a cycle ergometer in the 15%O<sub>2</sub> hypoxia chamber. Subjects were asked to exercise at 50% W<sub>max</sub> for 90min and followed by 85%W<sub>max</sub> to exhaustion. The blood samples were collected during fasting, pre-exercise, every 30 minute throughout the experiment, and immediately after exhaustion. Results The C, G, and C+G trials showed significantly better endurance performance (C:  $433.8 \pm 85.1$  sec; G:  $377.9 \pm 100.0$  sec; C+G:  $479 \pm 110.3$  sec) than P trial ( $245.5 \pm 60.4$  sec) ( $p < 0.05$ ). Plasma free fatty acid and plasma glycerol concentrations were higher in C and P trials than in G and C+G trials ( $p < 0.05$ ). Estimated rate of fat oxidation were higher in C and P trials than in G and C+G trials ( $p < 0.05$ ). There were no significant differences in plasma glucose concentration, and rating of perceived exertion between trials. Discussion Ingestion of caffeine, glucose, or caffeine+glucose 60min before exercise was found to improve endurance performance in an acute hypoxia environment, which was similar to the normoxia condition (Desbrow et al., 2012). The ingestion of caffeine showed significantly increase in plasma concentrations of free fatty acid and glycerol during exercise. The increased rate of fat oxidation in the C trial might contribute to the ergogenic effect on endurance performance (Ivy et al., 2009). ## EFFECT OF CHRONIC SUPPLEMENTATION WITH L-ARGININE ON THE EXPRESSION OF PROTEINS THAT REGULATE MUSCLE PROTEIN SYNTHESIS IN RATS TRAINED IN HIGH-INTENSITY EXERCISE.

Gomes, M.R., Bonvini, A., Tirapegui, J.

*University of São Paulo*

**Introduction** The arginine is an amino acid conditionally essential that participates in innumerable metabolic reactions like the urea cycle, the synthesis of creatine and production of nitric oxide. Besides those functions, arginine is associated most recently with muscle protein synthesis. Therefore the aim of this study was to investigate the effect of L-arginine chronic supplementation on the muscle protein synthesis, through mTOR pathway. **Methods** Wistar male adult rats were distributed into four groups: Trained-Arginine, sedentary-Arginine, Trained Diet-Control and Sedentary Diet-control. Both diets were elaborated based on the AIN-93 recommendations, considering that the enriched diet with arginine was added 2% of that amino acid. The animals training consisted of anaerobic exercise with ten-jump four series in a PVC cube filled with water to the level of 150% of the animal's body length. The jumps were performed with a load of 50% of the animals' body weight attached in its trunk, five days a week over six weeks. In the end of experiment, each animal were anesthetized to collect muscles, before and after an iv administration of insulin. The molecular analysis of the Akt-1, mTOR, 4E-BP1 and p70S6K were performed by western blotting method for its total and phosphorylated form. Data comparison was made using one-way ANOVA. **Results** There was neither increase in Akt-1, mTOR, 4E-BP1 and p70S6K content ( $p < 0,05$ ) nor in their phosphorylation ( $p < 0,05$ ) of both trained and sedentary rats. **Discussion** The present study demonstrated that arginine had no effect on the expression of proteins involved in the regulation of muscle protein synthesis in rats, against some studies in the literature. Yan et al (2008) found increased expression of mTOR supplementation with 0,6% arginine in the diet of pigs for 7 days. Studies using cultured cells showed increased expression of mTOR when cells were incubated with arginine (Kong et al 2012). The ineffectiveness of the arginine supplementation observed in this study may be explained by the fact that in vivo, this amino acid can be degraded easily, because according Dioguardi (2011) arginine supplementation increases progressively arginase activity that leads to the idea that the more arginine is supplemented more arginine is degraded. **Conclusion** There hasn't been any increase in the muscle protein synthesis through mTOR pathway with arginine supplementation in these experimental conditions. **References** Yao K, Yin Yi, Chu W, Liu Z, Deng D, Li T, Huang R, Zhang J, Tan B, Wang W, Wu G (2008). *J Nutr*, 138, 867-872. ## THE EFFECT OF DIETARY NITRATE SUPPLEMENTATION ON CYCLING AND RUNNING PERFORMANCE AND SUBMAXIMAL OXYGEN UPTAKE IN WELL-TRAINED TRIATHLETES.

Leckie, T., Eddens, L., Brickley, G.

*University of Brighton*

Dietary nitrate (NO<sub>3</sub>-) supplementation has been reported to improve physiological and performance responses during submaximal and high-intensity exercise in both cycling and running exercise modalities. High-intensity exercise adaptations include an increased endurance capacity during cycling time to exhaustion (TTE) trials, adaptations that have been subsequently demonstrated to have a performance enhancing effect in applied cycling laboratory performance tests (Lansley et al. 2011). Limited research exists concerning the effect of NO<sub>3</sub>- supplementation on high-intensity running. The aim of this study was to assess the effect of dietary NO<sub>3</sub>- supplementation on both cycling and running performance in well-trained triathletes. Eleven male triathletes (mean  $\pm$  SD, age 28  $\pm$  9 yr, height 180  $\pm$  7 cm, body mass 73  $\pm$  9 kg, V O<sub>2</sub>peak 64  $\pm$  9 ml  $\cdot$  kg<sup>-1</sup>  $\cdot$  min<sup>-1</sup>) were assigned in a randomised, double-blind, crossover design, following control tests, to receive 6 d supplementation with either dietary NO<sub>3</sub>- (BR; 70 ml  $\cdot$  d<sup>-1</sup> organic beetroot juice containing  $\sim$ 5.0 mM NO<sub>3</sub>-) or placebo (PL; 70 ml  $\cdot$  d<sup>-1</sup> organic NO<sub>3</sub>- depleted beetroot juice containing  $\sim$ 0.04 mM NO<sub>3</sub>-) with a 10 d washout. Following familiarisation tests, subjects performed identical main tests on day four and six of each supplemental condition. Day 4 consisted of measurement of submaximal cycling VO<sub>2</sub> and a 25 minute cycling performance trial. Day 6 included measurement of resting blood pressure (BP), submaximal running VO<sub>2</sub> and a 5 km running time trial. NO<sub>3</sub>- supplementation reduced resting SBP by 6% (BR: 117  $\pm$  10 vs. PL: 124  $\pm$  12 mmHg), DBP by 10% (BR: 57  $\pm$  8 vs. PL: 63  $\pm$  7 mmHg) and MAP by 7% (BR: 77  $\pm$  8 vs. PL: 83  $\pm$  9 mmHg) with a 20% reduction in plasma [aldosterone] (PL: 196  $\pm$  69 vs. 156  $\pm$  59 pmol  $\cdot$  l<sup>-1</sup>). Submaximal cycling and running VO<sub>2</sub> values were not significantly reduced in the BR condition. A non-significant 1.7% improvement in mean power output during the 25 min cycling performance trial was observed during NO<sub>3</sub>- supplementation (PL: 296  $\pm$  35 vs. BR: 301  $\pm$  35 W) along with a non-significant 0.8% improvement in 5 km running TT performance (BR: 1117  $\pm$  104 vs. PL: 1126  $\pm$  104 s). In this study dietary NO<sub>3</sub>- does not offer an ergogenic benefit, however there was considerable response heterogeneity. Importantly no adverse side effects were reported by any of the subjects. Future research exploring the variation in individual response to dietary NO<sub>3</sub>- and a secondary evaluation of the observed absent submaximal VO<sub>2</sub> response in a trained triathlete population would progress the literature. Lansley KE, Winyard PG, Bailey SJ, Vanhatalo A, Wilkerson DP, Blackwell JR, Gilchrist M, Benjamin N and Jones AM. (2011b). *Med Sci Sports Exerc*, 43 (6), 1125-1131.

## THE RELATIONSHIP BETWEEN LACTATE THRESHOLD AND LACTATE DEHYDROGENASE ACCORDING TO MCT1 GENETIC POLYMORPHISM

Mohamed, W.1, Soliman, A.1, Al-Haggar, M.2, Keshk, M.1

*Faculty of Physical Education, Mansoura University 1: Faculty of Physical Education, Mansoura University, Egypt 2: Faculty of Medicine, Mansoura University, Egypt*

Lactate transport and Lactate dehydrogenase activity seem to have a triphasic nature. The relationship among them are still rather complex and require a framework for their analysis. Both lactate influx into or efflux out of muscles depend on the required balance between oxidative metabolism and glycolysis. During exercise (> 80% of VO<sub>2</sub> max) the rate of glycolysis increases several fold and causes a progressive accumulation of lactate in muscle and blood reach to higher steady state levels until fatigue ensues. Therefore, we performed this study to analyze any relationship between lactate Threshold (LT) accumulation and Lactate dehydrogenase (LDH) on one side and MCT1 gene polymorphism on the other side. Three different tests were carried out prior to and after a training period of 12 weeks. The first two test consisted of 5 min running at five different velocities (9 km/h, 10.8 km/h, 12.6 km/h, 14.4 km/h) respectively. LT and LDH were measured immediately after each exercise by Spectrophotometer and Accusport devices. Genomic DNA were extracted from whole blood samples drawn using commercially available kits by High Resolution Melts Strategy. The quantitative PCRs were performed using the appropriate QPCR mix and Thermal Cycler machine. Two polymorphism were found; AA and, TT genotypes in 2 cases (18.2%) and 9 cases (81.8%) respectively. Before the training period there is no difference between groups in LT and LDH values. After the training

period the mean LT and LDH values for TT genotypes were significantly higher than those in AA genotypes (with a significant  $P=0.05$ ) (1.85 mM/L, 301.5 IU/L) and (6.51 mM/L, 346.11 IU/L) for the AA, TT genotypes respectively. The higher accumulation for LT and LDH observed in TT genotypes is not dependent on the type of effort but could be caused by increase in NADH/NAD caused by a reduced rate of oxidative phosphorylation from inadequate O<sub>2</sub> levels, with a consequence of impaired function of MCT1, which would lead to impaired lactate transporter into the less active muscle cells for oxidation, thus increasing blood lactate concentration that could explain the increased muscle fatigue.

### **LACK OF ANDROGENS ENHANCES ENDURANCE TRAINING-INDUCED ADAPTATIONS: POSSIBLE INHIBITORY ROLE OF ANDROGENS ON ENDURANCE**

Hamasaki, M., Okamoto, M., Koshiro, I., Lee, M., Soya, H.

*University of Tsukuba*

Introduction High-volume exercise training such as marathons leads to hypogonadism, or low gonadal hormone levels in the blood (Cumming et al, 1989). However, the physiological significance of this and its influences on performance are unclear, especially in male endurance athletes. Intriguingly, intramuscular injections of anabolic steroids into rats caused inhibition of exercise-induced angiogenesis in the soleus muscle (Soares et al, 1991). Additionally, in orchidectomized (ORX) rats, the citrate synthase (CS) activity of the soleus increased with 2 weeks of treadmill running (unpublished data). This leads the hypothesis that a low blood androgen level in male endurance athletes is a compensatory action to enhance endurance performance, although this has yet to be determined. To address this issue, we examined how adaptive changes with endurance training would alter in ORX rats. Methods Twenty-nine male Wistar rats (12 weeks old) were divided into two groups: (1) the sham group, in which a skin incision was made and sutured ( $n=14$ ), and (2) the ORX group, in which the rats were submitted to a bilateral orchidectomy ( $n=15$ ). After the surgery and recovery period, all rats trained for 2 weeks at treadmill running (30 min/day). After 2 weeks of running training, seven rats from each group were anaesthetized to evaluate the effects of orchidectomy on muscle adaptation to exercise. The endurance of the remaining rats was measured using a treadmill that analyzes expired gas during exercise. They ran to fatigue at 20 m/min<sup>-1</sup> with no incline. Total time to fatigue (TTF), running economy (RE) and heat production (HP) during running, which are considered indices of endurance performance, were measured. Blood was taken from the heart to determine plasma testosterone or free fatty acid (FFA) concentration, and tissues were collected rapidly from the seminal vesicle, prostate, and soleus (SOL) and plantaris (PL) muscles. Results and Discussion The ORX group had a lower plasma testosterone levels, seminal vesicle and prostate, indicating that the ORX group had appropriately removed testes. After 2 weeks of running training, there were no significant differences in plasma FFA levels or SOL and PL glycogen levels between ORX and sham groups. However, CS activity of the SOL, which are accounted for slow-switch-muscle of 90% and makes a major contribution to endurance performance, significantly increased in the ORX group. TTF also increased, while HP decreased in the ORX group; there were no effects on RE. Thus, ORX enhances endurance performance, probably by minimizing net energy loss, suggesting a possible inhibitory role of androgens in the development of endurance training-induced adaptation in male endurance athletes. ### **EXOGENOUS SUBSTANCES USE : TENDANCIES IN TUNISIAN PROFESSIONAL FOOTBALL**

Kouki Chaouachi, H.

*National Anti-Doping Agency*

Medical frame has an essential role in the athlete life particularly in team sports where the effect of the group can turn out sometimes more important with regard to the use of all types of exogenous substances (ES). For that purpose, this study examined the tendencies of the ES use among professional Tunisian football players of first (L1) and second league (L2) throughout quantitative and qualitative analysis of FIFA 01-forms recommended to list every match the ES declared taken by each player. In Tunisian professional football with its two levels, during the season 2009-2010, the general rate of ES use was 0.797/player/match. In spite of an aspect rather close of the fluctuation curves during the season, this rate present a highly significant disproportion between L1 and L2 (0.955 vs. 0.533 with no significant difference between the two competition phases either in L1 or in L2. In 2009-2010, qualitative analysis of ES administrations in both leagues demonstrated that vitamins and dietary supplements are the most administered (36.6 %) followed by anti-inflammatory drugs in particular antirheumatics, analgesics, myorelaxants and antibiotics. Crossed comparisons showed that this classification is not significantly affected either as per league (L1 or L2) or as per competition phase. However, the use rates of these classes are significantly higher in L1 than in L2 apart from analgesics. This study raised an ES use rate quite high in professional national championship even it remains, by far fewer than during the National Cup final match (2SE/player). Furthermore, it was noticed that the practice of massive ES administrations to the whole team is very widespread particularly for dietary supplements and vitamins. Moreover, very rare are the teams whose 01-form is blank and the football players with zero ES/match vs. a high number of players using more than 3ES/match. The major recommendation standing out from this study is the imminent need to rationalize medication in Tunisian professional football to avoid players any potential risk of doping (corticoids, morphinic analgesics) or health (antirheumatics). Medical framers will have to privilege therapies with minor risk like homeopathy to avoid the massive and repetitive ES administrations; even dietary supplements mustn't be presented in 'open-buffer' mode but rather tightened to the real sanitary and nutritional needs of every player who has to help by rejecting auto therapy and prescribed ES overdose.

## **SKELETAL MUSCLE CAPILLARY DENSITY AND MICROVASCULAR FUNCTION ARE COMPROMISED WITH AGING AND TYPE 2 DIABETES**

Groen, B., Hamer, H., van Kranenburg, J., Frijns, D., Vink, H., van Loon, L.  
*Maastricht University*

Departments of (1) Human Movement Sciences, NUTRIM School for Nutrition, Toxicology and Metabolism and (2) Physiology, CARIM School for cardiovascular disease, Maastricht University Medical Centre+ (MUMC+), The Netherlands. Introduction Adequate muscle perfusion is a requirement for the proper maintenance of skeletal muscle mass. Impairments in microvascular structure and/or function with aging and type 2 diabetes have been associated with the progressive loss of skeletal muscle mass. The objective of this study was to compare muscle fibre type specific capillary density and endothelial function (i.e. endothelial glycocalyx) between healthy young males, healthy older men, and age-matched older type 2 diabetes patients. Methods 15 healthy young men (24±1 y), 15 healthy older men (70±2 y), and 15 type 2 diabetes patients (69±1 y) were selected to participate in the present study. Whole-body insulin sensitivity (oral glucose tolerance test), muscle fibre type specific capillary density (muscle biopsy), sublingual microvascular density and endothelial thickness (sidestream darkfield imaging) were assessed to evaluate the impact of aging and type 2 diabetes on microvascular structure and function. Results Whole body insulin sensitivity was significantly lower at a more advanced age, with lowest values reported in the type 2 diabetic patients (OGIS: 443±13, 364±14, 291±10 in the young, older and older type 2 diabetic group, respectively; P<0.05). In line, skeletal mixed muscle capillary-to-fibre-ratio was much lower in the older and older type 2 diabetic patients when compared with the young (1.85±0.07, 1.55±0.06 and 1.41±0.10 in the young, older and older type 2 diabetic group, respectively; P<0.05). Sidestream darkfield imaging showed a significantly greater glycocalyx thickness in the type 2 diabetic patients compared with the young (1.89±0.07, 2.06±0.07, 2.26±0.12 µm in the young, older, and older type 2 diabetic group, respectively; P<0.05). Discussion Skeletal muscle capillary density is reduced with aging and type 2 diabetes and accompanied by a greater endothelial glycocalyx thickness, which is representative of a compromised functional capacity of the microvasculature. Skeletal muscle characteristics, capillary density, and microvascular function are compromised with aging and type 2 diabetes.

## **ANTHROPOMETRY AND LIFESTYLE CHARACTERISTICS OF ENGLISH COMMUNITY LEVEL RUGBY UNION PLAYERS**

Perkin, O.J., Roberts, S., Trewartha, G., England, M., Stokes, K.A.  
*University of Bath*

Introduction English community level rugby union represents the largest rugby playing population globally; however descriptive information for this group is sparse. This study provides basic anthropometric and lifestyle data from community level rugby players, with a comparison of these characteristics with the general public and across playing levels. Methods Medical staff at 102 rugby clubs disseminated self-report questionnaires to all 1st team squad players at the start of the 2012/13 season. Information was collected on height, body mass, age, smoking and drinking (AUDIT-C) status. Playing levels were divided into three groups for analysis: group A (RFU levels 3 and 4; semi-professional), group B (RFU levels 5 and 6; amateur), and group C (RFU levels 7 to 9; recreational). Anthropometric data were analysed by one-way ANOVA and Bonferroni post hoc with significance accepted at p<0.05. Results Data from 715 rugby players (Group A; 111, B; 249, C; 355) who completed the questionnaire were analysed, representing 39 clubs. Mean values were reported for height [mean (SD) 182 (7) cm], mass [94.1 (13.3) kg], BMI [28.3 (3.6) kg/m<sup>2</sup>], and age [25.2 (5.2) years]. No between group differences were reported in height. Group A and B reported greater mass than C; 98.0 (13.7) and 95.0 (12.7) vs. 92.3 (13.3) kg respectively. Group A reported higher BMI than C; 29.1 (3.3) vs. 27.9 (3.8) kg/m<sup>2</sup>, with group B not differing significantly from either. Group C reported being older than B [25.7 (5.9) vs. 24.3 (4.23) years]. 85% of players AUDIT-C scores indicated 'higher risk drinking habits', whilst 10% of players reported current regular smoking; 2, 8, and 14% for groups A, B, and C respectively. Discussion Community level rugby players who completed a lifestyle questionnaire reported greater height and mass than the age-matched (16-44 years) male general public in England (182 vs. 177cm, 94.1 vs. 81.3 kg, 28.3 vs. 25.9 kg/m<sup>2</sup>) (Health Survey for England (HSE 2011)). Higher level players reported greater body mass, which may reflect more focus on physical conditioning and benefits of greater body mass in the contact elements of rugby. Whilst current regular cigarette smoking was 13% lower than the 23% observed in the HSE (2011), the amount of AUDIT-C scores >5 may indicate increased risk of alcohol related health contraindications within community level rugby players. The self-report nature of the questionnaires may have introduced a bias in the results as may playing position bias in the sample. Even so, these data suggest that community level rugby players' physical characteristics and smoking habits are not typical of the general public. References Sutton (2012). ## **THE EPIDEMIOLOGY OF CONCUSSION IN ELITE RUGBY UNION PLAYERS: AN 8-SEASON REVIEW**

Cross, M.J., Trewartha, G., Williams, S., Kemp, S.P.T., Stokes, K.A.  
*University of Bath*

INTRODUCTION Estimates suggest that 1.6-3.8 million sports-related concussions occur annually (Langlois et al., 2006). Within the most recent season of the English rugby union Premiership, concussion was reported as the most common time loss injury from matches. Loss of consciousness (LOC) may only occur in 10% of concussions (Harmon et al., 2013) often making concussion difficult to diagnose. Repeated exposure to head contacts and recurrent concussive events are of particular concern due to the possible risk of long-term cognitive impairment. METHODS This study was based on data collected by the RFU English Professional Rugby Union Injury Surveillance Project (n=1752 participants) from 2002 - 2011. Medical staff at each club reported injury episodes weekly using an injury report form that detailed specific fields about each injury and a final diagnosis using the Orchard sports injury classification system. Following a concussion, athletes were monitored clinically according to each individual clubs' best practice guidelines. RESULTS A total of 379 concussions were recorded. Of these 95% occurred in match play and 5% occurred in training. The overall incidence of match concussions was 4.4 injuries/1000 player hours (95% CI 4.0 to 4.9). The mean severity of a concussion across the time period was 12 days (95% CI 10 to 15) and carried a median severity of 8 days. 7% of concussions were severe (>28 days absence) with 43% resolving within 7 days. The most common injury causations were player-on-player collisions (18%) and front on tackling (15%). 9% of concussions were classified as being a recurrent injury, with recurrent concussions resulting in an average severity of 15 days (95% CI 9 to 21). DISCUSSION The incidence rate and severity observed for concussions is in keeping with previous studies that have used a similar methodology within rugby union. Although this incidence rate is similar to that of other contact sports, the magnitude of these figures are still cause for concern and emphasise the importance of continued research into the potential risk factors for concussion. 35% of concussed players returned to full training/match play more quickly than the recommended International Rugby Board (IRB) guideline of 6 days. This highlights a need for a

clearer understanding and implementation of the graduated return to play protocols post concussive injury in professional rugby union. ### LOW VOLUME HIGH INTENSITY INTERVAL AND STEADY STATE EXERCISE BOUTS ELICIT SIMILAR ALTERATIONS IN PLASMA MARKERS OF OXIDATIVE STRESS

Wadley, A.J., Fisher, J.P., Chen, Y.W., Aldred, S.

*University of Birmingham*

**Introduction** The use of low volume, high intensity interval training (LV-HIIT) has attracted significant recent attention due to the diverse metabolic and physiological benefits it confers, but with a marked reduction in the required time commitment and energy cost in comparison to traditional steady state exercise. Acute increases in oxidative stress are thought to be essential in mediating post-exercise adaptations, however to date a direct comparison of the oxidative stress response to LV-HIIT and steady state exercise has not been made. This study aimed to assess the magnitude of acute oxidative change following a single bout of LV-HIIT, and compare this to two steady state exercise bouts of differing intensity. **Methods** Untrained healthy males ( $n=10$ , mean  $\pm$  SD: age  $22 \pm 3$  yrs; body mass index  $24.0 \pm 3.1$  kg/m<sup>2</sup>; maximal oxygen consumption  $42.7 \pm 5.0$  ml/kg/min-1) undertook two energy-matched steady state exercise bouts (moderate intensity: 27 min, 60% VO<sub>2</sub>MAX (MOD) and high intensity: 20 min, 80% VO<sub>2</sub>MAX (HIGH)) and a bout of LV-HIIT (10\*1 minute 90% VO<sub>2</sub>MAX intervals, interspersed with 1 minute intervals at 40% VO<sub>2</sub>MAX) on separate days. Blood samples were taken before (base), 1 minute prior to the cessation of exercise (ex) and 30 minutes following exercise. Oxidative stress was assessed by evaluation of plasma markers of protein carbonylation (PC), lipid hydroperoxides (LOOH) and total antioxidant capacity measured by ferric reducing ability of plasma (FRAP). Total peripheral blood lymphocytes (LYM) were also assessed. **Results** LYM increased during all exercise bouts ( $p < 0.05$ ), with HIGH (+140%) eliciting a significantly greater increase than both MOD (+41%) and LV-HIIT (+99%), and LV-HIIT being significantly higher than MOD. Markers of oxidative stress were significantly increased in all exercise bouts, but the magnitude of this response was not different between bouts. Increases in total antioxidant capacity during LV-HIIT (base  $953.0 \pm 171.1$  vs. ex  $1029.4 \pm 168.3$   $\mu$ M) were more similar to HIGH (base  $938 \pm 165$  vs. ex  $1031 \pm 152$ ) than MOD (base  $914 \pm 153$  vs. ex  $914 \pm 157$ ). **Discussion** These data indicate that despite a single bout of LV-HIIT eliciting a significantly greater response in lymphocytosis than MOD, LV-HIIT is not different to steady state exercise when assessing plasma markers of oxidative stress.

### INTERLEUKIN-6 AND INSULIN SENSITIVITY RESPONSES IN OBESE MEN DURING TRAINING AND DETRAINING

Nikseresht, M., Aghaalienejad, H., Taheri, A.H.

*Islamic Azad University, Ilam Branch, Ilam, Iran., Tarbiat Modares University, Tehran, Iran., Islamic Azad University, Ilam Branch, Ilam, Iran.*

**Introduction:** Obesity is associated with insulin resistance. Adipocytes release a variety of adipocytokines including interleukin-6 (IL-6). This study aimed to investigate to responses of IL-6 and insulin resistance in healthy middle-aged obese men after exercise training and detraining. **Methods:** Thirty-four healthy obese men were selected on a random basis for non-linear resistance (non-RT,  $n=12$ ), aerobic interval training (AIT,  $n= 12$ ) and a control group ( $n= 10$ ). At baseline, after 12-week of training and after 4-week of detraining, Blood samples were taken in fasting state from all subjects. The experimental groups performed three weekly sessions for 12 weeks, followed by a 4-week detraining period. Non-RT consisted of weight training at five different intensities with emphasis on muscular endurance. AIT consisted of running on a treadmill, four times 4 min at 80-90% of maximal heart rate, with a 3 min jog in between. **Results:** Serum IL-6 did not change significantly after 12 weeks of non-RT and AIT. However, after 4 weeks of detraining, a significant increase was found in this cytokine for the experimental groups. Both Non-RT and AIT resulted in a significant decrease in the insulin resistance. However, these improvements did not return into baseline level after detraining. The body fat percentage, waist circumference and VO<sub>2</sub>max were improved significantly after training and returned to baseline level after detraining. There were no significant correlations between serum IL-6 and body fat percentage, waist circumference, insulin resistance and VO<sub>2</sub>max at baseline, similarly alterations in responses to training and detraining were not significantly correlated. **Discussion:** Non-RT and AIT caused an improvement in insulin sensitivity in healthy obese men, but this improvement was not accompanied by decreased in IL-6. After exercise training, IL-6 remained unchanged, is similar to finding reported by previous studies (Donges et al., 2010; Libardi et al., 2012). Moreover, baseline IL-6 levels was similar to those observed in healthy subjects. Interestingly, serum IL-6 levels increased significantly in the non-RT (2.95 to 6.90 pg.mL<sup>-1</sup>) and AIT (2.65 to 6.50 pg.mL<sup>-1</sup>) groups after 4-week of detraining. Subcutaneous adipose tissue produces IL-6 at rest. There was considerable drop in glucose concentrations during the detraining period in experimental groups. The possible mechanism is that, increased IL-6 may be due to a sudden increase in body fat percentage and waist circumference and substantial drop in serum glucose. It is suggested that the regular exercise training should not be abruptly cut in active obese men. **References:** Donges CE, Duffield R, Drinkwater EJ. ### METABOLOMICS OF SALIVARY FATIGUE MARKERS AFTER 3 CONSECUTIVE DAYS OF SOCCER GAME IN MALE SOCCER PLAYERS

Ra, S.G.1,2, Maeda, S.1, Higashino, R.1, Imai, T.1, Miyakawa, S.1

*1: University of Tsukuba, Japan; 2: Research Fellow of JSPS, Japan*

**Introduction** Strenuous and consecutive exercise leads to fatigue symptoms and performance decline in athletes. Metabolomics is a comprehensive method to assess metabolite that involves the measurements of the overall metabolic signature of biological samples. **Purpose** The aim of this study was to examine of novel salivary fatigue markers by metabolomics after short consecutive days of game in soccer players. **Methods** One hundred twenty-two male soccer players participated in 3 consecutive days of soccer game program. To detect fatigued athletes, we measured indices of traditional fatigue symptoms, i.e., heart rate (HR), body weight (BW) and psychological status, before and after program, and setting the cut-off value as follows: increase in awakening HR (5 beats/min) (1), decrease in BW (2.25 kg) (2), and increase in the fatigue score (5 score) and decrease in the vigor score (5 score) in psychological test (1). Finally, we detected 37 fatigued players and their saliva was analyzed using metabolomics. **Results** Metabolomics identified 144 metabolites from the saliva of fatigued players, and some metabolites were significantly changed after the soccer game program. Interestingly, metabolites

that has been confirmed significant differences were all increased in after program ( $p < 0.001$ ). The identified metabolites were including 3-methylhistidine (3-MHis), glucose 1 and 6-phosphate (G-1-P, G-6-P), taurine, alanine (Ala) and branched-chain amino acids (valine, isoleucine, leucine: BCAA) and aromatic amino acids (phenylalanine, tyrosine, tryptophan: AAA). Discussion To our knowledge, this is the first study to identify salivary fatigue markers in soccer players after short consecutive game program. Activating protein broke down in the body, the 3M-His increases in the blood (3). Similarly, it has been reported that taurine is released in the blood from muscles during exercise (4). Moreover, G-1-P, G-6-P and Ala play an important role of glucose metabolism, and BCAA and AAA were precursors of intermediate metabolites of the TCA cycle. We inferred that increasing 3-MHis and taurine were result of exercise loads, and G-1-P, G-6-P, Ala, BCAA and AAA were increased in order to recovery the physiological conditions. Conclusion We concluded that some soccer players develop fatigue symptoms after short consecutive days of soccer game and energy related metabolites were increased in saliva in fatigued athletes. We propose that the detected salivary metabolites may be new fatigue markers in athletes. References 1. Koutedakis et al. (1990). *Br J Sports Med.* 24(4):248-52. 2. Budgett. ### DIFFERENT INDIVIDUAL RESPONSES OF THE HYPOTHALAMIC-PITUITARY GONADAL AXIS AFTER INTRANASAL LH-RH APPLICATION IN HEALTHY MEN

Krusche, T.1, Thomas, A.2, Schrader, Y.2, Thevis, M.2, Platen, P.1

*Ruhr-Universität Bochum*

1Department of Sports Medicine and Sports Nutrition, Faculty of Sport Science, Ruhr-University Bochum 2Center for Preventive Doping Research and Institute of Biochemistry, German Sport University Cologne Introduction During the last years the misuse of intranasal luteinizing hormone-releasing hormone (LH-RH) in elite sports has frequently been reported and is not detectable in anti-doping analysis so far. It is not clear how the application of external LH-RH influences the integrity of the internal hypothalamo-pituitary-gonadal axis (HPGA) in healthy adults. One aim of the study was to analyse the hormonal response of the HPGA after intranasal LH-RH application in healthy men. Methods 10 healthy moderately trained male students (22.8±1.7 yrs, 179.6±6.0 cm, 77.6±7.0 kg) were investigated 2 days before (d-2) a 7 day-period of intranasal LH-RH application (every 1.5 hrs from 7am-10pm (in total 4.4 mg/day)), as well as during the 1st (d1) and 7th (d7) day of intranasal LH-RH application. On these days, we analysed serum concentrations of total testosterone (T), free testosterone (fT), luteinizing hormone (LH) and follicle stimulating hormone (FSH) in early morning blood samples. Results T increased during the intranasal LH-RH application period from d-2 to d1 and d7 ( $p < 0.05$  and  $p = 0.08$ ; 5.5±2.1, 7.4±2.5, 9.2±3.8 ng/ml, respectively). Inter-individually, the difference of T varied between 5% and 113% (mean 37%) for d1 towards d-2, and between -6% and 294% (mean 78%) for d7 towards d-2. fT remained unchanged on d1 and increased significantly on d7 ( $p < 0.01$ ); 10.6±3.2, 14.1±6.8, 16.3±5.8 pg/ml, respectively). Inter-individual increase of fT differed between 12% and 107% (mean: 56%). LH increased from d-2 to d1 and d7 ( $p < 0.05$  and  $p = 0.09$ ; 5.1±2.5, 19.2±11.5, 8.3±2.4, mU/ml, respectively). Inter-individually the difference of LH varied between 16% and 664% (mean 313%) on d1 towards d-2, and between -21% and 246% (mean 93%) for d7 towards d-2, respectively. FSH remained unchanged over time in the whole group (5.1±7.0, 8.6±11.9, 4.4±4.5 mU/ml, respectively) and showed remarkable inter-individual variations (d1: increase between 5% and 132% (mean 68%); d7: decline or increase of -33% and 59% (mean 4%), respectively). Discussion Before the study, the effect of intranasal LH-RH application on endogenous hormone serum concentrations in healthy young men was unclear. The results of the study showed large variations in the individual reaction on exogenous LH-RH administration. The observed effects suppose the existence of responders and non-responders. In context of routine doping controls the results favor individual interpretation of hormone values and individual longitudinal data like a blood passport for athletes. Acknowledgement This project has been carried out with the support of WADA.

### ENTRY PHASE ALIGNMENT IN MEN'S BACKWARD DIVE PIKE <2018> FROM 3 M SPRINGBOARD DIVES

Takaya, N., Kaji, K., Yoshiro, S., Takamichi, N.

*Health Science University*

During competitive diving events, divers jump up from 1 - 3 m springboards or 5 - 10 m platforms and dive into the water. The impact forces are very large in the water entry phase, and therefore, the divers experience a lot of physical stress. Our previous study showed that there was high prevalence of low back pain (LBP) in elite junior divers and shoulder flexibility and age were related to low back pain among the male junior divers. In this study, we aimed to investigate the influence of the shoulder angle on the entry alignment and compare the differences in entry phase alignment between the divers in the LBP divers groups and no-LBP divers groups. We included 13 male elite junior Japanese divers. The entry phase was filmed laterally by using high-speed camera (shutter speed: 1 / 200 seconds). The shoulder and trunk, hip angles data for the entry phase (5 frames) were derived from the digitized film. The LBP experienced by divers were assessed via questionnaires during national training camps. The relevance of the shoulder, trunk, and hip angles was examined using the Pearson product-moment correlation coefficient. We divided the divers in 2 groups on the basis of LBP status. An intergroup comparison was carried out using Mann-Whitney's U test on the basis of entry phase alignment. Negative correlation ( $r = -0.623$ ) was observed in the shoulder flexion angle and trunk extension angle for the entry phase. Four of 13 male divers experienced LBP. The trunk angle showed a significant difference between the LBP groups (210.4 ± 5.7°) and no-LBP groups (199.9 ± 9.0°). Our results suggested that shoulder flexibility is important to prevent LBP in the elite male junior divers, because divers require full shoulder flexion in the water entry phase. Limited shoulder flexibility could cause lumbar hyperextension when adjusting the angle of water entry. The major findings of this study were as follows: (1) shoulder flexion angle was related to trunk extension angle for the entry phase; and (2) the LBP group has a larger trunk extension angle than the no-LBP groups.

### TOE DEFORMITY, PHYSICAL PERFORMANCE AND POSTURAL SWAY IN OLDER ADULTS USING A 3D FOOT SCANNER

Saghazadeh, M., Tsunoda, K., Kitano, N., Okura, T.

*Health and Sport Sciences*

Introduction Hallux valgus (HV), a lateral deviation of the big toe away from the midline of the body, is toe deformity prevalent in older adults which contributes to falls in this age group (Mickle et al., 2009). However, toe deformities have been generally poorly defined in balance and physical performance studies and are often coded as a single variable (i.e. present or absent) or clustered together with other pathologies and labeled 'lower extremity problems' (Menz and Lord, 1999). Therefore, the purpose of this study was to determine whether the degree of HV correlates with physical performance and postural sway in older adults using a 3D foot scanner. Methods This

cross-sectional study included 259 community-dwelling older adults ( $74.2 \pm 5.3$  years) recruited in Kasama City, Japan. Physical performance was assessed using: (1) timed-up-and-go (TUG), (2) standing time from long sitting position, (3) habitual walk and (4) choice reaction time. Postural sway variables were measured by force plate. In this study, right foot HV was measured by a 3D foot scanner machine in sitting and standing positions. Results After adjusting for potential confounders, Pearson's correlation analysis revealed significant correlations between HV and all physical performance measures in woman in both sitting and standing positions, respectively [(1:  $r = 0.258, 0.212$ ), (2:  $r = 0.251, 0.276$ ), (3:  $r = 0.259, 0.216$ ), (4:  $r = 0.196, 0.189$ )]. However, in men, HV correlated significantly only with habitual walk ( $r = 0.181, 0.171$ ). Absolute X distance ( $r = 0.220$ , sit;  $0.189$ , stand) and area ( $r = 0.213$  just sitting) from postural sway items correlated significantly with HV in women in both sitting and standing positions ( $P < 0.05$ ). Discussion Our results indicate that the degree of HV is an important determinant of physical performance and postural sway in older people, especially women. These results possibly occurred because toe deformities alter the weight bearing function of the toes, and, consequently, individuals cannot effectively exert pressure on the ground. Therefore, reduced sensory input from a deformed toe may lead to reduced mechanical stability, which, in turn, affects stability during the weight bearing and push phases of gait (Mickle et al., 2009). Further research is required to clarify whether therapeutic interventions by foot care specialists may improve balance in older people and decrease risk of falls. References MENZ, H. B. & LORD, S. R. (1999) Foot problems, Functional impairment, and falls in older people. *J AM Podiatr Med Assoc*, 89, 458-467. MICKLE, K. J., MUNRO, B. J., LORD, S. R., MENZ, H. B. & STEELE, J. R. (2009) Toe weakness and deformity increase the risk of falls in older people. *Clinical Biomechanics*, 24, 787-791.

### IMPROVING POSTURAL CONTROL IN RESPONSE TO A 4-WEEK BALANCE TRAINING WITH PARTIAL WEIGHT-BEARING

Freyler, K., Ritzmann, R., Gollhofer, A.

*University of Freiburg*

Introduction Balance training (BAL) improves postural skills, reduces the incidence of limb injuries and, as a consequence, is successfully implemented in therapy as a countermeasure against many postural dysfunctions (Taube et al. 2008). It is well known that improved postural control in response to BAL is associated with decreased cocontraction of antagonist muscles concomitant with a reduction in spinal excitability (Taube et al. 2008, Nagai et al. 2012). In patients suffering from motor impairments or reduced mobility, BAL with partial weight-bearing (PWB) might be the only approach for therapy. However, PWB during BAL must not necessarily address similar functional and neuromuscular adaptations. Therefore, this study aims to compare the effects of a 4-week BAL intervention with PWB on postural control with BAL under full bodyweight (BW). Methods 32 subjects were randomly assigned to a BT group (full BW) or a BTP group (PWB equal to 40% of the BW). The intervention consisted of a supervised visual feedback-based BAL that addressed dynamic stabilization in mono- and bipedal stance. PWB was applied by means of a harness attached to a ceiling-mounted height-adjustable system. Before and after training, centre of pressure (COP) displacement and electromyographic activity of the soleus (SOL), gastrocnemius medialis (GM), tibialis anterior (TA) and peroneus longus (PER) were monitored during monopodal stance on an instable surface. Cocontraction index (CCI) of SOL and TA was calculated. Soleus H-reflexes were elicited to evaluate changes in the excitability of the spinal reflex circuitry. Results The study revealed three main results: (i) for both groups, the COP displacement was reduced (BTP  $-6 \pm 13\%$   $p < 0.05$ ; BT  $-10 \pm 15\%$   $p < 0.05$ ) after the intervention. This reduction in COP displacement was accompanied by (ii) a decreased CCI of SOL and TA (BTP  $-20 \pm 40\%$   $p < 0.05$ ; BT  $-34 \pm 35\%$   $p = 0.07$ ) and (iii) a decrease in H-Reflex sensitivity (BTP  $-10 \pm 28\%$   $p < 0.05$ ; BT  $-11 \pm 48\%$   $p < 0.05$ ). GM and PER remained unchanged. Discussion We found that BAL with PWB led to a reduced COP displacement indicating an improvement in stance stability. This functional adaptation is accompanied by a decreased coactivation of the antagonist muscles TA and SOL and a reduced spinal excitability of the SOL motoneuron-pool. These aspects point toward fundamental changes regarding postural control strategies generally known from regular BAL (Taube et al. 2008). Based on these results, BAL with PWB is suggested to be an appropriate alternative especially for patients with motor dysfunctions or after surgery unable to conduct BAL under full body load. ### STABILITY OF CROSS-SECTIONAL RELATIONSHIPS BETWEEN CHANGES IN BIOCHEMICAL AND HEMATOLOGICAL MARKERS OVER A SOCCER HALF-SEASON

Patras, K., Sargiotis, D., Siaravas, S., Giannitopoulos, T., Evaggelou, A., Georgoulis, A.D.

*Orthopaedic Sports Medicine Center, University of Ioannina*

INTRODUCTION: Monitoring of selected biochemical/haematological variables is used in professional soccer to evaluate the health status/training process [1]. Furthermore identifying relationships between variables may be indicative of a common stress factor [2]. However in order to determine causative relationships, longitudinal changes must be investigated [3]. The present study examined whether interrelationships between biochemical and hematological variables change over the course of two consecutive mesocycles comprising the first half of the season. METHODS: Twenty-three professional soccer outfield players participated in the study. Blood samples were collected before the first competitive game (September), at the end of the first competitive mesocycle (November) and at the end of the second competitive mesocycle (January). Samples were analyzed for haematocrit (HCT), haemoglobin (HGB), aspartate aminotransferase (AST), alanine aminotransferase (ALT), phosphocreatine kinase (CPK), ferritin (FER), creatinine (CRE) and magnesium (Mg). Pearson correlations ( $r$ ) were calculated to assess the interrelationships between the variables [4]. Relationships ( $r \pm 90\%$  CI) were classified using a magnitude-based approach [4] and classified as practically important where there was a  $\geq 75\%$  likelihood of the correlation exceeding the smallest practically important (0.1) value using an Excel spreadsheet [5]. RESULTS: AST and CPK showed very large correlations (0.76-0.87) at every time period. All other variables showed cross-sectional relationships that varied significantly in magnitude over time. DISCUSSION: With the exception of CPK and AST all other variables showed relationships that varied with time and thus it is questionable whether they have causative relationship [3]. CPK changes had very strong relationship to AST changes that remained stable over the course of a half-season in professional soccer. The stability of the magnitude of the cross-sectional correlations over time indicates that these biochemical markers have similar rates of change. REFERENCES 1. **OXYGEN CONSUMPTION OF MILITARY TASKS DURING FIELD EXERCISES**

Pihlainen, K., Santtila, M., Häkkinen, K., Kyröläinen, H.

*Finnish Defence Forces*

**Introduction** Military operations consist of physically demanding tasks which typically are load carriage, digging and lifting loads (Sharp et al 1998, Knapik et al 2004). To avoid accumulation of fatigue, it is important to know the absolute and relative energy expenditure of soldiers during such tasks. Several studies have investigated physiological responses of military tasks in laboratory settings while very limited information is available of field conditions (Larsen et al 2011). Therefore, the purpose of the present study was to measure oxygen consumption (VO<sub>2</sub>) during military tasks in field circumstances. Following tasks of army soldiers were monitored: unloaded (M1) and loaded (M2) marching, artillery field preparation (AFP) and digging in defensive positions (D). **Methods** Subjects were 17 voluntary male conscripts (19.4±1.1 years, 179.3±7.3 cm, and 72.9±7.7 kg). Initial aerobic capacity (VO<sub>2</sub>max) was directly measured five weeks before the field exercise by using an incremental treadmill. Additional weight of 5.4 kg was carried during M1, AFP and D and 24.4 kg during M2. Direct VO<sub>2</sub> was measured by portable oxygen spirometers (Oxycon Mobile, CareFusion, San Diego, CA, USA and MetaMax, Cortex, Leipzig, Germany). Relative work intensity was individually determined by dividing VO<sub>2</sub> of each field task by initial VO<sub>2</sub>max. **Results** The initial mean VO<sub>2</sub>max of the subjects was 47.3±4.5 ml/kg/min. The mean VO<sub>2</sub> of M1 (n=8) was 19.9±2.7 ml/kg/min which refers to 43±9 % of VO<sub>2</sub>max of the subjects. Oxygen consumption of M2 (n=8) was 22.6±3.4 (48±9%), AFP (n=5) 17.9±3.0 (38±6%) and D (n=5) 24.0±4.4 ml/kg/min (50±9% VO<sub>2</sub>max), respectively. **Discussion** The direct VO<sub>2</sub> values measured in field tasks are in line with the previous findings of laboratory studies. The mean work intensity of soldiers in measured military tasks was close to 50% of their maximal aerobic capacity. This level has been suggested to be maximum limit of intensity for sustained work (Epstein et al 1988). Based on the present study, the minimum requirement of VO<sub>2</sub>max for the army soldiers seems to be 45.0-50.0 ml/kg/min. More studies are needed with direct measurements during military tasks in field conditions in order to reliably define the physical requirements for soldiers of different army branches. **References** Sharp MA, Knapik JJ, Walker LA, Burrell L, Frykman PN, Darakij SS, Lester ME, Marin RE (2008). *Med Sci Sports Exerc.* 40:1687-92. **FIXED CONCENTRATION LACTATE TESTS IN RUNNERS: WHAT IS THE IDEAL SPEED TO START?**

Dantas, J.1,2, Doria, C.1, Rossi, H.3, Rosa, G.3, Pietrangelo, T.1, Fano'-Illuc, G.1

1: *Gabriele d'Annunzio University (Chieti, Italy)*, 2: *State University of Londrina (Londrina, Brazil)*, 3: *Marathon Sport Medical Center (Brescia, Italy)*.

**Introduction** Fixed concentration lactate (LAC) tests are widely used to determine intensity parameters (e.g., heart rate (HR) or speed) for runners in order to prescribe and to control training workload. However, speed to begin the tests is chosen arbitrarily because lack a scientific support to this choice. Therefore, the aim of this study was to determine the ideal initial speed for LAC tests in runners. **Methods** Retrospective data from our laboratory concerning amateur runners (n=102) were used in this study. All volunteers, which have given their written informed consent had experienced at least of one competition (10 km to marathon races) and their average speed performed in the last race (AVS) were reported. All volunteers enrolled had undergone to a standard test<sup>1</sup> on treadmill in order to determine intensity parameters at LAC of 2 and 4 mmol (stages duration= 4 min; pauses=1 min; speed increment=1.5 km.h<sup>-1</sup>/stage). The criterion to stop the test was the achievement of a LAC ≥ 4 mmol. LAC, HR and speed were recorded in every stage and were shown as percent of maximal predicted HR<sub>2</sub> (%HRMAX= 211 - 0.64\*age) and percent of AVS (%AVS), respectively. For the aim of this study, 1st and 2nd stage data were analyzed. Descriptive statistical (mean, SD and CI95%) was used to show all data. **Results** For all volunteers the LAC values were < 2 mmol after the 1st stage (1.1 ±0.2; CI95%= 0.6 to 1.5 mmol). The mean of speed of the 1st stage was 69.1 ±4.2 (CI95%= 60.9 to 77.3) %AVS. After the 1st stage, 85 from 102 (83.3%) of the volunteers showed LAC ≤ 1 mmol (speed= 68.8 %AVS; HR= 71.4 %HRMAX) and other 17 volunteers showed LAC > 1 and < 2 mmol (speed= 70.7 %AVS; HR= 76.7 %HRMAX). The mean of speed for the 2nd stage was 80.1 ±4.8 (CI95%= 70.6 to 89.6) %AVS. HR values were 72.3 ±6.1 (CI95%= 60.2 to 84.3) and 79.0 ±5.9 (CI95%= 67.4 to 90.5) %HRMAX for the 1st and 2nd stage, respectively. After the 2nd stage, 17 volunteers had LAC ≤ 1 mmol (speed = 77.5 %AVS; HR= 76.1 %HRMAX), 73 had LAC between >1 and < 2 mmol (speed= 80.2 %AVS; HR= 78.9 %HRMAX), and 12 had LAC ≥ 2 mmol (speed= 82.9 %AVS; HR= 83.3 %HRMAX). **Conclusion** In according the data, the option for the nearest speed of 70 %AVS seems to be the ideal and secure speed to start LAC tests in runners. **References** 1. **THE RELIABILITY OF 200 AND 1000 METER ALL OUT TESTS ON DANSPRINT PADDLING ERGOMETER.**

Kristoffersen, M., Wisnes, A.R., Gundersen, H., Ivesen, V.

*Bergen University og College*

**Introduction** The Dansprint paddling ergometer (Dansprint, Denmark) is used by most Norwegian flat water kayakers, both in their common "off water" training, and in performance testing. In this study we examined the reproducibility of tests of 200 meter and 1000 meter, with the aim of evaluating the ergometers reliability. **Methods** 8 highly trained male and female national level flat water kayakers, aged 17- 25 yrs., participated in this experiment. The subjects were tested on 3 separate days with 3 days between. Both distances were performed on the same day with a two hour of rest in between. The subjects were instructed to keep a diet and activity log 24 hrs before the first test, and this was then used as a template for all the tests. The subjects were instructed to give maximal effort in each test. All the tests were performed on the same ergometer (Dansprint, Denmark) and in "pre-season". The software Dansprint analyzer (Dansprint, Denmark) was used to evaluate each test regard to paddling frequency, wattage, velocity, and time. Accumulated VO<sub>2</sub> was measured

during all tests, and a blood sample was taken one minute after the tests for lactate measures. Heart rate was measured using a Polar RS 800 CX, (Kempele, Finland) during the testes. Oxygen consumption was measured using a Jaeger Oxycon Pro in mixing chamber mode (Jaeger, Germany), and lactate was measured using a Lactate Scout (Biosen, Germany) device. Results In the 200 m tests, the paddling time improved significantly from test 1 to test 2 ( $p < 0.05$ ), but not from test 2 to test 3. On the 1000m tests, the times improved significantly on every test ( $p < 0.05$ ) Conclusion 200m testes can be performed on the ergometer, if sufficient pre-tests to elucidate learning effect are performed. There is need for more than 3 learning sessions in the ergometer before testing 1000m.

### COMPARISON OF PULL DOWN STRENGTH BETWEEN RECREATIONAL AND EXPERTS CLIMBERS

Gaspari, A., Piunti, R., Souza, T., Nogueira, F., Berton, R., Lixandrão, M., Chacon-Mikhail, M.P.

*University of Campinas - Brazil*

**Introduction** The importance of muscular strength in sport climbing has been investigated, mainly through handgrip strength<sup>1,2,3</sup>. However there are no studies that evaluate muscle strength in specific pull down climbing movement (shoulder abduction accompanied by elbow flexion). This study evaluated muscle strength in recreational (RC) and experts climbers (EC) in a specific movement of the climbing (pull down). Our hypothesis is that EC have greater strength than RC. **Methods** Seventeen climbers were selected for this study, 8 EC (minimal climbing level: 8A/Fr in last year) and 9 RC. Each subject performed three maximum isometric contractions (Biodex System 4 Pro, Medical Systems, USA) using their dominant member in the motion of pull down (at 90° of elbow flexion and 135° of shoulder abduction), with a 3 minutes rest interval between attempts. The peak torque generated was computed and compared between groups by an independent T-Test. **Results** The EC demonstrated greater ( $p < 0.008$ ) pull down strength ( $213.81 \pm 25.89$  Nm) than the RC ( $171.41 \pm 31.27$  Nm). Also, the pull down strength relative to body mass was higher ( $p < 0.005$ ) for EC ( $2.48 \pm 0.50$  Nm/kg) compared to RC ( $3.33 \pm 0.59$  Nm/kg). **Discussion** Previous study showed that handgrip strength is higher for EC than RC<sup>2</sup>. The present study demonstrated that the EC had higher levels of strength also when a specific pull down climbing movement is performed. Thus, the present study suggests that upper body strength is an important factor for the determination of climbing level and performance. **Conclusion** It is concluded that EC elicits higher levels of strength than RC in specific pull down climbing movement; therefore it is important to include this specific training in climbing training. **Reference** 1- Mermier et. ### PACING IN ISOLATED AND NON-ISOLATED SPORTS – INFLUENCE OF COMPETITORS

Skorski, S.1, Renfree, A.2,3, St Clair Gibson, A., Meyer, T.1

*1Saarland University, 2University of Worcester, 3Northumbria University*

**Introduction** Most analyses of pacing pattern (PP) in endurance sports distinguish between events with reference to the metabolic demand due to the time of completion (e.g. short-, middle- and long distance events) (Abbiss & Laursen, 2008). Hence, it could be suspected that PP is similar in events of the same duration independent of the sport. However, in some sports athletes are more isolated from their competitors than in others, assuming less tactical influences. The aim of this study was to compare PP in middle-distance events with similar duration in a non-isolated (running; RUN) and a more isolated sport (swimming; SWIM). **Methods** Finals of the London Olympic Games of the following events were compared: 1500m RUN ( $n=12$ ) vs. 400m SWIM ( $n=8$ ), 800m RUN ( $n=8$ ) vs. 200m SWIM ( $n=8$ ) and 5000m RUN ( $n=15$ ) vs. 1500m SWIM ( $n=8$ ). Altogether 59 male athletes were included in the analysis. Split times (ST) were accessed via the websites iaaf.org and swimrankings.net. For 800m RUN, ST were available every 200m, for 1500m and 5000m RUN every 400m. In SWIM events 50m ST were chosen for 200m, and 100m ST for 400m and 1500m to ensure similar numbers of ST for both sports. PP is expressed in relation to mean velocity for all calculations. Furthermore, differences between ST (m/s) were calculated in percent of the preceding ST. Repeated-measures ANOVAs were used to analyse for differences between SWIM and RUN. The post-hoc Scheffé-Test was carried out to determine ST differences within one race. **Results** PP was significantly different between sports in all events ( $p > 0.001$ ). SWIM showed an even PP in 1500m and 400m ( $p > 0.99$ ), whereas in 5000m and 1500m RUN the second half was significantly faster than the first one ( $p < 0.001$ , increase:  $+0.64 \pm 0.34$  m/s). In 200m SWIM and 800m RUN the first half was significantly faster than the second in both sports ( $p < 0.02$ ), with a higher decrease in velocity in RUN (decrease: -5.7 and -8.4%, respectively). Regarding ST differences 1500m and 400m SWIM splits were constant over the whole race ( $p > 0.06$ , mean ST difference:  $0.50 \pm 1.8\%$ ; MIN: 0.004%; MAX: 5.56%). In 5000m and 1500m RUN ST differences varied stronger over the whole event ( $p < 0.001$ , mean ST difference:  $1.71 \pm 4.67\%$ ; MIN: 0.83%; MAX: 12.2%). **Discussion** Even though overall performance time was similar in the analyzed running and swimming events, PP was different between sports in all distances. Although swimmers display a consistent profile, the ability of runners to do so seems to be „impaired“ by tactical factors associated with the more direct presence of competitors. **References** Abbiss C, Laursen PB (2008) *Sports Med*, 38, 293-252

### THE 10-WEEK SOCCER TRAINING EFFECTS ON MUSCLE POWER AND CREATINE KINASE CONCENTRATION.

Caruso, F., Pascoal, E.H.F., Borges, J.H., Spigolon, L.M., Franciscon, C.A., Fernandes, P.T., Borin, J.P.

*Unicamp*

**Introduction** Evaluate how the content training distribution influences in the muscle soreness Creatine Kinase's concentration (CK) and muscular performance is an important tool in the training. This work aims to assess the 10-week effects of training and its relationship in the muscular power performance and CK in U19 soccer players. **Methods** 13 athletes of U19 participated in this study,  $18,40 \pm 0,88$  years,  $179,52 \pm 6,96$  cm,  $73,70 \pm 7,89$  kg. The study was approved by the Research Ethics Committee under the protocol 596/2011. Forty-nine training sessions were analysed in 11 matches along 10 weeks. We evaluated the athletes in two moments, at the beginning (M1) and at the end of the 10 weeks (M2). The jump height (CMJ) was measured according to Bosco et al. (1983) protocol and the CK activity was determined by UV Espectrofotometer (Biospectro, SP-220, Brazil) with the athletes were fasted. The content training followed the proceedings described by Proia et al., (2012). The CMJ data was analysed by the Student t-test while the CK concentration was analysed by the Wilcoxon test. The  $\alpha$  was fixed in 5%. **Results** In the analysed period there was an anaerobic lactic capacity predominance (1140 min), strength training (1090 min) and official matches (935 min). No significant changes were verified in the CMJ values ( $53,70 \pm 9,60$  cm to  $55,61 \pm 9,14$  cm) but the CK change from M1 to M2 ( $64,20 \pm 85,45\%$ ,  $p = 0,0429$ ). **Discussion** The training organization in the evaluated period and the quantity of matches could have affected the found results because the lower body power can be reached its approximated maximal values characteristic of the period (Verkhoshansky, Stiff, 2010) as well as the CK improvement after M2 (Ispirlidis et al., 2008). **References** Bosco, C., Luhtanen, P., Komi, P.V. (1983). *Eur J Appl Physiol*, 50(2), 273-282. Ispirlidis, I., Fatouros, I.G., Jamurtas, A.Z.,

### RELIABILITY OF MUSCLE RESPONSE MEASUREMENTS WITHIN DIFFERENT ELECTRICAL STIMULATION INTENSITIES USING TENSIO MYOGRAPHY

Simola, R., Harms, N., Ferrauti, A.

*Ruhr University Bochum*

**Introduction** In the last few years, different methods, techniques and devices have been used to evaluate neuromuscular function in rehabilitation and sports training settings. Recently, a non-invasive method, tensiomyography (TMG), which allows the contractile properties assessment from radial muscle belly displacement just after a single electrical stimulation, has been introduced. Although the reliability of TMG was already reported (Simunic, 2012), to the best of our knowledge, it is unclear its reliability from submaximal electrical stimulus. Therefore, the aim of this study was to analyze TMG reliability within maximal and submaximal electrical stimulus. **Method** 20 male sport students were tested two times over one week period. TMG measurements were conducted using a specific electrical stimulator (TMG-S2), TMG-OK 3.0 software, as well as a displacement sensor tip with prefixed tension, which was positioned at 90 degrees to the muscle belly. Muscles analyzed were rectus femoris (RF), biceps femoris (BF) and gastrocnemius lateralis (GL) left and right sides, after a single 1 ms maximal or either a submaximal electrical stimulation (40mA). Maximal electrical stimulation was found through step increase of 20mA. Time contraction (Tc), determined from 10% to 90% of the maximal response, delay time (Td), determined from onset of electrical stimulus to 10% of maximal response, maximal radial muscle displacement (D), sustain time (Ts), determined as time between 50% of maximal response during muscle contraction and relaxation and relaxation time (Tr), determined from time of fall from 90% to 50% of the maximal response (Krijaz et al., 2008), were analyzed. Absolute reliability was assessed by the standard error of measurement (SEM) whereas the relative reliability by the intraclass correlation coefficient (ICC). **Results** The highest significant values ( $p < 0.01$ ) for TMG reliability were reported in maximal electrical stimulation (ICC=0.85-0.94; 0.83-0.91; 0.55-0.92; 0.67-0.88; 0.91-0.94) for Tc, Td, Tr, Dm and Ts respectively, in all muscles. Regarding submaximal electrical stimulation, Dm, Tc and Td also showed significant ( $p < 0.01$ ) high scores (ICC=0.91-0.94; 0.76-0.92; 0.70-0.92) in different muscles respectively. **Discussion** Maximal electrical stimulus have demonstrated high reliability. Submaximal values indicated a lower reliability for some parameters. In some muscles, under submaximal stimulus, Tr and Ts have not been repeatable. TMG may be considered as a reliable method to evaluate contractile properties within maximal and submaximal electrical stimulus. **References** Simunic, (2012). J Electromyogr Kinesiol, 22(4), 527-30. Krizaj et al., (2008). J Electromyogr Kinesiol, 18(4), 645-51.

### CARDIODRIFT: A FACTOR TO BE CONSIDERED IN TARGET HEART RATE DURING RECREATIONAL RUNNING

Hanakam, F., Ferrauti, A.

*Ruhr-University Bochum; Faculty of Sports Science*

**Introduction** Recreational running is one of the most common physical activities for an increasing number of people with different standards (i.e., social backgrounds). Among recreational runners, the use of heart rate (HR) monitors is a typical method to quantify the training load, easy to handle and also praised by the sport industry. Coaches and exercise physiologists recommend the use of different HR formulas, although these formulas do not take into account the Cardiodrift (CD). CD is a term used to describe the increase of the HR during aerobic exercise, which can be related to a reduced stroke volume, an increased core temperature and dehydration. During recreational running one can obtain a constant HR but has to reduce the running speed in order to achieve this. Yet from a practical point of view maintaining a constant speed should be the aim of the training. Therefore, the aim of the study was to develop a HR-Formula, which takes into account the CD. **Methods** 135 recreational runners (i.e., men and women) (age:  $40.0 \pm 13.4$  yrs; height:  $173.4 \pm 9.1$  cm; body mass:  $68.3 \pm 11.1$  kg) participated in a matched crossover study. On three experimental days separated by one week, the athletes completed three 45 min runs, with a constant velocity corresponding to 85, 90 and 95% of the 4 mmol/l threshold (v4). HR formulas were developed for each running velocity, related to gender, age and performance, using the coefficient of determination ( $R^2$ ). **Results** Results showed a significant increase in HR from 15 to 45 min of running duration in all intensities in both, men and women and independent from age and performance ( $p < 0.01$ ). The absolute HR showed no differences regarding the performance level of runners, but was significantly higher in women and in younger runners. There was no relationship between HR and blood lactate, age or performance level. Blood lactate remained stable at 95% v4 and decreased significantly ( $p < 0.01$ ) at 85 and 90% v4. **Discussion** HR monitors are a useful way to monitor the training load, although the CD should be taken into account. In the present study we developed a formula, which takes into account the natural increase of the HR while running and made a table, which predicts the training target HR. The formula presented here would be useful for the HR monitor manufacturers, as they could integrate it into their watches next to the determinants of age, gender and intensity. **References** Coyle, E.F., Boa, F.G. & Gaze, D.C. (2001). Exerc Sport Sci Rev, 29, 92-99.

### TEST-RETEST RELIABILITY OF A FIELD-BASED FITNESS TEST BATTERY USED IN AUSTRIAN YOUTH SOCCER

Gonaus, C., Müller, E.

*University of Salzburg*

**INTRODUCTION** Fitness tests are implemented in youth soccer to determine current fitness levels, to identify and select talented players, and to monitor players' development (Stratton et al., 2004). However, especially in well-trained athletes, there is a lack of "quality control" of fitness tests (Hopkins et al., 1999). The purpose of this study was to determine relative and absolute reliability of a field-based fitness test battery performed by elite Austrian soccer players from the age of 11 to 18 years. **METHOD** Forty-one elite male youth soccer academy players (age  $15.7 \pm 0.7$  yrs, body size  $1.75 \pm 0.08$  m, weight  $63.7 \pm 9.9$  kg) conducted a battery of 10 fitness tests on two separate occasions 7 days apart: 20 m straight-line sprint (with 5 and 10 m split times); 5 x 10 m shuttle sprint (SS); hurdles agility run (HAR); reaction test (RT); foot tapping (FT); 20 m multi-stage endurance run (ER); counter movement jump (CMJ); 40 cm drop jump (DJ); 2 kg standing overhead medicine ball throw (MBT); and sit-and-reach test (SR). All players passed through a familiarisation session on a separate occasion. Paired t-tests were calculated to detect systematic changes in the mean. Intraclass correlation coefficient, ICC (2, 1), was used to assess relative reliability. Since all data proved to be homoscedastic, absolute reliability was quantified by standard error of measurement, SEM (Atkinson and Nevill, 1998). **RESULTS** A significant ( $p < .01$ ) systematic bias was detected in 5, 10, and 20 m, RT, ER, and SR, indicating increased (RT, ER, SR) and decreased (5, 10, 20 m) retest performances. Moderate to high ICC values of .81-.97 were found in 20 m (mean  $\pm$  SEM:  $3.20 \pm 0.04$  s); SS ( $11.75 \pm 0.14$  s); FT ( $13.1 \pm 0.3$  Hz); ER ( $11.6 \pm 0.2$  km/h); MBT ( $9.3 \pm 0.4$  m); and SR ( $7 \pm 1$  cm). While CMJ ( $36.2 \pm 2.4$

cm); DJ coefficient ( $6.7 \pm 0.8$ ); 10 m ( $1.86 \pm 0.02$  s); and HAR ( $11.77 \pm 0.24$  s) displayed acceptable ICC scores of .74-.79., values for 5 m ( $1.09 \pm 0.03$  s), .56, and RT ( $642 \pm 40$  ms), .48, were classified as low. CONCLUSION The systematic bias detected in RT, ER and SR might be attributed to learning effects. Additional familiarisation trials would be preferable (Atkinson and Nevill, 1998). Most of the current tests displayed acceptable to high relative reliability for this homogenous group of players. Furthermore, small within-subject variations throughout all tests, quantified by low SEM, pointed out that the test battery was a reliable tool for fitness assessment in youth soccer. Therefore, applying these tests in talent identification and development settings seems to be appropriate for fitness evaluation. REFERENCES Atkinson G, Nevill AM. ### EFFECTS OF HIGH-INTENSITY CIRCUIT TRAINING ON BLOOD PRESSURE, LIPOPROTEINS AND TRIGLYCERIDES IN MIDDLE AGED OVERWEIGHT MEN

Moro, T.1, Pacelli, F.Q.1, Bianco, A.2, Paoli, A.1

1. University of Padova, 2. University of Palermo

**Introduction** High intensity circuit training have showed to be able to improve body composition, physical fitness and health-related factors in older individuals 1,2 The aim of this study was to determine the physiological effects of an high-intensity circuit training (HICT) on several cardiovascular disease risk factors in healthy, overweight middle-aged subjects, and to compare the effects of HICT to traditional endurance training (ET) and low-intensity circuit training (LICT). **Methods** 30 subjects (ages 50-65 yr, BMI  $29.8 \pm 0.9$ ) were randomly assigned to one of the three exercise treatment groups: HICT, LICT and ET. The three groups exercised three times per week, for 12 weeks. HICT consists in 7 min on cycloergometer performed with HIT technique (30 sec at 85% of VO<sub>2</sub>max and 3 min and 30 sec at 50% of VO<sub>2</sub>max repeated for two times) and resistance training (RT) exercises (latissimus dorsi pull-downs, pectoral machine, lateral shoulder raise; horizontal leg press) performed with HIRT technique<sup>3</sup>, all circuit was repeated two times (with 7 min of HIT at the end). LICT consist in the same circuit but with cycloergometer performed at 65% of VO<sub>2</sub>max and RT performed with 3 sets for 15 repetitions. ET consisted in 60 min at cycloergometer performed at 65% of VO<sub>2</sub>max. Pre- and post-training, participants underwent to anthropometric and blood pressure measurements: BW (body weight), FM (fat mass), WLC (waist line circumference), DBP and SBP (diastolic and systolic). Moreover some blood parameters were checked pre and post training: CHOLt (total cholesterol), LDL (low density lipoprotein-cholesterol), HDL (high density lipoprotein-cholesterol), TG (triglycerides). Before and after training also LAb100w (blood lactate produced at 100 Watt during submaximal test) and VO<sub>2</sub>max were determined. **Results** Compared to other groups, CHIT showed significantly higher reductions in BW, FM, WLC, DBP, CHOLt, TG and LAb100w and significantly greater increases in high density HDL and VO<sub>2</sub>max whilst HDL increased in similar manner in all groups. CLT resulted in the greatest reduction in SBP. **Discussion** Our findings indicate that high-intensity circuit training is more effective in improving some cardiovascular disease risk factors and physical performance than endurance training alone or lower intensity circuit training. **References** 1 Paoli A. *J Sports Med Phys Fitness*. 2010 Mar;50(1):43-51 2 Romero-Arenas S. *Exp Gerontol*. 2013 Jan 23. pii: S0531-5565(13)00013-2 3 Paoli A. *J Transl Med*. 2012 Nov 24;10:237

### WHOLE-BODY CRYOTHERAPY <-110 °C> IMPROVES ECCENTRIC MUSCLE PERFORMANCE RECOVERY AFTER HIGH-INTENSITY EXERCISE

Ferreira-Júnior, J.B.1,2, Bottaro, M.1, Vieira, C.1, Soares, S.1, Cleto, V.A.1, Vieira, A.1, Magalhaes, I.E.J.1, Simões, H.G.3, Brown, L.E.4

1: UnB (Brasília, DF, Brazil), 2: IFPM (Paracatu, MG, Brazil), 3: UCB (Brasília, DF, Brazil), 4: CSUF (Fullerton, CA, USA)

**Introduction** Whole-body cryotherapy (WBC) refers to brief exposure to extremely cold air (around -110 °C) in a temperature-controlled chamber. WBC has gained wide acceptance as a procedure to improve neuromuscular performance (Banfi et al., 2009). Furthermore, athletes of various sports, such as swimming, athletics, judo, jiu-jitsu, among others, frequently compete or train more than once in the same day. Thus, one session of WBC may help these athletes maintain their performance between matches. However, controlled studies on the effects of WBC between high-intensity exercise on neuromuscular recovery are lacking. Therefore, the aim of this study was to evaluate the effects of a single WBC bout on strength recovery between-training sessions. **Methods** Twelve young men ( $23.9 \pm 5.9$  yrs) were randomly exposed to two different conditions separated by 7 days: 1) WBC (Subjects were exposed to 3 min of WBC at -110 °C); 2) Control (CON). All subjects performed two knee extension training sessions: 1) before each condition and 2) 30 min after. The training consisted of 6 sets of 10 repetitions at 60°.s<sup>-1</sup> for concentric (CC) actions and 180.s<sup>-1</sup> for eccentric (EC) actions. **Results** CC Peak torque (PT) decreased significantly ( $p < 0.05$ ) after WBC (9.4%) and CON (7.5%) training sessions. Total work (TW) also decreased after WBC (6.5%) and CON (5.2%). There was no significant difference ( $p > 0.05$ ) between conditions in PT or TW. Additionally, EC PT decreased significantly ( $p < 0.05$ ) after WBC (5.6%) and CON (16.0%) training sessions. EC TW also decreased after WBC (2.0%) and CON (11.6%). However, the decrease in EC PT and TW were significantly ( $p < 0.05$ ) less after the WBC when compared to the CON condition. **Discussion** The main finding of the present study was that WBC may improve EC recovery after a bout of high-intensity exercise. EC muscle actions are stronger and have less energy cost because it also involves passive tension from the elastic properties of the muscle, not just active tension from cross-bridge cycling. In addition, Herzog et al. (2008) adds that there is an increase in the stiffness of the titin protein during eccentric actions. Increases in muscle-tendon stiffness resulting from exposure to cold have been well documented (García-Manso et al., 2011). Thus, the improvement in EC performance in the present study may be due to increases in muscle-tendon stiffness associated with WBC (-110 °C). **In conclusion**, the present study showed that WBC may be used after exercise to enhance between-training session recovery of EC muscle performance. **References** Banfi G, Melegati G, Barassi A, et al. ### ADDING WHOLE BODY VIBRATION TO PRE CONDITIONING EXERCISE IMPROVES ON-ICE SPRINT PERFORMANCE IN ICE HOCKEY PLAYERS

Slettaløkken, G., Ellefsen, S., Rønnestad, B.R.

Lillehammer University College

**Introduction** Training methods to acutely enhance sprint performance and thus impose a greater training stimulus may be of great value to ice hockey players. Post activation potentiation (PAP) exercises with added whole-body vibration (WBV) have been suggested to be a potential way to acutely improve sprint performance. We have recently shown that adding WBV with a vibration frequency of 50 Hz to

body-loaded half-squats improves subsequent 40 m sprint performance in soccer players (3). However, not all studies do find a significant effect of adding WBV (1, 2). The aim of the present study is to investigate the effect of adding WBV to body-loaded half-squats, performed as preconditioning activity to on ice-sprint in ice-hockey players. Method Fifteen male junior elite level ice hockey players participated in the study. Four separate test sessions were performed, wherein each session included a standardized warm-up followed by one of the following preconditioning exercises; 30 s of half-squats without WBV, or 30 s of half-squats with WBV at 50 Hz. A 40 m sprint was performed one minute after the preconditioning exercise with intermediate timing after 10 m and 20 m. For each subject, both protocols were repeated twice on separate days in a randomized order and the best 40 m time was used for statistical analysis. Perceived wellbeing in the legs was measured before warm-up, after warm-up and after the preconditioning activity (method presented in ref. 4). Results Performing preconditioning exercise with WBV at 50 Hz resulted in superior 10, 20, and 40 m sprint performance compared to preconditioning exercise without WBV ( $1.88 \pm 0.10$  vs.  $1.84 \pm 0.10$  s,  $3.17 \pm 0.13$  vs.  $3.14 \pm 0.13$  s, and  $5.53 \pm 0.15$  vs.  $5.39 \pm 0.2$  s, respectively; all  $p < 0.05$ ). There was no difference in perceived wellbeing in the legs between the testing mode before and after warm-up. However, after preconditioning activity with WBV the players felt better in their legs than after precondition activity without WBV ( $p < 0.05$ ). Discussion The overall finding was that preconditioning exercise performed with WBV at 50 Hz seems to have a positive effect on on-ice sprint performance in junior elite level ice hockey players. Performing PAP exercises with WBV at the right frequency (50 Hz) during warm-up sessions may improve sprint performance and thus improve the quality of sprint training. A part of this effect may be related to the observed improvement in perceived wellbeing of the legs after WBV. References 1. Bullock et al., JSCR, 2008; 22:1371-74 2. ### VARIATION OF MUSCLE BALANCE AND ISOKINETIC PEAK TORQUE DURING PRESEASON SOCCER PLAYERS OF U-19 CUP.

Caruro, F., Pascoal, E.H.F., Borges, J.H., Franciscan, C.A., Spigolon, L.M.P., Fernandes, P.T., Borin, J.P.

*Unicamp*

Introduction: In the scope of sports training the control of the internal load is connected to the fact that adaptations occurring in the body of the athletes are linked to intensity and magnitude, seeking to ensure that the athlete will increase their performance (Issurin, 2010). Objective: The objective of this study was to analyze the variation of muscle balance flexors and extensors of the knee and the peak torque of these muscles along the preseason training in soccer players in the under-19 category. Methodology: 13 subjects belonging to the under-19 team of Desportivo Brasil, in a preparatory stage to Sao Paulo Juniors Cup 2013, participated in 10 weeks of training and conducted two evaluations at the beginning (M1) and at the end (M2) of the preparatory phase. The peak torque (PT) and the ratio between agonist and antagonist (RFE), both members were obtained using a Biodex System 4 @ isokinetic dynamometer, in a series of five repetitions concentric of  $60^\circ/s$ . For the statistical analysis was used initially normality test of Shapiro-Wilk, and then, Wilcoxon test for paired comparison. The study was approved by the Research Ethics Committee under the protocol 596/2011. Results: The PT in the knee extensor muscles was lower in M2 with respect to M1, showing significant difference ( $p \leq 0.05$ ) in both states. For the knee flexor muscles in both members there was no difference ( $p > 0.05$ ). RFE was lower in M1 compared to M2, and the comparison between moments does not have a significant difference ( $p > 0.05$ ). Discussion: The results indicate the existence of changes in the magnitude of RFE, but within the normal range and maintaining proportionality between members throughout the preparatory period, as well as a significant decrease in the extensor PT, featuring a decrease in the ability to generate force of the quadriceps muscles. ### EFFECTS OF STRENGTHENING-AEROBIC COMBINATION EXERCISE AND RHYTHMIC EXERCISE ON SUBJECTIVE PAIN & PHYSICAL FITNESS IN KOREAN SENIOR FEMALES

Lee, B.K.1, Kang, H.J.2, Kim, S.B.1, Im, J.H.3, Ahn, J.H.4, Kook, Y.J.5, Ahn, H.J.6, Jun, S.Y.7

1: SM-UIChungNam, Korea), 2: SCH-UIChungNam, Korea), 3: KAISTIDaejun, Korea), 4: SC-H(Seoul, Korea), 5: CP-H(Seoul, Korea), 6: M-CSTI(Seoul, Korea), 7: HS-C(Seoul, Korea)

INTRODUCTION The purpose of this study was to investigate the effects of strengthening-aerobic combination exercise and rhythmic exercise on subjective pain and physical fitness in senior females. METHODS The physical fitness were measured by Senior fitness test(Rikli & Jones, 2001). The subjects were classified into groups with strengthening-aerobic combination group(SAG), rhythmic exercise group(RG), and control group(CG). There were senior females of  $72.4 \pm 5.5$  years, total 29 persons. The SAG included bicycling for aerobic exercise as well as wrist and ankle weight sandbag for strengthening exercise. The program for SAG was performed 60 min/day, 2-3 times/week for 8 weeks. The RG executed 70 min/day rhythmic program, 2 times/week for 8 weeks. Rhythmic program were include 'Gustaf's Skool, Circassian Circle, Nigino shell Yoshi, I'm Busted, Goodnight waltz, Laringka, Jenka'. Data were analyzed with paired t-test, independent t-test and two-way ANOVA for repeated measures by SPSSWIN program. This study was modified from the raw data of Lee, Kang, & Kim(2013). RESULTS The results were as follows; The SACG were significantly improved on cardio-respiratory fitness and upper muscular strength(left grip strength). The RG were significantly improved on lower muscular endurance, upper right flexibility, resting HR, & DBP. In subjective pain, the SACG had a positive effects on back pain. Both groups showed improvements in the other categories of subjective pain even though the improvements didn't show reach statistical significance. CONCLUSION Both strengthening-aerobic combination exercise and rhythmic exercise were effective program for senior female, and the rhythmic exercise was more effective than the combination exercise for improving the physical fitness of senior females. This study recommend that the development of rhythmic exercise and combine exercise program should be the useful program for Korean senior females. Reference Lee, B.K., Kang, H.J., & Kim, S.B. **COMPARISON BETWEEN GRAB START AND TRACK START IN COMPETITIVE SWIMMING START: ABOUT IMPULSE DURING A MOVEMENT ON THE STARTING BLOCK**

Sakai, S.

*University of Tsukuba*

Comparison between Grab start and Track start in Competitive Swimming Start: About impulse during a movement on the starting block Sakai, S.1, Takeda, T. 2, Tsubakimoto, T. 1, Takagi, H. 1 1: University of Tsukuba ( Japan ), 2:University of Waseda ( Japan ) Introduction Recently, Grab start and Track start have been mainly used in swimming competitions. The take-off velocity from the starting block is caused by acting a force on the block by hands and feet. Thus a characteristic of start technique must be clarified by measuring the force acting on the block. Although several measurements of the force acting on the starting block have been done, there was no report which measured forces exerted through hands or feet separately. A degree of contribution by hands and feet for acquiring the take-off velocity has not been clarified yet. Therefore, the purpose of this study was to compare between Grab start and Track start focusing on impulse during a movement on the starting block by measuring forces exerted by hands or feet separately Method We made a new starting block with built-in biaxial (horizontal and vertical) force gauges which consisted of hand-, front-foot-, rear-foot-part. The horizontal/vertical component of take-off velocity was calculated as each component of impulse during a movement on the starting block divided by subject's weight. A degree of contribution by hands or feet was estimated by means of comparing impulse exerted through hands or feet. Results and Discussion In Grab start, although large positive horizontal reaction force by feet was observed, negative reaction force by hands was measured. This negative force was necessary to attract a body with the starting block until the body moving fore-and-downward so that the take-off angle came to negative. In addition, the negative vertical reaction forces by hands and the positive vertical reaction force by feet were observed. However, a total of reaction force by hands and feet was slightly larger than the reaction force correspond to the weight of the subjects. Therefore, a function of vertical reaction force seemed to mainly support the body weight while moving on the starting block. In Track start, the positive horizontal reaction force was measured by all of hands, front foot and rear foot. Moreover, a degree of contribution to take-off horizontal velocity by the rear foot was the biggest, and accounted for 65% of the total force. For the vertical reaction force, the negative force by hands and the positive force by feet were observed. However unlike Grab start, the front foot mainly supported the body weight, and a couple of forces by hands and rear foot acted in an opposite direction. Therefore, Track start was able to incline a body forward quicker than Grab start. Reference Takeda T, Nomura T. (2006). Portuguese J Sports Sci, 102-105. Maglischo E.W. **THE EFFECT OF HEAD UP MOTION ON HAND DISPLACEMENT IN FRONT CRAWL BY LIFESAVER.**

Hara, R., Gando, Y., Muraoka, I.

*Waseda University*

Introduction Lifesaver and open water swimmer do head up motion during swimming at ocean. Some researches of head up swimming with water polo players were reported ( Karla, 2012 ; Dopsaj, 2007 ). Lifesaver and open water swimmer are swimming with moving up and down of the head, which is different from head up swimming of water polo player. No studies were focused on head up swimming of lifesaver. Therefore, the aim of the present study was to examine the effect of head up motion on hand displacement in front crawl by lifesaver. Methods Ten surf lifesavers provided written informed consent to participate in the study. Each swimmer performed four swim trials ( two front crawls and two head up swimings ) in 50m swimming pool. Each trial was swum at 80% of their each best performance velocity which were kept by a pacemaker. Two underwater video cameras were used to capture the right and left hands in two strokes at 200Hz. A digitizing system was used to manually digitize the third fingertip. The direct liner transformation method was used to obtain the three dimensional coordinates of landmark. Duration of the stroke, stroke length ( SL ), hand displacement were measured on left and right hands, respectively. Results All subjects did the head up motion after the entering of the right hand into the water. On right hand, head up swimming had significantly shorter stroke length than front crawl ( head up swimming :  $2.15 \pm 0.15$  m, front crawl :  $2.35 \pm 0.15$  m ). On left hand, head up swimming had significantly shorter maximum forward displacement than front crawl ( head up swimming :  $0.62 \pm 0.15$  m, front crawl :  $0.95 \pm 0.32$  m ). Discussion Maglischo ( 2003 ) said that swimmers should try to remain the horizontal components as possible to the water surface for reducing the drag and head up motion disturb the horizontal swimming form and increase drag force. In this study, head up swimming showed shorter stroke length than front crawl on right hand. This result indicates that head up swimming increased drag force and it would make shorter stroke length than front crawl. On left hand, head up swimming showed shorter maximum forward displacement than front crawl. These findings indicate that after the entering of the left hand into the water, left hand catches the water immediately and begins the propulsive phase during head up swimming. **EFFECTS OF SLIP-INDUCED CHANGES IN ANKLE MOVEMENT ON MUSCLE ACTIVITY AND GROUND REACTION FORCES DURING RUNNING ACCELERATION**

Ketabi, S., Kersting, U.G.

*Aalborg University*

Introduction Ground contact in running is always linked to a minimum amount of slipping, e.g., during the early contact phase when horizontal forces are high compared to vertical forces. Studies have shown altered muscular activation when expecting slips [2-4]. It is not known what the mechanical effect of such slip episodes are on joint loading or performance. The aim of the present study was to examine the effect of changes in ankle movement on ankle joint loading, muscle activity, and ground reaction forces during linear acceleration. Methods Four young, healthy subjects were investigated while their run was perturbed by a moving force plate. GRF data were sampled

at 1000 Hz and corrected for inertia effects from platform movement. Eight pairs of bipolar surface electromyography (EMG) electrodes were used to record the activity of the thigh and leg: rectus femoris (RF), biceps femoris (BF), vastus medialis (VM), Tibialis anterior (TA), vastus lateralis (VL), soleus (SO), gastrocnemius lateralis (GL) and gastrocnemius medialis (GM) on the perturbed limb (biovision, Germany, 2000 Hz). Kinematic data of 45 reflective markers placed on anatomical landmarks were collected with an 8-camera motion capture system (Qualisys AB, Gothenburg, Sweden, 250 Hz). Three slipping conditions were compared: No movement (control), slip of 4 and 6 cm posteriorly. Subjects performed sprint starts from a standing position with the 4th step on the platform. Results The kinematic data were applied to a full-body model in C-motion and the center of mass position extracted. Only the largest slip amplitude resulted in a notable change in center of mass trajectory or angle of GRF vector direction, while ankle movement was changed systematically, showing a greater range of movement during contact. Only marginal differences were observed with a trend for increased gastrocnemius activity for the 6 cm slip. No significant differences were found for the horizontal force component for these subjects. Further testing is under way to consolidate these findings. Conclusion Ankle movement during the acceleration phase of running did not alter ground contact mechanics substantially. However, at larger amplitudes alterations in muscle activity were observed. Future research should focus on the functional implications of micro movements on injury risk and performance including the timing of slipping. Reference 1. A. J. Chambers, R. ## USING BALL RESIN MAY AFFECT HANDBALL THROWING PERFORMANCE

Tsai, Y.S.1, Chen, H.P.2, Hsu, C.H.2

*Taipei Physical Education College*

**Introduction** In order to increase ball control ability, it is common for handball players to put ball resin on hands or fingers during competition. However, its effects on throwing movements, ball velocity, and accuracy are not clear. The purpose of the study was to investigate the effects of using ball resin on handball throwing performance. **Methods** Ten male handball players with right hand dominance (age: 21.9±1.3 years, height: 176.9±3.0 cm, weight: 76.6±7.6 kg, experience: 11.3±2.2 years) were recruited from Division I college handball teams in Taiwan. Each player performed cross-over step throw from a distance of 7 meters to hit 3 targets of the goal (center, left upper corner, right upper corner). Each target was made by a piece of cloth with an area of 0.5m\*0.5m. Five shoots were conducted for each target with and without a certain amount of resin evenly placed all over the handball. Throwing movements including throwing arm, trunk, pelvic, and pivot leg movement were recorded using a 3D electromagnetic motion analysis system at 240 Hz. Ball velocity was recorded with a sports radar gun. A ball that hit any area of the target and passed the goal line inside the goal was considered score. Throwing accuracy for each target was determined by the scoring rate of each target. Paired t-tests were performed to compare differences in results for all assessments with and without using handball resin. **Results** Ball velocity was significantly increased with ball resin while throwing towards center (21.86±1.67 vs. 22.80±1.80 m/s, p=0.003) and left upper corner (21.65±1.41 vs. 22.71±1.66 m/s, p=0.016) target. However, throwing accuracy was only significantly decreased while throwing towards right upper corner target with ball resin (1.00±0.00 vs. 0.88±0.13, p=0.015). While throwing towards center target with ball resin, maximum shoulder external rotation velocity, maximum hip flexion angle, maximum trunk flexion velocity, and maximum wrist flexion velocity were increased. While throwing towards left upper corner target with ball resin, only maximum shoulder external rotation velocity was increased. While throwing towards right upper corner target with ball resin, maximum elbow flexion angle was decreased and maximum hip flexion angle was increased. Throwing movement time was not significantly increased while throwing towards any target with ball resin. **Discussion** Throwing with ball resin may increase ball velocity that may contribute to score. However, this situation may potentially decrease throwing accuracy while throwing towards right upper corner of the goal, although the number of our throws may not enough for the accuracy test. Several changes in biomechanical throwing movements were observed while throwing towards different targets with ball resin. Whether these movement changes significantly affect the results of this study needs further investigation.

## OPTIMAL CYCLING TIME TRIAL POSITION MODELS

Fintelman, D., Sterling, M., Hemida, H., Li, F.X.

*University of Birmingham*

**Introduction** The aerodynamic drag of a cyclist in time trial (TT) position is strongly influenced by the torso angle (Underwood et al. 2011). To minimize drag, cyclists lower their torso angle. Along with the drag the cyclists' peak power output decreases. There should be a trade-off between the loss in power output and drag as function of cycling velocity. This hypothesis is supported by the energy expenditure which is a function of the workload divided by the gross efficiency. The workload to overcome drag decreases with smaller torso angles, while the GE decreases accordingly. Previous literature suggested that the aerodynamic losses outweigh the loss in power output (Lukes et al. 2005). However, these statements are only valid for elite TT cycling velocities, e.g. > 45 km/h. To our best knowledge, there is no published prediction at which speed the aerodynamic power loss starts to dominate. Therefore the aim of this study is to predict the optimal TT cycling position as a function of a wide range of velocities. **Methods** Two models were developed to determine the optimal torso angle of TT cyclists: a power output model and a metabolic efficiency model. The power output model predicts the optimal cycling position by maximizing the peak power output minus the power losses due to drag and roll resistance. The metabolic efficiency model minimizes the required cycling energy. Model input parameters were experimentally collected of 19 trained competitive time trial cyclists. The main input variables were the power output, frontal area and gross efficiency of the cyclists in different torso angle positions (0,8,16,24°). The optimal cycling torso angle was predicted for speeds between 18-50km/h. **Results and discussion** It has been demonstrated that for both models, the optimal torso angle is dependent on the cycling velocity. The torso angle showed a sigmoid-like shape, with decreasing torso angles at increasing velocities. The power output model curve was shifted to a higher velocity, which could be explained by the different approach of the models. The aerodynamic losses outweighed the power losses for velocities above 45km/h, which goes in line with the literature. For cycling velocities below 30km/h the power loss and gross efficiency due to position change were dominant. Furthermore, it is shown that a fully horizontal torso is not optimal. Finally, it is suggested that despite some limitations, the models give valuable information about the optimal TT cycling position at different speeds. This study showed it is beneficial to ride in a more upright TT position when velocities are below 30km/h. **References** Lukes R, Chin S, Haake S (2005). *Sports Eng.*, 8(2): 59-74. ## ESTIMATION OF THE FLUID FORCES AROUND A FOOT BY A PRESSURE DISTRIBUTION ANALYSIS DURING BREAST-STROKE KICKING

Tsunokawa, T.1, Nakashima, M.2, Sengoku, Y.1, Tsubakimoto, S.1, Takagi, H.1

1:University of Tsukuba(Japan), 2:Tokyo Institute of Technology(Japan)

**Introduction** The propulsive force produced by a swimmer is one of the key factors determining swimming velocity in human swimming. In breaststroke, the propulsive force produced by lower limb's motion was larger than the propulsive force by upper limb's motion. If the methodology to predict the fluid force acting on the foot is established it could be a useful information to improve swimming performance. Therefore, the purpose of this study was to investigate a validity and a reproducibility of a methodology to estimate the fluid forces acting on a foot by the pressure distribution analysis using a robotic leg which can reproduce human's breaststroke kicking motion. **Method** The robotic leg which mounted the foot model performed a breaststroke kicking motion at three motion ranges and two motion speeds. The robotic leg was fixed above the water channel with a three-dimensional dynamometer, and eight pressure sensors were attached to the foot model. The fluid force acting on the foot model was clarified by two methods which used a dynamometer ( "F<sub>dynam</sub>" ) and used pressure sensors ( "F<sub>press</sub>" ). In the present study, we calculated the intra-class correlation coefficients ( ICCs ) of F<sub>press</sub> within and between trials to investigate the reproducibility and the correlation values between F<sub>dynam</sub> and F<sub>press</sub> to investigate the validity. **Results** The ICCs within trials were 0.993 and 0.984 for maximum of F<sub>press</sub> and impulse of F<sub>press</sub>, respectively. And the ICCs between trials were 0.992 and 0.982 for maximum of F<sub>press</sub> and impulse of F<sub>press</sub> respectively. The maximum of F<sub>press</sub> showed significant correlations between the maximum of F<sub>dynam</sub> (  $r = 0.888$  ) and between the impulse of F<sub>dynam</sub> (  $r = 0.820$  ). And the impulse of F<sub>press</sub> showed significant correlations between the maximum of F<sub>dynam</sub> (  $r = 0.870$  ) and between the impulse of F<sub>dynam</sub> (  $r = 0.881$  ). **Discussion** As significant ICCs values and significant correlations were observed, a validity and a reproducibility of the methodology to estimate the fluid force around a foot were accepted. Therefore, the methodology to estimate the fluid force around a foot could apply for hydrodynamic investigation of breaststroke kicking technique, and could get objective and consecutive information during a whole of kicking motion. If the methodology will be applied to the swimming training, swimmers could check their training effects or their conditions. **References** Takagi H, Wilson B. ## CONTRIBUTION TO PROPULSION OF KICKING IN FRONT CRAWL SWIMMING

Ichikawa, H., Tahara, R., Taba, S., Taguchi, M.

Fukuoka University

**Introduction** It was supposed that the faster the swimming velocity was, the more difficult the kicking motion in front crawl swimming accelerated water backward and produced propulsive force. The aim of this study was to investigate the propulsive force of kicking and clarify how the kicking contributed to the propulsion in front crawl swimming. **Methods** A male well-trained swimmer (age: 22.0 yrs., best record of 50m Fr.: 24.9sec) participated two experiments as a subject. The first experiment was to measure the velocity in front crawl swimming with maximal effort. In second experiment, the swimmer was towed by the towing system, which could measure towing tension and velocity, in two conditions such as gliding posture and kicking trial with five different velocities from 1.2 to 2.3m/s. The swimming acceleration was measured using a wireless logger system with inertial sensors attached on swimmer's low back. Based on our model of dynamics in swimming direction, the kicking propulsive force "F<sub>p</sub>" was calculated as "F<sub>p</sub> = m a - F<sub>t</sub> - F<sub>d</sub>", where "m" and "a" were swimmer's mass and swimming acceleration, "F<sub>t</sub>" and "F<sub>d</sub>" were the towing tension and passive drag of whole body, respectively. The passive drag was calculated by the towing velocity in the kicking trials and the coefficient of drag derived from the towing tension in the gliding posture trials. **Results** The mean velocities in the kicking trials were 1.26, 1.51, 1.82, 2.05 and 2.29m/s, respectively. The 4th and 5th trials were faster than the mean velocity in front crawl swimming with maximal effort 1.96m/s. The mean propulsive forces of kicking were -59.4, -83.5, -104.5, -234.4 and -228.3N, respectively. It was observed that the maximal propulsive forces of kicking were positive values in all kicking trials. **Discussion** The observed positive propulsive forces in the faster trials showed that the kicking motion would be able to produce propulsive force even in fast swimming. However, the mean propulsive forces were negative in all trials. It was suggested that the whole motion of kicking would produce resistance and be one of the factors to deceleration. The results cannot explain the advantage of kicking in swimming performance, which the swimming with kicking is faster than without kicking. The reasons would include that our dynamic model was taken account of swimming direction only. The kicking motion would produce the vertical hydrodynamic force and keep the whole body horizontal (Yanai, 2001), so the vertical force would contribute to decrease the resistance of whole body "F<sub>d</sub>". It was suggested that the advantage of the vertical force of kicking would exceed the disadvantage of the resistance in swimming direction, so the kicking would contribute to swim faster in front crawl swimming. **References** Yanai, T., (2001). *Journal of Biomechanics*, 24, 235-243

## CHANGES OF PHYSIOLOGICAL TREMOR AFTER MAXIMUM INTENSITY EFFORT IN MALE AND FEMALE YOUNG SWIMMERS

Mazur-Rozycka, J.1, Gajewski, J.1,2, Zmijewski, P.1, Rozycki, S.2, Busko, K.1,2, Michalski, R.1

1: Institute of Sport (Warsaw, Poland), 2: University of Physical Education (Warsaw, Poland)

**Introduction** It was demonstrated that the maximum amplitude of the exercise-induced tremor occurred with some delay in relation to the physical effort performed (Gajewski, 2006). The aim of this study was to determine the changes of postural physiological tremor following maximum intensity effort performed on arm ergometer by young male and female swimmers. **Methods** Ten female (age 15.0±0.9 years, body mass 58.9±6.3 kg, body height 171.6±6.5 cm and training experience 6.2±1.6 years) and nine male (age 14.8±0.5 years, body mass 67.3±6.4 kg, body height 180.6±7.2 cm and training experience 6.4±1.8 years) young swimmers served as a subjects in the study. Hand tremor was measured accelerometrically in a sitting position before the 30-second anaerobic test on arm ergometer and then 5, 15 and 30 minutes post-test. An accelerometer was placed on one-kilogram load held as motionless as possible on the subject's hand (forearm in horizontal position, back and elbow supported). The 32-second course of acceleration was recorded (200 Hz sampling frequency) for each subject. Power spectrum density function was estimated using the fast Fourier transform procedure. Mean log-powers in 1 to 5 Hz (L1-5) and 10 to 20 Hz ranges (L10-20) were extracted for further analysis. The mixed-design ANOVA (fixed effect: gender) was employed to detect differences between subsequent measurements. **Results** Low-frequency tremor log-amplitude (L1-5) increased (repeated factor:  $p < 0.001$ ) from -7.96±0.45 to -7.33±0.58 and from -6.85±0.53 to -6.29±0.59 in women and men, respectively (gender:  $p < 0.001$ ) 5 minute

post-test. High-frequency tremor log-amplitude (L10-20) increased from  $-8.26 \pm 0.87$  pre-exercise to  $-7.88 \pm 0.81$  5 minutes post-exercise ( $p < 0.01$ ). No effect of gender was found. The post-hoc comparison showed that the highest tremor log-amplitude (L10-20) occurred 5 minutes post-exercise. Recovery from increased tremor took 30 minutes. Discussion The study confirmed a previously reported significant increase of tremor amplitude after physical effort (Gajewski, 2006). Tremor spectra measured in young female and male swimmers differed only in low-frequencies. The increased tremor amplitude was observed even 30 minute post-exercise. Exercise-induced changes in tremor were similar in males and females. Just as we thought, the increased tremor following fatigue appeared 5 minutes after completion of exercise. Such changes in tremor after exercise may be result of temporary disorders of control mechanisms in the nervous system. ### **INTRACYCLIC ACCELERATION VARIATIONS ASSESSMENT IN ELITE LONG DISTANCE SWIMMERS WITH AN ACCELEROMETER DEVICE**

Company Badia, G.

*barcelona university*

**INTRODUCTION** The aim of an efficient swimming, especially important for endurance swimmers, is to keep the momentum as constant as possible in order to maximize its economy avoiding the increase of energy required to overcome the water resistance in every acceleration (Colwin, 1992). The study of the intracyclic variation of the horizontal velocity of center of mass is being used to determine this parameter, and results show that high level swimmers make biomechanical adaptations to maintain low velocity fluctuations (Seifert et al., 2010). The aim of this study is to use an accelerometer, a very small and unobstructive device which allows to obtain an easily and accurate quantification of the intracyclic acceleration variations (Callaway, Cobb, & Jones, 2009), to determine this parameter and the associate changes with increasing submaximal velocities. **METHODS** As a preliminary study, two elite endurance swimmers were monitored at three different competitive paces (85%, 90% and 95% 1500m pace) during 500m using a triaxial accelerometer device situated in the sacrum. **RESULTS** Raw graph data define a specific profile for each swimmer regardless of the pace. Statistically, both swimmers show significant differences ( $p < 0.05$ ) in nearly all the descriptive acceleration parameters (mean, SD, max, min, rang) and with the stroke parameters (stroke length and stroke frequency) in the 3 intensities. They also have significant correlation ( $p < 0.05$ ) of all these variables with the changing velocity except for the stroke length. **DISCUSSION** The obtained data shows that monitoring swimming with an accelerometer define a specific graphic profile for each swimmer, resulting from the individual technical adaptations to drag and force generation, and it also allows to determine directly its accelerometer and stroke characteristics. With them, we can assess its usual values and their changes with increasing speed. So, this device can be used to control regularly swimmers training and their adaptation to changing constraints in different tasks. **REFERENCES** Callaway, A. J., Cobb, J. E., & Jones, I. (2009). ### **ELECTROMYOGRAPHIC ANALYSIS OF MUSCLE RECRUITMENT PATTERNS ON STATIONARY AND SLIDING ROWING ERGOMETERS**

Osborne, M., Pritchard-Peschek, K., Manning, J.

*Queensland Academy of Sport*

**Introduction** To better replicate on-water rowing movements, the addition of slide rails allows the mass of the ergometer to move beneath the rower during the recovery phase of the stroke. Although the general patterns of muscle recruitment during the stroke cycle of stationary ergometry have been identified<sup>1-2</sup>, little information exists on the differences in technique, and thus muscle recruitment patterns between stationary and sliding ergometer rowing. The purpose of the present study was to identify potential differences in rowing technique between stationary (STAT) and sliding (SLIDE) ergometers by determining the sequence of muscle recruitment patterns. **Methods** Seven elite U23 male heavyweight rowers completed two 2000 m trials on either a stationary or sliding Concept II ergometer, followed by two 60 s trials in each condition at the same respective speeds and stroke rates to determine muscle recruitment patterns using electromyographic (EMG) activity. **Results** There was no difference in 2000 m performance between trials (STAT:  $6:12.7 \pm 5.3$  s;  $432.7$  W vs. SLIDE:  $6:13.9 \pm 4.2$  s;  $428.5$  W;  $P > 0.05$ ), although stroke rate was higher in the SLIDE ( $36.5 \pm 4.0$  strokes-min<sup>-1</sup>) compared to the STAT trial ( $29.7 \pm 1.7$  strokes-min<sup>-1</sup>;  $P > 0.05$ ). Biceps femoris, trapezius and latissimus dorsi were recruited earlier in the recovery phase of the SLIDE compared to the STAT trial ( $P < 0.05$ ). **Discussion** Differences exist between STAT and SLIDE ergometry during the recovery phase, possibly in an attempt to control the rower and ergometer's momentum when approaching the catch position. Technique is therefore different between rowing modes, and coaches may need to modify technical instructions to rowers accordingly. **References** 1. Lamb, D.H. ### **BODY STABILITY IN THE VERTICAL POSITION AND THE KINEMATIC PARAMETERS OF UPPER LIMB MOVEMENT IN SYNCHRONIZED SWIMMING**

Rutkowska-Kucharska, A.

*University School of Physical Education, Wrocław*

**Introduction** The aim of this study was to investigate dependences between the kinematic parameters of upper limb movement during support scull and a swimmer's body stability in the vertical position. In addition, this paper also proposes an objective criterion for the division of the exhibited upper limb movements in terms of movement cycles and phases. **Methods** Twelve position markers were placed on the pubic symphysis, head and middle finger and at the transverse axes of selected upper limb joints. The entire movement was filmed by cameras placed in watertight housings. The following parameters were calculated: the time of the entire scull cycle; the time of the first and second phase of the scull cycle; the flexion and extension angle of the elbow and wrist joint; the flexion; the adduction and abduction angle of the shoulder joint; the adduction and abduction angle of the forearm to/from the trunk; the ranges of movement of the wrist, elbow and shoulder joints; the range of movement of forearm adduction towards the trunk; and the range of movement of shoulder adduction towards the trunk. **Results** The head marker was characterized by a significantly larger range of movement in the forwards-backwards and right-left directions than the pubic symphysis. Statistical analysis indicated that a significant difference exists

between the sculling angle and the elbow joint angle not only in the angles themselves but also for the ranges of movement. When analyzing the angles as well as the ranges of movement created by these joints, it can be found that the largest movement range is exhibited in the adduction movement made by the forearm. Statistical analysis found that the first phase (the shoulder movement in the lateral direction) is significantly shorter than the second phase (the shoulder movement in the medial direction). Discussion A comparison of the time of the sculling movements found that the support scull cycle times were similar to the ones reported in the studies by Hall (1995), Rostkowska et al. (2005) and Homma and Homma (2008). The results of this study found that the time of the movement cycles had little variability in the group of examined swimmers. The scull angles proposed in the study can constitute a criterion for dividing the upper limb movement of support scull into phases. It was found that the ability to maintain body stability by swimmers in the vertical position is dependent upon the range of movement by the elbow and wrist joints. Homma and Homma (2008) presented an analysis of the exhibited angular movements by measuring the minimum, maximum and ranges of movement of the elbow. Their study was found to confirm the results found in this study on the flexion of the wrist joint. References Hall, S.J. (1995). ### COMPARATIVE ANALYSIS OF THE REACTION TIME FOR HIGH LEVEL SPRINTERS AND HURLERS IN THE YOUTH, JUNIOR AND ABSOLUTE CATEGORIES

López, J.L.1, Álamo, J.M.2, Padullés, J.M.3

1: UVic-GREAF (Vic, Spain), 2: UB (Barcelona, Spain), 3: INEFC-SSRG UB (Barcelona, Spain)

**Introduction** At the sprint start, reaction time (RT) is the interval between the presentation of an eliciting stimulus (sound of gun) and the initiation of the subject's response. It has been proven that RT has no influence whatsoever over the final results obtained in a sprinting race; RT is neither a determining variable in sprints up to 10 m; and nor are there any major differences between men and women at the main competitions (López, 2006). **Methods** Purpose: To analyse if there are any significant differences between RT in high level young sprinters from the Youth and Junior categories and high level Absolute athletes. We have analysed the final rounds at the IAAF World Championships Daegu 2011, Moncton 2010 and Lille 2011 (Absolute, Junior and Youth categories, respectively). For the 100 m and 200 m events, the variables compared were the official time to finish line and RT. For 110 m hurdles and the 100 m hurdles, only the RT was studied. Results When comparing each one of the events from the 3 categories as a whole, we observed that there were statistically significant differences ( $p < 0.01$ ) between the average times to finish line in the 100 m and 200 m for both men and women. When comparing RT, we observed that there were no statistically significant differences ( $p < 0.05$ ) between the 3 categories in the men's and women's 100 m and 200 m and the 110 m hurdles. There were, however, statistically significant differences ( $p < 0.05$ ) in the 100 m hurdles. When studying the RT of the 6 races analysed, no statistically significant differences were found, which means that the previous results were corroborated. For further contrasting purposes, the championships were compared in pairs. For the men's 100 m, there were statistically significant differences ( $p < 0.05$ ) between all the categories in times to finish line but none in RT. In the women's 100 m and the men's and women's 200 m, there were also statistically significant differences ( $p < 0.01$ ) between the Absolute category and the Junior and Youth categories in the average times to finish line, but not between these two. There were no statistically significant differences in RT between any of the categories in the men's and women's 100 m and 200 m, and the men's 110 m hurdles. Discussion The results obtained corroborate that RT values for Youth, Junior and Adult sprinters are thus very similar. Nevertheless, when observing displacement velocity, formulated as time to finish line, the results obtained in the aforementioned categories vary, since many other aspects influence this value, i.e. strength, speed resistance and technical skill. ### GENDER DIFFERENCE DURING DEFENSIVE CUTTING ACTION: THREE DIMENSIONAL MOTION RECONSTRUCTIONS FROM VIDEO SEQUENCES

Sasaki, S., Koga, H., Kaneko, S., Krosshaug, T., Yamaguchi, S., Fukubayashi, T.

Tokyo Ariake University of Medical and Health Sciences

**Introduction** Defensive performance is one of the very important factors for success in the modern football games. Recently, defensive cutting actions in male in football game situations have been analyzed (Sasaki et al., 2013); however, female's cutting actions were unknown. The purposes of this study were to analyze female's defensive movements in game situations and to determine the difference between male and female athletes. **Methods** Seven defensive scenes (4 males and 3 females) in which a subject was responding to an offender's dribble attacking were analyzed using a model-based image-matching technique. We calculated centre of mass height, and trunk, hip and knee kinematics during defensive cutting actions. A relative centre of mass heights was expressed as a ratio of each participant's height. Each parameter was checked at the point of initial foot contact (IC), the point of the lowest centre of mass height (COM low), and the point of foot off (FO). Results Females (mean (SD): 3.3 (1.4) cm) had bigger change in centre of mass height between IC and COM low compared with males (6.9 (1.0) cm). A relative centre of mass heights at IC in females (0.39 (0.03) cm/m) were higher than those in males (0.44 (0.02) cm/m). Furthermore, trunk and hip flexion angles at IC in females (38 (4) deg.; 19 (15) deg.) tended to be smaller than those in males (64 (15) deg.; 47 (13) deg.). Discussion Compared with males, in football games which is not lab-setting, females contacted to ground in higher centre of mass point and displayed a bigger change in centre of mass height between IC and COM low. This could be a reason that females showed the posture of smaller trunk and hip flexion angles at IC. A small displacement and low centre of mass gravity would be beneficial in agility skill (Bradshaw et al., 2011). Females demonstrated a low trunk forward inclination angle (Nagano et al., 2011) and less hip flexion angles (McLean et al., 2004) compared with males during cutting manoeuvres. These findings from lab-setting trials support our findings from the present field play study. Therefore, coaches for female athletes should check the posture at the moment of initial foot contact during defensive cutting actions. ### A CASE STUDY OF EXTERNAL KINETICS FOLLOWING THE SPRINT START IN A UNILATERAL TRANSTIBIAL AMPUTEE

Bezodis, I.N.I, Charalambous, L.I, Exell, T.A.2, Archer, M.3, Potthast, W.4, Irwin, G.1

1: *Cardiff Metropolitan University (UK)*, 2: *University of Southampton (UK)*, 3: *Sport Wales, (Cardiff, UK)*, 4: *German Sport University (Cologne, Germany)*

Introduction Stance limb force production is vital to sprint running performance. Previous studies of maximum velocity sprinting have shown both single- and double-leg amputees generate lower vertical ground reaction force (GRF) than the intact limb or healthy controls (Brüggemann et al., 2008; Weyand et al., 2009; Grabowski et al., 2010), which may be related to reduced capability. Able bodied athletes create higher vertical GRF in the first than second step of a maximal sprint (Salo et al., 2005). To the authors' knowledge there is no previously published data of sprint start GRFs in amputee athletes. The aim of this study was to describe the external kinetics in the first two steps of a maximal sprint in order to gain a greater understanding of amputee sprint performance. Methods One T44 athlete (100 m PB 12.74 s, mass 88.0 kg) performed seven maximal 20 m sprints from blocks. Force plates (1000 Hz) captured the first two stance phases after the blocks (first: blade, second: intact limb). Temporal and kinetic data were used to calculate discrete GRF values and impulse via the trapezium rule. Change in velocity was calculated by dividing impulse by mass. Mean and standard deviation were calculated across all trials. Results Mean peak vertical GRF was  $1222 \pm 131$  N in the first and  $1787 \pm 132$  N in the second stance. Net horizontal and vertical impulses were  $68.8 \pm 17.4$  and  $-10.0 \pm 22.1$  Ns in the first and  $74.8 \pm 3.2$  and  $68.2 \pm 20.9$  Ns in the second stance respectively, equating to horizontal and vertical velocity changes of  $0.81 \pm 0.21$  and  $-0.12 \pm 0.26$  m/s in the first and  $0.88 \pm 0.04$  and  $0.74 \pm 0.25$  m/s in the second stance. Vertical impulse and velocity change in the first stance were negative in six trials. All other values were positive. Discussion Reduced vertical GRF production in the first, bladed stance compared to second, intact limb stance conflicted with previous able bodied start data (Salo et al., 2005), but matched patterns in amputees at maximum velocity (Grabowski et al., 2010). Vertical force impairment in the first stance was such that the athlete was unable to raise their mass centre during contact. Horizontal impulses were lower in the first stance than the second, further suggesting reduced force producing capabilities due to the blade. ### A RELIABILITY ANALYSIS OF KINETIC AND TEMPORAL VARIABLES RELATING TO VERTICAL JUMP PERFORMANCE

Nicholson, G., Bissas, A.

*Leeds Metropolitan University*

Introduction: A typical kinetic analysis of countermovement jump performance (CMJ) usually involves the calculation of performance variables such as jump height, power & velocity. However further levels of analysis can offer advanced variables which may reveal important information about mechanical mechanisms underlying performance changes (Cormie et al. 2009) providing these advanced variables exhibit satisfactory between-session reproducibility. Hence, this study aimed a) to identify new mechanical variables associated with CMJ performance and b) to quantify their reproducibility using a range of reliability statistics. Methods: Seven males ( $23.6 \pm 2.7$  years) accustomed with jumping activities completed 2 identical testing sessions separated by 48 hrs. The sessions comprised a dynamic warm-up, 2 practice & 3 maximal CMJ's performed on a force plate (1000Hz). Jump height (JH) was calculated via the take-off velocity method & 68 other variables were derived from the force-time curves. Pearson correlation coefficients were calculated to determine associations with JH. Three methods for assessing reliability were also used after the data were assessed for heteroscedasticity: 95% Limits of Agreement (LOA), Coefficient of Variation (CV) & Intraclass Correlation Coefficient [(3,1) consistency]. Results: Out of the 68 variables analysed, 25 correlated significantly with JH ( $p \leq 0.05$ ). Although 11 of these variables (e.g. power & velocity) were derived from the initial level of analysis, 14 of the advanced variables also displayed significant correlations. 51 of the 68 variables showed acceptable levels of reproducibility, these were derived from the initial & advanced levels of analysis. A key variable such as the duration from peak velocity to take-off was particularly indicative of the overall trend demonstrating a CV of 1.97%, a random error of 6.23% and LOA of  $0.00 \pm 0.002$  s. The remaining 17 variables showed high levels of variability (random error >20%), these were mainly related to the duration & slope characteristics of certain key phases (e.g. passive unloading). Discussion: Even though commonly used variables (e.g. power) do not offer advanced mechanical information, they still provide reliable details about CMJ performance. It is clear that more in depth bio-mechanical information can be gained from multiple levels of analysis; however, the resulting variables do not all display adequate stability for use during consecutive sessions. Whilst it may be worthwhile to conduct a comprehensive analysis of the CMJ to understand how certain interventions bring about changes in performance, the present findings highlight the need to consider a range of reliability statistics before interpreting such findings. References: Cormie, P. et al. (2009) *J Strength Cond Res* 23(1): 177-186.

### THE RELATIONSHIP BETWEEN PLAYER TECHNIQUE AND FORCES GENERATED IN RUGBY SCRUMMAGING

Churchill, S.M., Preatoni, E., Stokes, K.A., England, M., Trewartha, G.

*University of Bath*

Introduction The scrum is integral to the game of rugby union. Although the International Rugby Board (IRB) laws state that players must not "charge" at each other and that players should remain stationary until the ball has been thrown into the scrum (IRB, 2013), modern scrummaging often endeavours to achieve a high-impact engagement. Little is known about how player technique influences the forces experienced at impact and how these forces may then influence the forces produced during the sustained push phase of scrummaging. Therefore, our aim was to understand the relationships between player kinematics, engagement forces, and forces during the sustained push phase. Methods Twelve elite professional rugby union forward packs performed up to four scrummaging trials against a scrum machine and one trial was selected for analysis. The scrum machine (Dictator, Rhino Rugby, UK), was instrumented with a bespoke three-dimensional force measurement system (Preatoni et al., 2012). Player kinematics were obtained by manual digitisation of multiple two-dimensional 50 Hz video sequences as described by Preatoni et al. (2012) and parameters recorded at movement onset (@onset), at engagement with the machine (@engage), and during the sustained push phase. Vertical and compression forces were recorded throughout each scrum and peak and average values extracted during both the initial engagement phase and sustained phase. Pearson correlations were used to determine associations between player technique and performance. Results and Discussion The further

the front row was from the scrum machine @onset, the greater the velocity of the front row @engage ( $r=0.790$ ,  $p=0.002$ ). A high velocity of the front row @engage was associated with greater peak compression force, although this was not significant ( $r=0.434$ ,  $p=0.158$ ). However, a higher peak compression force was only weakly correlated with a greater compression force during the sustained push ( $r=0.190$ ,  $p=0.554$ ), indicating that a large "hit" at engagement did not result in better generation of force during the sustained push phase. Therefore, there was little "carry-over" effect from a large hit at engagement. Furthermore, larger peak compression forces were associated with greater peak downward forces ( $r=0.530$ ,  $p=0.076$ ). These results suggest that employment of an aggressive engagement technique which strives to achieve a high-impact engagement may not contribute to better sustained scrum performance, and the accompanying large downward forces may increase the risk of scrum collapse, which disrupts play and is potentially injurious. ## GROUND REACTION FORCES OF WORLD CLASS RACE WALKERS

Hanley, B., Bissas, A.

*Leeds Metropolitan University*

Introduction Race walking is an abnormal form of gait where no visible loss of contact with the ground is permitted and the knee must be straightened from heel strike until the 'vertical upright position' (IAAF rule 230.1). The absence of knee flexion during early stance does not occur in normal walking (Levine et al., 2012) and might therefore have an effect on ground reaction force (GRF) patterns. Little research has been carried out on GRFs in race walking despite the value of kinetic data in analysing this unique form of gait. The aim of this study was to measure and describe typical ground reaction force patterns of world-class race walkers. Methods Sixteen international race walkers performed multiple trials at their season's best pace in a laboratory setting. The group consisted of nine men (stature: 1.79 m ( $\pm$  0.05); mass: 68.0 kg ( $\pm$  6.8)) and seven women (stature: 1.67 m ( $\pm$  0.05); mass: 55.8 kg ( $\pm$  3.9)). Each athlete race walked along a 45 m indoor track at a speed equivalent to their season's best time for 20 km or 50 km. Ground reaction forces (Kistler, Winterthur) were recorded of the contact phases of both legs within the same trial (1000 Hz). Athletes completed at least ten trials each and the three closest to the target time were analysed for kinetic variables provided there was no evidence of targeting by the walker. Results In the vertical direction, a distinct impact peak was identified in the GRF traces of 13 of the 16 participants. In all those traces with an impact peak, the impact peak value was smaller than the loading peak ( $p < 0.001$ ). The loading peak force was also greater than the midstance force and the push-off peak force ( $p < 0.001$ ), but these two final vertical peaks were not different from each other. In the anteroposterior direction, a brief anterior impulse beginning at initial contact and lasting 17 ms ( $\pm$  6) was identified in the traces of all but one participant. The following braking phase lasted 41.1% ( $\pm$  5.9) of total stance time. In the mediolateral direction, there was a pattern of medially directed forces from 28.7% ( $\pm$  5.1) to 62.3% ( $\pm$  5.2) of total stance time, after which laterally directed forces were observed until toe-off. Discussion Although the GRFs of elite race walkers were similar to normal walking, there were some distinct differences. The final vertical push-off peak was much flatter, possibly due to the need to fully extend the knee until midstance, and to prevent vertical lift and subsequent loss of visible contact. The medially directed forces during midstance appeared to occur due to contralateral pelvic tilt which is itself a response to the fully extended knee, while the final lateral forces acted to return the pelvis to a neutral position prior to the next step. ## THE RELATIONSHIP BETWEEN FOOT ALIGNMENT AND HIND-FOOT KINEMATICS DURING WALKING.

Fukano, M., Akiyama, K., Fukubayashi, T.

*Waseda University*

Introduction Variations of foot alignment, such as low arch or high arch are thought to be an intrinsic risk factor because of kinematic changes of the lower extremity [1]. The purpose of this study was to examine the relationship between static foot alignment and the hind-foot kinematics during walking. Methods Seven healthy male subjects participated in this study. IRB approved informed consent was obtained from all subjects. All subjects performed one gait-cycle task on their right foot in the test area. Each trial was recorded using lateral fluoroscopy at a rate of 60 Hz. Radiographic images of the subjects' feet were obtained under static conditions with and without weight bearing for measuring static foot alignment. In addition, CT scans from 15cm proximal to the lateral malleolus to the plantar surface were obtained for each foot/ankle using with a slice thickness of 0.4 mm. In vivo three dimensional bone positions during walking were determined using 3D-2D model-image registration techniques [2] with bone models, that were developed from CT data, and single plane fluoroscopic images between the time of heel contact and toe off. Pearson product-moment correlation coefficients were used to determine the relation between static foot alignment and hind-foot kinematics during walking. Results The primary talocrural joint motion during stance phase was in sagittal plane. All subjects experience talocrural plantar flexion from footstrike to approximately the first half stance phase, while they experienced dorsiflexion during the last half of stance phase. Subtalar joint motion was complex with significant calcaneal dorsiflexion, eversion and external rotation throughout stance phase. For the relationship between static foot alignment and the talocrural and subtalar joints, increasing the calcaneal pitch angles both with and without weight bearing conditions were positively associated with increased range of motion of the talocrural and the subtalar joints during stance phase. Decreasing navicular height tended to be associated with increased range of talocrural joint motion during stance phase. Discussion Hind foot function is critical to ambulation, yet our knowledge of hind foot kinematics during locomotion is limited. These results indicate that the static measurement obtained radiographic image has possibility to predict range of talocrural and subtalar joint motion during walking. References [1]. ## SEX DIFFERENCES IN LANDING KINEMATICS DURING JUMPING EXERCISE

Daniuseviciute, L., Brazaitis, M., Linonis, V.

*Kaunas University of Technology*

The aim of the study was to evaluate sex differences in landing from a jump in relation to lower extremity landing kinematics. Healthy and physical active females ( $n=10$ ) with normal menstrual cycle and healthy and physically active males ( $n = 10$ ) whom age 19-23 years participated in the study. All the subjects were physically active, but did not take part in any formal physical exercise or sport program. After 10-15 min of not-intensive warming-up (slow pedaling velogometer, with the heart rate of 120-130 b / min) 100 drop jumps were started on vertical jump force plate (New Test, Finland). Subjects were standing on 75 cm stage, then stretched the right leg forward and made drop jumps on vertical jump force plate. Before jumping the electrodes and telescopic end-blokes were attached and scoreless

values were set. Jumping height (H), EMG signal and angles of electrogoniometer were measured of every drop jump. During one drop jump EMG of vastus lateralis, biceps femoris, peak values of hip, knee and ankle angles were calculated. When participant got to braking phase (beginning of drop jump to the peak knee joint angle), was named as phase T 1; push-off phase (peak knee joint angle to the end of jump), was named T 2 phase. EMG values were analyzed by RMS (root mean square). The fatigue index of H in males was  $3.44 \pm 0.042\%$ , and females  $4.62 \pm 0.041$ . There was reverse significant relationship between changes in females EMG vastus lateralis (T2 phase) and peak knee angle ( $r = -0.75$ ,  $P < 0.05$ ), also peak hip angle ( $r = -0.81$ ,  $P < 0.05$ ) during last ten drop jumps. There was reverse significant relationship between changes in males EMG vastus lateralis (T2 phase) and peak knee angle ( $r = -0.73$ ,  $P < 0.05$ ), also peak hip angle ( $r = -0.78$ ,  $P < 0.05$ ) during last ten drop jumps. We found reverse significant relationship between changes in females EMG biceps femoris (T2 phase) and peak knee angle ( $r = -0.77$ ,  $P < 0.05$ ), also between peak hip angle ( $r = -0.83$ ,  $P < 0.05$ ) during last ten drop jumps. There was reverse significant relationship between changes in males EMG biceps femoris (T2 phase) and peak knee angle ( $r = -0.7$ ,  $P < 0.05$ ), also between peak hip angle ( $r = -0.78$ ,  $P < 0.05$ ) during last ten drop jumps. Women demonstrated lower peak hip, knee joint angles and lower EMG values in T2 phase when landing from a drop jump. Furthermore, correlations between H, EMG fatigue indexes and landing kinematics were generally larger for women than men. insert authors here

#### VALIDATION OF AN INERTIAL SENSOR AGAINST OPTOELECTRONIC MOTION CAPTURE UNDER DYNAMIC CONDITIONS

Kiani-Dehkordi, K.1, Lees, A.1, Butler, P.B.2, Barton, J.G.1

1: RISES, LJMU (Liverpool, UK) 2. TMC, (Shropshire, UK)

**Introduction** Capturing 3D kinematics has been used widely in both clinical and biomechanical environments based on the detection of reflected infrared or visible light within a laboratory, for example with the Oqus system (Qualisys, Gothenburg, Sweden). To quantify the effects of an intervention on segmental movement, access to a valid tool usable both inside and outside of the laboratory is required. Therefore the aim of this study was to examine the validity of the XSens MTx inertial sensor unit against the Oqus motion capture system under dynamic conditions. **Methods** A combination of the Oqus motion analysis system, the XSens inertial sensor unit and the Targeted Training Equipment (TTE) were used. The TTE has an unstable rocking base that has been modified so that it can be released producing the same amplitude and frequency of movement for each trial. The Oqus system recorded the XYZ coordinates of four markers which were used to calculate the TTE object's tilt angle using Visual3D (C-Motion, Germantown, USA). The XSens attached to the TTE was used to capture the tilt angle simultaneously derived from the full algorithm and also from integrated angular velocity. The Root Mean Square Differences (RMSD) between the Oqus and XSens angle profiles were then calculated in MS Excel. **Results** A significant association was found between the Oqus and Xsens systems ( $p < 0.05$ ). The RMSD between the Oqus angle and XSens full algorithm angle was  $0.24 \pm 0.08^\circ$  and the RMSD between the Oqus angle and XSens angle derived from angular velocity was  $0.46 \pm 0.16^\circ$ . Under the dynamic condition of rocking the TTE over  $12^\circ$  both modes of angular calculations produced less than  $1^\circ$  error as compared to the Oqus system. **Discussion** The XSens inertial sensor unit produced a similar output to the Oqus system with a small error of less than  $1^\circ$ . A particular advantage of the XSens method of calculating tilt angle is that it is not constrained to be used in a laboratory. This makes it possible to test movement responses in clinical environments or even at home. One potential problem with angles derived from angular velocity is the signal drift which is a typical limitation for this type of measurement. Another limitation of the XSens sensor is that its full algorithm is affected by ferromagnetic materials but this effect can be eliminated by keeping a distance from such materials. McGinley et al. (2009) reported that a common clinical assessment error of  $2^\circ$  or less is acceptable. Thus, the XSens MTx sensor is a valid tool for recording angular movement under dynamic conditions. **References** MCGINLEY, J. L., BAKER, R., et al. 2009. Gait Posture 29, 360–369. #### EFFECTS OF STRENGTH OF SHOULDER INTERNAL ROTATORS ON THE COMPETITION RESULTS IN ARMWRESTLING

Wang, L.H., Hong, M.K., Wu, H.W., Lo, K.C.

National Cheng Kung University

**Introduction** Technique and strength are the greatest contributing factors to winning an arm wrestling (AW) match (Hong, et al., 2011). We tried to find the relationship between strength of shoulder internal rotation and results of AW. This study would, by biomechanical analysis, evaluate the hypothesis that shoulder internal rotators play an important role on normal males in AW match. **Methods** Totally sixty healthy male volunteers who neither have any surgery experience on limbs nor any injury on limbs in last six months were recruited in this study. Thirty athletes were classified as training group; the others were classified as normal group. Winning or losing a match was determined by the rules of WAF (World Arm Wrestling Competition Federation) and World of Armwrestling. The dynamometer of maximum strength was measured with Biodex system (Biodex System 4 Pro, New York, USA). Strength of shoulder internal rotation of all participants should be tested. All subjects were tested before the AW experiment in order to evaluate their shoulder internal rotation force. **Results** Most subjects had maximum strength in eccentric contraction and lower speed ( $45^\circ/\text{sec}$ ). Comparison of detail of strength at different velocities and types of muscle contraction between winner and loser was conducted. The strength of shoulder internal rotation at angular velocity of  $45^\circ/\text{sec}$  ( $p = .001$  in eccentric contraction;  $P = .004$  in concentric contraction) and  $60^\circ/\text{sec}$  ( $P = .032$  in eccentric contraction;  $P = .041$  in concentric contraction) indicated significant differences between winner and loser in overall. **Discussion** Most subjects had maximum strength in eccentric contraction and at slower angular velocity, which indicated that participants had performed maximum strength on dynamometer. Nevertheless, the training subjects' greater strength in larger angular velocity might attribute to the specific characteristics of the sport they played (Bompa, 1999). The strength of arm shoulder internal rotation observed suggested that winner had greater torque values (Newton meter; N-M) than loser. The peak torque values were significantly higher in winner than loser overall in normal group, but not in training group. Winners had no greater peak torque than losers in training group for the following reasons: 1) Some winners of the training group had better technique than winners of normal group, hence they could win even though they had weaker strength than loser. Losers could have greater strength but just used the shoulder internal rotation, which resulted in failure. 2) It's been described that two of ten pairs reversed the situation because the winner did not use full force on dynamometer. 3) It's been presented that two losers of ten pairs did not use full force to content during match. **References** Hong MK, Lin CY, Liao YS, Hong CK, Wang LH. ## LINEAR AND ANGULAR KINEMATICS DURING SWIMMING AT ANAEROBIC THRESHOLD

de Jesus, K.

*Faculty of Sport Sciences, University of Porto*

**Introduction** The anaerobic threshold (AnT) is a frequently used parameter to assess swimming aerobic performance, but the proper incremental protocol step lengths for its determination is still a controversial issue. Fernandes et al. (2011) concluded that short step lengths (i.e. 200m) are valid for AnT assessment, but it remains questionable if swimmer's kinematics is affected by the step duration. We aimed to compare the front crawl linear and angular kinematics at the AnT intensity in three variants of a swimming incremental protocol. **Methods** 8 national level swimmers (21.2±2.2yrs, 1.80±0.06m and 74.1±4.3kg), performed 3 variants of a front crawl incremental protocol (7x200-300-400m) until exhaustion (increments of 0.05m/s, 30s intervals and 48h between protocols). The individual AnT was assessed using the blood lactate vs. velocity curve modelling method. 2 cameras (above and below water surface in the sagittal plane) recorded 2 stroke cycles in each penultimate lap of the step at AnT. Velocity (v), stroke frequency (SF), stroke length (SL), maximal finger depth (MF), backward displacement of the hand (BD), absolute trunk inclination (TI) and hip's intracycle velocity variation (IVV) were calculated. Friedman's test was used to compare protocol variants ( $p \leq 0.05$ ). Results Linear and angular parameters showed similar behaviour at AnT for 7x200-300-400m, respectively: (i) v: 1.26±0.20, 1.22±0.22 and 1.26±0.27m.s<sup>-1</sup>; (ii) SF: 0.49±0.08, 0.43±0.03 and 0.50±0.07Hz; (iii) SL: 2.57±0.35, 2.62±0.35 and 2.66±0.24m; (iv) MF: 0.69±0.07, 0.67±0.08 and 0.66±0.03m; (v) BD: 0.60±0.11, 0.57±0.13 and 0.59±0.13m; (vi) TI: 7.88±4.87, 8.31±4.27 and 9.84±6.62°; IVV: 0.21±0.09, 0.19±0.07 and 0.21±0.05. **Discussion** The different step lengths did not affect the linear and angular kinematics at AnT intensity. V, SF and SL followed the trend as described before for the 200m protocol: (i) at AnT, v and SF begin to increase, while SL slight decreases (Fernandes et al. 2011); (ii) at the same velocity presented in this study, some estimators suggest a change in IVV and TI (Zamparo et al. 2009). Aiming to collect reliable and valid data with low impact (i.e. at shorter time) in swimmers' activities, the current data suggest that the 200m step length is a suitable option to be used in incremental intermittent protocols to AnT assessment. Future studies are required to determine the kinematic and coordinative behaviours throughout an overall incremental swimming protocol. **References** Fernandes R et al. ## HIP-KNEE COORDINATION AND SNATCH PERFORMANCE FOR A NOVICE WEIGHTLIFTER

Ho, K., Lorenzen, C., Wilson, C., Williams, M., Saunders, J.

*Australian Catholic University*

**Introduction** Body positions at specified phases of the snatch have been used to assess technique. The positions adopted, both at the set-up and termination of the second-pull have been identified as markers of technical competence. Yet, it is how the weightlifter transitions from set-up to finish that may be the key to performance. Joint coordination during the snatch has not been investigated in depth. The few studies that explored 'timing', have focused attention on the duration of each phase or concentrated on describing the presence of the double knee bend and its benefit to performance. The aim of this study was to explore coordination through the timing of peak lower limb joint extensions, during the snatch for a novice weightlifter. It was anticipated that a joint coordination sequence that differentiates successful and failed attempts may emerge following data analysis. Such findings would help inform coaching practices. **Methods** A novice weightlifter (age=26years; mass=75kg; stature=171cm; 1RM=90Kg) performed 66 lifts at loads between 88-94%1RM. 3D motion analysis (ViconTM 500Hz) captured the data. Barbell and lower limb joint kinematic variables were normalized to the first peak bar displacement after the second pull. Time to peak joint extension was expressed as a percentage of the normalized lift. Logistic regression was used for statistical analysis. Results Time to peak joint extension occurred at 78.4±2.3% (hip) 78.6±2.4% (knee) and 79.2±2.3% (ankle) for all lifts. No single peak joint extension predicted a successful outcome (hip  $p=0.45$ ; knee  $p=0.67$ ; ankle  $p=0.59$ ); yet, a model including both time to peak hip extension and peak knee extension could predict successful lifts ( $p=0.01$ ; ROC=0.73). In this model, both parameter estimates were significant (hip:  $p=0.01$ ; knee:  $p=0.01$ ) and the size and direction of the relationship was indicated by the odds ratios of 29.41 for hip and 0.04 for time to peak knee extension. **Discussion** Coordination of proximal joints only was found to be significant to the outcome, the probability for success improved when peak hip extension occurred later in the lift and peak knee extension occurred prior to the hip. Effective force production relies on joint coordination in the second pull (Stone et al., 2006). Interaction of the hips and knees develop the force for the vertical jump and is often compared to Olympic weightlifting (Canavan et al, 1996). Our findings are consistent with the suggestion that the stretch-shortening cycle of the knee extensors initiates force production and hip extension continues contributing force in the second pull. **References** Canavan P, Garrett G, Armstrong L. (1996). *J Strength Cond Res*, 10(2), 127-130. Stone M, Pierce K, Sands W, Stone M. (2006). *Strength Cond J*, 28, 50-65.

## 3D KINEMATIC ANALYSIS OF CROATIAN WOMEN HIGH JUMP RECORD – 2,08 M

Bakovic, M., Antekolovic, L.

*Faculty of Kinesiology, University of Zagreb*

**Introduction** Croatian record holder for the women's high jump has been dominant female high jumper in the world for the past several years and she has repeatedly tried to break the world record (2,09m). The aim of this study was to determine kinematic parameters of the her high jump record which is second best jump in the history of women's high jump (2,08m). **Methods** Acquisition of the video recordings necessary for the kinematic analysis was made during IAAF Grand Prix meeting in Zagreb, 31st August 2009. Three digital Sony HDR-HC9E cameras, each with frequency of 50Hz were used. The cameras were recording last two strides of approach, take-off and flight phase. Data analysis was performed according APAS (Ariel Performance Analyses System) protocol standards. Data for the parameters most frequently used in high jump technique studies were calculated. Results Lengths of the strides (penultimate and last) were 233,99 and 208,58cm. Toe to bar distance was 84,00cm. Take off contact time was 0,160sec. Horizontal center of mass (CM) velocities: third last stride (6,89m/s), penultimate stride (7,06m/s), touchdown (6,47m/s) and take off (4,30m/s). Vertical CM velocity at take off was 3,63m/s. CM heights at: touchdown (99,73cm), amortization (106,51cm), take off (130,05cm), maximum CM height (205,54cm) and CM height relative to the bar height (-2,46cm). Knee angle of amortization and angle of take off were 143,31° and 40,17°. **Discussion** Values for the lengths of two last strides of the approach vary greatly due to individual characteristics of jumpers. Some jumpers shorten the last stride to increase the CM height at the beginning of take-off while others lengthen it to lower down CM. Ratio of the lengths of penultimate and last strides changes with the increase of the bar height with tendency to shorten the last stride (Antekolovic et al., 2006). We found that last stride is shorter than the penultimate for 10,85%. Shortening the last stride allows better positioning the take off foot on the

ground, shorter contact time and less decrease of the horizontal speed. Horizontal speed parameters (6,89 and 7,06 m/s) and take off time (0,16sec) are in average range values (6,3-7,5m/s and 0,14-0,18sec) for elite female high jumpers (Dapena, 2000). Take off time is the factor with biggest need for improvement. References Antekolovic Lj, Blazevic I., Mejovsek M., Coh M. (2006). #### ANALYSIS THE TRACKING EYE OF 10 EXPERTS AND 10 NOVICES SAILOR IN A VIRTUAL SIMULATOR.

Manzanares Serrano, A., Menayo Antúnez, R., Segado Segado, F.

*Universidad Católica de San Antonio Murcia*

**Introduction** The visual search strategy is a determining factor in sports where the environmental conditions influenced, like in the case of the sailing. This is due to the influence of the information captured by the sense of sight over decision-making and motor behaviour performed by athletes (Vickers, 2007). The approach we have used aims to describe the visual conduct of experts and novices racer for the previous minute to the start signal. **Methods** The sample was made up by 10 expert and 10 novices sailors, all of them competed on the Optimist Class, in the Region of Murcia (Spain). An automated system of measurement, which integrates the following instruments: a) VSail-Trainer® sail simulator and b) Eye Tracking System®, was used. Research variables were the number of fixations, the location of the fixations and the fixations time on each location made by the competitor. The event was made up by one start of simulated race, with stable conditions of wind, competitor and sea. The simulated race reflected the same conditions as a real start. **Results** The results showed that expert sailors made a greater number of visual fixations than novice sailors. Looking at the distribution of fixations over 16 locations present in the projection of the start of simulated race, we can see that the expert sailors perform a greater number of fixations on the most important locations such as buoys of start, the clock, rivals and telltales among others, while novices sailors performed a greater number of fixations in less relevant locations such as out of screen, others places and boat hull. This also happens with the fixation time because novice sailors spent more time on less relevant localizations. **Discussion** The visual search strategy made by expert sailors is more active than in beginners, because the less experienced sailors tend to make a lower number of visual fixations with a higher fixation time. This is consistent with the theory expounded by Seung-Min Lee (2010) in volleyball, where novice athletes use a less active and more focused on specific localizations visual search strategy, while the expert athlete, uses a more active strategy. **References** Seung-Min. #### GAZE BEHAVIOUR OF ASSISTANT REFEREES DURING THE JUDGING OF OFFSIDE IN FOOTBALL.

Koedijker, J., Schnyder, U., Kredel, R., Hossner, E.J.

*University of Bern*

**Introduction** The offside rule in football is one the most controversial rules in sports due to the relatively high error rate. The occurrence of errors is unsurprising as the task of the assistant referee (AR) is to judge whether an attacker is in offside position at the exact same moment that the ball is played on another part of the field. Sanabria et al. (1998) argued that errors occur because ARs shift their gaze from the attacker with the ball to the second-last defender at the moment of the pass. However, this hypothesis was rejected by studies of Oudejans et al. (2000) and Catteeuw et al. (2009). Unfortunately, methodological limitations (e.g. head-mounted camera rather than eye-tracker), experimental design (e.g. computer experimentation, employment of rather predictable situations) and empirically not completely satisfactory alternatives, make it seems rather premature to discard the gaze shift hypothesis completely. Therefore, the aim of this study was to investigate gaze behaviour of ARs on the field during the judging of offside, to our knowledge, a first attempt to study gaze behaviour of referees in such a dynamic and natural setting. **Methods** Three expert- (FIFA) and 3 near-expert (national level) ARs each judged 36 relatively complex, predetermined attack situations played by the U-21 team of a professional Swiss football club. During the experiment, ARs wore a lightweight, mobile eye tracking device (EyeSeeCam) that was connected to a lap top worn in a backpack to ensure complete mobility. Subsequently analyzed gaze variables are the number of saccades during a complete situation as well as the fixation locations at the moment of the pass. **Results** Results show that on average the experts incorrectly judged 12% of the situations compared to the near-experts who erred in 17% of the situations. First analyses show that ARs, irrespective of expertise and situation type, rarely fixate the passer during the moment of the pass, but focus the offside line well in advance. Interestingly, the experts seemed to make a lower number of saccades over the course of a played situation compared to the near-experts, who appear to shift their gaze more often between the passer and offside line. **Discussion** The current study confirms earlier findings stating that ARs do not shift gaze from the passer to offside line at the moment of the pass. Further, this finding also brings about a new set of relevant questions about how (and how accurate) ARs actually are able to determine the moment of the pass – until now an unaddressed topic in the field. **References** Catteeuw, P, Helsen, W, Gilis, B, Van Roie, E, Wagemans, J (2009). ## THE EFFECT OF MOTOR SKILL TRAINING AT LOW VERSUS HIGH SPEED IN SOCCER PERFORMANCE

Kvalø, M., Ingvaldsen, R.P., Hansen, B., Aune, T.K.

*Nord Trøndelag University College*

**Introduction** A generalized motor program is an abstract memory representation of a class of movements that share invariant features (Schmidt, 1975). The generalizability of such programs is according to Schmidt (1991) a matter of the variability of the practice building them. The theory states that an acquired motor program can be executed in countless ways and transferred from one set of requirements to another, simply by selecting the optimal values of temporal and spatial parameters of the program (Kwon et al., 2011). The purpose of the study was to explore the effect of training at low versus high speeds, when the test required the players to perform at their maximum. Method 16 male soccer players at level 4 and 5 in the Norwegian league, volunteered for the experiment. The task was receiving the ball, turning and stopping the ball inside a defined square. The subjects were randomly allocated to a low-speed group (LS) training the task at or below their breakdown speed, and a high-speed group (HS) training at or slightly above their individual breakdown speed. The players were tested before and after the training period. A ball projection machine was used to set the speeds of the balls. Results Comparison of the pre and post data showed a significant improvement for both groups in breakdown speed ( $p < 0.05$ ), and interestingly the relative improvement for the HS group were significantly larger compared to the LS group ( $p < 0.05$ ). In the post test there were a significant improvement for the HS group with respect to the time between the first and second touch ( $p < 0.05$ ), as compared to the LS-group. Additionally, there was an increase in time between the first and the last touch controlling the ball for the LS-group ( $p < 0.05$ ). Discussion Indicators for high skill performance in soccer are a short time interval between the first and second touch, and between the first and last touch in controlling the ball. The results indicate that training close to ones breakdown speed is not only beneficial for improving these skill indicators, but also that there is only positive transfer of skills from high to lower speed, and not from low to higher speed. This can be an indication that the generalizability of motor programs works best inside the parameter range, and not so well when the aim of the training is to extend the range of the program. ## AMPLIFICATION OF ERROR: A LEARNING STRATEGY TO IMPROVE MOTOR SKILLS

Milanese, C.1, Corte, S.1, Salvetti, L.1, Cavedon, V.1, Agostini, T.2

*1:School of Exercise and Sport Sciences, University of Verona, Italy. 2: Department of Psychology, University of Trieste, Italy*

**Introduction** The correction of technique errors in motor skills represents one of the major issues in motor control and motor learning literature. A good technique is an essential prerequisite in performance improvement and injury reduction. The aim of this study is to test the efficacy of an alternative teaching strategy called Method of Amplification of Error (MAE) and to compare the relative effectiveness of MAE to the traditional direct instruction (DI) and to a no-feedback control condition (C). MAE assumes that amplifying the subject's "main" error in a given motor skill would allow him to better understand what is not-to-be-done, thereby correcting motor errors. Methods Twelve golfers were assigned to one of three groups: DI feedback, MAE feedback and C without feedback, based on their handicap (H), (1 professional, 2 medium H and 1 high H for each group). During the training session each athlete performed 20 swings (7 swings pre-training (T0), 6 swings feedback training and 7 swings post-training (T1)). After a week the athletes performed retention test (T2). Participants used their own driver and wore appropriate golf shoes. The feedback focused on the "main" error diagnosed as the incorrect position of the participant's centre of mass projection. Kinematic outcomes were recorded with a motion analysis system (VICON 1.5.1, 8 cameras, 500Hz), a dedicated software (VICON Workstation 5.2) was also used for digitalization and reconstruction of the marker positions. Nonparametric statistical analysis was performed using SPSS version 16.; the Mann-Whitney test was conducted to assess significant differences between groups at three levels: T0, T1 and T2. Statistical significance was set at  $P \leq 0.05$ . Results At baseline (T0) kinematic outcomes were similar between groups ( $P > 0.05$ ). At T1 and T2 MAE showed a greater improvement ( $p < 0.05$ ) than DI and C for club speed (T1: 4.83%; -2.35%; 0.55%, T2: 6.19%; -1.4%; -0.26%, respectively), as well as for ball speed. In fact, MAE showed higher percentage change values than DI and C at T1 and T2 (4.11%; -6.33%; 1.6%; 9.87%, 0.94%; 1.9%, respectively). The same pattern was found for the duration of the swing phases: MAE showed a significantly decreased of tempo at T1 and T2 from the take away to the late backswing and from the early downswing to the ball contact ( $p < 0.05$ ). Discussion In this study the effect of amplification of error strategy in golfers with different ability levels was evaluated. The present findings suggest that MAE is an effective strategy for correcting the pattern of motion in a short time. Further research is necessary to evaluate the persistence of MAE feedback effects over time and their impact on the learning of other sport tasks.

## INDIVIDUAL AND ENVIRONMENTAL FACTORS ASSOCIATED WITH MOTOR SKILLS IN CHILDREN

Coelho, E., Mourão-Carvalho, I.

*University of Trás-os-Montes and Alto Douro*

**Introduction:** This study investigates the association among individual characteristics (age, gender and BMI), schoolyard's characteristics (area, type of equipment) and motor skills in childhood. Methods: The sample included 203 children (89 girls and 114 boys) aged 5-6 years ( $5,91 \pm 0,419$ ) of kindergarten. The Gross Motor Development Test second edition (TGMD-2) was applied to assess motor skills, and weight and height to calculate the BMI. Areas of schoolyards kindergarten were calculated using the AutoCAD software and equipment were characterized according four categories: no equipment; playground equipment; sport equipment and playground+sport equipment. Logistic regression was used to estimate the magnitude of association between variables. Results: Children shows four levels of motor competence: very poor 14,3%, poor 13,8%, below average 21,7% and average+above average+superior 50,2%. The results from binary logistic regression, associated age as a risk factor of motor competence (OR= 0,240; 95% CI 0,108-0,536 95%). The characteristics of the schoolyard as the area (OR= 0,282; 95% CI 0,092-0,863) and equipment (OR= 0,147.; 95% CI 0,53-0,410) are preventive factors. Conclusions: Motor skills with age decrease. Larger areas of the schoolyards and a greater variety of equipment are associated with a higher motor competence.

### IS SURROUND INHIBITION REALLY FUNCTIONAL?

Márquez, G., Keller, M., Lundby-Jensen, J., Taube, W.

*Catholic University of Murcia. University of Fribourg. University of Copenhagen.*

**Introduction.** Research investigating activity in the primary motor cortex (M1) has indicated that at the onset of a finger movement, unwanted contractions of adjacent muscles are prevented by inhibiting the cortical areas representing those muscles. This phenomenon is called surround inhibition (SI) [1]. It seems that this mechanism is relevant for the performance of selective finger movements, since an enhanced SI has been shown in professional musicians [2] and a lack of SI was evident in the affected hand of patients with focal hand dystonia [1]. However, SI has never been tested in a functional setting. Therefore, the present study tested the implications of SI during real piano playing, and how SI was affected by the task complexity and the previous experience. **Method.** For this purpose 19 subjects (10 untrained subjects and 9 experienced musicians) were asked to play piano with three different fingers (thumb, index and little finger) of the right hand in two different conditions: playing piano rhythmically with one finger (single finger condition) and with three fingers (three fingers condition). In order to assess SI, Transcranial Magnetic Stimulation (TMS) was applied over the contralateral motor cortex using an intensity that evoked a motor evoked potentials (MEP) in all tested muscles (FDI, APB and ADM). MEPs were elicited during the movement preparation and at the onset of movement execution (phasic phase). SI for the inactive muscles were calculated by the ratio of the MEP size measured during one of the two phases (preparation or phasic) to the MEP size measured during a control condition (resting hand position). The ratio between the MEP size in those muscles that did not participate in the actual finger movement (surround muscles) and the control MEP elicited during a control condition (resting hand position) was taken as indication for the amount of SI. A three way RM-ANOVA was performed with TASK COMPLEXITY (single finger vs. three finger condition), PHASE (preparation vs. phasic) and GROUP (musicians vs. controls) as factors. This analysis was performed for SI of FDI, APB, and ADM. **Results.** Results display a statistically higher SI in the preparation phase than in the phasic phase during the single finger condition for all three muscles. The analysis revealed statistically higher FDI SI for the three finger than for the single finger condition when tested in the phasic phase. However, in the preparation phase, results revealed higher APB SI during the three finger condition than in the single one, and the opposite for the ADM muscle. No significant differences in the SI were found between groups although the piano player demonstrated generally higher SI values. **Discussion.** Our results have shown a task and phase specific modulation of surround inhibition but there was no significant experience related modulation of this neural pathway during a functional task like piano playing. **References.** [1]Beck et al. ### AMETROPIA/DEFECTIVE VISION, VISUAL DEFICITS AND MOTOR PERFORMANCE IN SCHOOL SPORTS

Jendrusch, G., Krabbe, J., Feja, L., Platen, P.

*Ruhr-Universität Bochum*

**Introduction** In childhood and puberty essential physical and school developments take place. Poor eyesight in this phase – which is marked through fast/big changes in motor performance and on physical, psychological and emotional level – represents a handicap, as is known. Concluding, the basic correlation between a good eyesight and a safe, successful engaging in sports activities, as well as a motor development are documented through numerous studies. A database concerning the topic “Defective vision in school and its consequences on motor abilities” does not yet exist. **Methods** Against this background a study at 17 elementary schools and 6 high schools concerning ametropia/defective vision in school sports, together with a simultaneous survey of motor abilities (German motor performance test DMT 6-18; Bös et al., 2009) has been carried out. Participants were tested with 8 tests to assess a complete motor fitness profile involving strength, endurance, coordination (under time pressure and under precision demands) and flexibility. In parallel, various tests to detect ametropia and visual deficits have been carried out (visual acuity test, auto-refraction, stereoacuity and contrast sensitivity test). A total of 1.222 children/teenagers (52.2 % male; 47.8 % female) at the age of 5-18 participated in the test (mean age: 8.9±1.7 years). **Results** A synoptic view of the visual test results showed that 25.4 % of the children were classified (according to how they participated in school sports) as ametropic (needing correction of defective vision). This means, a defective vision has been discovered for the first time in the context of the visual test, or else they participated in school sports without actually needed visual aids, or rather, with insufficient correction. Another 15.1 % of the children had noticeable deficits in the visual performance profile, which is what made the observance of the development of the visual performance soon necessary. The children with defective vision attained significantly worse overall results in the motor performance test than the ones without defective vision (2p<0.05). 38.3 % of the pupils with defective vision achieved results below or far below average in the motor performance test (emmetropic students: 12.1 %). The coordination test “balancing backwards” showed analog results (2p<0.05). **Conclusion** The high rate of ametropia/defective vision and the correlation between eyesight in deficit and weaknesses in motor performance shows that regular visual tests are necessary in order to enable the detection and correction of deficits early. Simple screening tests should be implemented in the everyday school (sports) life. **References** Bös, K. et al. (2009). *Deutscher Motorik-Test 6-18 (DMT 6-18)*. Hamburg: Czwalina.

### MUSCLE RELAXATION OF THE FOOT INDUCES INTRACORTICAL INHIBITION OF THE HAND MUSCLE

Kato, K.1, Nakata, H.2, Nakagawa, K.1, Uchida, Y.2, Kanosue, K.2

*Waseda University*

**Introduction** Muscle relaxation is an important factor to make good performances in sports, but the mechanism has not been well understood. Previous study using fMRI suggested that The primary motor cortex was activated during voluntary muscle relaxation as well as during contraction (Toma et al., 1999). Therefore, muscle relaxation is an active process requiring cortical activation, rather than just the end of muscle contraction. The study on motor control of multilimb motion showed that muscle contraction in one limb influences the muscle activities in other limbs (Baldissera et al., 2002). The objective of this study was to clarify how the relaxation of one muscle influences on corticospinal excitability in other remote muscles by using single-pulse transcranial magnetic stimulation (TMS) (Ex.1). Then, we investigated the contribution of short interval intracortical inhibition (SICI) using double-pulse TMS (Ex.2). **Method** Ten participants voluntarily relaxed their right foot from dorsiflexed position in response to an auditory signal. Single (Ex.1) and double (Ex.2) TMS was given on the hand area of the left primary motor cortex at different timing before and after the onset of relaxation. Motor evoked potentials (MEPs) were recorded from their right extensor. SICI was evaluated from the MEP amplitudes of single and double pulse. **Result** In Ex.1, the MEP amplitudes of the hand muscles increased compared to the resting condition in the period of before relaxation onset of the foot. On the other hand, in the period just after relaxation onset (0ms ~ 100ms), the MEP amplitudes of the hand muscles decreased. In Ex.2, The SICI decreased before the relaxation onset of foot, it increased after the relaxation onset. **Discussion** The corticospinal excitability of hand muscle decreased in response to the relaxation of foot (Ex.1). Moreover, the result of Ex.2 indicated that muscle relaxation of foot increas-

es SIC1 and hence may assist in reducing cortical excitability in hand muscles. Thus, the decrease of MEP observed in Ex.1 was produced in the cortical area. References Toma K et al., *J Neurosci*. 19:3527-3534. 1999 Baldissera F et al., *J Physiol*. 539: 903-911. 2002

### THE INFLUENCE OF CATCH TRIALS ON THE CONSOLIDATION OF MOTOR MEMORY IN FORCE FIELD ADAPTATION TASKS

Focke, A., Stockinger, C., Diepold, C., Stein, T.

*Karlsruhe Institute of Technology*

**Introduction** In neuroscience it is generally accepted that human motor memory contains neural representations of the physics of the musculoskeletal system ("internal models", Kawato, 1999). Force field studies are an established tool to analyze the characteristics of such internal models (Shadmehr and Mussa-Ivaldi, 1994). Following acquisition, internal models undergo changes over time denoting the consolidation of a motor memory (Robertson et al., 2004). The aim of the study was to investigate whether catch trials during force field learning, on which the force field was turned off suddenly, could also influence the consolidation of motor memory in more complex tasks (higher viscosity, unsupported arm) compared to previous studies (Overduin et al., 2006). **Methods** Forty-six subjects performed 256 center-out movements at a robotic manipulandum in two different velocity-dependent force fields (35 N-s/m). Two control groups learned force field A on day 1 and were retested in the same force field on day 3 (AA). Two test groups additionally learned an interfering force field B on day 2 (ABA). While control and test group 1 performed all trials under force field conditions, for the control and test group 2, 48 catch trials (~19%) were embedded pseudo-randomized within the 256 movements. To quantify performance, for each trial in the force field the enclosed area between the hand trajectory and the straight line joining start and target point was calculated (Caithness et al., 2004). Mean scores of the first and last 16 movements were calculated and compared, whereas catch trials were excluded from the calculation. **Results** The results showed a consolidation of force field A for both control groups. Test groups showed no consolidation of force field A (with catch trials) and even a poorer performance on day 3 (without catch trials). **Discussion** It can be stated that for our experimental set up (higher viscosity, unsupported arm) catch trials did not lead to consolidation of motor memory in terms of memory stabilization from day 1 to day 3, when an interfering force field was learned on day 2. The higher complexity of the task seems to lead to worse consolidation processes. Maybe an increase of trial number would enhance the performance during the adaptation-phase (Diskrell et al., 1992). Further studies should continue concentrating on tasks of different complexity as the consolidation of motor memories needs to be investigated in various settings to be understood sufficiently. **References** Caithness, G, Osu, R, Bays, P, Chase, H, Klassen, J, Kawato, M, Wolpert, DM, Flanagan, JR (2004). *J Neurosci*, 24, 8662-8671. ### LEARNING AN ENERGY-DEMANDING AND BIOMECHANICALLY CONSTRAINED MOTOR SKILL, RACEWALKING: MOVEMENT REORGANIZATION AND CONTRIBUTION OF METABOLIC EFFICIENCY AND SENSORY INFORMATION

Heugas, A.M., Majed, L., Chamon, M., Siegler, I.A.

*Univ Paris-Sud, UR CIAMS (EA 4532)*

**Introduction** Many studies on motor learning focused on understanding the process of passing from a novice status to increased levels of expertise when learning a complex motor task involving a large number of degrees of freedom. But only a few studies also examined, inspired by the metabolic optimization theory (Sparrow, 1983), energetic and perceived exertion factors in order to establish a link between movement reorganization, metabolic efficiency and perceived exertion (Lay et al., 2002). In doing so, this study investigated how novices learn an energy demanding and biomechanically constrained athletic task like racewalking. The first aim was to examine if movement reorganizes according to some fundamental strategies, proceeding in different stages (Newell, 1985). The second aim was to investigate the link between movement reorganization, metabolic efficiency and perceived exertion. **Methods** Seven participants undertook 7 racewalking learning sessions on a motorized treadmill, with increased velocity as the experiment progressed, in order to reach a goal performance speed of 10 km.h<sup>-1</sup>. Peripheral/central perceived exertion ratings, kinematic (gait parameters; relative phases) and metabolic data (VO<sub>2</sub>; HR) were collected during the 1st, 4th, 6th and 7th session. **Results** Repeated-measures (Learning Session-Speed) ANOVAs on kinematic data showed a proximal-to-distal directional trend in movement reorganization, with significant practice-related changes in pattern coordination and decreased variability. Early movement reorganization occurred at the 1st session ("coordination stage") and progressed until the 4th session ("control stage") to reach a plateau. In contrast, metabolic efficiency and peripheral perceived exertion continued optimizing until the last session. Peripheral perceived exertion presented the highest correlation with the global movement reorganization variables. **Discussion** These results support the existence of an early/immediate reorganization in movement with learning, presented in Newell's (1985) model as the "coordination stage" and in favor of a directional trend, from proximal to distal levels. The optimization trend of metabolic aspects occurred probably concurrently with the control stage. More specifically, it seems that peripheral perceived exertion could be an important factor in refining movement and in minimizing metabolic energy expenditure. **References** 1. ### VISUAL SEARCH AND ANTICIPATION IN INTERNATIONAL ICE HOCKEY PLAYERS

North, J.S., Saunders, L.M.

*St. Mary's University College*

The skill of anticipation is critical to success in sport, where performers must make predictions of what is likely to happen under severe time constraints. This skill is especially important at an elite level where perceptual-cognitive aspects of performance are more likely to discriminate players than physical or physiological characteristics (Williams & Reilly, 2000). The majority of research into anticipation in sport has compared participant groups sampled from opposite ends of the skill continuum (i.e., experts vs. novices). We tested an international ice-hockey squad and conducted within group analyses to investigate if differences in visual search behaviour emerged between the most successful and least successful anticipators within the squad. Participants were presented with dynamic, life-size video sequences that were filmed from a first person perspective and represented a 1 vs. 1 situation that a player may encounter in an ice hockey match. The participants' task was to anticipate what action the opponent would produce next. Initially, the international squad was compared against a novice group to assess construct validity of the test. The international squad were significantly more accurate in

their anticipation decisions than the novice participants. The international squad was then ranked according to their anticipation accuracy with the most accurate and least accurate players selected for further testing. In the second phase of testing, visual search data was recorded from these two players whilst making anticipation decisions. Significant differences emerged in visual search strategy, with the most successful player making more fixations, of a shorter duration, across more features within the display in comparison to the least successful player. The research shows that even within an international squad, significant differences are present with regards perceptual-cognitive skill and contributes to recent findings on the complex and multi-dimensional nature of expertise. The potential value of perceptual-training programmes is highlighted. Reference Williams, A. M., & Reilly, T. (2000). #### THE INFLUENCE OF SOAP OPERAS IN THE BUILDING OF THE WOMEN'S BODY IN THE 80'S

Toledo, E., Schiavon, L.M.

*UNICAMP/UNESP*

**THE INFLUENCE OF SOAP OPERAS IN THE BUILDING OF THE WOMEN'S BODY IN THE 80'S** Introduction This paper is part of a research carried out about the validation process of fitness center gymnastics in the Modern Era, focusing in the 80's decade, in Brazil (Toledo, 2010). Considering the high level of audience of Brazilian soap operas and their trendsetter role, the aim of this research is to bring up data and reflections about their influence (and theirs characters) on the building of the feminine body model, in this decade. Method This research is historical and documental (Gil, 2007), with a qualitative approach when analysing the sources (Arostégui, 1995). Universe: VEJA (from 1980 to 1989), Brazil's highest circulation magazine in the 80's (currently it maintains this position). Randomic sample of 93 VEJA magazine editions, including the supplement VEJA São Paulo (about 30% of the universe). Results and Discussion Through the analysis of VEJA's articles and images it was clear the relationship with the building of a new feminine body, gym and television's celebrity. This building was influenced by the United States of America (Courtine, 1995) and European countries, on behalf of both sportsmanship and a beautiful, dexterous and strong body (Ehrenberg, 1991; Silva, 2001). The most beautiful Brazilian actresses, performing in the soap operas in this time, report in the articles the use of workout to obtain a harmonious, beautiful and successful body. Body building (practice booming in this time), the "Cooper" method and the "Jane Fond Workout" were pointed out as the new body practices they adopted. The articles exalted these new practices and praised the actresses' bodies, raising in the readers what they have still been consuming through the images of the soap operas: the desire of a new body model, lean and with defined muscles, given by workout, in line with the search of excitement (Elias and Dunning, 1992). #### THE HISTORICAL PRODUCTION OF THE PHYSICAL EDUCATION COLLEGE OF MATO GROSSO FROM THE DOCUMENTAL ORGANIZATION

Ferreira, T., Moreira, E.C., Toledo, E.

*Universidade Federal de Mato Grosso*

**Introduction** Based on preliminary studies, it is know now, that the records of the history/memory of the Physical Education and of the Sport in the State of Mato Grosso, are found kept in several ways and in different sources, being still inaccessible to the Academic community that intents to work in the area. It's noticeable then, the importance of elaborating and developing studies that rescue and organize the printed documents that contain the history of the Physical Education College of the Federal University of Mato Grosso – FEF/UFMT, making it possible the usage of such information by consulting an organized material. **Methods** The present study is characterized as a descriptive historical research, once it objectives the accomplishment of documental records of the FEF/UFMT. The study adopts a qualitative approach, because there is a comprehension depth of the social phenomenon through the analysis of printed records. (RICHARDSON, 1999). **Results** An information gathering of the first primary sources found was made, amongst selected papers for this study. Among the most relevant, at the moment, there are the teachers' Class Diaries of 1982 and 1991; documents of partnership agreement between the FEF/UFMT and the State of Mato Grosso Culture and Education Bureau, aiming at the execution of combined development project of the institution's levels of Licensure, of 1982; partnership agreement between the FEF/UFMT and the Instituto Euvaldo Lodi, to develop the project: "Diagnose of the Physical Education and Sports of Greater Cuiabá", of 1979; physical ability tests for candidates to the Physical Education course, from 1988 to 1993; records of the first Congresses, Meetings, Symposiums, and Development Courses in the area of Physical Education in Cuiabá, Mato Grosso; letters and complaints from academics dissatisfied with the available pedagogical structure and FEF/UFMT's facilities; teaching plans of the teachers who taught classes at the College from 1980 on, besides printed materials, used in classes as well as evaluations applied by the academics at that time. **Discussion** From de documental gathering accomplished, it was verified that historical elements of the sport were already part of the UFMT even before the creation of the FEF. That verification was possible after the rescuing, organizing, reading and classifying of the documents found, in other words, the files keep important information within a historical, administrative and personal context. The information in such documents need to be preserved for being records of the institutional memory and for their contribution as source for future research, that help the development of the institution. References RICHARDSON, R. J. Pesquisa social: métodos e técnicas. 3. ed. São Paulo: Atlas, 1999.

## FROM FRAGMENTATION TO SYNTHESIS IN SCIENCE

Balagué, N.1, Hristovski, R.2, Torrents, C.3

1: INEFC Barcelona (Spain), 2: Ss. Cyril and Methodius University, Skopje (Rep. of Macedonia), 3: INEFC Lleida (Spain)

**Introduction** In the past two decades progressive advances have been made in explaining and modeling different levels of organized matter through universal dynamical concepts. The aim of this study was to examine the change of linguistic space, i.e. conceptual landscape and profile of scientific fields under the absence and presence of general explanatory principles derived from nonlinear dynamic systems theory (NDST) and statistical physics (SP). Specifically, we aimed to model the conceptual space of science as a self-organizing system, and to emphasize the position of sport science within it. Methods Characteristic general concepts from ten scientific fields (classically seen as quite separate) were treated as linguistic degrees of freedom. The dimension reduction and the analysis were conducted using cluster and hierarchical principal component analysis. Distances  $d$  between science fields were calculated as  $d = 1 - q$ , where  $q$  is the cosine similarity (the overlap order parameter) between the vectors that defined the conceptual spaces of scientific fields. The order parameter  $q$  as a measure of conceptual coherence was projected within the space of the first two principal components. This procedure enabled us to visualize the structure of basins of attraction, i.e. the domains of conceptual coherence, and the saddle points representing the linguistic barriers between scientific fields. Results The absence of NDST-SP interpretative concepts led to growing fragmentation of scientific disciplines; the maximal distance, as a measure of fragmentation, was  $d = 0.78$ , and showed a tendency for growth. However, the presence of NDST-SP explanatory concepts, characteristic over the last two decades, brought about a stabilization of this fragmentation, with maximal distance of  $d = 0.66$ . In particular, the tendency towards fragmentation within the domain of sport science was suppressed. This was evidenced by the decreased value of population entropy, i.e. the dimension of the space spanned by significant principal components. Discussion Whereas separate scientific fields maintain their context-dependent language (distances do not go to zero), general concepts form an embedding explanatory space within which a stabilizing synthetic knowledge becomes feasible. Scientific research may be envisioned as a self-organizing process within linguistic space in which, as a result of cooperative processes between scientific fields, a new hierarchical structure and synthetic world view has emerged (Hristovski, 2012). ## ATHLETES' AND DOPING CONTROL OFFICERS' ON-SITE EXPERIENCES DURING REAL DOPING CONTROLS

Peters, C., Postler, T., Schulz, T., Oberhoffer, R.

Technical University of Munich

**Introduction** During doping controls interpersonal contact and communication between athlete and doping control officer (DCO) may influence the control situation, resulting in a neutral and relaxed or displeasing and uncomfortable atmosphere. Therefore, the aim of the present study was to survey German athletes and DCOs concerning their on-site experiences during doping controls. Methods In a cross sectional survey 115 DCOs received a DIN A4 envelope containing one sealed DIN A5 envelope for the DCO himself and a second sealed one to be handed to the athlete during the next doping control. In a written short-form questionnaire both groups were asked to judge the behavior of their counterpart independently of each other. Facts, personal observations, subjective impressions and individual perceptions with regard to the currently finished doping control were asked. Participation was voluntarily and anonymously and considered issues of privacy and confidentiality. Results 43 high elite athletes (response rate 37.4%) and 54 DCOs (response rate 47%) completed the questionnaires (42 matches). Athletes stated more frequently to be prompted for something than DCOs confirmed to have requested: to draw up the jumper (A: 21/39 vs. DCO: 19/49) or to drop the trousers (A: 27/39 vs. DCO: 16/50). Although some DCOs (12/49) prompted to allow a nonrestrictive view of the urine leaving their body just every second athlete (20/39) stated a careful observation during urinating in reality. Altogether athletes confirmed DCOs working professionally (yes: 42/43; 1 no comment) in collecting urine and/or blood samples. Discussion Significance of the survey is limited (small samples, self-selection in participation, social desirability of answers, etc.). Nevertheless, it provides an informative basis on different perceptions of athletes and DCOs during the same doping control. Overall, DCOs behavior was confirmed to be professional, which is in agreement with results from a Switzerland survey (Lamprecht et al., 2010). However, while DCOs possibly assumed to have reminded only, athletes took this remembrance as a prompt more frequently. In addition to the detailed briefing of DCOs with regard to sampling procedure educational programs should include recommendations for the interaction with athletes more often. References Lamprecht M, Gebert A, Stamm H. (2010) Athletenbefragung 2010: Befragung der Athletinnen und Athleten zu Dopinginformationen und Dopingkontrollen. ## 'UNDERMINING' OR 'OVERMINING': IS THERE A THIRD WAY IN THE UNIFICATION OF SPORT SCIENCE?

Jonasson, K.

Malmö University

In the announcement for the 18th annual congress of the European College of Sport Science (ECSS), the organizers discuss the benefits and pitfalls of reductionism in the field of sport science. This paper addresses the question of unification of disciplines in 'hyphen sciences' such as sport science. While having the multi- and interdisciplinary organization ECSS as a point of departure, and perhaps as a point of arrival, the presentation concerns different attempts at unifying the study of sport. Epistemological, ontological, and disciplinary endeavors to create a comprehensive system of knowledge of sport will be scrutinized. These varying attempts will be discussed with the concepts 'undermining' and 'overmining' (Harman, 2009). The object-oriented philosopher and speculative realist Graham Harman utilizes these concepts to demonstrate that most attempts at describing reality end up in either undermining, i.e. small reductionist schemes (atoms, cells, etc.), or in overmining, i.e. grandiose determinist structures (nature, capitalism, etc.). Instead of giving oneself up to those two strategies we might, Harman suggests, depart from the "middle kingdom" of objects, actors and heterogeneous networks that the sociologist/anthropologist of science Bruno Latour (1993) has pointed out. The paper thus concludes, contrary to the announcement of the conference – i.e. that "the 2013 ECSS Congress in Barcelona seeks to help sport science make its own leap forward towards an understanding of ourselves not as part of a technical world but as interacting parts of an indivisible whole: nature" –, that sport science mustn't skip the step of the 'technical world' since this, as is argued within science and technology studies, is the intermediary region between different disciplines. ## HOW FAIR IS FAIR PLAY

Plested-Alvarez, M., Casals-Rispau, S., Vallejo-Rendón, G.

*GITT, University of Antioquia*

Introduction: We determined some socio-sportive and psico-social concepts that negatively influence the moral, ethical and social concept of 'fair play' that sportspeople and the people around them have. The tracing methods and the analysis done, allowed the elaboration of a conceptual map (Plested, M.C., Giraldo, B.S., 2001) that are discussed in this study. We concluded that in some cases fair play is conceptualized through actions which actually represent unfair play. We propose some cultural and pedagogical sportive ways to solve this social conflict. Methods: A qualitative methodology was applied to terminologically analyze the statements (Budin, 1998). The concept of 'representative virtual psychological space of each implicated' (Sánchez Medina, G. 1987) was applied. Common conceptual units were found across all cases which demonstrate that a social network underlies (un)fair play so that it was analyzed as a social case study. Discussion: Not only in the amateur sport it's easy to find this kind of (un) fair play. "Professional sports may be one of the most misunderstood occupations in the world. The public sees the mansions, the bling, and the fancy cars. What it doesn't feel is the insecurity of a profession that averages just two and a half to four seasons before someone younger, faster or stronger comes along. It doesn't see the scam artists who suck away salaries and it doesn't see the egotism and sense of entitlement that can lead a ... to believe that the rules that govern society do not apply to them" as said in Scandals of the decade. It is necessary to change some sport parameters and structures taking into account the cultural, social and family environments and also of the staff of each of those sportspersons. Results: After tracing the life details of sportspersons, it was systematically found that the specific staff was part of the scene, working under his or her instructions or those of a trainer or a relative. "Doing something hidden or behind their soul mate is nothing to be ashamed of until they are caught". "His team was forced to forfeit its games and his father and coach were banned from [that] League". Some of the specific teaching parameters in sport need to face up some universals like remaining silent in case of psychological, moral, material or physiological damages. Unfortunately, it seems that this is a fixed parameter of those who call themselves 'members of a civilized sport culture'. We want to present some positive ways to solve it. References: Budin, G. ## PHYSICAL EDUCATION: HUMANITIES/SOCIAL SCIENCES OR BIOLOGICAL SCIENCES?

Chaves, A., Correia, R., Ferraz, O.L., Tani, G.

*Universidade Federal do Triângulo Mineiro/ Universidade de São Paulo*

Introduction By questioning if Physical Education falls within humanities/social sciences or biological sciences, we face great difficulty in finding answers. It is known that this definition is fundamental to professional training and development courses. According to Silveira e Tani (1996), physical education is still incipient as a field of study and it is difficult to define its identity. This study aims to investigate how Brazilian undergraduate and graduate students identify physical education as an area of study. Methodology A field study was conducted involving 21 subjects: 9 women around the average age of 27.37 years old and 12 men around the average age of 29.84 years old, undergraduate and graduate Physical Education students in public and private educational institutions. It was used a questionnaire with three reflective questions about the field of study of Physical Education. Data was analysed according to the Collective Subject Speech (CSS) by Lefèvre and Lefèvre (2003) and to the rate of answers percentage. Results Regarding the questionnaires, 61% of subjects said Physical Education is characterised as humanities/social sciences as much as biological sciences, for 29% of subjects as biological sciences, for 5% as humanities/social sciences and 5% of them were uncertain about the topic. As far as its specific research area, 38% said it is related to biological area, 24% to humanities/social studies, 19% to both and 19% were not able to define it. When they were asked to reflect about Physical Education as humanities/social sciences and/or biological sciences while elaborating a research project, 43% of subjects said they did not taken it into consideration, 38% said they thought it as biological sciences and 19% as humanities/social sciences. Conclusion It was found that only a minority has been concerned about the academic identity of Physical Education. As the assessment of Physical Education as an area of study has not been undertaken in Brazil, whereas the researchers in this field little address the matter, the fact that graduate students are not concerned with the topic can contribute to the continuity of the uncertainties and ambiguities related to the issue. ## TIME AND SPORT

Hogenova, A.

*Charles University*

Time and Sport Keywords: Time, intentionality, sport, body, Dasein This text discusses the implications of the Aristotelian concept of time for understanding the human body. Aristotle saw time as a number of movements, and thus established the implications which we find today in the phenomenon of "Gestell". Heidegger introduces us to the present, which contains pastness (die Gewesenheit), which penetrates into the future, so we have Dasein which is a temporal schedule in which the present includes the past and the plan of the future. What does this mean for sport? It is necessary to return to the primordial spring of sport, the primeval desire to move, the primitive unity of the human body and soul with the world around that is shown in motion. Then we realize that e.g. business in sport is an added value, we realize that the Olympics have to be an utterly deep and undeniable expression of the reverence to the gods on Mount Olympus. Then we look around with different eyes, phenomenological eyes. The body has a special kind of negation, a special kind of absence, a special kind of privation. It contains everything and yet it contains a fundamental absence. The body is embodied temporally, not in an Aristotelian way, i.e. successively. Science describes succession, successivity; however, it overlooks the processes that occur concurrently, co-existentially, simultaneously How is it possible that we cannot see or understand this miracle of simultaneity? Why is this so? Because we work on Aristotelian time which is difficult to escape from and understand differently. Scientific description of the human body in sport is also only made in Aristotelian time, which we can all realize if we let the question emerge from the concealedness we call obviousness. **DO CHESSPLAYERS HAVE GREATER COGNITIVE SKILLS THAN FOOTBALLPLAYERS?**

Birch, J.

*Oslo and Akershus University College of applied sciences*

DO CHESSPLAYERS HAVE GREATER COGNITIVE SKILLS THAN FOOTBALLPLAYERS? We are often inclined to argue that the primary skills of chess are cognitive ones like memory, mathematics and analytical planning (Binet 1966). We are also often inclined to argue that the primary skills in football are motor skills like eye-foot coordination, balance, spatial orientation and speed of reaction (Schreiner 2010). Several studies though, argue that what separates expert footballers from intermediates are not motor skills but perceptual and planning skills (Vayens et al. 2007, Savelsbergh et al. 2002). Research on chess players suggest that the expertise of high performance do not rely on excellent memory or high IQ (Bilalić 2007), but on perceptual skills and picking out relevant information (Chase & Simon 1973, de Groot 1978). This is even more so in rapid-, blitz- and bullet chess (Calderwood et al. 1988). It seems that the intuition that sport performance goes on without thought, and hence does not involve cognition, stems from the observation that successful action does not need a pre-reflective or accompanying reflective phase. The same seems to be the case in bullet chess. Does that lead us to claim that bullet chess players play on automation, without cognition, even without consciousness? If we still believe that bullet chess players do indeed perform cognitive, intentional and flexible action, should we not think about football players in the same way? The talk aims to undermine the idea that athletes are mindless, not intelligent or without cognitive skills. On the contrary, even though sport (or chess) performance goes on without declarative thought, perceptual and cognitive skills lie at the very core of successful action. References Binet A. (1966). **ACUTE EFFECT OF AEROBIC EXERCISE LONG TERM ON THE LEVEL OF CENTRAL SEROTONIN IN OLDER WOMEN**

Barros, J.F.1, Lopes, K.M.D.C.2, Browne, R.A.V.1, Elsangedy, H.M.1, Farias Junior, L.F.1, Nunes, R.N.1, Lima, R.M.3, Oliveira, R.J.3

*Universidade Federal do Rio Grande do Norte*

Introduction Exercise is considered a challenge to homeostasis, since several regulatory mechanisms and adaptation (peripheral and central) are activated during or after practice, as perceived changes in neurotransmitter systems, in particular, in the serotonergic system (Meeusen and Piacentini, 2001). Thus, the aim of this study was to investigate the acute effect of aerobic exercise of long duration on the central serotonin levels in older women. Methods Transversal study in which the sample consisted of 17 elderly women, physically active ( $\geq 6$  months) which were divided into two groups: group undergoing aerobic exercise at anaerobic threshold intensity for 1 hour (EG; n= 9;  $63.0 \pm 2.54$  years old; BMI=  $26.31 \pm 2.22$  kg.m<sup>-2</sup>;  $VO_{2peak}$ =  $21.34 \pm 1.76$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) and control group (CG; n= 8;  $62.62 \pm 4.4$  years old; BMI=  $26.76 \pm 3.29$  kg.m<sup>-2</sup>;  $VO_{2peak}$ =  $20.11 \pm 1.92$  ml.kg<sup>-1</sup>.min<sup>-1</sup>). Blood samples were collected in moments of rest (pre-exercise), immediately post-exercise and 20 minutes after exercise for subsequent comparison of prolactin levels, which has been used as a marker of neuroendocrine activity of serotonin. Results The GE ( $5.14 \pm 1.55$  ng/ml) and CG ( $4.60 \pm 1.39$  ng/ml) did not submit significant change ( $p > 0.05$ ) in prolactin level immediately after exercise (GE=  $5.70 \pm 1.73$  and GC=  $4.53 \pm 1.39$  ng/ml), respectively, and also did not show after 20 minutes of post-exercise recovery (SG=  $5.15$  and BF=  $4.6$  ng/ml), respectively. Discussion The results showed no significant increase in prolactin levels of EG immediately after exercise, which might be explained by lipolysis due to the demand of free fatty acids as an energy substrate causing displacement of tryptophan from the albumin binding sites, producing increase in the levels tryptophan-free and hence increased the precursor of serotonin in the central nervous system (Huffman et al., 2004). Thus, it is assumed that aerobic exercise long-term may cause acute increase in serotonin levels central verified by the prolactin level in elderly women physically active. **14:00 - 15:00****Mini-Orals****PP-SH03 Physical Education and Pedagogics [PP] 1****TEACHING INDICATORS RELATED TO THE BODY EXPRESSION BASIC CONTENTS**

Coterón, J.1, Padilla, C.2, Torrents, C.3, Sánchez, G.4

*1. Universidad Politécnica de Madrid. 2. Universidad de Cádiz. 3. INEF Cataluña. 4. Universidad de Salamanca*

Introduction Interest on Body expression as educational content is growing. Body expression is an educational subject with contents of creative dance, mime and body language. However, studies examining the most significant indicators for teaching this subject are scarce and contradictory. The aim of the present study was to examine which were the most significant indicators of Body expression about Technique, Methodology and Creativity and their association with teaching contents (Body, Space and Rhythm) in undergraduate students of Physical Activity and Sport Sciences. Methods A sample of 79 undergraduate students of Physical Activity and Sport Sciences completed the CUVORE questionnaire (Gil & Coterón, 2012) after attending 30 sessions of Body expression. The importance that they gave to all variables was measured. Data were analysed using SPSS 16.0. We performed a multiple logistic regression analysis (stepwise method) to state how teaching variables (Technique, Methodology and Creativity) might predict the importance given by students to contents. Results The significant results found are described. Methodology ( $t=3.84$ ,  $p<0.01$ ) and Technique ( $t=3.36$ ,  $p<0.01$ ) predicted Body

contents ( $R^2=0.41$ ,  $p<0.01$ ). Likewise only Methodology ( $t=4.89$ ,  $p<0.001$ ) predicted Space contents ( $R^2=0.23$ ,  $p<0.01$ ). Methodology ( $t=2.91$ ,  $p<0.01$ ) and Creativity ( $t=2.49$ ,  $p<0.05$ ) predicted Rhythm contents ( $R^2=0.27$ ,  $p<0.01$ ). Methodology emerged as the main predictor in all contents. Discussion The present study indicates that participants scored Methodology as the most important indicator. These findings provide support for evidence that is important to develop strategies to enhance skill acquisition (Mainwaring et al., 2010). Furthermore, in line with our results Torrents et al. (2008) found in a study with similar sample the relation between Creativity and Rhythm. These results suggest that creativity tasks supported by music might be an appropriate strategy for the better acquisition of rhythmic skills. These findings provide information about the student's perception and suggestions on teacher's pedagogical approaches for the teaching of this subject. References Gil, J., Coterón, J. (2012). EmásF. ### CHALLENGES FOR A RESEARCH METHODOLOGY OF CIRCUS ACTIVITIES PEDAGOGY IN PHYSICAL EDUCATION

Ontañón, T., Bortoleto, M.

*Universidade Estadual de Campinas*

Introduction The inclusion of circus activities as a physical education subject has consolidated in recent years (HIRT & RAMOS, 2008), tending to increase gradually (PRICE, 2012). After analyzing 257 documents on the area, we observe a large number of reported experiences of teachers who use the circus activities in their classes (ONTAÑÓN, 2012). This scenario reveals the urgency of knowing these experiences, seeking to highlight the achievements and difficulties founded, so others professionals can join in an effective and secure way. This requires developing a specific research methodology in order to know the relevant aspects of these experiences. Methods To determinate best instruments and methods to research in a school environment, we follow the methods proposed by Anguera (1999) and Woods (1996). Additionally, we used four categories of analysis developed by researchers of the "Group of Research in Circus Arts" (CIRCUS) at the University of Campinas (Brazil). Results The most suitable instruments for this work are interview and direct observation (non-participatory and systematized) accompanied by a field diary to register the information related in the categories described below: - Historical and cultural circus context: relations between circus history and culture with the content worked in class. - Pedagogy of circus activities: description of the goal of the classes, the methodology, and other aspects such as the use of the ludic element as a catalyst of learning, standards to select the content, planning, progression and evaluation systems. - Safety culture: information about the security measures used in class. - The teacher and the institution: information about the teacher formation, approaches to the circus and institutional support. Discussion The observations allow us to know the general aspects of the educational project but we try also to identify broader issues (MACRO) and specificities (MICRO) that characterize each of the experiences, and therefore, their potential and limitations. In addition, interviews enable us to experience the data triangulation, which, according to Anguera (1999) will help us to validate subsequent analyzes. References ANGUERA, T. ### TEACHING DANCE: A COMPARTIVE STUDY OF USING PREFERRED LEARNING STYLES IN THE TEACHING OF DANCE BETWEEN ENGLISH AND DANISH DANCE ACADEMIES

Cunliffe, D.1, Rist, R.2, Ratcliffe, C.3

*1: SSU (Southampton, UK), 2: TPSPA (Tring, UK), 3: RDBS (Copenhagen, Den)*

Introduction The art of teaching dance is a dynamic and ever-changing array of perceptions and interpretations, yet often breaks down at the point of transferring the information from the dance teacher to the pupil. A variety of teaching methods have been extensively used; Movement based approach (Marx, 2009) and Student-centred approach (McCarthy-Brown, 2009), yet neither of these methods have addressed utilising preferred learning styles of individual pupils in the teaching delivery, and as such, traditional teaching methods of dance have failed to maximise learning potential. Therefore, this study aimed to investigate how teachers from differing cultures of dance utilised the knowledge of how children learn to better inform their teaching practice. Methods Appropriate ethical clearance was granted from a University before gatekeeper permission was granted to assess the preferred learning styles of school aged pupils ( $n=20$ , mean age 14years), from one Dance Academy school within the United Kingdom and Denmark respectively. Parental permission was also gained for all children to participate, prior to the completion of the Learning Styles Questionnaire for Children (LSQ-C). In addition, two semi-structured interviews were conducted with 3 consenting teachers of dance from each of the participating schools to ascertain a) their current teaching strategies and b) any change in their teaching practice. Results The mean scores of the LSQ-C for all children across the two schools exhibited a non-significant difference. Exploratory factor analysis (EFA) established that teachers of dance between the two sub-cultures follow similar teaching practices. When teaching strategies were compared against using knowledge of individual pupil's preferred learning styles, no difference was evident between the two sub-cultures. Discussion The exploratory analysis led to the initial conclusion that dance teachers deliver their lessons in the manner in which they were originally taught. However, there were variances of teaching strategies when knowledge of their pupils' preferred learning styles were gained, with experienced teachers unwilling to adapt/change their teaching philosophies across both sub-cultures. In contrast, the less experienced teachers were more willing to experiment by altering their teaching practices to suit the individual needs of their pupils with much greater success in pupil learning. Whilst these results support the work of dance teachers who educate children through the practical delivery of movements, it must be stressed, that from this study, by not adapting the lesson to suit the needs of the individual pupil could alienate the eventual learning of children. Therefore, dance teachers need to ensure they select a differentiated delivery strategy to allow all children to learn. References Marx, (2009). Rec & Dance, 80(4), 12-17. McCarthy-Brown, N. (2009). ### TRADITIONAL SPORTING GAMES AND EMOTIONS IN GIRLS AND BOYS

Lasierra, G.

*INEFC-Lleida*

Introduction The distribution of physical and sporting activities into motor action domains (MAD) provides teachers with a series of anchors around which they can organize motor tasks in physical education (PE) (Parlebas, & Dugas, 1998). Each category of games (or MAD)

produces different types of relationships and, therefore, has different kinds of impacts on players (Oboeuf, Collard, & Gerard, 2008). This study examined the emotions reported by PE students when performing activities in four MAD (psychomotor domain and three socio-motor domains: co-operation, opposition and co-operation/opposition). Methods Participants were 220 students from six secondary schools in the Spanish regions of Catalonia and Valencia: 119 girls (54.09 %) and 101 boys (45.90 %), all twelve years old. The Games and Emotions Scale (GES) (Lavega, March, & Filella, 2013) was applied in order to identify the intensity of the emotions experienced. The 34320 observations were analysed using a model based on generalized estimating equations (GEE), with Gaussian family, identity link function and exchangeable correlation structure. Results The statistical analysis revealed significant differences ( $p < .001$ ) between the experiences of positive and negative emotions, with the highest ratings being given to positive emotions ( $M = 5.94$ ,  $SD = .118$ ). The results also revealed significant differences ( $p < .001$ ) between the psychomotor domain (lowest ratings for positive emotions) and the socio-motor domains. Girls reported significantly more intense emotions ( $p < .001$ ) in all the domains except for opposition games. Discussion Participation in traditional games triggered, above all, pleasant experiences. The reported emotions varied notably between the socio-motor domains and the psychomotor ones, this being consistent with previous literature (Oboeuf et al., 2008). Parlebas and Dugas (1998) similarly found that these two broad families of games trigger very different processes. The present study confirms that socio-motor experiences can make a key contribution to emotional well-being in both male and female students. References Lavega, P., March, J., & Filella, G. (2013). Sports games and emotions. Psychometric properties of the Games and Emotions Scale (GES) and its use in Physical Education. *Revista de investigación educativa*, 31(1), 151-165. Oboeuf, A. ### PHYSICAL EDUCATION AND EMOTIONAL WELL-BEING: THE EMOTION OF JOY IN COOPERATIVE GAMES

Araujo, P., Filippetto, M.C., Lavega, P.

*Instituto Nacional de Educación Física de Catalunya /INEFC-Lleida*

Introduction One of the main contributions of physical education is to improve social and emotional wellness through enjoyable learning (Bisquerra, 2003). The cooperative motor interaction offers great possibilities to promote positive learning based on a pact rules. Participants in a cooperative game must overcome four types of relationships established by the internal logic: relationship with the other participants, with space, with time, with the material (Parlebas, 2001). Bisquerra (2003) highlights the joy as key positive emotion to generate personal and social well-being. This study aimed to identify which aspects are associated with the emotion joy by students to participate in cooperative games with and without victory. Methods A total of 117 university students (INEFC) (Age  $M = 19.6$ ,  $SD = 2.23$ ) participated in this study. Four sessions and twenty games were applied. After each game the students described a comment about the more intensely emotion they felt following the 'Games and Emotions Scale' (Lavega, Filella & March, 2013). We conducted a content analysis of 191 comments to identify units of meaning associated with joy. Results We identified five main arguments to explain the presence of the joy associated with the internal logic of cooperative games: 1) Pact: positive participation in the pact group, 2) Relationship with others: positive motor interaction, 3) Relationship with time 3.1 Dynamic game, 3.2 joyful participation in the competition, winning or losing, 4. Relationship with material: overcoming the difficulty of manipulating an object successfully. Discussion The arguments identified confirm the key role of cooperation to elicit the joy through positive experiences oriented to the emotional well-being (Johnson & Egelard, 1992). Cooperative games behave like a micro-society (Parlebas, 2001) where the protagonists learn to build democratic positive relationships of pact. The comments show the strength of the internal logic of cooperative games to elicit the emotion of joy. References Bisquerra, R. (2003). ### EXPRESSION OF EMOTIONS IN COOPERATIVE GAMES: A GENDER PERSPECTIVE

Serna, J., Lavega, P., Araujo, P., Sáez de Ocariz, U., López, V., Font, R.

*INEFC-Lleida*

Introduction Although the contribution of cooperation to societal wellbeing has been widely recognized by various disciplines it has received scant attention in the field of physical education. This study examined the relationship between certain key features of the internal logic of cooperative motor games and the emotions reported by female and male participants. Methods Participants were 170 students from four secondary schools in Catalonia: 87 girls (51.18 %) and 83 boys (48.82 %), all twelve years old. After playing two cooperative games (four sessions) the students were immediately given the validated "Games and Emotions Scale" (Lavega, March, & Filella, 2013) and asked to rate the intensity of the different emotions they had experienced. The data (19890 observations) were analysed using a model based on generalized estimating equations (GEE), with Gaussian family, identity link function and exchangeable correlation structure. Results The statistical analysis revealed significant differences ( $p < .001$ ) between the three types of emotions. The highest ratings corresponded to positive emotions ( $M = 6.15$ ,  $SD = .171$ ), followed by ambiguous emotions ( $M = 3.11$ ,  $SD = .184$ ) and, finally, negative emotions ( $M = 1.07$ ,  $SD = .164$ ). There were also significant differences ( $p = .043$ ) between cooperative games with a fixed-role system (single role) and those that allowed a local exchange of roles (games with more than one role). No significant differences were found when comparing the intensity ratings of men and women. Discussion The social nature of cooperative motor games not only encourages but also requires participants (both women and men) to relate positively to one another. Games which allow players to switch roles involve a greater repertoire of motor responses and relationships, thereby exploiting to the maximum the positive interactions which may occur between participants (Green & Rechis, 2006). This research highlights the key role that these games can play in terms of providing a natural environment in which positive emotions can be fostered within a relational context (Salen, & Zimmerman, 2003). **EMOTIONS IN THE INTROJECTIVE MOTOR TASKS. A GENDER PERSPECTIVE**

Font-Lladó, R.1, Rovira, G.1, López-Ros, V.2, Lavega, P.3

1: UdG-EUSES (Girona, Spain); 2: UdG (Girona, Spain) 3: UdL (Lleida, Spain)

Introduction The introjective motor tasks, specially self-awareness, have a positive effect on personal and social well-being (Kabat-Zinn, 2003). The aims of this study were: (a) identify the emotional experience during cooperative and psychomotor introjective motor tasks in men and women. The research used Lazarus' (1991) model of basic emotions grouped into positive, negative and borderline (in this case, ambiguous). Method A total of N= 86 (69 men, 17 women) first year students of the undergraduate degree of Sports and Exercise Science at EUSES-UdG participated in the study. The Games and Emotions Scale (GES) (Lavega, March & Filella, 2013) was applied in order to identify the intensity of the emotions experienced. The subjects participated in four practical introjective sessions (2 psychomotor tasks without motor interaction and 2 cooperative tasks with playmates; Parlebas, 2001). Results Results showed higher values for the positive emotions than for negative and ambiguous emotions ( $p < .001$ ). Men and women experienced the emotions with the same intensity. However, there does exist significant difference between the intensity of negative emotions experienced by women and those experienced by men. A significantly higher emotional intensity was generated by the cooperative tasks ( $M = 1.06$ ) than in the psychomotor ones ( $M = 0.9$ ,  $p < .001$ ). Both men and women experienced similar intensity whereas in psychomotor, women ( $M = 0.75$ ) experienced emotions with significantly less intensity than men ( $M = 1.05$ ,  $p = 0.25$ ). Discussion During the introjective motor tasks, the intensity of positive emotions was significantly more than negative or ambiguous. The results reveals that introjective motor tasks have a positive effect on personal and social well-being. These findings are consistent with previous literature (Kabat-Zinn, 2003). Cooperative motor tasks elicited more intensity of emotions than psychomotor domain. This suggests that social interaction could have an effect on the intensity of emotions felt. Men experience negative emotions with more intensity, even though the intensity of positive emotions is much the same in men and women. Lavega et al (2013) found similar results . **ELEMENTARY-SCHOOL PHYSICAL ACTIVITY AND GENDER-RELATED NEEDS**

Song, J.

*Jeonju National University of Education*

This study of the operation of the after-school physical activity and gender analysis of the needs of students to activate the After-school athletic activities were aimed at. To this end, the city, Jeollabuk-J-school and elementary school physical education conducted seven school students in grades 5-6 in 300 people (150 people men, women 150) that is considered bad faith of the seven students, except for 293 people (148 people Male, Women's 145 people), by gender, physical activity needs of the school survey was to collect information, after-school athletic activity is of the operation of seven schools to see the large schools (30 classes or more), teacher name, junggyumohakgyo (20-29 class or higher) teacher name, a small school (less than 20 classes), teacher name, sampling a total of three teachers were in-depth interviews. Information collected SPSS (Ver 15.0) program, causing a chain were analyzed using analytical methods. Analyzed results are as follows: First, the elementary school of the operation of the school physical activity compulsory for the majority of the school is run by a few select On, and plans for setting up students and their parents are trying to cater to the needs of the school's facilities, but circumstances or. Instructor due to supply problems have not been able not meet the requirements. Second, information about after-school physical activity requirements on how and where in the school gymnasium, the school athletic director preferred appeared as a teacher, athletic boys in Home football, table tennis, girls dodgeball, badminton and much preferred. Boys in gym class and other requirements in the appropriate personnel, teachers were required integrity, girls get free time, the auditorium expansion, and after-school hours, abolish MORE demanded a ban.

**AGE GROUP EFFECTS IN POSITIVE OUTCOMES IN FEMALE VOLLEYBALL PLAYERS**

Santos, A.J., Gonçalves, C.E.

*University of Coimbra*

Introduction During the involvement in sport context the young athletes live experiences that can lead to positive results. The enjoyment is an important factor for adhesion and maintenance in sport (Kimiecik & Harris, 1996). The sport can serve as inhibitor of risk-behaviors, promoter of resilience and pro-social individuals recurring to the developmental assets framework (Benson, 2002). The values acquired through sport participation and reflect in sport attitudes are important due to moral judgment is not isolated from the social context, such as team, and can be transferred for other context (Shields & Bredemeier, 2009) This study pretends to verify the age effects on sources of enjoyment, development assets and sport attitudes of youth female volleyball athletes. Methodology The sample was composed by 326 subjects with ages between 12 and 16 years ( $M = 14.15$ ,  $SD = 1.09$ ). They responded to the Sources of Enjoyment in Youth Sport Questionnaire, Developmental Assets Profile and Sport Attitudes Questionnaire. An ANOVA test was performed. Results It wasn't verified age effects in sport attitudes and developmental assets. Relatively to sources of enjoyment it was verified differences in the affiliation with peers ( $p = .007$ ). The athletes present low levels of cheating and unsportsmanship, and reveal good level of positive factors. Discussion The differences observed could be due to the number of years involved in sport, and the relationship developed with the peers during the maintenance in sport. It seems that Volleyball as norms and rules that lead to low levels of anti-social attitudes in sport. Conclusion The coaches must pay attention the age group needs of the athletes but also to other individual and contextual characteristics to improve the youth development. Benson, P. L. (2002). Adolescent development in social and community context: a program of research. *New directions for youth development*, 95(95), 123-47. doi:10.1002/yd.19 Kimiecik, J. C., & Harris, A. T. (1996). ## ENJOYMENT AND POWER REGULATIONS IN PE

Furuly, C.D.

*NTNU Trondheim*

Introduction Research shows that many students stop enjoying physical education (PE) as they grow older. Boys enjoy PE more than girls, and the difference increases with age. (Prochaska, Sallis, Slymen, & McKenzie, 2003). Changes during the transition from primary school to junior high school are often pointed out as the reason why enjoyment in PE decreases. (Andrews & Johansen, 2005). Some research also show that shame during showering and changing before and after lessons leads to less enjoyment in PE, especially for girls (Wabakken, 2010). According to Foucault the society are more regulated than ever, and humans are not so emancipated from power as we think we are. (Markula & Pringle, 2006). The aim of this study was to map female students experience with changes in PE during the transition from primary school to junior high school. Locker room rules and behavior was also explored. Methods Interviews with eight girls from two different 8th grade classes (13-14years old) and observations of four PE lessons were conducted. The interviews were conducted during lessons with one student at a time and had a duration from 10 to 20minutes. The girls were chosen with help from the teacher and with a goal of finding someone who didn't enjoy PE too much. Results All of the interviewed girls enjoy PE. The study found that these girls enjoy PE more in junior high school, than they did in primary school. The teachers behavior and the classmates attitude towards winning were mentioned as reasons for this. The two classes had different locker room behavior; while the girls in one class changed and showered together, the other class showered and changed one or two at a time or alone in the bathroom. Discussion In contrast to a lot of research the study finds that the girls enjoy PE more in 8th grade than during primary school. Discipline and regulation increase from primary school to junior high school through the introduction of grades and more organized lessons. The study also shows signs of more regulation and rules in the locker room. More power and regulation are usually seen as a negative thing, but according to Foucault it can also be something positive. (Markula & Pringle, 2006). The results are further discussed in relation to Foucault and previous studies. References Andrews, T., & Johansen, V. (2005). ## EFFECTS OF DIFFERENTLY ORIENTED PHYSICAL EDUCATION PROGRAMS ON PHYSICAL EDUCATION ENJOYMENT IN ITALIAN HIGH-SCHOOL STUDENTS

Di Michele, R.1, Spiga, F.1, Semprini, G.1, Toselli, S.1, Ceciliani, A.2, Brasili, P.1, Merni, F.1

*University of Bologna*

Introduction Enjoyment of physical education (PE) is important to develop a positive attitude towards physical activity and sports practice. A variety of physical, psychological, and educational factors have been reported to affect PE class enjoyment, including body mass index (BMI), self-efficacy, perceived competence, and curriculum content (Fairclough, 2003; Barr-Anderson et al., 2008). This study aimed to analyse, in Italian adolescents, the effect of two different physical education programmes on PE enjoyment while considering the moderating effect of BMI, physical performance and selected self-perception variables. Methods 37 Italian high-school students (M:18, F:19), aged 15 to 17 years, participated to two-month PE interventions. A group (M:8, F:10) attended a non-traditional team sports program oriented towards fun and motivation, while another group (M:10, F:9) attended a program focused on individual fitness activities. Before intervention, the BMI, self-efficacy, perceived competence, explosive strength, and aerobic fitness were assessed. A physical activity enjoyment scale (PACES) (Kendzierski and De Carlo, 1991) was administered pre- and post-intervention. Results The mean pre-intervention PACES score was not significantly different between the team sports (61.6, SD:8.1), and the fitness (63.4, SD:7.8) groups. A significant effect PE programs was observed, with a mean score increase of 2.4 (5.9) in the team sports program, and a mean decrease of 2.9 (4.4) in the fitness group. This outcome was similar in boys and girls, and no moderating effect was noticed for physical performance, self-efficacy, and perceived competence. BMI only showed an effect, though limited, with a 1-unit higher BMI associated to a 0.5 lower difference in the PACES score change, for each given group. Discussion The present results show that a highly motivating PE program may increase PE enjoyment in adolescents independently from their perceived competence, self-efficacy and performance level. This emphasizes the usefulness to include, in high-school PE curricula, activities focusing on fun and entertainment rather than on performance enhancement. ## THE EFFECTS OF FOLK DANCE ACTIVITIES ON STUDENT'S ACADEMIC ACHIEVEMENTS AND SOCIAL HARMONY ABILITIES WHO LIVE IN ORPHANAGES

Aydın, M.1, Korkmaz, I.1, Meric Bingul, B.1, Bulgan, C.2, İra, N.1

*1:KOU(Kocaeli, Turkey), 2:HU (Istanbul, Turkey)*

Introduction: In every community, there are many young people and children who need some protection for any reason, such as abandonment, family neglect, socio-economic inability and disintegration of families etc. In such cases, the government has to bear the children's care and education (Tufan and Sokezoglu, 2009). The schools are not enough for children and their future preparation if they are living in orphanages. Sportive and recreational activities not only helpfull to improve their physical, mental and social development but also contribute to develop their academic and social harmony abilities. The aim of this study was to determine the effects of traditional folk dance activities on student's academic achievements and social harmony abilities who live in orphanages. Method: Twenty-four primary school students (12 males and 12 females) were participated to this study voluntarily. All students were lived in Kocaeli Kassel Children Village in Turkey. During their two academic semesters, it was applied Traditional Turkish Folk Dance activities every week. Activities were continued 2 hours and they were 2 days in a week. Students' academic scores and social harmony abilities from last year and also this year were collected and analysed by using SPSS program. The average and frequency values were calculated and also Wilcoxon Signed Test was used for evaluation of the differences between the semesters. Results: In results, students' fall semester scores was found  $3,6125 \pm 0,68987$  and spring semester scores was found  $3,8083 \pm 0,68138$  after the folk dance activities. It was found that significant differences between the semesters of student's academic achievements and also participation of social activities ( $p < 0,05$ ). Conclusion: It is necessary to increase the success of academic achievements as well as to increase their ability to live independently of

children who are in under protection (Cetin, 2008). Gilman et al, (2004) were found that activities in out of the school were effected positively to mental health of children who had academic failures and communication problems (Erkan and Safoz, 2009). In this study, it was found that significant differences in academic achievements of children before and after the activities ( $p < 0,05$ ). We believe that these differences were due to the increase of students' self-expression, socialization and more concentration to their courses. In social harmony abilities, it was found a significant difference in participation of social activities ( $p < 0,05$ ) but it were not found differences in other social abilities. It shows that folk dance activities were increased students' willingness to participate to activities. References: Cetin, H., (2008), Journal of Firat Sağlık Hizmetleri, Cilt:3, Sayı:9 Erkan, Saföz. ### **A STUDY ABOUT THE DEVELOPMENT AND APPLICATION OF THE WORKBOOK FOR FOSTERING PUPIL'S CREATIVITY AND CHARACTER IN ELEMENTARY SCHOOL PHYSICAL EDUCATION**

Shin, K.

*Jeonju National University of Education*

**Introduction** The curricular change in Korea has been approached by top-down innovation (Jewett, Bain, & Ennis, 1995) which is developed by experts outside the school. Recently the ministry of education emphasized creativity and character as the critical contents in the school curriculum including physical education according to the 2009 revised physical education curriculum. Although the interest and endeavours of developing creativity and character have already existed, few studies of the exact concepts and properties of these qualities have been conducted especially in the elementary school physical education. Therefore the aim of this study was to develop the workbook and to confirm its application effect on pupil's creativity and character by using qualitative method. **Methods** This study focused on developing the workbook for fostering creativity and character. First of all, the notions of them were investigated through literature inquiry, and then the workbook was designed after eliciting the elements related with creativity and character from the textbooks of physical education. The effect of applying workbook in physical education class was investigated by using qualitative method with two elementary teachers. They participated in this study as the practitioner of the workbook. Thus data were collected through observation and interview. They were analyzed using domain analysis and taxonomic analysis which were presented by Spradley(1979). Trustworthiness of data analysis was established by using a member-checking procedure and peer debriefing throughout the research process. **Results & Discussion** Craft(2001) found out that creativity can be developed through systematic education and training. Berkowitz(2002) emphasized the necessity of character education for preventing youth violence. Based on these propositions, two workbooks were developed separately. One was for creativity, the other was for character. Creativity can be developed through participation in the cognitive activities of games. The workbook for developing creativity emphasized the scientific principles of materials, knowledge about the contexts of games through participation in game modifying, and understanding the game properties. The workbook for developing character influenced by the 2009 revised physical education curriculum which emphasize various virtues involved in physical activities such as fair play, team work, and understanding others. As a result of testing both teachers and their students, all of them agreed with the effectiveness of the workbook for developing creativity and character. Participants also presented kind of suggestions and information about making and applying the workbook.

### **COMPARATIVE ANALYSIS OF TV VIEWING IN WEEKDAYS AND WEEKEND DAYS IN FUNCTION OF SOCIO DEMOGRAPHIC FACTORS AND PHYSICAL ACTIVITY.**

Abarca-Sos, A., García-González, L., Aibar, A., Murillo, B., Julián, J.A.

*UNIVERSITY OF ZARAGOZA*

**Introduction** The decrease of physical activity (PA) in adolescence has been commonly associated with the increase of sedentary behaviors (SB) (Marshall, et al., 2004), but the link between these variables and their influence factors are undefined (Pate, et al., 2011). **Methods** A representative sample of adolescent of Aragon region (Spain) participated in this study: 1609 adolescents (14,45  $\pm$  1,27 years; 879 boys and 730 girls). Studied variables were: PA, TV viewing in weekdays and weekend days, father and mother professional level and environment. The University of Zaragoza (Spain) provided ethical approval for this research. Two hierarchical linear regressions were conducted to analyze influence factors of TV viewing in weekdays and weekend days following the procedures of another study in Spanish adolescents (Devís-Devís, et al., 2009). **Results** Results showed significant relations between TV viewing in weekdays and gender ( $\beta = -0,060$ ,  $p < ,05$ ), type of school ( $\beta = ,081$ ,  $p < ,01$ ), professional level of father ( $\beta = ,087$ ,  $p < ,01$ ) and PA ( $\beta = -0,075$ ,  $p < ,05$ ). However, significant and negative relations were found between weekend days and gender ( $\beta = -0,060$   $p < ,05$ ) and age ( $\beta = -0,082$   $p < ,01$ ), and positive for type of school ( $\beta = ,072$   $p < ,05$ ). **Discussion** Boys and adolescents in public schools spent more time watching TV both type of days, similarly to a study developed in Spain (Devís-Devís, et al., 2009). In contrast, it can be observed that TV viewing is associated to different variables in function of the type of day: PA is inversely related to TV viewing in week days, age emerged as the strongest predictor in weekend days and father professional level was not related with TV viewing in weekend days. The weekend day organization is freest than week days one and, consequently, adolescents have more autonomy (Pate, et al., 2011). Finally, PA in weekdays displaces SB because free time is fewer in comparison to weekend days (Te Velde, et al., 2007). **References** Devís-Devís J, Peiró-Velert C, Beltrán-Carrillo VJ, et al. ## SWEDISH ELITE SPORT AT A CROSSROADS? SOME RESULTS FROM A STUDY OF GOVERNMENT SUPPORT FOR ELITE SPORT

Norberg, J.

*Idrottsvetenskap*

**Introduction** In 2011, the Swedish government commissioned The Swedish National Centre for Research in Sports (CIF) to examine the structure and impact of government support for elite sport. A study was conducted in collaboration with several research groups under the guidance of Johan R Norberg, researcher at CIF. The result was reported back to the government in May 2012. **Methods** CIF:s survey begins with a comprehensive analysis of the Swedish elite sport system, based on quantitative data relating to sports federations' economy, scope and results at international championships. Thereafter follows a qualitative study concerning the current state of Swedish elite sport, based on interviews with athletes, coaches and sports managers in eight strategically selected sports. Thus, the report also includes a review of international tendencies in elite sport support, a survey of programs for coaching development in Swedish sports and an analysis of sports policy implications of the Swedish government's increased support for elite sport. **Theoretically**, the survey takes its starting point in current research on increased competition in international elite sport (De Bosscher et al 2008, Houlihan & Green 2008). **Results** The study shows that Swedish elite sport has always had a relatively marginal position – at least on a political level (Bergsgard & Norberg 2010). Government support for sport has mainly come in the shape of subsidies to sports facilities, grants to youth sport activities and economic support to the administration of the national sporting federations, while targeted investments in elite sports been few. Furthermore, such investments have had an ambivalent position, viewed as somewhat inappropriate in a social democratic welfare regime based on ideals of breadth and equality rather than elitism and ranking. Thus, the Swedish sports model differs from many comparable countries with a strong focus on "sports for all" rather than elite sport. This is reflected in the organization and conditions of Swedish elite sports. One one hand, local clubs and publicly financed facilities have created good opportunities for young people to try out different sports and develop their skills. One the other hand, there have been few public subsidies to help athletes to take the final step from promising talent to the international elite. **Discussion** In recent years, the Swedish government has taken steps to strengthen the international competitiveness of Swedish sport. This raises the question whether Sweden is about to join "the Global Sporting Arms Race" or if the Swedish government's support for sports will continue to focus mainly on sports-for-all, voluntarism and youth sports. **References** Bergsgard, N. & J. R Norberg (2010) "Sports policy and politics – the Scandinavian way", in *Sport in Society*, Vol 13 De Bosscher et al (2008). *The Global Sporting Arms Race*, Oxford: Meyer & Meyer Sport Houlihan, B. & Green, M. (2008). *Comparative Elite Sport Development*. Oxford: Elsevier

## THE ACADEMIZATION PROCESS IN SWEDEN

Wirén Aakesson, J.

*Institution of Sport Sciences, Malmo University*

**Introduction** Sport research within social science, and sport science (sport studies) education at an academic level are relatively new phenomenon's in Sweden. Research started in the 1970s and before the 2000s there were only a few academic sport educations. Today, research and education are comprehensive and diversified. Also, the sport labor market has been expanding and changing, with more employment opportunities, on the one hand, and a smaller proportion of these being qualified jobs, on the other. The study deals with the Sport Academization process. The purpose is to attain extended knowledge and a deeper understanding of higher sport science education and its relationship to sport research, and the sport labor market - from a perspective of knowledge. **The research questions** are: What knowledge is produced within social science sport research, what knowledge is mediated through higher sport education, and what knowledge is demanded in the sport labor market? How does the production, mediation and demand for academic sport knowledge relate to each other? Do they differ, and if so, in what ways and why? **Four theoretical concepts** are particularly central in the study: knowledge (Berger & Luckmann 1966), paradigm (Kuhn 1962), discourse and institution (Foucault 2008). Bauman's theories about social processes and discourses of different eras are also central (Bauman 1998). **Methods** The empirical material consists mainly of various documents, such as: dissertations, journal articles, educational curriculums, job listings, and various statistical materials. The documents have been analyzed quantitatively, with statistical analysis, and qualitatively, through discourse analysis. **Results** The study shows that there are discrepancies between produced, mediated and demanded knowledge. The largest proportion of research has been produced within the fields of pedagogy, psychology and history. At the same time, almost half of the educations are within Sport Management. Also, preliminary results show that the demand for knowledge on the labor market is mainly expressed through demands of practical knowledge, i.e. knowing how to do things, rather than having knowledge and understanding about things. **Discussion** The main interpretation of observed differences is that research, education and labor market is based on different contemporary logics (ideas and ideals). The differences between mentioned knowledge entities highlights important questions about whether and how research, education and the labor market within sport should be governed. **References** Bauman, Zygmunt (1998). *Work, consumerism and the new poor*. ## QUALITY OF LIFE RESEARCH IN FUTSAL PLAYERS

Santos, A.

*University of São Paulo*

**INTRODUCTION:** Studies on quality of life has been used to indicate the well-being of individuals and groups, as well as identify areas of intervention that can improve people's lives. There are few studies that investigate athletes quality of life and therefore, the use of information in this area has taken little advantage in creating strategies for broad development of athletes. The knowledge in this area can help define a training framework that supports the performance and development of the futsal players. **OBJECTIVE:** The aim is to examine the quality of life in futsal players through a descriptive study. **SUBJECT & METHOD:** The sample comprised 37 participants, 28 men and nine women. They had over 18 years with mean age 21,9 years (SD=3,9). The athletes were affiliated to the futsal federation and took part in formal tournaments. The Quality of Life Index is a generic instrument that characterizes and estimates quality of life in terms of importance-weighted life satisfaction using a specific technique that results in values with the possible range from 0,0 to 30,0 (Ferrans & Powers, 1985; Kimura, 1999). **RESULTS:** The sample presented total QLI 23,9 (SD=3,2) with the minimum of 15,3 and maximum of 29,3. The domains and some factors are as follows: (A) health and functioning domain (24;SD=3) which includes factors like pain (17;SD=7) and sex

life (27;SD=4); (B) socioeconomic domain (16;SD=3) which includes factors like friends (26;SD=4) and financial needs (19;SD=8); (C) psychological and spiritual domain (25;SD=3) which includes factors like faith in God (28;SD=3) and achievement of personal goals (23;SD=5); (D) family domain (22;SD=5) which includes factors like family health (24;SD=6) and children (28;SD=4). **DISCUSSION:** The lowest value was found in the socioeconomic field. The conditions for training and competition should contemplate a career and retirement plan to ensure properly the welfare of athletes. The highest values are in the psychological and spiritual domain. Coaches should recognize the importance to these aspects in promoting the emotional stability of the players (Woods, 2011). These results can help managers and coaches to take decisions that contribute to the performance, based upon the concept of integral human development, both inside and outside the sport scene. **REFERENCES** Ferrans CE, Powers MJ. ### **NORWEGIAN PROFESSIONAL FOOTBALL PLAYERS PERCEPTION OF HIGHER EDUCATION, AND THE IMPORTANCE OF FOOTBALL CULTURE.**

Ødegård, A.

*University of Science and Technology (NTNU)*

**Introduction** The combination of professional football and higher education has been of interest for researchers for many years, but has become even more relevant the last decade do a unstable labour-marked (McGillivray, Fearn, & McIntosh, 2005; McGillivray & McIntosh, 2006). Using Pierre Bourdieu's (1990; 1992) theory of field and capital, this study aims to identify Norwegian professional football players attitude towards higher education. The study will also seek to understand how the football culture, that exist within teams, affect the combination of football and higher education. **Methods** The study will use data generated from in-depth qualitative interviews with 10 professional Norwegian male footballers, witch can be classified as established professionals (19-23 years old). This study will take place between 21-25 march 2013 in La Manga, Spain, during a pre-season training camp. There has been conducted a pre-project witch has given some preliminary results. The preliminary results are based on interviews done with three professional football players in the Norwegian first-division. **Discussion** The primary results show that Norwegian professional football players have a mixed feelings when considering their relationship with higher education. While it does not seem uncommon that professional football players take higher education, their motivation towards seems to be low. The result of this seems to be low grades, or drop-out. Their negative attitude and motivation towards higher education seems to mainly come from their attachment to their football and team culture. The culture seems to downgrade the importance of higher education and rather seems to value material and physical goods. The findings correlates with previous research were it has been found that footballers seems to not value cultural capital, but rather physical capital (McGillivray, et al., 2005; McGillivray & McIntosh, 2006). This can be seen as a problem in today's modern society, where the football labour marked is more insecure, with shorter contracts, lower wages, and a constant danger of career-ending injuries. **References** Bourdieu, P. ### **THE SOCCER SCOUT AND SOCIAL NETWORK THEORY: A QUALITATIVE STUDY OF THE NORWEGIAN TALENT SCOUT IN SOCCER**

Michalsen, Ø.

*Norewegian University of Science and Technology*

**Introduction** This study uses traditional Social Network theory, including The Strength of Weak Ties, Structural Holes and The-Small-World-Phenomenon, to try and understand the soccer scouts role, content and work - related social network. In this study the soccer scout is limited to the talent scout. The talent scouts primary objective is to identify players any club wishes to register with. Previous studies in the field of talent identification focus largely on preferable attributes and skills possessed by young players. Other studies concentrate on which abilities and attitudes talent scouts rank as valuable, while many highlight The Relative Age Effect. Studies regarding talent scouts and Social Network Theory are seemingly scarce. Theory Social Network theory explore the characteristics of relations between participants (Schieffloe, 2003), while The Strength of Weak Ties outlines the significance of relations influenced by inequalities, hence access to new areas of domains (Granovetter, 1973). Structural Holes refers to the potential relationship between two parties (often in) two different social focuses, and the values of establishing the relation (Burt, 2002). The-Small-World-Phenomenon offers insight that our social network is, in theory, much larger than first assumed, due to the systematizing of frequently experiences of coincidences (Watts, 2004). **Method** Five semi - structured interviews were conducted with five different soccer scouts on national and international level in Norway, with the purpose of identifying the scouts role description and key aspects of their work - related social network. **Analysis** Preliminary findings suggests that the talent scouts social networks (i.e. colleagues etc.) are imperative to all scouts. The importance are highlighted by the logic of The Strength of Weak Ties as it gives scouts entry to new information about players and leagues. Other findings show that the scouts willingness to broadcast information are affected by the competitiveness of other clubs. Scouts awareness to the essentials of a broad, deep, close and trustworthy network will most likely showcase their ability to act on potential player targets. Furthermore the findings indicates that these scouts' attention to their social networks are random and accidental. **References** Burt, R. S. (2002). The Social Capital of Structural Holes. In M. F. ### **A MODEL OF DESIGNING INFORMATION SYSTEMS FOR MONITORING THE HEALTH LEVEL OF UNIVERSITY STUDENTS**

Shklyarenko, A.1, Kovalenko, T.2, Pushechkin, N.1, Pashkov, L.1, Ulyanov, D.2

*1: Kuban State University, the branch in Slavyansk-on-Kuban (Slavyansk-on-Kuban, Russia), 2: Volgograd State University (Volgograd, Russia)*

**Introduction** Designing information systems for monitoring has to be based on modern information technologies and on choosing a friendly interface easy enough for non-professional users, who may have little knowledge in the field computing. **Methods** The method of

research is to analyze modern information technologies and to choose the most uncomplicated interface for users with little experience in computing. The source of research was the work on creating the information system for monitoring health based on the principles of prenosological diagnostics of students of Slavyansk-on-Kuban branch of Kuban State University, Slavyansk-on-Kuban, Russia. Results As the processed information on the health of the testees has more than 20 parameters, creating a single database table is considered to be non-optimal. The data are stored in three linked tables: the table of health level, the table of optimal physical load and the table of adaptive potential. The created version of the information system project consists of an executable project module and a set of XML database files. The main form of the project is the table form of the health level. The main menu of the health level table form contains 2 dropdown submenus: Database and Reports. Database menu is used to choose actions with the health level table in whole. You can save it as an XML file, download as an XML file, clear all the contents. Item Reports of the main menu of the optimal physical load form allows to move to the auxiliary report building form. In the upper part of the form you can see the view of the result in HTML format. The lower part of the form alternatively shows the diagrams of the health level and the optimal physical load. To build a diagram you have to choose the corresponding menu item of the upper menu of the form. Having checked the correctness of the diagram built, you are to choose the menu item Save and save the final result as an HTML file. Discussion The created information program clearly demonstrates the state of health level and physical activity individually for first-year students of Physical Education Department and Social Economics Department of Slavyansk-on-Kuban Branch of Kuban State University, Russia. The program is used to monitor the process of correcting the health level and physical activity. It is uncomplicated and gives no difficulty in using the estimation of the students' health state. Peculiarities of Designing Medical Diagnostic Systems // Information Technologies in Health Care Service. 2002. #8-10. p.10-11.

### COMPARISON OF PHYSICAL ACTIVITY MEASURES USING SMARTPHONE BASED CALFIT AND ACTIGRAPH

Donaire-Gonzalez, D., de Nazelle, A., Seto, E., Mendez, M., Nieuwenhuijsen, M., Jerrett, M.

*Center for Research in Environmental Epidemiology (CREAL)*

Background: Epidemiological studies on physical activity lack inexpensive, objective, valid and reproducible tools for measuring physical activity levels of subjects. Novel sensing technologies built in smart phones offer the potential to fill this gap. Objective: We sought to validate estimates of physical activity and determine the utility for large population based studies of the smartphone-based CalFit software. Methods: A sample of 36 subjects from Barcelona, Spain, wore a smartphone with CalFit software and an Actigraph accelerometer for five days. The usability and physical activity measures (vertical axis counts (VT) and duration and energy expenditure predictions for light, moderate and vigorous intensity from Freedson's algorithm) of both devices were compared. Statistical analyses included: (i) Kruskal-Wallis rank sum test for usability measures, (ii) Spearman correlation and linear regression for VT counts, (iii) concordance correlation coefficient (CCC) and Bland-Altman plots for duration and energy expenditure measures. Results: Some 64% of participants were women, mean  $\pm$  standard deviation age was  $31 \pm 8$  years, and body mass index was  $22 \pm 2 \text{ kg}\cdot\text{m}^{-2}$ . The usability allowed that 25 of 36 (69%) subjects recorded at least three days with at least 10 recorded hours of physical activity. The linear association and correlations for VT counts were high (Adjusted R-squared = 0.85 and correlation coefficient 0.932 [95% CI: 0.931 to 0.933]). CCCs showed high agreement for any intensity of physical activity (from 0.73 to 0.91). Conclusions: The CalFit system may provide valid estimates to quantify and classify physical activity. Because cell phones are already carried by many people, CalFit may prove to be more cost effective and easily deployed for large-scale population health studies than specialized instruments that are not routinely carried.

### ESTIMATING THE MOBILITY MODEL OF SOCCER PLAYERS IN VARIOUS SITUATION OF A MATCH

Jamalian, A., Mehrabi, S., Rezvani, R., Hadi, B.

*Sama Technical and Vocational Training College, Islamic Azad University, Andisheh Branch, Andisheh, IRAN*

Introduction In a soccer match, the coach of team dictates his/her program to players, so they should not move or run during the match in their desired manner. It can be assumed that players of each team have their Mobility Model (MM). The MM of players could be an important parameter for assessment of team solidarity. The aim of this study was estimating the MM of soccer players of a typical team in various situation of a match such as defense, attack and counter-strike. Method We used four MM which are very similar to MM of soccer players: Random Way Point (RWP), Pursue, Freeway and Reference Point Group Mobility (RPGM). These models are inspired from literature on the subject of Mobile Ad-hoc Networks and more models can be fined in [1]. First we extracted the certain position of each player from video sequences and then calculated the velocity vector for each player within every second and, using them, calculated the parameters for performance evaluation such as Average Relative Speed and etc. In next phase, we used a Learning-Automata based algorithm by using TFSLA [2] to estimate the mobility model of players. TFSLA is a Fixed Structured Stochastic Automaton (FSSA). As it is mentioned in [3], FSSA are faster than Variable Structured Stochastic Automata (VSSA), so that they are suitable for real-time applications. Results In Defense: RWP = 39%, Pursue = 12%, Freeway = 5%, RPGM = 44%. In Attack: RWP = 4%, Pursue = 25%, Freeway = 13%, RPGM = 58%. In Counter-Strike (as Attacker): RWP = 5%, Pursue = 44%, Freeway = 39%, RPGM = 12%. In Counter-Strike (as Defender): RWP = 3%, Pursue = 52%, Freeway = 34%, RPGM = 11%. Discussion In Defense situation, some players walk randomly and some other run according to the ball position. So the average MM in most cases is either RWP or RPGM. In Attack situation, most of players move regarding the ball possessor and some others pursuing him/her and because of this, RPGM and Pursue model are ranked 1 and 2 respectively. However, in Counter-Strike situations, most players pursuing the ball possessor regardless of his/her team. Even in many cases they pursue each other like vehicles in a freeway. Hence, the average MM is something like Pursue Model or Freeway. References [1] T. Camp, J. Boleng and V. Davies. ### DEVELOPMENT OF A SYSTEM FOR REAL-TIME TRAINING CONTROL FOR GROUP-TRAINING IN ROAD CYCLING

Jaitner, T.1, Kuhlmann, C.H.1, Perl, J.2

*1: Dortmund University of Technology, 2: Johannes Gutenberg University Mainz*

Introduction In junior road cycling practicing in groups is an important type of practice. The German Cycling Federation suggested a ratio of 30:70 between single and group practice. In group practice, the necessary power output depends on the position of the rider in the

group. In the slipstream the power output can be reduced up to 36% while reaching the same speed than in the first position. In the same amount the cardiovascular load and the metabolism load is reduced in rear positions (Neumann, 2000). To optimise group training to individual specifications, speed, the group formation, the position of each rider in the group and the sequence of position changing must be adapted to the individual performance potential of each athlete. Hence, for an individual optimal training effect for all athletes participating in the group training a computer-based online-monitoring and real-time training control tool has to be developed. Using cycling computers like SRM™, Ergomo™ etc., athletes can observe data like speed, power output at the crank, cadence, heart rate etc., easily for themselves. But there is a technological deficit in systems which are able to interact between different athletes to ensure that every single athlete can reach the maximum benefit from a group training. Methods The Training Control System (TCS) consists of a hardware component, a software component and mathematical algorithms for training control (Jaitner and Trapp, 2008). Every bike is equipped with a commercial power measurement system (Ergomo™ or SRM™) and an Ultra Mobile Personal Computer (UMPC). The power measurement system is connected to the UMPC via serial port to transfer sensor data like speed, power, cadence, heart rate as input value for the training control algorithm. Training Control is based on the PerPot model (Endler and Perl, 2012), that has been adapted to cycling. It provides online feedback about optimal speed, group position, cadence, power and heart rate to each cyclist of the group and proposes changes in these variables via the display of the UMPC. Results and Discussion In the first experiments the TCS was able to control and to regulate the group and every single position during practice in the described way. Athletes were able to respond to the suggestions of the TS. Hence, they adapted their individual training load to the TCS-suggested intensity by changing the specific variable. Further studies have to be made to quantify the advantage of the TCS for every individual athlete participating in the group training. References Endler, S., Perl, J. (2012). #### DIFFERENCES IN ISOMETRIC STRENGTH BETWEEN DOMINANT AND NON-DOMINANT UPPER EXTREMITY IN COMPETITIVE TENNIS PLAYERS

Corbi, F.1, Baiget, E.2, Fuentes, J.P.3, Fusté, A.4, Fernandez-Fernandez, J.5

1: INEFC-Lleida, UDL (Lleida, Spain), 2: UVIC (Vic, Spain), 3: UEx (Cáceres, Spain), 4: FCT (Barcelona, Spain); 5 Faculty of Sports Science, Ruhr-University Bochum (Germany)

Introduction Tennis is physically demanding and imposes high-impact loading upon the upper extremity. Repetitive stress on the dominant side in tennis players creates anatomical differences between dominant and non-dominant upper limbs. Some of these differences are an increased size in bone mass and muscle structures and a greater arm concentric internal rotation strength compared to the non-dominant side (Ellenbecker & Roetert, 2003). The aim of this study was analyse isometric strength ratios between dominant and non-dominant upper extremity in competitive tennis players. Methods Twelve male competitive tennis players (mean  $\pm$  SD; age:  $17.2 \pm 1.0$  years; height:  $180.1 \pm 6.2$  cm; weight:  $71.9 \pm 5.6$  kg) from the International Tennis Centre of the Catalonia Tennis Federation (FCT) participated in the study. Measurements were conducted using a strain gauge (500N) connected to a portable MuscLab™ system, and included maximal isometric voluntary contraction (100 Hz) in the wrist, elbow and shoulder flexion/extension, and shoulder internal/external rotation, in both sides (dominant and non-dominant). Results All variables were significantly different in the dominant side compared to the non-dominant side (p values ranging from 0.05 to 0.001). The average difference (%) between sides ranged between  $10.7 \pm 9.4$  % in shoulder external rotation and  $11.5 \pm 4.2$  % in shoulder extension to  $26.4 \pm 12.7$  % in shoulder internal rotation and  $24.6 \pm 7.0$  % in wrist extension. Discussion The repetitive stressors and loading sequences of tennis practice create muscular imbalances leading to characteristic injury patterns and musculoskeletal adaptations. The main results of this study showed the existence of an asymmetry in isometric strength values between dominant and non-dominant upper limbs, supported by previous research in this area (Ellenbecker et al., 2009). Traditionally these differences have been reported using isokinetic devices (Saccol et al., 2010), but the present results indicate that isometric testing also has the potential to evaluate the strength ratios between dominant and non-dominant side in tennis. We can suggest that isometric testing in sports also has the potential to analyze the effects of injury and guide the rehabilitation process. References Chandler, J. et al. (1992). #### VARIABLES THAT CAN INFLUENCE THE PERFORMANCE OF THE OLLIE TRICK

Tessutti, V., Almeida, W.

UNIFEO

Introduction Skateboard is a sport with a huge number of participants, however there is a lack of studies analyzing its movement biodynamic. When you analyze the correct motion of a sport, you can find that there is a proper coordination to perform it. The goal of this study was to evaluate kinematically the Ollie, a trick from skateboarding, through the observation of all body coordination, and others components that can influence the quality of this trick. Methods This is a study where was made the kinematics analysis of the Ollie trick, in the sagittal and frontal plan of the skateboard. The sample of 5 individuals with  $23,8 \pm 3,49$  years old,  $177,2 \pm 2,38$  cm of height, weighing  $68,8 \pm 6,30$  Kg. An obstacle made of wood was used to be passed over, using the Ollie. When the skateboarder could pass it over successfully 4 times in a row, the obstacle's height was raised. It was used a high speed digital camera Fuji Film HS10 (Japan), with a speed of 30 frames per second (sagittal) and 120 frames per second (frontal). To ensure the proper execution of the trick, it was placed an obstacle which has a regulable height. The distance of the obstacle was decided by the skateboarder. After 4 consecutive correct tricks, the obstacle's height was raised in 5 cm. Motion analysis software Dartfish 6.0 (Switzerland) was used to the kinematic evaluation. Five components were measured during the trick: the skateboard's speed in the approach to the obstacle, the distance that the front's wheels lose touch with the ground, the board angle in relation to the horizontal, in the moment when the front wheels were above the obstacle,

and the period of squat to initiate the trick. Results It's verified that the skateboard's speed in the approach to the obstacle was  $13,85 \pm 1,31$  km/h. The board's angle in relation to the horizontal was  $31,11 \pm 3,69^\circ$ , and the board's angle in the moment when the front wheels were above the obstacle was  $45,59 \pm 6,01^\circ$ . The distance that the front's wheels lose touch with the ground was  $78,78 \pm 13,65$  centimeters, and the period of squat to initiate the trick was  $196,18 \pm 82,35$  ms. Discussion The results showed speed and distance as important components of Ollie, as well as the period of squat to initiate the trick and the use of the dominant leg, acting like the impulse's originator. Measuring Ollie's execution, it was possible to note that there is a synchronization between the body segments, although, in some situations the sequence of these segments use is not the ideal, and as result, the movement performance is affected. The survey could conclude that the speed, the board angle and the distance are relevant components, as well as legs and arms synchronization, because once there is no coordination on it, Ollie's performance is affected.

## THE RELATIONSHIP BETWEEN APPROACH SPEED AND JUMP TRAJECTORY IN 3-DAY EVENT HORSES

Dondanville, A.

*Marshall University*

Introduction Both professional and amateur riders compete in the Olympic discipline of 3-Day Eventing, sometimes with deadly consequences (1). Of particular concern are horse falls (1) where the horse hits and somersaults over the jump. The upward force necessary to clear a jump is generated at take-off (4). If the approach is too fast, energy is wasted in a braking mechanism (propping), inhibiting upward impulse. Conversely, if the approach is too slow, the horse may not have enough horizontal velocity to clear the fence width (4). Modern cross country requires repeated velocity changes from 350-600mpm (3), which makes creating optimal take-off conditions (4, 5) difficult. Therefore, the aim of this study was to explore the relationship between approach speed and the resulting jumping trajectory. Methods Horse/rider pairs (n=22) were filmed jumping both a vertical and a square oxer from each lead at three different speeds (Collected, Working, and Forward). A camcorder recorded two approach and two landing strides and the jump itself, electronic timers measured the last stride's velocity, and a reflective ball attached near the center of the horse's scapula was a visual reference to determine trajectory. Results The take-off trajectory of 264 efforts was determined using Dartfish software by connecting a line drawn between the reflective ball locations as the leading front limb and trailing hind limb left the ground. An ANOVA comparing trajectory to actual speed ( $p < .01$ ), take-off distance to actual speed ( $p < .001$ ), and landing distance to actual speed ( $p < .001$ ) showed significant differences. Further ANOVA analyses revealed that jumping trajectory, take-off distance, and landing distance were significantly different when comparing working to forward and collected to forward paces ( $p < .01$ ). Conclusion If the horse fails to transfer enough horizontal velocity into vertical impulse to clear the jump's vertical height or the horizontal velocity decreases as a result of overcompensated vertical impulse, the possibility for falls increases. These data show that as approach speed increases, jumping trajectory flattens, necessitating a longer take-off distance to allow the flight apex to clear the center of the jump. References 1. ## STABILIZATION OF THE ANTICIPATED POINT OF TOUCH DOWN IN TENNIS EITHER BY DECELERATION OF THE RACKET HEAD BEFORE THE HIT OR THE USAGE OF TOPSPIN

Hochstein, S.1, Blickhan, R.1, Wagner, H.2

1: *Friedrich-Schiller-University Jena, Institute of Sport Science, Motion Science (Germany)*, 2: *Westfälische Wilhelms-University Münster, Institute of Sport Science, Motion Science (Germany)*

Introduction It is a general finding that for goal directed striking sports such as tennis, table tennis, golf, volleyball, hockey and soccer the general time-course of the end segment's velocity, e.g. the velocity of the tennis racket, is surprisingly similar [1,2]. Around the anticipated point of impact the end segment decelerates. In all such sports the ball is not hit or released at the instant of maximum velocity of the end segment but during a following decelerating phase at lower velocity. Here we show that both deceleration prior to stroke of the racket-head and the usage of topspin enhances the precision of the point of touch down of the ball. Methods A simplified analytical model of hitting a ball (not including drag and lift) is used to obtain the variation of the point of touch down with respect to the racket-head velocity and acceleration. A second model simulates the motion of the tennis ball during flight in consideration of the drag and the lift (magnus effect) with respect to the spin using the equation of motion solved by the MATLAB toolbox SIMULINK. Results An optimum trajectory of the end segment exists which guarantees a constant point of touch down even though the horizontal location of the actual strike may occur before or after the anticipated point of impact. This optimum involves a deceleration before impact. The results of the simulation of the flight (parameter study with varying initial conditions: ball velocity, angle and spin) show that the more topspin the smaller are the variations of the point of touch down. Discussion Based on the simple hit model we showed that these time-courses enhance the robustness of the strikes. It appears that there are different strategies to make the strike robust against small variations in initial conditions without the need of a sensor and a feedback-loop or controller-system. One strategy is to decelerate the racket-head before the strike. However, there are also tennis players with high positive racket-head acceleration which realize high hit rates [4]. Consequently, another strategy to stabilize the anticipated point of touch down is realized by using the topspin. Hence, tennis players have the choice to realize a higher accuracy by either slowing down the racket-head before they hit the ball or by using topspin. ## MAXIMAL PUNCHING FORCE AND POWER IN BOXERS AND TAEKWONDO ATHLETES

Busko, K., Michalski, R., Staniak, Z., Mazur-Rozycka, J., Gajewski, J.

*Institute of Sport (Warsaw, Poland)*

Introduction Changes in the maximal muscle torques or power output may reflect the results of the applied training loads. Force of the punches is rarely measured in athletes. Aim The aim of this study was to compare boxers and taekwondo athletes with respect to the

maximal punching force, maximal power and height of jump measured in counter movement jump. Methods The studies involved six boxers (age 16.8±1.0 years, body height 185.7±6.0 cm, weight, 75.8±7.0 kg, training experience 2.1±1.2 years) and seven taekwondo athletes (age 17.8±0.7 years, body height 180.1±4.1 cm, weight, 63.6±6.4 kg, training experience 6.4±1.5 years). Measurements of maximal punching force were carried out on a boxing dynamometer. Each participant performed six punches of rear hand (hook and straight punches) from a typical for himself position. The maximal power output and the height of rise of the body mass center during vertical jumps were measured on a force plate for counter-movement jumps (CMJ). MANOVA procedures with post-hoc Tukey test were employed for comparison of means. Results The maximal relative straight punching forces were 32.49±5.21 N/kg and 27.15±3.06 N/kg for rear hand in boxers and taekwondo athletes, respectively. The maximal relative hook punching forces were 34.25±6.18 N/kg and 30.19±7.19 N/kg for rear hand in boxers and taekwondo athletes, respectively. The values of CMJ relative maximal power and height of rise of the body mass centre were 29.83±7.13 W/kg, 0.430±0.050 m in boxers, respectively and 33.68±6.12 W/kg, 0.496±0.039 m in taekwondo athletes, respectively. The significant difference between the group was observed in height of jump and the both punches. Discussion The measured force of the punches depends on the method of measurement, technical skill athletes, the type of punch (straight or hook), inflicting a punches limbs (lead or rear hand), and the type of the boxing gloves used. The peak punch force ranged from 1990 to 4741 N in study Waliko et al. (2005). For the elite, intermediate and novice groups, respectively, the maximal straight punching forces were 4800±227 N, 3722±133 N and 2381±116 N for the rear hand (Smith et al., 2000). In this study, the values obtained by the boxers are in line with the work of Smith et al. (2000) for novice group. Conclusion In conclusions, the results of the present study demonstrate that the taekwondo athletes had better performance of lower limb than the boxers but maximal punching force was greater in the boxers than the taekwondo athletes. Acknowledgements The study was supported by Ministry of Science and Higher Education No. R RSA1 000951. References Smith MS, Dyson RJ, Hale T, Janaway L. (2000). J Sports Sci 18(6), 445-450. ### NORDIC WALKING AND PLANTAR PRESSURE. IS IT BENEFICIAL FOR DIABETICS?

Aparicio, I., Giménez, J.V., Lucas-Cuevas, A.G., García-Pérez, J.A., Pérez-Soriano, P., Llana-Belloch, S.

UNIVERSITY OF VALENCIA

Introduction Regular physical activity (PA) is stated to reduce the risk of all-cause mortality. Diabetes (DM) is strongly affected by sedentarism and an active lifestyle may even prevent the appearance of DM. Within this population, it is estimated that 25% of DM patients develop foot problems (Pai et al, 2010). Previous research has found that plantar pressure (PP) in Nordic Walking (NW) is different in some areas of the foot compared to the natural walking pattern (Pérez-Soriano et al, 2011). For this reason, the objectives of the study were to analyse the modifications in PP after NW practice in order to find out whether these changes in PP may be beneficial for people with DM with foot problems, such as ulcers. Methods This study involved a total of 57 volunteers (12 male and 45 female [63.7 ± 2.5 years]) who walked at least 1h/day and were free of injury and pain in their lower extremities so that their normal gait pattern would not be modified. The participants were measured at two different speeds: V1: 0,9 ± 0,1 m/s and V2: 1,5 ± 0,1m/s. PP was analysed using instrumented insoles (Biofoot/IBV®) and the foot was divided into nine zones for a better understanding of the PP: Medial heel (MH), lateral heel (LH), medial arch (MA), lateral arch (LA), lateral metatarsal (LM), central metatarsal (CM), medial metatarsal (MM), hallux (H) and toes (T). Results Mean peak pressure (Pma) under H, LM, MA and LA was higher in Walking PRE (Wpre) compared to Walking POST (Wpost) and NW. However, Pma was higher under MM, CM, and MH in NW and Wpost than in Wpre (p<0.01). The percentage of time within the step to reach the Pma (TPx) was higher under H, MM, CM and LM when Wpre compared to Wpost and NW (p<0.01). Discussion After NW training, Pma resulted in beneficial values under MM, CM, and MH. Moreover, TPx was reduced after NW training under MM, CM, LM and H both in the NW and Wpost conditions. This finding is very positive for people with DM, since the metatarsal zone experiences the highest risk of ulceration as a consequence of PP increases (Pai et al 2010). It was observed a significant adaptation in the pressure pattern since Pmax and TPx was reduced in the aforementioned foot areas both in NW and Wpost conditions. Taking into account that these areas are prone to ulcers, NW can be considered as a valuable alternative for diabetics who want to do physical activity. ### RELIABILITY OF NONLINEAR MEASURES OF CENTER OF PRESSURE IN STANDING BALANCE TASKS.

Caballero, C., Barbado, D., Moreno, F.J.

Miguel Hernández University

Introduction There are several works in the literature reporting the reliability of the traditional Center of pressure (COP) variables in standing balance tasks (Ruhe et al, 2010), but little is known about the reliability of nonlinear measures of COP (Doyle et al, 2005). The aim of this study was to analyze the reliability of COP parameters that characterize the dynamic of COP and the performance of balance task in stable and unstable conditions. Methods Thirty volunteers took part in this study (Age 27 ± 6.48 years; Height 1.74 ± 0.09 m; Mass 73.94 ± 10.77 Kg). Participants were asked to stand still (30s) both on a stable and on an unstable surface over a force platform. After ten minutes they performed a posttest. Displacement and velocity of the COP were assessed. Test performance was assessed by variables of standard deviation (SD), mean velocity (MeanV) and bivariate variable error (BVE). Dynamics of COP were measured through Sample Entropy (SampEn), Fuzzy Entropy (FuzzyEn), Permutation Entropy (EP) and Detrended Fluctuation Analysis (DFA). Standard error of measurement (SEM) and intra-class correlation coefficients (ICCs) were used to analyze the absolute and relative reliability, respectively. Results In the stable condition, SD and BVE reliability were low (ICC varied from 0.49 to 0.10; SEM from 33 to 38.03%). However, MeanV showed moderate/good values of reliability (ICC=0.86 to 0.76; SEM=14.9 to 21.15%). In the unstable condition, all performance variables showed good values of reliability (ICC=0.92 to 0.71; SEM=14-22%). Regarding COP dynamics, in the stable condition, SampEn and FuzzyEn reliability were low or moderate (ICC=0.64 to 0.34; SEM=6.08 to 32.3%), PE and DFA relative reliability were low or moderate (ICC=0.74 to 0.26) but their absolute reliability was good (SEM=3.1 to 12.9%). In the unstable condition, all variables had high relative reliability values (ICC=0.93 to 0.66) but the variables of velocity showed more absolute reliability than in displacement (Velocity: SEM= 2.54 to 17.15%; Displacement: SEM=15.64 to -23.11%). Conclusions In the stable condition only the MeanV has proved to be a reliable tool for measuring stability performance. Regarding nonlinear COP dynamics, PE was the most reliable variable, although, FuzzyEn of COP velocity and DFA of COP displacement showed good values of reliability too. Under the unstable condition, all variables were reliable. Nevertheless, nonlinear tools seem to be more reliable than traditional measures of COP (Doyle et al. 2005) despite the condition. ## PERFORMANCE AND COORDINATION IN REPEATED SPRINT EXERCISE FOR THE UPPER BODY

Ettema, G., Skålvik, T., Spencer, M., Sandbakk, Ø.

*Norwegian University of Science and Technology*

**Introduction** Performance in repeated sprint activity is of high importance in many sports. Most studies on repeated sprint have so far focused on activity of the lower extremity. However, in various sports (water-polo, sledge hockey, wheelchair basket, cross-country skiing) the upper extremity is of high importance or even fully responsible for propulsion. In this specific study, we investigated which power determining factor (cycle rate, cycle length, pull force, pull velocity) was responsible for any decline in performance as well as if coordination (timing of muscle activity) plays any role in this respect. **Methods** Twelve male well trained cross-country skiers (mean: 25 yrs, 1.80 m, 75 kg) performed eight bouts of 8 s all-out upper body exercise (arm pulls) on a modified Concept2 ergometer, with a resisting backward arm pull and a free forward retrieval movement. A repetition started every 30 s. The athletes were seated in a sledge-hockey seat such that they could perform arm movements that resembled synchronous double-poling in skiing, without lower body propulsion. Force, displacement and electromyography (EMG) for biceps brachii (long head) and triceps brachii (short head) was recorded continuously. **Results** Average power during the 8 s bouts amounted to 281 Watts, ranging from  $310 \pm 19$  Watts in bout one to  $264 \pm 11$  Watts in bout six, thereafter power plateaued ( $270 \pm 14$  Watts in bout eight). Successive sprint bouts affected power ( $p=0.003$ , ANOVA repeated measures) and force ( $p<0.001$ ). Expressed as decrement (Spencer et al., 2006), it amounted to 11.7 (power) and 10.3% (force). The changes in power and force were strongly associated, but no clear changes for the other variables were detected. Muscle activity of biceps and triceps muscles did not change in amount from bout to bout, but the timing of triceps activity, as monitored by the ratio of integrated EMG during pull and retrieval phase, decreased in the two last repetitions ( $1.27 \pm 0.04$ ) from the first six ( $1.33 \pm 0.05$ ). **Discussion** Pulling force was the only factor that was associated with the changes in power over the bouts. All other variables that directly relate to power (cycle length, cycle rate, pulling speed) did not show any significant change nor similarity with the changes in power. This is possibly due to the properties of the Concept2 ergometer that increases internal resistance (fan airflow) with increasing pull force. Changes in timing of triceps indicate a shift in its role during pull and retrieval movements. The mechanisms and possible functionality is currently unclear. However, these findings indicate that coordination in repeated sprinting may alter and may thereby affect performance. **Reference** Spencer et al., 2006. *J. Sci. Med. Sports* 9: 181-184.

## A COMPARISON BETWEEN YOUNG AND OLD: LOWER LIMB JOINT COORDINATION DURING VERTICAL JUMPING

Carlisle, A.J.1, Strike, S.C.1, Schoeman, M.2

*1 University of Roehampton (London UK), 2 University of the Free State (Bloemfontein, SA)*

**Introduction** Vertical jumping is a closed skill often used to assess musculoskeletal capacity. The overall aim is to displace the body's centre of mass in a vertical direction. With advancing age, a decline in jump performance has been noted but no significant relationship between muscle cross sectional area and age (Runge et al., 2004). This suggests that parameters other than strength maybe important when performing the jump, such as joint coordination. Therefore the aim of this research was to examine joint strategy and coordination in the lower limbs during maximal vertical jump in old and young participants. **Methods** Movements were recorded using a Vicon 9-camera system with the instruction given to jump as high as possible. The participants in the old group (O) were aged over 61 and in the young group (Y) were 18-30 years. The trial with the greatest vertical displacement was analysed for each participant. Sagittal plane coordination of hip-knee (H-K) and knee-ankle (K-A) were examined using vector coding to produce joint coupling angles (Wilson et al., 2009). The data was time normalised, left and right limbs were analysed separately but combined for statistical analysis. As the jump progresses from a rapid countermovement to propulsion an easily identifiable transition phase (TP) was identified and analysed. **Results** The jump height achieved in the old group at 0.077(0.05) was significantly lower than that achieved by the young group at 0.310(0.04) m. Two coordination strategies were adopted at the H-K: 85% of Y and 73.5% of O adopted a strategy which resulted in the knee continuing to flex while the hip extended, while for the rest of the group the knee extended first. The younger group took significantly longer % time in TP ( $Y=16.4(6.95)$ ;  $O=10.9(5.44)$ ;  $p=0.05$ ) to perform the transition from synchronised joint flexion to synchronised joint extension and the transition velocity was significantly lower ( $Y=12.65(7.54)$ ;  $O=18.64(10.78)$ ;  $p=0.024$ ). There were no significant differences in the coordination patterns at the K-A between the groups. **Discussion** Two different strategies to transition from joint flexion to joint extension were adopted, but age does not seem to be a factor in the choice of strategy. The relatively high standard deviation about the mean suggests variability in both groups indicating neither group adopts any single coordination strategy while jumping. Young jumpers spent significantly more time in the H-K TP with an overall slower velocity than the older group, while no such differences were seen in the K-A TP. It is thought that this relates to the underlying movement pattern and could be a contributing factor to greater jump height alongside other factors such as range of motion and power generation at the joints. **References** Runge, M., Rittweger, J., Russo, C.R., Schiessl, H. and Felsenberg, D., 2004. *Clin Phys Func Imag*, 24(6), pp. 335-340. ## IDENTIFICATION AND QUANTIFICATION OF HORSE RIDING TECHNIQUES IN ENDURANCE RACES

Viry, S.1,2, Sleimen Malkoun, R.1, De Graaf, J.B.1, Frances, J.P.3, Temprado, J.J.1, Laurent, M.1, Nicol, C.1

*1: ISM (Marseille, France), 2: BRD Concept (Anglet, France), 3: JPF Stables (Venelles, France)*

**Introduction** In endurance races, while trying to decrease race time, the rider must continuously manage horse's gait and speed through appropriate riding techniques to optimize and preserve the global horse's functional state. Although fatigue-induced by prolonged riding is well described in the literature (Nagy et al. 2010), most studies focused on the horse, less on the rider and scarcely on the horse-rider dyad (HRD). But, the rider and the horse are two interdependent components whose interactions significantly determine the final outcome of the race and the preservation of the horse health. The recent development of mobile technologies allows recordings of combined horse and rider movements during the 90 to 130 km of such events. This study aimed to characterize the coordination patterns exhibited by expert horse-rider dyads along endurance races. **Methods** Eight HRD of international and national levels were recorded during endurance races using two tri-axial accelerometers (Equimetrix® and Locometrix®). Accelerometer data analysis concentrated on the relative horse and rider's vertical displacements to identify horse's gaits, riding techniques and horse-rider coupling patterns. Instantaneous speed and rider's heart rate were recorded in parallel. To examine potential changes, the race was divided into three time periods. Mann-Whitney U test assessed the expertise level influence on the evolution of each parameter, with  $p<0.05$ . **Results** Analysis of the Lissajous plots revealed for all HRD the use of four coordination patterns: two riding techniques per horse's gait (trot and canter). The international HRD were characterized by a higher speed during the last third of the race. This was associated with higher speed at the canter. The proportion of the sitting canter increased from 10 to 40% whereas the use of the rising trot decreased from 30 to 20%. In the two-point canter, they presented an increased ratio between the amplitudes of the rider and horse's vertical displacement, and a rise in

the rider's heart rate from 145 to 160 bpm. Discussion Dynamic system approach may thus allow identification and quantification of the four major riding techniques used in endurance races. The analysis revealed a clear influence of the expertise level on the racing speed that increased only for the international HRD. This is attributed to the observed rise in both speed and proportion of the sitting canter. In the two-point canter, in which the rider remains in equilibrium in his stirrups, the increase in speed might be more costly as reflected by larger vertical displacements of the rider and increasing heart rate. ### **INTER- AND INTRA- JOINT COORDINATION IN LOWER LIMB JOINTS OF CLASSICAL BALLET DANCERS DURING TIPTOE STANDING**

Tanabe, H.1, Fujii, K.1, Kouzaki, M.1

*1: Kyoto University (Kyoto, Japan)*

**Introduction** One of the fundamental elements of what makes dancers' behavior attractive is their lithe legs. Dancers might have different postural control, the process of which is each joint fluctuation, compared to non-dancers. Irrespective of the importance of tiptoe standing for classical ballet dance, its postural control has not been clarified. Moreover, on the contrary to traditional COP analysis, investigating the inter- and intra- joint coordination can elucidate the postural control process from the mechanical aspect. Therefore, we aimed to investigate the feature of inter- and intra- joint coordination acquired by ballet training. **Methods** Nine female classical ballet dancers and nine healthy female participants with no formal dance experience were asked to perform heel-toe and tiptoe standing for approximately 40s, during which the displacement of center of pressure (COP) and kinematic data of metatarsopharangeal (MP), ankle, knee, and hip joints in both sagittal and frontal planes were measured by laser sensors. As traditional parameters of postural stability, COP path length and rectangular area were calculated. Intra- and inter- joint coordination were investigated by using the principal component analysis (PCA). **Results** There was no difference in the COP path length and the rectangular area between groups. For heel-toe standing, there was no notable difference between groups. During tiptoe standing, the results of PCA showed that dancers' ankle and knee fluctuates with in-phase in anteroposterior direction, while non-dancers had anti-phase coordination between adjacent joints. In addition, dancers' sway amplitude of knee was significantly smaller. As for intra-joint coordination, dancers' MP and ankle exhibited the tendency to sway anti-phase, which means left-front or right-rear during tiptoe standing. **Discussion** Dancers' smaller knee fluctuation is considered to be due to ballet training, one of the fundamental instructions of which is to keep the knees locked. As for dancers' inter-joint coordination between the ankle and the knee, the coupling of both fluctuations up to higher frequency band (which is covered by beta-band) was associated, while the coherency of non-dancers was significant only below 10 Hz. One possible explanation for this is that dancers' posture is well controlled by motor cortex. Also, in-phase joint coordination leads the arch-looking configuration, suggesting that dancers' joint coordination might be an element of their lithe legs, that is, beautiful object. In addition, the existence of intra-joint coupling patterns suggests that the neuromuscular intra-joint control might have coupled strategy.

### **RELIABILITY AND LEARNING EFFECT OF THE COP PARAMETERS DURING UNSTABLE SITTING**

Barbado, D., Moreside, J.M.2, Elvira, J.L.L., Moreno, F.J., Vera-Garcia, F.J.

*Sports Research Centre, Miguel Hernandez University of Elche*

**Introduction:** Although unstable sitting tests have been successfully used to assess postural control of the trunk (Cholewicki et al., 2000), the reliability of these protocols seems to be poor (Van Dieën et al., 2010). The aim of this study was to analyze the reliability and learning effect of a trunk postural control test performed on an unstable sitting platform. **Method:** Twenty-three physically active males performed the test 3 times, with 1 week between each testing session. Each test consisted of 5 seated 60 s balance trials with the unstable seat placed on a force platform (Kistler 9286A). Test performance was evaluated by standard deviation (SD), bivariate variable error (BVE) and PATH (total path length traveled by CoP per second). The regularity and long-range autocorrelation of both COP displacement (COPD) and COP velocity (COPV) were assessed by approximate entropy, sample entropy, fuzzy entropy (FuzzyEn), permutation entropy (PE) and detrended fluctuation analysis (DFA), respectively. The standard error of measurement (SEM) and intraclass correlation coefficient (ICC) were used to analyze the absolute and relative reliability, respectively. Repeated-measures ANOVAs were performed to analyze the learning effect. **Results:** There was a significant decrease of SD, BVE and PATH between trials and between days. In addition, there were significant increases of regularity parameters and DFA between days, but only significantly so between trials for PE. The reliability of SD and BVE between trials and between days was low to moderate (0.20).

### **ERGONOMIC FACTORS IN INDUSTRIAL WELDING**

Rein, R.1,2, Feodoroff, B.2, Biallas, B.1, Wilke, Ch.1

*German Sport University Cologne*

1: Department of Neurology, Institute of Health Promotion and Clinical Movement Science, German Sport University Cologne, 2: Centre for Sport and Health Research, Institute of Health Promotion and Clinical Movement Science, German Sport University Cologne **Introduction** A large percentage of the work force in industrialized countries is occupied with welding related activity and health statistics indicate that in particular industrial welders are prone to work related disorders (Burdorf, Naaktgeboren, Post, 1998). Apart from neurological and respiratory system disorders (Bowler et al. 2006), disorders of the musculoskeletal system show a large prevalence resulting in a significant economic factor (Alexopoulos et al., 2008). Unfortunately, few studies investigating ergonomic factors of the musculoskeletal system in industrial welding are available at present. Thus, to identify possible factors leading to muscular disorders in industrial welding the current study investigated expert and novice welders. **Methods** Six professional welding instructors and seven novice welders from the same welding school participated in the study. Three different welding positions were investigated. Key anatomical landmarks of the trunk and the upper body were identified using passive reflective markers and marker trajectories were recorded using high-speed infrared video. Bilateral muscle activations of selected trunk and arm muscles were recorded using sEMG. All trials were performed using a commercial virtual-reality welding simulator. **Results** Experts displayed superior welding performance compared with novices. Movement trajectories indicated great inter-individual differences in welding movements in both experts and novices. Muscle activation patterns showed stronger asymmetric activation of trunk muscles for novices due to greater trunk flexion and trunk torsion. Further, novices displayed greater arm movement ranges compared with experts. **Discussion and conclusion** The results suggest that welders choose individual movement solutions according to their own set of biomechanical constraints. Nevertheless, significant differences between groups indicated more upright and frontal postures in experts resulting in bilateral symmetric muscle activations minimizing individual muscular

forces. Currently, during novice welding training emphasis is placed exclusively on the welding product. However, to decrease the risk of musculoskeletal disorders later during working life, postural aspects of welding should be considered as well. ##### ISOKINETIC MUSCULAR STRENGTH OF ATHLETES IS NOT AFFECTED BY MENSTRUAL CYCLE

Paiva, R.F.L., Mascarin, N., Vaisberg, M., Bella, Z.I.K.J., Andrade, M.S.

*UNIFESP/EPM*

**Introduction** Women participation in sports, like as soccer player, has increased in last years; consequently injuries incidences also increase (Fonseca et al, 2007; Renstrom et al, 2008; Souza, 2012). The higher female incidence of ligamentous injuries seems to be associated to hormonal changes during menstrual cycle (Hewett et al, 2007; Adachi et al, 2008), but researchers know much less about hormonal effects on muscular performance, especially in athletes. The aim of this study was to evaluate isokinetic muscular strength of thigh muscles on a group of female soccer players at follicular and luteal phases. **Methods** Seventeen eumenorrheic soccer players were evaluated (age: 22.35±6.42; height 165.3±7.8; weight: 61.8±7.7). The phases of the menstrual cycle (luteal and follicular), was determinate by monitoring for 3 consecutive months. Evaluation of knee flexors and extensors muscles peak torque (PT) and total work (TW) was performed with 5 repetitions at 60°/s in each phase of the menstrual cycle. The study protocol was approved by the Research Ethics Committee of UNIFESP (No.160410). For data analysis we used the t test for dependent variables with significance level to 5%. Results Extensor muscles PT for non-dominant limb showed lower values in luteal phase when compared to follicular phase (P<0,001), but other analyzed variables (flexors PT and extensors and flexors TW) showed no difference between phases. Extensor and flexor muscles PT and TW for dominant limb showed no differences between the menstrual phases. **Discussion** In this study isokinetic muscular strength did not change from follicular to luteal phases of menstrual cycle in female soccer players athletes. However, these findings were limited from athletes isokinetic thigh muscular strength; and further research evaluating strength variation during menstrual cycle, using other measures of neuromuscular function such as functional tests or eccentric action, is needed. ##### VMO RECRUITMENT AFTER THERAPY FOR PATELLOFEMORAL PAIN MEASURED BY MUSCLE FUNCTIONAL MRI

Pattyn, E., Van Tiggelen, D., Witvrouw, E.

*University of Ghent*

**Introduction** In literature and in clinical practice, restoration of quadriceps strength and -function has been demonstrated to be imperative for a successful recovery from patellofemoral pain (PFP) (Powers, 1998). Treatment generally includes exercise interventions to strengthen and optimize the use of the quadriceps and in particular the vastus medialis obliquus (VMO) (Syme et al., 2008). The aim of this study is to examine by muscle functional magnetic resonance imaging (mfMRI) if patients with PFP actually exhibit an altered activation of the muscles that play a significant role in the dynamic balance of the patella after treatment with exercises. **Methods** Thirty-six patients with PFP (16 male and 20 female, mean age 23.8 ± 6.7) underwent MRI of the quadriceps before and immediately after a squat exercise. The transverse relaxation time (T2) shift, which is an indication of muscle recruitment, was calculated for the vasti muscles. The measurements were repeated after a seven-week rehabilitation period including neuromuscular co-ordination, stabilization and strengthening exercises, stretching and home exercises. **Results** The T2 shift of VMO was lower after the therapy than before (post treatment 3.90 ± 2.79 ms vs. pre treatment 5.26 ± 3.60 ms; P=0.041), while the T2 shift of the vastus lateralis (VL) and the vastus medialis-intermedius (VMVI) were not significantly different before and after the treatment period (P=0.260 and P= 0.066). **Discussion** The results indicated that exercise therapy partially altered the recruitment of the dynamic stabilizers of the patella. After treatment for PFP, the VMO was less active during functional activity while there was no difference in activation of the VL and VMVI. It could be hypothesized that the patients have been taught in therapy to use more accurate movement strategies in functional tasks in view of decreasing patellofemoral joint stress. Perhaps the decreased use of the VMO is accompanied by enhanced and more efficient recruitment of non-local muscles. These assumptions should be verified by evaluation of hip, calf and hamstrings muscle recruitment in further mfMRI investigations in PFP. References Powers C. (1998). *J Orthop Sports Phys Ther*, 28(5), 345-354. Syme G, Rowe P, Martin D, Daly G (2009). *Man Ther*, 14(3), 252-263.

##### PASSIVE DEHYDRATION EFFECTS ON EXPLOSIVE STRENGTH PERFORMANCE

Castro, M., Salinas, H., Astudillo, S., Rosales, G., Perez, C.

*Mayor university*

**Introduction:** Dehydration on athletes has been regarded as a factor impairing athletic performance. Despite this, there is evidence of dehydration methods that have shown increases on vertical jump, which has been associated to a higher muscle power to body mass ratio. There are three methods to generate dehydration: active dehydration, passive dehydration, and mixed method. Active dehydration makes it impossible to isolate dehydration effect from that of muscle glycogen decrease. There is very limited literature regarding the

effects of passive dehydration on vertical jump height and short sprint speed. The objective of this study is to determine whether the weight loss caused by a passive dehydration protocol in wet sauna, affects jump height and time of 30 m. sprint. Métodos: Ten healthy, recreationally active males were voluntarily recruited. (Age  $26,6 \pm 6,6$  years, height  $170,1 \pm 8,1$  cm, body mass  $73,15 \pm 11,34$  Kg.) Before and after dehydration process participants were tested on vertical jump height (SJ and CMJ) and 30 m. sprint times (TC). Dehydration process consisted of three 10 minutes periods on wet sauna ( $55^{\circ}\text{C}$ , 95% RH). Resulted: All participants reached a body mass loss between 0.6% and 1.7% (0.4 - 1.3 kg). Average values for the test group on velocity (TC) in 30 m. and jumping ability tests (SJ and CMJ) indicate a significant difference between pre and post dehydration results ( $\alpha = 0.05$ ). Discussion: The results found show that the dehydration protocol used improves the results of the three variables. The average performance improvements in SJ and CMJ and TC are 2.8%, 5.2% and 3.1% respectively. A study by Viitasalo J.T. showed the effects of three methods of weight reduction in maximum force, rate of force development, vertical jump height and mechanical energy, obtaining results in the same direction of the findings of the present study, but by reaching higher dehydration levels. ### **LONGER HAMSTRINGS ELECTROMECHANICAL DELAY IMPAIRS EARLY PHASE EXPLOSIVE FORCE PRODUCTION AND MAY COMPROMISE KNEE JOINT STABILITY**

Hannah, R., Minshull, C., Smith, S.L., Folland, J.P.

*Nottingham Trent University*

Introduction: A low ratio of hamstrings-to-quadriceps (H/Q) strength is suggested to increase the risk of non-contact anterior cruciate ligament (ACL) injury [1]. The time available to develop force to stabilise the knee and prevent injury during landing and turning movements may be a little as 50 ms [2], which is considerably less than the time required to develop maximal muscle force (300 ms, [3]). Since maximum force seems unlikely to be attained in the time available, the capacity for knee joint stabilisation may depend more on the relative ability of the knee muscles to exert force explosively during the initial phase of contraction. However, the time course of the rise in explosive force of the hamstrings and quadriceps from their initial activation, and thus the explosive H/Q force ratio, has not been documented. Methods: The neuromuscular performance of untrained males ( $N = 20$ ) was assessed during a series of voluntary isometric knee flexion and extension contractions; explosive and maximal voluntary efforts (knee angle  $150^{\circ}$ ). Force and EMG of the hamstrings and superficial quadriceps were assessed in short intervals from agonist EMG onset and at maximum voluntary force (MVf). Hamstrings force was expressed relative to quadriceps force (%) to produce hamstring-to-quadriceps ratios of explosive H/Q force and H/Q MVf. For the explosive contractions, agonist electromechanical delay (EMD) and agonist neuromuscular activity (normalised to maximal EMG) were calculated. Results: The quadriceps MVf was 79% greater than the hamstrings ( $P < 0.001$ ), but by contrast, quadriceps explosive force was >5-fold greater than the hamstrings from 25-50 ms ( $P < 0.001$ ). Consequently the explosive H/Q force ratio was very low at 25 and 50 ms (0-17%) and significantly different from H/Q MVf ratio (56%,  $P < 0.001$ ). Hamstrings EMD was ~2-fold greater than quadriceps EMD (44.0 vs 22.6 ms,  $P < 0.001$ ) resulting in a 21 ms later onset of force in the hamstrings that appeared to explain the low explosive H/Q force ratio in the early phase of activation. Agonist EMG was similar between the two muscle groups in the first 100 ms of activation, suggesting the prolonged hamstring EMD was not due to a difference in neural drive to the involved muscles. Conclusions: Prolonged hamstrings electromechanical delay appears to impair early phase (0 – 50 ms) explosive force production relative to the quadriceps and may compromise knee joint stability during this period where ACL injuries are thought to occur. ### **PEAK ECCENTRIC HAMSTRING STRENGTH AND SINGLE-LEG-HOP-AND-HOLD-FOR-DISTANCE CAN PREDICT HAMSTRING INJURY IN BACHELOR PE STUDENTS**

Goossens, L.1, Witvrouw, E.2, De Clercq, D.1

*Ghent University*

Introduction Various studies reported high incidences of hamstring injuries in sports such as soccer, rugby and sprinting (1,3,5). In these homogeneous groups, risk factor analyses showed non-uniform outcomes concerning muscle strength measures (4). The aims of this study were to describe the epidemiology of hamstring injuries in Physical Education Teacher Education (PETE) students and to conduct a risk factor analysis including various functional muscle strength measures. Methods 102 freshmen academic bachelor PETE students were followed prospectively for occurrence of sports injuries during one academic year. At the start of the academic year, maximal muscle strength tests using a hand-held dynamometer (hip ab- and adductor, gluteus, concentric (CON) and eccentric (ECC) hamstrings, quadriceps, hip internal and external rotators) were taken from 81 subjects. 69 of these also completed a single leg hop and hold for distance (SLHH) test. Results 16 hamstring injuries occurred to 10 subjects, 8 of these completed all tests. There was a hamstring injury risk of 0.16 and an incidence rate of 0.45 hamstring injuries/1000 hrs. Logistic regression analyses showed that, after taking account of gender, maximal ECC hamstring strength (ODD=0.977;  $p=0.043$ ), CON hamstring /ECC hamstring strength ratio (ODD=970.500;  $p=0.019$ ) and SLHH (ODD=0.884;  $p=0.005$ ) were significant risk factors for having a hamstring injury. Discussion Hamstring injury incidence rate is lower in PETE students compared with male soccer (0.90) (1) and rugby players (0.77) (3) and competitive sprinters (0.87) (5). Hamstring injury risk is higher in PETE students than in male soccer players (0.10) (1) but lower than in competitive sprinters (0.34) (5). In contrast to results of an earlier study (2), our data show that lower ECC hamstring strength is a risk factor for having a hamstring injury. So far, unilateral functional tests like the single-leg Counter Movement Jump were not predictive for having a hamstring injury (1). Nevertheless, our results reveal a higher risk of suffering from a hamstring injury with a lower score on the SLHH, possibly due to the large eccentric component of this task. This offers great perspectives for a structured screening of athletes-at-risk in the field. References 1.Arnason A, Sigurdsson S B, Gudmundsson A, Holme I, Engebretsen L, Bahr R. ## THE EFFECT OF KINESIO TAPING IN MUSCLE ACTIVATION DURING ISOKINETIC ECCENTRIC MOVEMENT IN SOCCER PLAYER

Wu, S.N., Lou, P.C., Lin, C.Y., Hu, C.Y., Lin, H.T.

*Kaohsiung Medical University*

Introduction Soccer has becoming one of the most popular sports in the world. During player kicking, muscle eccentric contraction was occurred in the supporting leg and kicking foot. However, muscle eccentric contraction was easy to lead injury and muscle fatigue. Recently, KINESIO tape was usually used to prevent exercise injuries. It could improve blood circulation and stimulate skin proprioception because of its stickiness, and it could hereby enhance the muscle function and make it stronger (Konishi, 2012). Previous study showed that the KINESIO tape might postpone muscle fatigue in kicking players' rectus femoris muscle (Fu et al., 2008). Therefore, our purpose of the study is to investigate the effect of KINESIO tape in muscles activations during eccentric exercise. Methods Six male soccer players who are play for their college at least two years (averaged age is  $22.1 \pm 1.6$  yrs, height is  $172.1 \pm 6$  cm, and weight is  $68.6 \pm 6.6$ kg) were participated in this study. Biodex<sup>®</sup> (system 3, Biodex Medical System Inc., USA) was used for isokinetic exercise at two various testing velocities ( $60^\circ/\text{sec}$ ,  $90^\circ/\text{sec}$ ). Twenty and thirty continuous cycles were tested for two testing velocities respectively. Each subject tested in both non-taping and KINESIO taping conditions. Electromyography system (Trigno<sup>™</sup>, DELSYS, MA) was used for muscle activation detection and electrodes were attached on the non-dominant leg's rectus femoris, and the dominant leg's medial and lateral gastrocnemius. The muscle maximum voluntary contraction (MVC) was used for normalizing muscle activation. The functional test such as run-return, single leg with eye close, and sound reflection were tested before and after the eccentric exercise (Ergen et al., 2008). Paired t-test was used to test the differences of muscle activation between non-taping and KINESIO taping. Results Results showed that there was no significant difference in mean muscle activation between KINESIO and non-taping, however, the mean muscle activation in last 1/3 cycles was larger than in first 1/3 repetitions in KINESIO taping. Moreover, there had significant difference in the "sound reflection" test (KINESIO tape vs. non-tape: 212.1 ms vs 272.1 ms,  $p < 0.05$ ). Discussion KINESIO tape might activate the skin proprioception and improve sound reflection ability. The decreased muscle activation of leg in the last 1/3 cycles may result from the other muscles cannot complete the work and have to recruit more fibers in taping muscle. Some subjects reflected that KINESIO taping could reduce pain after eccentric contraction. KINESIO taping could help muscle to have better performance during eccentric exercise. References Konishi Y. ## INFLUENCE OF TESTING POSITION ON HAMSTRING / QUADRICEPS RATIO IN SOCCER PLAYERS

Hautier, C.1, Morel, B.1, Vigne, G.2, Monnot, D.2, Dellal, A.2,3

1: CRIS, University Lyon 1, Lyon, France, 2: Medical Centre Excellence FIFA, Santy Orthopédicae clinical, Lyon, France, 3: OGC NICE, France

Introduction Previous studies suggest that a high hamstring to quadriceps isokinetic force ratio (H/Q) may stabilize the knee during jump landings and cutting, and prevent anterior cruciate ligament injuries (Croisier et al, 2008). Subjects are usually seated on the dynamometer chair when performing isokinetic measurements. However, these protocols impose an  $80^\circ$  to  $120^\circ$  Hip angle which is not in line with the hip angles when injury occurs. The aim of the present study was to compare H/Q ratios and EMG levels in two testing positions, seated (Hip angle  $80^\circ$ ) and lying in supine position (Hip angle  $26^\circ$ ). Methods 10 male soccer players accepted to participate in this study. EMG activity of the Vastus Lateralis, Vastus Medialis (VM), Rectus Femoris (RF) and Biceps Femoris (BF) of the dominant leg were measured using surface EMG electrodes (EMG Triode electrode, Thought Technology, Montreal, Canada). Subjects performed in a randomized order, seated and lying isokinetic tests composed of maximal concentric and eccentric contractions at 30, 60 and  $240^\circ \cdot \text{s}^{-1}$ . Conventional H/Q ratios have been calculated for each position and velocity as well as EMG level. Comparisons have been performed using a single factor analysis of variance. Level of significance was set at  $p < 0.05$ . Results Players produced significantly ( $p < 0.01$ ) lower knee extension moments in lying position compared to seated position at  $60^\circ \cdot \text{s}^{-1}$ ,  $240^\circ \cdot \text{s}^{-1}$  and  $30^\circ \cdot \text{s}^{-1}$ . No differences were observed in knee flexor moments at  $60^\circ$  and  $240^\circ \cdot \text{s}^{-1}$  whereas eccentric moments measured at  $30^\circ \cdot \text{s}^{-1}$  were lower when lying ( $p < 0.01$ ). Conventional H/Q ratios were significantly higher in lying position at  $60^\circ \cdot \text{s}^{-1}$  (0.67 vs 0.53,  $p < 0.01$ ) and  $240^\circ \cdot \text{s}^{-1}$  (0.75 vs 0.58) but not at  $30^\circ \cdot \text{s}^{-1}$ . No differences have been observed in EMG activation level of extensors and flexors muscles whatever the position and the velocity. Discussion This study demonstrated that conventional H/Q ratios are significantly influenced by the testing position. These differences can't be explained by modifications in muscle activation levels. On the other hand, RF and BF muscle lengths are different in the two conditions. RF is shortened at the end of the knee extension movement when seating and its contribution to total force is near to zero for the 40 last degrees of extension. In the same way, BF is shortened at the end of the knee flexion movement when lying and its contribution to total force is lowered during the 40 last degrees of flexion. This phenomenon must be taken into account to test H/Q ratios in soccer players in the most meaningful protocol. ## THE ANALYSIS OF ELECTROMYOGRAPHIC ACTIVITY OF ANKLE MUSCLES DURING BALANCE TRAINING.

Masunari, A.1,2, Kunugi, S.2, Kondo, H.2,3, Yoshida, N.4, Kobayashi, N.4, Miyakawa, S.2

1: IPU (Ibaraki, Japan), 2: NTU (Ibaraki, Japan), 3: NTUT (Ibaraki, Japan), 4: THU (Tokyo, japan)

Introduction The balance training is one of the neuromuscular trainings and performed on a rehabilitation of ankle instability. However, these trainings only assign the players the task of maintaining postures but do not assign another task. It is often found in the sports scenes such as the football to perform tasks more than two, and the training method had better be closer in the competition scene to use the dual task training. This is another report that the balance board training combined with the task of catching a ball could prevent the recurrence of the ankle sprain. Although such training is often used clinically, effects of conditions applied to the muscle activity is not clear. Therefore, the aim of this study was to analyze the electromyographic activity of the muscles surrounding the ankle joint on different types of condition. Methods Nine healthy male college football players participated in this study. Surface electromyograms (EMG) were recorded during balance exercises in four conditions; standing one leg (SL), standing one leg and playing catch (SLP), standing one leg on the balance board (SLB), standing one leg on the balance board and playing catch (SLBP). The tibialis anterior, tibialis posterior, peroneus longus, peroneus brevis, gastrocnemius lateralis and soleus were chosen for analysis, and root mean square (RMS) was calculated from the electromyographic signal at each muscles. Results There was a significant increase in the tibialis anterior activity at SLBP compared to SL ( $p < 0.05$ ). As for the other muscles, there were no significances. Discussion The tibialis anterior exhibited greater electromyographic activity by increasing the difficulty of the balance task. Postural sway of the anterior-and-posterior direction was increased by standing on the balance board, and playing catch on the balance board increase the postural sway more. Tibialis anterior controls the Postural sway

of the anterior-and-posterior. Therefore, there is a possibility that the increased activity of the tibialis anterior muscle to control these body sway. ### RATE PRESSURE PRODUCT RESPONSE TO DYNAMIC AND ISOMETRIC SETS OF RESISTANCE EXERCISE

Marocolo, M., Maior, A.S., Katayama, P.L., Neto, O.B., Freitas, D.G.S., Mota, G.R.

*Federal University of Triangulo Mineiro, Castelo Branco University, Estácio de Sá Faculty*

**Introduction** The dynamic or isometric protocols of resistance exercise [RE] have been recommended for improvement of cardiovascular conditioning. Rate-pressure product [RPP] correlates with myocardial oxygen consumption, and the magnitude of blood pressure [BP], heart rate [HR] and RPP responses during RE are directly related to intensity, repetitions, sets and rest interval (Salles et al. 2010). Thus, the aim of this study was to compare the acute responses of RPP after dynamic and isometric exercises using different intensities. **Methods** Nineteen active men ( $22.7 \pm 2.2$  yrs) attended the laboratory 7 times with 48h among visits. They performed anthropometric and hemodynamic measurements and one maximum repetition tests (1RM) in leg press (LP) and bench press (BP). Following tests were carried out: LP and BP isometric, LP and BP dynamic (at 25, 50, 75% of 1RM for 1st, 2nd and 3th sets respectively; 3min rest between sets; isometric 40 s and dynamic 10 repetitions per set). In sequence, in the 6th and the 7th visits the volunteers did only LP exercise isometric and dynamic (3 sets at 75% 1RM, respectively). The RPP was obtained immediately after each set. **Results** RPP was higher in LP than in the BP in all protocols. It was showed that the RPP was increased proportionally with the exercise intensity. While in the BP the isometric protocol causes higher responses of the RPP, in LP the higher responses occurred in the dynamic protocol. Additionally, we showed a cumulative effect of the sets in RPP response, in both RE protocols with 75% 1RM in all 3 sets. **Discussion** Our main finding is that RPP was significantly higher in LP compared to BP in both RE protocols. It may be due muscle mass, once that the LP has more muscle mass than the BP. Gálvez et al. (2000) demonstrated that the magnitude of HR increasing is related to recruited muscle mass and intensity. Absolute RPP responses on lower limbs are significantly higher than upper limbs in both RE protocols. For lower limbs exercise, those responses are greater for dynamic compared to isometric protocol, while the same comparison for upper limbs shows higher responses for isometric compared to dynamic protocol. **References** Gálvez, JM, Alonso JP, Sangrador LA, Navarro G. (2000). Effect of muscle mass and intensity of isometric contraction on heart rate. *J Appl Physiol*, 88: 487-492.

### EFFECTS OF PELVIC FLOOR MUSCLE TRAINING IN JAPANESE FEMALE ATHLETES

Yamamoto, S.1, Maruo, A.2, Tanaka, S.3

*Mukogawa Women's University*

**Introduction** Pelvic floor muscle training (PFMT) is utilized to improve the pelvic floor muscle (PFM) and symptoms of stress urinary incontinence (SUI). However, there have been few studies of PFMT in female athletes reported. We compared the effects of PFMT between Japanese female athletes and non-athletes. **Methods** We investigated 14 female university students [6 athletes with SUI (group I-A), 4 athletes without SUI (I-B), 4 non-athletes (II)], mean age  $20.5 \pm 0.9$  years], each of whom underwent PFMT. The outcome measure tools used were the International Consultation on Incontinence Questionnaire - Short Form (ICIQ-SF) and an original questionnaire. PFM strength was evaluated by a pad test. **Statistical analyses** included one-way ANOVA and Kruskal-Wallis test results. P values  $< 0.05$  were considered to be significant. **Results** The weight of the pad increased by  $0.08 \pm 0.20$ g in group I -A and  $0.02 \pm 0.16$  g in group I-B, while it decreased by  $0.11 \pm 0.16$ g in group II, though the differences among the 3 groups were not significant. Of 8 actions queried regarding the desire to urinate or urinary incontinence, many students noted that urine leakage changed to a desire to urinate after training. **Discussion** A previous study noted that a minimum of 6 weeks of PFMT was needed to obtain the desired effect (Bo et al., 1990). However, only 3 of the present students were able to train for more 6 weeks, thus no statistically significant differences were found regarding changes in pad weight among the 3 groups, though a slight decrease in pad weight was noted in group II. Therefore, a training effect was easily noted in the present non-athletes. On the other hand, the PFM of the athletes in the present study was developed by participation in daily club activities and considered to have a certain level of strength. As for the desire to urinate or urine leakage, many students noted improvements as a result of PFMT. Thus, we considered that PFMT should be continued and female athletes with SUI require additional PFM training as compared to non-athletes (Bo, 2004). **References** Bo, K., Hagen, RH., Kvarstein, B., et al. ### HAMSTRING EXTENSIBILITY AND SAGITTAL SPINAL POSTURE IN HIGHLY TRAINED PADDLERS.

Perez-Soto, J.J., Lopez-Minarro, P.A., Muyor, J.M., Alacid, F., Vaquero, R., Garcia-Canto, E., Rodriguez, P.L.

*University of Murcia*

**Introduction** Hamstring muscle extensibility has been associated to changes in lumbopelvic rhythm and spinal posture. However, most studies included non-athlete population. Therefore, the purpose of this study was to determine the influence of hamstring muscle extensibility on sagittal spinal curvatures and pelvic inclination in paddlers. **Methods** A total of 100 highly trained paddlers (mean age:  $16.11 \pm 0.91$  years) participated in the study. The thoracic and lumbar angles as well as pelvic inclination were measured with a Spinal Mouse in relaxed standing and maximal trunk flexion with knees extended (sit-and-reach test). Hamstring muscle extensibility was determined in both legs by passive straight leg raise test (PSLR). The sample was divided into three groups: group 1 (lower extensibility;  $PSLR < 75^\circ$ ,  $n=35$ ); group 2 (intermediate extensibility;  $PSLR = 75-90^\circ$ ,  $n=34$ ); and group 3 (greater extensibility;  $PSLR > 90^\circ$ ,  $n=31$ ). **Results** The one-way ANOVA analysis showed no significant differences between groups in standing. With regards to the sit-and-reach test, thoracic angle was more reduced in the greater extensibility group (group 1:  $59.15 \pm 11.53^\circ$ ; group 2:  $55.60 \pm 10.51^\circ$ ; group 3:  $48.02 \pm 14.23^\circ$ ,  $p < 0.001$ ). Pelvic inclination was higher in the group 3 (group 1:  $-12.15 \pm 11.06^\circ$ ; group 2:  $-6.44 \pm 11.81^\circ$ ; group 3:  $0.35 \pm 11.89^\circ$ ;  $p < 0.001$ ). However, no significant differences were found in lumbar angle (group 1:  $31.26 \pm 8.10^\circ$ ; group 2:  $30.56 \pm 6.28^\circ$ ; group 3:  $32.17 \pm 7.64^\circ$ ). Post hoc analysis showed significant differences between all pairwise comparisons for thoracic angle and pelvic inclination ( $p < 0.01$ ). **Discussion** Hamstring extensibility has been shown to affect lumbo-sacral posture due to the muscles' direct attachment on the ischial tuberosities (Gajdosik et al., 1994; Congdon et al., 2005). As the subject bends forward, the pelvis freely rotated forward until the passive tension in the hamstrings begins to influence pelvic rotation (Shin et al., 2004). The subjects with lower hamstring extensibility showed a higher posterior pelvic tilt when maximal trunk flexion was performed, which can overload the spine. Furthermore, a relationship between hamstring

extensibility and thoracic posture was detected. Paddlers with lower extensibility have greater thoracic flexion in the sit-and-reach test. This posture could indicate that they were compensating for their pelvic restriction when a maximal trunk flexion movement with knees extended is performed. ### STRAIN GAUGE EVALUATION OF FUNCTIONAL FEATURES OF DIFFERENT ANKLE TAPINGS

Nakanishi, K.1, Watanabe, H.2, Ashihara, M.3, Kaji, K.1, Takahashi, M.1, Takahira, N.1

1:Kitasato University Graduate School of Medical Sciences. 2:Kitasato University School of Allied Health Sciences. 3:Sagamihara Kyodo Hospital

**Introduction** Lateral ankle sprains are the most frequently encountered sports injuries. Ankle taping has commonly been used to prevent these sprains. Although there are several methods of ankle taping, to our knowledge there have been no reports of the functional features of each type of taping used. Our aim was to examine the functional features of the tapings used to prevent ankle sprain by measuring the loads on the tapes under lateral cutting movement and running stop movement. **Methods** The subjects were 9 male healthy volunteers (age, 22.1±1.4 years; height, 168.4±3.7 cm; body weight [BW], 63.4±5.8 kg). For measurement, a KFG5-120 strain gauge (Kyowa Electronic Instruments Inc.) was bonded to white tape 38 mm wide (Johnson & Johnson Inc.). Four calibrated tapes (stirrup, SU; horseshoe, HS; lateral heel lock, LHL; figure-of-eight, FE) were individually applied to the subject's ankle on the dominant side by the same examiner. The force plate (AMT Inc.) and strain force on the tapes were set to a sampling frequency of 1000 Hz, and the subjects performed lateral cutting movement and running stop movement on the force plate. Strain forces on the tapes were converted into weight by using calibration curves and defined as the loads on the tapes. Loads on the tapes were corrected by body weight and used in our analyses. **Results** The loads on all four tapes during both movements were significantly greater than at rest ( $P < 0.01$ ). During lateral cutting movement, the load on SU (15.7%±5.9% of BW), LHL (15.6%±6.2% of BW), and FE (13.0%±4.6% of BW) were significantly larger than that on HS (7.7%±3.2% of BW) ( $P < 0.01$ ). During running stop movement, the loads on the tapes reached 5.3%±2.5% of BW for SU, 6.4%±2.4% of BW for HS, 6.3%±4.1% of BW for LHL, and 9.9%±3.8% of BW for FE; the load on FE was significant greater than that on SU ( $P < 0.01$ ). At the same time, a backward ground reaction force of 756±303N was applied to the subject's foot. **Discussion** During lateral cutting movement, the loads on SU and LHL were large. As lateral cutting movement is a major cause of lateral ankle sprains, SU and LHL play an important role in preventing lateral ankle sprains. During running stop movement, the load on FE was large. Moreover, a large backward component of ground reaction force was applied to the subject's foot. Therefore, a large anterior-posterior force was applied to the ankle joint, and FE might have helped to brake this force.

### CHARACTERISTICS OF TRUNK MUSCLE BALANCE IN DANCE SPORT PLAYERS

Wachi, M., Kurihara, T., Sanada, K., Toda, Y., Shimozaki, Y., Isaka, T.

ritsumeikan university

**Introduction** Dance sport players often intend to improve their core stability, because straight posture directly affects to the dance performance. They focused on perfecting alignment of the human skeleton (Deckert et al., 2007), and it causes the trunk muscle activated. Therefore, a hypertrophy in trunk muscle is one of the features of dancers, but excessive and/or incorrect core training may induce muscle imbalance. The aims of this study are to measure the cross-sectional areas (CSA) of trunk muscle and compare these muscle balances between dancers and age-matched subjects. **Methods** Nineteen young dance sport players (10 male, 9 female, age 19.3 ± 1.0 yrs, height 166.9 ± 7.7 cm, weight 56.3 ± 7.1 kg, means ± S.D.) and twenty sedentary young subjects (12 male, 8 female, age 18.6 ± 0.7 yrs, height 167.3 ± 8.9 cm, weight 60.5 ± 8.2 kg) were participated. Dancers were experienced at least 1 year of training (2.37 ± 1.86 yrs) and regularly exercised 4 days per week. CSA of trunk muscles (rectus abdominis (RA), abdominal obliques (AO), psoas major (PM), quadratus lumborum (QL), multifidus (MF), erector spine (ES)) were measured using magnetic resonance imaging (MRI) at L4/5 (disk between 4th and 5th lumbar spine). The bilateral difference (BL-Diff) of each muscle was evaluated as BL-Diff = [(large side - small side)/large side\*100] (Hides et al., 2008). The anteroposterior balance (AP-Bal) was calculated by AP-Bal = [(RA + AO) / (MF + ES) \* 100]. **Results and discussion** BL-Diff were 12.4 ± 10.5% (RA), 9.7 ± 5.2% (AO), 7.6 ± 5.6% (PM), 14.6 ± 11.7% (QL), 10.4 ± 6.8% (MF), and 10.0 ± 5.8% (ES) in dancers and 10.0 ± 7.8% (RA), 8.3 ± 5.7% (AO), 5.7 ± 4.1% (PM), 16.8 ± 9.1% (QL), 7.2 ± 6.3% (MF), and 9.8 ± 7.1% (ES) in normal subjects. No significant difference was seen any in BL-Diffs between groups. AP-Bal of dancers was significantly larger than that of normal subjects (29.1 ± 14.8% for dancers, 18.8 ± 10.0% for normal subjects,  $p < 0.01$ ). These results imply sagittal plane of trunk movement executed more than lateral movement in dance sport. Throughout the dance movement, the expert dancers hold their posture in upright position (Steven et al., 2007). However, anterior pelvic tilt and lumbar lordosis are a common technical fault among pre-professional ballet dancers (Deckert et al., 2007). To keep upright posture without anterior pelvic tilt or lumbar lordosis, activation of abdominals are required. Therefore, AP-bal in dancers was larger than that in normal subjects. (1997). *Clin Biomech*, 12, 181-184 Chatfield S, et al. (2007). *J Dance Med Sci*, 11, 76-84

### THE EFFECT OF ANKLE TAPING ON THE GROUND REACTION FORCE IN VERTICAL JUMP PERFORMANCE

Koyama, K.1, Honda, I.1, Yanase, R.1, Kato, T.1, Yamauchi, J.2,3

1:Toin University of Yokohama, 2:Tokyo Metropolitan University, 3:Future Institute for Sport Sciences

**[Introduction]** Ankle joint injuries are the most common injuries across a wide variety of sports (Rovere et al., 1998). One of most common ankle injuries is an ankle sprain, which is often caused by an inversion of foot so that the muscles, tendons and ligaments on the outside of the ankle are injured. Accordingly, ankle taping is commonly used when athletes return to play after ankle injuries in order to prevent re-injuries. The prescription of an ankle taping is designed to protect the structures re-injured the connective tissues so as to limit the joint movement. On the other hands, ankle taping may restrict ankle plantar-flexion movement in some degrees (Quackenbush et al., 2008). Such limitation of movement may affect to the athletic performance. However, despite requiring ankle taping in many sport activities, there are only few researches on the study of the effect of ankle taping on the muscle force generating capacity in the dynamic movement. Therefore, the purpose of this study was to investigate the effect of closed basket weave ankle taping on the vertical ground reaction force in vertical jump performance. **[Method]** Thirteen healthy young men (age, 20.2±1.3year; height, 1.76±0.05m; body weight, 66.1±6.1 kg; mean±SD) performed the vertical jump performance on the force plate with (CON) or without ankle taping. Ankle taping with closed basket weave technique (CLO) was performed on the right ankle joint. Vertical jump ability was assessed by using four styles of

vertical jump as follows: a countermovement jump without using arm swing (CMJ) and squat jump without using arm swings (SJ). In CMJ and SJ, subjects placed their arms in front of their chest throughout the entire jump and kept their torso in an upright position in order to emphasize using the leg extensor muscles. Subjects attempted to jump as high as possible and performed three trials of each type of vertical jump with sufficient time for recovery between attempts. Height of vertical jump was calculated from the ground reaction force (GRF) measured with the force plate (Kistler, Switzerland) at 1 kHz. Impulse and maximum GRF were also calculated and time-series GRF was recorded. The highest trial of each type of vertical jump was used for further analysis. [Result] Jump height was significantly lower for CLO than CON (CLO:  $36.6 \pm 6.6$  cm vs. CON:  $38.1 \pm 6.7$  cm,  $p < 0.01$ ). In the time-series GRF, GRF was also significantly lower for CLO ( $12.8 - 19.4$  N/kg) than CON ( $13.3 - 20.3$  N/kg) before take off, and these decreases in CLO represent 2.9-6.4% of CON. On the other hands, impulse and maximum GRF were not significantly different in each condition. [Discussion] These results suggest that ankle-taping (CLO) limits the range of ankle plantar flexion and force generation of plantar flexor muscles during vertical jump, causing to an impairment of jump performance. #### ACCELEROMETRY OF SELF-PACED CHILDREN'S GAMES DURING ACTIVE PLAY

Moghaddaszadeh, A., Matta, H., Jamnik, V., Belcastro, A.N.

*York University*

**Introduction** When monitoring children's physical activity, accelerometer (ACC) assessments of vector magnitude (VM) and vertical axis (V-A) are effective for estimating energy expenditure of locomotor activities. During self-paced physical activity (PA) the linear relationships for VM and V-A are modified (i.e., higher intercept and less slope), promoting increased mean standard error and decreased explained variance. The implication is that ACC profiles derived from linear equations (treadmill calibration) are limited when assessing children's active play; however factors contributing to this limitation with self-paced PA are uncertain. The purposes of the study were to determine: a) the nature of the relationships between counts from individual axes and VM for self-paced/unregulated children's games; and b) assess what impact a dominant axes may have on these relationships. **Methods** Children's ( $n=15$ ,  $9.3 \pm 1.2$  yrs; BMI  $20.5 \pm 4.0$ ) cardiorespiratory and metabolic responses to treadmill activity (4, 6 and 8 km/h (0% grade)) and active playing of 6 games were determined using FITMATE. Accelerometers (ActiGraph GT3X) collected PA counts (10sec epochs) for all activities. The linear regression equations (VM for time, VO<sub>2</sub>) generated for each activity, and relative contribution of each axes, were compared (ANOVA) and assessed at  $p=0.05$ . **Results** During treadmill activity the linear relationships for VM with speed (at 4, 6, and 8 km/h) and oxygen consumption (VO<sub>2</sub>) were  $0.90 \pm 0.03$  and  $0.82 \pm 0.05$ , respectively ( $p > 0.05$ ). The linear relationships (VM with time and measured VO<sub>2</sub>) averaged over 6 self-paced games were  $0.061 \pm 0.035$  and  $0.006 \pm 0.002$  ( $p < 0.05$ ). Linear regressions for each game resulted in a range of intercepts, for VM and time, from  $520 \pm 198$  cnts/10sec to  $1189 \pm 196$  cnts/10sec ( $p < 0.05$ ) compared to treadmill values of  $193 \pm 95$  cnts/10sec ( $p < 0.05$ ). The measured VO<sub>2</sub> values for self-paced games were consistently higher at lower counts (VM) for all games. The percent difference in axis contribution to VM between the dominant and lowest axis was  $41 \pm 14\%$  and  $7 \pm 5\%$  for treadmill activity and self-paced games, respectively ( $p < 0.05$ ). **Discussion** This study reveals that characteristics of children's self-paced PA impacts the linear relationship identified by ACC for locomotion activities. The higher estimates of VO<sub>2</sub> at constant VM for self-paced active play using linear regression calibrations from increasing treadmill activity (speed) is related to the presence of a dominant axis with ACC counts for treadmill, but not with ACC counts for self-paced active playing of games. The finding that axes dominance may underestimate VM up to 30% when total counts are similar may require ACC assessments of active play to be corrected.

#### THE EFFECTS OF A 6 WEEK ACSM EXERCISE INTERVENTION ON BODY COMPOSITION IN SEDENTARY OLDER MEN.

Herbert, P.2, Sculthorpe, N.1, Ratcliffe, J.1, Baker, J.1, Richards, J.3, Grace, F.1

*University of the West of Scotland*

**1**Institute for Clinical Exercise and Health Science, University of the West of Scotland, Hamilton, Scotland ML3 0JB **2**University of Wales, Trinity Saint Davids, Camarthen Campus, Camarthen SA31 3EP **3** Institute of Sport and Physical Activity Research, University of Bedfordshire, Bedford MK41 9EA **Introduction** The American College of Sports Medicine (ACSM) recommends a weekly exercise dosage of 150 minutes for adults (Garber et al., 2011) in order to improve and ensure long term physiological wellbeing. However, there is a lack of supporting evidence for the efficacy of these recommendations in older adults. The present study set out to examine the effect of a 6 week intervention using the ACSM guidelines on body composition in sedentary older males. **Methods** Untrained older males (UT,  $n=22$ ,  $62.4 \pm 5.4$  yrs) underwent 6 weeks of training in accordance with the ACSM's guidelines for the development and maintenance of cardiorespiratory fitness ( $\geq 30$  min.d<sup>-1</sup> on  $\geq 5$  d.wk<sup>-1</sup> for a total of  $\geq 150$  min.wk<sup>-1</sup>). Harpenden skinfold calipers were used to determine skinfold thickness at the biceps, triceps, subscapular and suprailiac sites on the left side of the subjects' body. Triplicate measures were obtained with average values used as criterion. Body density was estimated using the sum of skinfolds using procedures of Durnin and Womersley (1974). Percentage body fat (%BF) was estimated from body density using Siri's (1956) equation. Fat Free Mass (FFM) was calculated by subtracting fat mass (FM) from total body mass (TBM). Body Mass Index (BMI) was calculated by dividing subject body mass by height squared. Measures were obtained (Pre) and following 6 weeks of training (Post). At both time points, UT were compared with a group of master athletes (MA,  $n=17$ ,  $60.4 \pm 5.2$  yrs) acting as a positive control. Data were analysed using SPSS v 20 software using an ANOVA. Simple effects were investigated using a paired samples t-test. The alpha level was set at 0.05. **Results** Body composition did not change from Pre to Post in the MA group. However, TBM and BMI decreased significantly ( $p < 0.05$ ) in addition to % BF decrease ( $p < 0.01$ ) and subsequent increase in %FFM in the UT group from Pre to Post. When compared with the MA group, UT had significantly higher BF at all time-points ( $p < 0.01$ ). **Discussion** Data from the present study suggest that the ACSM guidelines are effective as a short term exercise intervention in improving body composition in older sedentary populations. Further, short term exercise interventions which conform to the ACSM guidelines can produce significant loss of fat mass. It remains to be seen whether body composition changes can translate to

improved metabolic regulation in ageing populations. References Garber, C. E., Blissimer, B., Deschenes, M. et al. 2011. *Med Sci Sports Exerc*, 43, 1334-59.

### REST AND EXERCISE FAT METABOLISM ADAPTATIONS IN RELATION WITH DIFFERENT AEROBIC TRAINING VOLUME

Brazo-Sayavera, J.I, Barrientos, G.2, Muñoz, D.1, Marcos, M.1, Timón, R.1, Olcina, G.1

1. *University of Extremadura*; 2. *Pontifical University of Salamanca*

**INTRODUCTION** The aerobic training volume required to induce changes in fat oxidation is not well known (Achten & Jeukendrup, 2004). The aim of this study was to analyse changes in plasma nonesterified fatty acids (NEFA) and triglycerides during rest and exercise in groups with different aerobic training volume in order to determine fat metabolism adaptations. **METHODS** "Well-trained" (WTr) (n=20) VO<sub>2</sub>max 68.31±8.65 ml·min<sup>-1</sup>·kg<sup>-1</sup> (20 hours of training pw), "Trained" (Tr) (n=20) VO<sub>2</sub>max 45.91±7.54 ml·min<sup>-1</sup>·kg<sup>-1</sup> (4-7 hours of training pw) and "Untrained" (UTr) (n=20) VO<sub>2</sub>max 35.49±4.93 ml·min<sup>-1</sup>·kg<sup>-1</sup> performed an incremental maximal test on cycloergometer starting at 100 watts, increasing workload each 3 minutes 25 watts until exhaustion. At the end of each step during testing protocol, blood sample was collected. Plasma nonesterified fatty acids and triglycerides were determined by spectrophotometry (Coulter model 6706319, Coulter Electronics LTD., England). Four points were chosen to compare NEFA and triglycerides concentrations (Baseline (B), Aerobic Threshold (AT), Anaerobic Threshold (AnT) and Final (F)). ANOVA and repeated measured test was performed for statistical analysis. A p<0.05 was used to determine statistical significance. **RESULTS** Baseline plasma NEFA concentration was higher in untrained group (WTr: 5.74±3.22mg/dL; UTr: 9.46±3.80mg/dL; p<0.05). Well Trained subjects showed lower plasma triglycerides concentrations in all points measured than other groups. Well-trained (B: 74.59±25.02mg/dL; AT: 76.68±18.19mg/dL; AnT: 80.52±17.35mg/dL; F: 86.73±22.04 mg/d) Trained (B: 93.5337.40 mg/dL; AT: 98.9339.54; AnT: 103.8739.85; F: 109.2141.12 mg/dL) and Untrained (B: 82.79±37.81mg/dL; AT: 89.75±35.49; AnT: 95.18±36.55; F: 98.57±35.31mg/dL). **DISCUSSION** The differences between groups in plasma fatty acids may be due to the adaptations observed in endurance athletes who increasing fat oxidation and it has been suggested that an increased capacity to oxidize fat is related to endurance capacity (Achten & Jeukendrup, 2004). Our data suggest that moderate exercise (4-7 hours per week) could be enough to cause a fat mobilization to be considered part of interventions aiming at body weight/fat reduction. **REFERENCES** Achten, J., & Jeukendrup, A. E. (2004). Optimizing fat oxidation through exercise and diet. [Review]. *Nutrition*, 20(7-8), 716-727. doi: 10.1016/j.nut.2004.04.005

### EFFECT OF OBESITY-RELATED GENE POLYMORPHISMS ON WEIGHT LOSS IN WRESTLERS

Nishimaki, M.1, Sakamoto, S.1, Hayakawa, Y.2

1:*Waseda University*,2:*Sigakkan University*

**Introduction** Single nucleotide polymorphisms (SNPs) of UCPI, ADRB3, and ADRB2 are associated with metabolic changes (Kahara et al., 2002). However, there is little understanding of the relationship between these SNPs and rapid weight loss in wrestlers (Shimizu et al., 2007). Therefore, the aim of our study was to examine the effects of SNPs in the UCPI, ADRB3, ADRB2 genes on rapid weight loss in wrestlers. **Methods** We studied 23 female wrestlers, aged 18.2 ± 2.1 years, who needed to lose weight rapidly before competing in national championships. Saliva samples were collected from these study subjects by using an Oragene™ DNA Self-Collection Kit. We developed a genotyping method by using quenching probes. The Q-Probe is a singly labeled oligonucleotide bearing a fluorescent dye that is quenched via electron transfer between the dye and a guanine base at a particular position. **Results** The rate of weight loss was higher in ADRB2 heterozygous individuals than in wild-type individuals (-2.3% ± 0.9% vs. -4.8% ± 2.7%, paired t-test, p = 0.049). The rate of change in body mass index (BMI) during rapid weight loss term was higher in ADRB2 heterozygous individuals than in wild-type individuals (-5.0% ± 2.7% vs. -1.9% ± 1.2%, paired t-test, p = 0.030). The percentage of body fat and BMI before rapid weight loss was lower in ADRB3 wild-type individuals than in heterozygous individuals, although the difference was only slightly significant. The percentage of body fat at 1 month after a wrestling match was lower in ADRB3 wild-type individuals than in heterozygous individuals (19.9% ± 3.3% vs. 23.4% ± 3.4% respectively, paired t-test, p = 0.022). **Discussion** We found that the ADRB2 Arg16Gly polymorphism was significantly associated with accelerated weight loss and reduced BMI in these female wrestlers. Thus, individuals with the ADRB2 Arg16Gly polymorphism may be at an advantage when rapid weight loss is required before wrestling matches. **References** Kahara T, Takamura T, Hayakawa T, Nagai Y, Yamaguchi H, Katsuki T, Katsuki K, Katsuki M, Kobayashi K. ### BENEFITS OF INTERVALLIC AEROBIC EXERCISE ON PARAMETERS OF METABOLIC SYNDROME IN GENETICALLY OBESE RATS.

Aparicio, V.A., Andrade, A., Kapravelou, G., Marfinez, R., Bustos, L., Nebot, E., Camiletti-Moiron, D., Aranda, P., López-Jurado, M., Delgado-Fernández, M., Galisteo, M., Arrebola, P., Porres, J.M.

*University of Granada*

**Introduction** The regular practice of physical exercise provides unquestionable health benefits, including preventive effects on obesity, abnormal lipid and glucose metabolism, and oxidative stress. This study aimed to test the protective effect of intervallic aerobic exercise on metabolic syndrome parameters like hyperglycemia, hyperlipidemia and impaired antioxidant defenses. **Methods** A total of 40 male Zucker rats were divided into 4 experimental groups: lean exercise, lean sedentary, obese exercise, and obese sedentary. The study lasted for 8 weeks. Training took place 5 days a week increasing in intensity and duration. It was performed in a computerized treadmill with special design for rats (Haram et al.2008). VO<sub>2</sub> max was determined after performing an incremental test based on the protocol developed by Wissloff et al. (2001). Other parameters evaluated were plasma glucose, t-cholesterol, LDL-cholesterol and triglycerides, and hepatic antioxidant enzymes Cu/Zn-SOD, Mn-SOD, and catalase. **Results** The protocol of aerobic intervallic exercise improved the aerobic capacity of experimental animals as reflected in a trend towards increased VO<sub>2</sub>max and significantly higher VO<sub>2</sub>max speed and incremental test duration time. Significant hepatomegalia and steatosis, and higher levels of plasma glucose, t-cholesterol, LDL-cholesterol and triglycerides were observed among obese rats when compared to their lean controls, whereas all these parameters were lowered in the group of obese animals that performed exercise. The hepatic activity of Cu/Zn-SOD and Mn-SOD was significantly altered in obese rats and improved with exercise. **Discussion** The completion of an aerobic interval training protocol as an intervention to mitigate the symptoms of metabolic syndrome had positive effects on plasma lipid levels, response to oral glucose administration, liver status, and liver antioxidant capacity in an experimental model of genetically obese rats. Such improvements are related to the improve-

ment in aerobic capacity by the exercise groups as described by Haram et al. (2008). The beneficial effects of aerobic intervallic exercise in liver antioxidant status were more noticeable in obese when compared to lean animals, and point out to a buffering action of exercise on the oxidative stress conditions induced by the metabolic syndrome. ### **INTERVAL TRAINING IMPACTS BLOOD PRESSURE MORE EFFECTIVELY THAN WORK MATCHED CONTINUOUS TRAINING IN OVERWEIGHT AND OBESE FEMALES.**

Lyall, G.K., Harris, E., Birk, G.K., Weeks, A., Khalil, A., Ferguson, C., Lawton, C., Dye, L., Birch, K.M.

*University of Leeds*

**Introduction:** The risk of cardiovascular disease (CVD) is significantly increased with obesity. A key element of this risk is the impact of obesity upon blood pressure and vascular function. Exercise training can improve CVD risk through improvement of these risk factors, however the relative effectiveness of traditional continuous exercise (CON) versus interval exercise (INT) training upon these parameters is not clear. The aim of this study was to compare the impact of heavy intensity work matched CON with that of INT training upon indices of vascular health in overweight and obese premenopausal women. **Method:** 20 sedentary females (42±6yrs) with a BMI>28 (mean 32±4kg/m<sup>2</sup>) and %Body Fat (mean 42.5±3.8%) were assessed at baseline for resting blood pressure (BP), resting heart rate, body composition, pulse wave velocity (PWV) using applanation tonometry and maximal aerobic capacity using a ramp-incremental (12W/min) step test. Participants were then matched for BMI and age and randomly assigned to either the INT (n=10) or CON (n=10) training group. Each participant trained on a cycle ergometer twice/week for 12 weeks. Both groups exercised within the heavy intensity exercise domain (~120% lactate threshold) with work being matched through total energy expenditure. The INT training involved repeated 40s exercise with 80s recovery (20W) bouts. Baseline measures were repeated after 12 weeks. Data were assessed by two-way mixed mode ANOVA. **Results:** Baseline data did not differ between groups (P > 0.05). Following training there was a trend for increased VO<sub>2</sub>max in both groups (INT pre 2051.2±389.1, post 2086.9±347.1, CON pre 2136.6±262.4, post 2224.7±259.8 ml/min: p=0.07). Superior benefits were seen for INT training for systolic BP (CON pre 124.8±14.5, post 124.1±14.0: INT pre 124.3±10.8, post 118.7±6.9mmHg: gpxtime interaction: p>0.05), systemic vascular resistance (CON pre 27.9±8.2, post 29.8±6.1: INT pre 27.3±4.9, post 24.3±3.3mmHg.min/L: gpxtime interaction: p=0.06) and fat free mass (CON pre 59.0±4.3, post 57.6±3.7: INT pre 56.1±2.4, post 57.2±3.4%: gpxtime interaction: p=0.07). There were no training induced changes in BMI, W:H, PWV, or diastolic BP in either group (P > 0.05). **Discussion:** These results indicate that heavy intensity INT training for 12 weeks reduces systolic BP and systemic vascular resistance in a population of overweight and obese females. In addition there were superior changes in fat free mass associated with the higher work rates undertaken during INT. Arterial stiffness assessed via PWV did not change following either exercise training regime.

### **EFFECT OF PHYSICAL EXERCISE IN CHILDREN DIFFERING IN BODY MASS**

Bunc, V., Skalská, M., Hráský, P.

*Faculty of P.E. and Sports Charles University*

**Introduction** Alongside a range of health problems associated with increased body mass (BM), overweight or obesity is an important limiting factor for realization of regular physical exercise and qualitative life style. **Methods** The study goal was to assess the effect of movement intervention in children differing in BM. Study was carried out in 98 children with normal BM (age 12.4 ± 2.2 years), 68 overweight children (age 12.1 ± 2.0 years) and 59 obese children (age 12.7 ± 2.6 years). Body composition was determined by whole body multi-frequency bioimpedance method by tetrapolar configuration of electrodes using prediction equations that are valid for the Czech child population. The maximum functional variables were determined on a treadmill with a slope of 5% during a progressive walking test until subjective exhaustion. The initial speed on the treadmill was 4km.h<sup>-1</sup>, and was increased each minute by 1 km.h<sup>-1</sup>. The cardiorespiratory variables were measured in an open system using an online method by TEEM 100 (Aerosport). All analyzers were checked before and after each test by calibration gas of known concentration. The ventilation was controlled before and after test by a mechanical pump. The energy demand of physical exercise was measured by a Caltrac monitor, and simultaneously by an assessment of energy cost during the exercise from the general relationship between the exercise intensity and the energy that a person needs to cover the activity. The differences between both methods were lower than 12%. **Results** Weekly movement program for children with normal BM ranged the energy content from 1360 kcal (5685 kJ) to 2620 kcal (10952kJ) (mean 1980 ± 310 kcal - 8276 ± 1296 kJ) in children with overweight from 1650 kcal (6897 kJ) to 2310 kcal (9656 kJ) (mean 1920 ± 230 kcal - 8026 ± 960 kJ) and in obese children, then from 1940kcal (8109 kJ) to 2550 kcal (9045 kJ) (mean 2260 ± 290 kcal - 9447 ± 1212 kJ). Relative changes in %BF ranged from 15.4 to 16.6%, the similar changes were found in body cell mass (BCM) from 14.2 to 16.1% and in relationship ECM/BCM - 15.0 - 16.3%, and in VO<sub>2</sub>peak from 13.9 to 15.7%. Changes in peak treadmill walking speed ranged from 12.8 to 15.3%. **Discussion** In children differing in BM are absolute changes in somatic and functional parameters like a result of imposed movement intervention substantively and statistically significant. On the contrary, differences in relative terms are insignificant. We may conclude that a similar intervention movement program may invoke the similar changes in body composition and in both motor and functional performance in children differing in BM, i.e. independently on actual body mass assessed child.

### **THE ENERGETIC COST OF ZUMBA CLASS IN MIDDLE AGED WOMEN**

Strejčová, B., Konopková, R., Řehořková, M., Bunc, V.

*Faculty of Physical Education and Sport*

**Introduction** These days, there is a decrease in the activity of the population and as a result there is an increase in the percentage of overweight or obese people. In general, the criteria for improving the cardiorespiratory capacity are: training frequency 3-5 days per week, an intensity of 65-90% from maximal heart rate (HRmax); 50-85% of maximal oxygen uptake (VO<sub>2</sub>peak) and duration of 20-60 min of continuous and intermittent activity using large muscle groups (ACSM, 2010; Laukkanen et al., 2001). These aspects lead to us to find new forms of acceptable movement activities. Nowadays, people fancy dance fitness programmes such as Zumba. Therefore the aim of this study was to compare the cardiorespiratory cost of such exercise with other aerobic exercises and to assess the energy expenditure during Zumba class in middle age women group. **Methods** The subjects were recruited from the clients of a private fitness club. A group of 6 women (age range 27-37 years) volunteered to participate in the study. Anthropometric data (body weight, high, total body fat) were 68.5±10.8 kg, 170.3±6.6 cm, 27.4±6.6 % and maximal aerobic capacity (VO<sub>2</sub>peak) during running test on the treadmill with maximal heart rate was 27.4±6.6 ml•kg<sup>-1</sup>•min<sup>-1</sup> and 183±15 bpm. Oxygen uptake (VO<sub>2</sub>) was measured during the whole Zumba class. The

energy cost was calculated converting the estimated VO<sub>2</sub> to kcal, using the constant of 5 kcal (4.18 kJ) on 1 l VO<sub>2</sub> oxygen consumption with respiratory exchange ratio equals number 1 (Otto et al., 2011). Results The percentage of average HR, VO<sub>2</sub> during whole Zumba class compared with maximal running test were in the 76.7 % from the maximal HR and 51.2 % from the VO<sub>2</sub> peak. The intensity of the whole Zumba class is on the 68.4 % of maximal running test with the oxygen consumption. In the whole the lesson was consumed 404.8 kcal (resp. 1692.2 kJ). The intensity of whole lesson reported by HR was covered by 67.5 % from maximal HR-high intensity exercise. In the central phase there was the highest energetic cost (336.3 kcal, resp. 1405.9 kJ). Discussion Our results showed that the energy cost of Zumba is in the middle exercise intensity of maximal oxygen consumption according ACSM (ACSM, 2010). Regardless of the variety of the participants and the apparent effect, there is the growing popularity of Zumba classes as the new trend of fitness. It could be used thanks to the intensity and energy expenditure as weight reduction program for obese patients via funny dancing activity. References ACSM. (2010). ### **RESISTANCE TRAINING ALONE OR COMBINED WITH DIETARY MODIFICATIONS? SEARCHING FOR OPTIMAL STRATEGIES TO MAINTAIN MUSCLE MASS IN HEALTHY ELDERLY**

Strandberg, E.I, Hosford-Donovan, A.I, Ponsot, E.I, Wåhlin-Larsson, B.I, Kadi, F.I

*Örebro University*

Introduction It is well documented that resistance training is beneficial for maintenance of muscle mass in elderly (Peterson et al., 2011). However, there are very few studies performed on healthy elderly women which are considered to be successfully aged. There is also little information about the effects of combined training and dietary interventions on muscle mass. The purpose of this study was to determine the effects of long-term resistance training and dietary interventions on whole body composition and muscle mass, biomarkers of inflammation and oxidative stress in healthy and physically active elderly women. Methods 61 healthy elderly women (65-70 yrs) were randomized into a control group (C), a training group (T) and a training group assigned to a diet with anti-inflammatory properties according to Nordic nutritional recommendations (TD). Both training groups performed a 24-week training program consisting of resistance exercises for both the lower- and upper body. Leg strength was assessed using 1 RM test in leg-extension, and body composition was determined using Dual X-ray Absorptiometry (DXA). Muscle biopsy samples were obtained from the mid-portion of m.vastus lateralis using the percutaneous needle biopsy technique. In plasma samples, levels of oxidative stress markers were evaluated using a sandwich enzyme-linked immunosorbent assay (ELISA) and levels of inflammation markers were assessed using GC 2010 gas liquid chromatograph (Shimadzu, Japan). Immunohistological and biochemical analyses are performed on muscle biopsies. Results Preliminary results show the occurrence of significant increase in 1 RM of leg-extension in training groups, approximately 20 % in T and 22 % in TD, whereas no changes were found in C. In contrast to changes seen on performance markers, a significant reduction of approximately 4.35 % in total body fat occurred only in TD but not in T or C. Similarly, a significant increase in leg lean mass occurred in TD but not in T and C. Significant associations were found between inflammatory markers, oxidative stress markers and fat mass. Cellular and molecular events behind the effects observed are under investigation. Discussion This study clearly demonstrates that in healthy and physically active elderly women, resistance training should be associated with dietary modifications in order to promote positive effects on muscle mass. Cellular and molecular pathways involved in the response to the combination of resistance training and dietary interventions should be depicted. References Peterson M., Sen A., Gordon P. (2011). MSSE, 43 (2), 249-258.

### **DOES RESTING METABOLIC RATE REMAIN ELEVATED FOLLOWING HIGH INTENSITY INTERMITTENT EXERCISE?**

Kelly, B., King, J.A., Goerlach, J., Nimmo, M.A.

*Loughborough University*

Introduction Interest surrounding high intensity intermittent training (HIIT) has increased due to findings demonstrating a striking capacity to improve diverse metabolic health parameters after very brief interventions (Gibala & Little, 2010). HIIT can favourably alter body mass and composition with changes occurring with a low training volume and associated energy expenditure (EE) (Boutcher, 2011). This investigation sought to characterise the EE and excess post exercise oxygen consumption (EPOC) (11 h post-exercise) of two common HIT protocols. Methods Oxygen consumption ( $l \cdot min^{-1}$ ), respiratory exchange ratio (RER), and EE ( $kJ \cdot min^{-1}$ ) were measured in nine healthy males over 12 h under three conditions; resting control (CON), H1E1 (10 x 60 s intervals) and H1E2 (10 x 4 min intervals). The abbreviation H1E refers to an acute bout of high intensity exercise as opposed to a training programme consisting of HIIT. All parameters were recorded continuously during the exercise period (EP) and for ~1h post exercise (RP - rapid phase of EPOC). Thereafter, the first 15 of every 30 min period was measured until ~2015 h (SP - slow phase of EPOC). Results Total EP (0h - 1h) EE during H1E1 (1151 (205) kJ) was significantly lower than H1E2 (2788 (322) kJ);  $p < 0.05$ ). The EE during exercise recovery periods in H1E1 and H1E2 contributed to ~293 and ~473 kJ respectively. EE during the RP period (1h - 2h) immediately after exercise was significantly higher after H1E1 (431 (50) kJ) and 2 (431 (42) kJ) compared with control (368 (46) kJ);  $p > 0.05$ ), with no differences between exercise conditions. During the SP period (2 h - 12 h) there were no significant differences in EE or fuel utilisation in any experimental condition. In the RP period RER was significantly lower in H1E1 (0.78 (0.06)) and H1E2 (0.76 (0.04)) compared with CON (0.87 (0.06));  $p < 0.05$ ), with no significant differences between exercise conditions. Conclusion • This study reveals that during exercise H1E2 expends significantly more energy compared to H1E1 with both exercises expending more energy than a control trial. • For ~ 60 minutes after exercise RMR is significantly elevated above that of control for both exercise conditions. There is no difference between exercise conditions. • Between 2-12 hours there is no significant difference in RMR between any experimental condition. • Collectively over the 12h period H1E1 and H1E2 showed a greater EE compared with control, with EE in H1E2 being significantly higher than H1E1. A time-efficient exercise strategy to improve muscle insulin sensitivity. J Physiol 588: 3341-2

### **INCREASES IN RESTING ENERGY EXPENDITURE AND ORGAN-TISSUE MASSES WITH WEIGHT GAIN IN ATHLETES**

Higuchi, M., Miyauchi, S., Oshima, S., Asaka, M., Kawano, H., Torii, S.

*Waseda University*

Introduction: Although overweight athletes have greater resting energy expenditure (REE) and fat-free mass (FFM) including high metabolic rate organ-tissue, the associations between REE and each internal organ-tissue mass in athletes with great changes in body weight are not yet clear. The previous cross-sectional study suggested that high REE in overweight athletes was due to greater absolute FFM,

including low and high metabolic rate organ-tissues, such as skeletal muscle (SM), liver, and kidney, and that the ratios of liver, brain, heart, and kidney masses to FFM in Sumo wrestlers were similar to those in non-athletic control peers. However, it has not been confirmed by longitudinal study whether the combination of overfeeding with physical training increases organ-tissue mass of FFM except for skeletal and heart muscles in athletes. Therefore, we determined whether overfeeding and physical training in collegiate male American football players increases REE and high and low metabolic rate organ-tissue masses in cross-sectional and longitudinal studies. Methods: Freshmen (n = 10) and senior American Football players in their second and third years of college (n = 17) participated in the cross-sectional study. In the longitudinal study, freshmen (n = 10) were followed-up for one year of overfeeding and physical training. FFM, SM, adipose tissue, liver, kidney, brain, and heart volumes were estimated by DXA, MRI, or echocardiography. Measured REE was determined by indirect calorimetry. Predicted REE was estimated as the sum of individual organ-tissue masses multiplied by their metabolic rate constants. Results: In the cross-sectional study, senior players showed higher measured REE than freshmen (2010 vs. 1656 kcal/day,  $P < 0.01$ ). Senior players had higher FFM and organ-tissues mass, but no differences in ratio of organ-tissue mass to FFM. In the longitudinal study, SM, liver, heart, and kidney masses in freshmen increased after one year, but there were no changes in ratio of organ-tissues to FFM. Measured and predicted REEs increased by 5.3% and 8.9%, respectively, with overfeeding and physical training ( $P < 0.01$ ). CONCLUSION: The present cross-sectional and longitudinal investigations indicated that there are increases in not only low metabolic rate organ-tissue masses, such as SM and AT, but also in high metabolic rate organ-tissue masses, such as the liver and kidney, with a combination of overfeeding and physical training in collegiate male American football players. Furthermore, these increases in low and high metabolic rate organ-tissue masses may lead to increased REE of these athletes. These findings suggest that changes in REE in athletes with overfeeding and physical training respond to variation in body composition or each organ-tissue mass in overweight athletes.

### EFFECTS OF 4-WEEKS LOW-VOLUME HIGH-INTENSITY INTERVAL TRAINING IN OBESE INDIVIDUALS

Vargas-Fernández, E.I, Sehle, A.I, Gruber, M.I, Kaiser, S.I, Vieten, M.I

1: University of Konstanz 2:Klinikum Konstanz

Introduction Obesity strongly increases the risk for insulin resistance, type 2 diabetes and cardiac disease. Low-volume, high-intensity interval training (HIT) has recently been suggested as a time effective exercise strategy to improve cardiovascular and skeletal muscle metabolism (Gibala et al., 2012). Acute and short-term (2 weeks) HIT has been shown to improve glucose homeostasis and muscle metabolism in type 2 diabetic patients (Gibala et al., 2012), however, to our knowledge, the long-term effects of this exercise model in obese people have yet to be studied. Methods Nine obese participants ( $51 \pm 2$  yrs; BMI  $40 \pm 2$  kg/m<sup>2</sup>) performed 12 sessions of low-volume HIT over a period of 4 weeks. Each session consisted of 5 to 12 repetitions of 1 min cycling at  $\approx 90\%$  of the maximal heart rate with 1 min of active recovery between each repetition. Pre- and post-training peak power output (W<sub>max</sub>) and peak oxygen consumption (VO<sub>2peak</sub>) were measured by a maximal exercise test on a cycle ergometer. In addition, glucose tolerance was assessed via a 2 h oral glucose tolerance test (OGTT) and resting metabolic rate (RMR) was measured by indirect calorimetry. Finally, blood lipid profiles were studied via standard techniques. Results Twelve sessions of training resulted in a significant increase of exercise performance (PRE  $144 \pm 10$  W<sub>max</sub> vs. POST  $164 \pm 12$  W<sub>max</sub>;  $p < 0.05$ ), without any significant increases in VO<sub>2peak</sub>. In addition, we observed a 20% increase in RMR (PRE  $1977 \pm 250$  kcal/day vs. POST  $2376 \pm 236$  kcal/day;  $p < 0.05$ ). The area under the curve (AUC) calculated during the OGTT showed a significant reduction of 8% post training ( $p < 0.05$ ). Finally, serum levels of high-density lipoprotein (HDL) increased 10% (PRE  $49 \pm 4$  mg/dL vs. POST  $54 \pm 5$  mg/dL;  $p < 0.01$ ) after training. Discussion In line with the effects of short-term low-volume HIT (Gibala et al., 2012), we have found an improvement on exercise performance and glucose homeostasis after 4 weeks of a similar training program. Moreover, we demonstrate that this approach also increases the RMR and serum levels of HDL, both parameters associated to metabolic health improvements. In conclusion, these data add further support to show that low-volume HIT is an efficient strategy to enhance cardiorespiratory fitness and metabolic profile in obese people. References Gibala, M. J., Little, J. P., Macdonald, M. J., & Hawley, J. A. (2012) Physiological adaptations to low-volume high-intensity interval training in health and disease. *J Physiol.* doi: 10.1113/jphysiol.2011.224725.

### STAY SLIGHTLY COOL TO STAY WARM IN THE MOUNTAINS

Draper, N., Corry, C., Fryer, S., Dickson, T., Hamlin, M.

University of Canterbury

Introduction There is an old adage that states to stay warm in the mountains you need to stay slightly cool. Yet typically clothing manufacturers advocate for a three layer clothing system for use by mountaineers (Nimmo, M. 2004; Long, 2003). Twight and Martin (1999) advocated for an alternative approach. The aim of this study was to compare the two different clothing systems, in simulated alpine conditions, to examine differences in physiological responses and effects on manual dexterity/skilful movement. Methods Ten healthy males, mean  $\pm$  (SD): age  $21.6 \pm 1.9$  yr, height  $1.81 \pm 0.09$  m, and mass  $80 \pm 3.4$  kg completed written informed consent and a medical health history questionnaire prior to taking part in the study. Participants completed the test twice (separated by 7 days) wearing one of the two clothing systems. The test protocol was conducted on a Woodway (Waukesha, Wisconsin, USA) treadmill and included a 5 min warm-up (4 km.hr, 9% gradient) before the participants completed two 20 min steady state exercise periods (4 km.hr, 9% gradient) each followed by a 10 min stationary (rest) period. Two way repeated measures ANOVA tests were calculated to assess for differences in thermal comfort, oxygen consumption, heart rate, core temperature and time to complete tying into the harness. Results There was a significant interaction effect  $F(3,24) = 21.50$ ,  $p < 0.0005$ , with post-hoc testing indicating significant differences at the end of each period except the second exercise period. There were no other significant differences between the clothing systems for the physiological measured assessed. Discussion The Twight system (Twight and Martin, 1999) has been proposed as an alternative clothing strategy for mountaineers. The aim of this study was to examine potential benefits of the Twight system over traditional layering during exercise in a simulated alpine environment. Results of the study indicated there were significant benefits with regard to thermal comfort but these were not realised in statistical differences between the physiological and skill-related measures (oxygen consumption, HR, core temperature, tying-in time). The length of the protocol could be usefully extended in a future study to examine these parameters in a longer duration protocol more akin to the days experienced by mountaineers. Such a study might result in the differences in thermal comfort being also seen in the physiological and skill-related measures. References Long, S. (2003). Hill Walking. **THE EFFECT OF MECHANICAL OVERLOAD ON FASTING-RELATED MUSCLE ATROPHY**

Ogata, T.

*Hiroshima Shudo University*

Introduction Fasting, or extreme calorie restriction, is frequently used for rapid weight loss in athletes who participate in sports with weight classes. However, fasting not only causes weight reduction, but also causes muscle atrophy as a result of nutrient deficiency. Fasting-related muscle atrophy is more common in fast-twitch muscles than in slow-twitch muscles. Therefore, we hypothesize that different sensitivities exist in fast-twitch and slow-twitch muscles in response to fasting, and that these sensitivities are partially associated with the frequency of mechanical stress in each muscle type. The purpose of the present study is to examine the relationship between fasting and muscle activity in response to functional overload in the rat plantaris muscle. Methods 8-week-old Fischer 344 rats were assigned to four groups: control (n=6), fasting (n=6), functional overload (FO; n=8), and FO+fasting (n=9). Rats in the fasting group were deprived of food for 72 hours and given ad libitum access to water. FO was applied to the plantaris muscle for 2 weeks. FO was applied by cutting synergists of plantaris muscle in FO rats. Western blot analysis was used to determine changes in mTOR and p70S6K phosphorylation in isolated plantaris muscles. Results The decreased reduction rate of plantaris muscle weight was observed in FO+fasting compared to fasting rats. Phosphorylated mTOR was elevated in the FO+fasting group but was not observed in the fasting group. In addition, levels of phosphorylated p70S6 kinase were higher in the FO+fasting group compared to the fasting group. Discussion Increased mechanical stress reduces fasting-related muscle atrophy. The elevation in phosphorylated mTOR observed in mechanically overloaded muscle may partially explain the reduction in muscle atrophy in FO+fasting rats. These findings suggest that frequent mechanical stress causes preferential atrophy in fast-twitch muscles compared with slow-twitch muscles.

**ANALYSIS OF MUSCLE BLOOD BIOMARKERS RELATED TO BIOMECHANICAL VARIABLES OF A CONCENTRIC EXERCISE UNTIL VOLITIONAL FAILURE**

Carmona, G.1, Guerrero, M.2, Bedini, J.L.3, Bescós, R.1, Cussó, R.2, Moras, G.1, Lloret, M.2, Rodas, G.4, Cadefau, J.2,3

*INEFC*

1: INEFC-UB (Barcelona, Spain), 2: Dep. de Ciències Fisiològiques I. UB (Barcelona, Spain), 3: Hospital Clínic (Barcelona, Spain), 4: Futbol Club Barcelona (Barcelona, Spain) Introduction Exercise-induced muscle damage is widely described in literature (Clarkson & Hubal, 2002; Schoenfeld, 2012). Using different blood markers of muscle damage it would be feasible to determine the overall magnitude of damage into the muscle, as well as the type of fibres affected. Methods Seven healthy volunteers performed an exercise test in a pneumatic leg press Air300 (KeiserTM, USA). The test consisted in a maximum of 10 sets with repetitions until volitional failure (Burd et al., 2010) at workload equivalent to 75% of 1RM. The power of each repetition was recorded using a linear encoder integrated to Musclelab 4020e (ErgotesTM, Norway) system. Three blood samples were taken (1: before exercise test; 2: 24 h post exercise; 3: 48 h post exercise) of each subject to analyse the plasmatic concentration of myosin muscle isoforms (fast and slow) and creatine kinase (CK). ELISA method was used to determine myosin concentration in plasma (adapted from Guerrero et al., 2007). Results CK levels were significantly increased at 24 hours post-exercise and significantly decreased at 48 hours post-exercise. In contrast, a different pattern was shown in myosin isoforms, which experimented a moderate raise at 48 hours post-exercise and only slow myosin was found statistically significantly elevated. Moreover, the 48 hours fast myosin serum peak value was strongly correlated to maximum strength (one maximum repetition -1RM-) ( $r=0,94$ ;  $p<0,01$ ) and fatigue index ( $r=0,78$ ;  $p<0,05$ ). On the other hand, the significant increase of slow myosin was correlated with the total amount of repetitions ( $r=0,79$ ;  $p<0,05$ ). Finally, the CK 24 hours peak value was inversely correlated with fatigue index ( $r=-0,82$ ;  $p<0,05$ ). Discussion High serum levels of CK indicated muscle damage, which would be associated with an increase of membrane permeability (Baird et al., 2012). Although the concentric exercise (even until volitional failure) seems to produce a modest degradation of the contractile apparatus the serum increases in both fast and slow myosin isoforms, could be related with the exercise pattern performed by subjects. Interestingly, this fact may explain a major or less recruitment of the different types of muscle fibres during the physical exercise. References Baird MF, Graham SM, Baker JS and Bickerstaff GF. **COMPARISON OF MUSCLE DAMAGE INDUCED BY MAXIMAL ECCENTRIC CONTRACTIONS BETWEEN ELBOW FLEXORS AND KNEE EXTENSORS OF OLDER ADULTS**

Nogueira, F.1,2, Libardi, C.1,2, Nosaka, K.3, Vechin, F.1,2, Cavaglieri, C.1, Chacon-Mikahil, M.P.1

*1:UNICAMP (Brazil), 2:USP (Brazil), 3 ECU (Australia)*

Introduction Unaccustomed eccentric exercise (ECC) results in muscle damage characterised by delayed onset muscle soreness and prolonged decreases in muscle function. Previous studies showed that the magnitude of muscle damage following ECC is smaller for knee extensors (KE) than elbow flexors (EF) in young individuals, probably due to a protective effect in the lower limb muscles conferred by submaximal ECC performed in daily activities (1,2). However, it is not known whether this is also the case for older individuals. It is possible that the greater decreases in leg muscle function with ageing compared with arm muscle function narrows the difference in the susceptibility to muscle damage between EF and KE. This study compared changes in muscle damage markers following maximal ECC between EF and KE of older adults. Methods Eight older adults ( $61.6 \pm 1.8$  y,  $75.6 \pm 3.5$  kg,  $1.66 \pm 0.04$  m) with moderate level of daily life activities performed 5 sets of 6 maximal isokinetic ( $90^\circ/s$ ) eccentric contractions of the EF ( $80-20^\circ$ ) and KE ( $30-90^\circ$ ) in a randomised, counterbalanced order with 2 wks between bouts. Maximal voluntary isometric (MVC-ISO) and concentric contraction torque (MVC-CON),

optimum angle (OA), range of motion (ROM), muscle soreness and serum creatine kinase (CK) activity were measured before, immediately after (except CK), and 24, 48, 72 and 96 h following ECC. Normalised changes in the variables following ECC were compared between EF and KE by a mixed model ANOVA. Results All dependent variables except OA showed significant changes over time after both EF and KE ECC, demonstrating muscle damage regardless of the limb utilised. However, the magnitude of change in the variables was small for both exercises. Only MVC-ISO and ROM demonstrated smaller decreases after KE compared with EF (group effects,  $p < 0.05$ ), but no significant muscle  $\times$  time interaction effects were found for the changes in any of the variables. Discussion The previous studies with young adults reported significantly smaller changes in muscle damage variables after ECC of KE when compared with EF (1,2). The results of the present study suggest that the difference in the susceptibility to ECC-induced muscle damage between EF and KE becomes smaller with ageing. It may be that neuromuscular adaptation of the KE to submaximal eccentric contractions performed in daily activities is attenuated with ageing. It is concluded that the KE of older adults are relatively as susceptible to muscle damage as EF, or at least, the difference in muscle damage between EF and KE is small for older adults. ## REPEAT BOUT EFFECT ON ECCENTRIC EXERCISE INDUCED MUSCLE DAMAGE AND GLYCAEMIC RESPONSE

Hughes, J., Johnson, N., Brown, S., Stannard, S.

*University of Gloucestershire*

Introduction Following eccentrically biased exercise there are alterations in whole body glycaemic control (Kirwan et al., 1991). These alterations are associated with reduction in the quantity of glucose transporters available for translocation to the cell membrane (Asp et al., 1995), therefore reducing the muscle's ability to adequately synthesise glycogen following eccentric biased exercise (Costill et al., 1990). Following an initial bout of eccentric biased exercise, skeletal muscle experiences a "repeat bout" effect (Byrnes et al., 1985). That is, a subsequent bout of eccentric work performed by the same muscle results in reduced muscle soreness and reduction in function. The purpose of this study was to investigate whether disruptions to the glucose and insulin response to an oral glucose tolerance test (OGTT) following eccentric exercise can be attenuated after a repeated bout of eccentric exercise. Methods Eight male participants performed an initial bout of squat exercise (SE1), followed 14 days later by another (repeat) bout of squat exercise (SE2). OGTTs were administered at baseline and 48 hours after SE1 and SE2, and circulating glucose and insulin were measured. Fasting levels of glucose, insulin, serum CK activity and performance measures (MVC, counter jump performance (CMJ) and perceived soreness) were also assessed pre, 24, 48 and 96 hours post SE1 and SE2. Results A trial  $\times$  time interaction was evident for CK, describing a significantly bigger increase following SE1 than SE2 ( $P = 0.006$ ). A significant trial  $\times$  time interaction was also evident for CMJ ( $P = 0.022$ ), with a greater decrease in height following SE1. A main effect of trial for perceived soreness ( $P < 0.001$ ) was revealed between SE1 and SE2 indicating a repeat bout effect had occurred. There were no significant differences in the fasting insulin ( $P = 0.968$ ) and glucose levels ( $P = 0.834$ ) following either SE1 or SE2. There were also no significant differences in the response of glucose or insulin ( $P = 0.905$ ;  $P = 0.762$  respectively) to the OGTT following the SE1 and SE2 in comparison to a control trial. The area under the curve (AUC) for both glucose and insulin following SE1 and SE2 also showed no significant difference from that of the control measure ( $P = 0.742$  and  $P = 0.955$ ). Discussion In conclusion, a bout of eccentric biased (squatting) exercise resulted in mild muscle damage. Recovery from the initial bout of eccentric exercise conferred a protective effect on the muscle performance following a subsequent bout of the same exercise performed 14 days later. However, this "repeat bout" effect was not associated with an altered glycaemic or insulinaemic response. References Asp, Daugaard & Richter (1995). *J Physiol*, 482, 705-712. ## EFFECT OF ANTIOXIDANT-RICH DATES ON ECCENTRIC EXERCISE-INDUCED MUSCLE DAMAGE

Zainuddin, Z., Ibrahim, H., Che Hashim, S.

*Universiti Teknologi Malaysia*

Introduction Dates which already know contain high antioxidant-rich originally cultivated from middle-east countries with scientific name "Phonex Dactylifera" are very common among muslims especially in fasting months. Proven scientifically for its high antioxidant nutrients, ingestions of these dates may assist the recovery of muscle damage as supplementation with antioxidants or beta-hydroxy-beta-methylbutyrate appears to provide a prophylactic effect in reducing muscle damage. The purpose of this study was to examine the effect of the dates intake during the recovery process following eccentric exercise on indirect markers of muscle damage. Methods Ten healthy male subjects (age:  $24.4 \pm 1.5$  y; height:  $168.3 \pm 7.1$  cm; weight:  $67.3 \pm 8.5$  kg) without history of muscle injury of upper arm and had not participate in specific strength training or exercises were involved in this cross-over design study. One arm was used for the experimental condition and the other arm for control condition in a randomised fashion with a 2-week interval. The exercise consisted of 6 sets of 10 eccentric contractions of the elbow flexors using a dumbbell equivalent to 70% of isometric maximal voluntary contraction with a 60 s rest between sets. In the treatment condition, the subjects ingested  $\pm 10$  g of dates (Phonex Dactylifera) a day for seven consecutive days following exercise. In the control condition, no dates were ingested during the recovery days. Muscle damage markers included upper arm circumference, range of motion (ROM), delayed onset muscle soreness (DOMS) and maximum isometric strength. These were measured before and one hour after exercise, and 1, 2, 3, 4 and 7 days after exercise. Repeated measure ANOVA were used to examine day to day changes following damage. Results No significant differences between conditions were evident for changes in MVC, ROM and DOMS, although they showed significant changes over time. Upper arm circumference showed a significant ( $P < 0.05$ ) difference between conditions, where there are significantly smaller increase experimental condition compared with the control condition Discussion It is concluded that dates fruit is only effective in reducing the diameter of the swelling but not effective to lessen DOMS and other indicator of muscle damage References Anwar-Shinwari, M. (1987). Iron content of date fruits. *Journal of the College of Science-King-Saud-University*, 18(1), 5-13. Cheung, K., P. A. Hume, et al. (2003). 'Delayed onset muscle soreness. ### EFFECT OF NEUROMUSCULAR ELECTROSTIMULATION VIA THE PERONEAL NERVE ON MUSCLE SORENESS AND SERUM CREATINE KINASE ACTIVITY FOLLOWING INTENSE INTERMITTENT EXERCISE

Ferguson, R.A., Dodd, M.J., Aw Yong, X.H., Kent, H.E., Malley, A.J., Price, S.M., Thorpe, B.A.

*Loughborough University*

**Introduction** Numerous techniques are reported to enhance recovery following intense exercise under the premise that enhanced blood flow facilitates the removal of metabolites associated with muscle damage; however, there is equivocal support for such claims. A novel technique of neuromuscular electrostimulation (NMES) of the lower limb via the peroneal nerve has been shown to augment venous, arterial and microvascular blood flow (Tucker et al., 2010) which could enhance the recovery process following intense intermittent exercise. The aim of the present study was to examine the effects of NMES on muscle soreness and serum creatine kinase (CK) activity following intermittent exercise. **Methods** Twenty-one (age  $21 \pm 1$  years, height  $179 \pm 7$  cm, body mass  $76 \pm 9$  kg, predicted  $\text{VO}_2\text{max}$   $54 \pm 5$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) healthy males performed a 90 min (2 x 45 min) intermittent shuttle running test on three occasions. Following exercise, one of the following interventions were applied: passive recovery (CON), graduated compression socks (GCS) or neuromuscular electrical stimulation (NMES). Interventions were applied 1 hr after the exercise and maintained for at least 12 hrs. Perceived muscle soreness (PMS) was measured and a venous blood sample taken pre-exercise and 0, 1, 24, 48 and 72 hrs following exercise. PMS was rated on a visual analogue scale ranging from 0 to 10. Serum CK activity was measured spectrophotometrically. PMS was analysed using a Friedman's ANOVA for non-parametric data. Serum CK activity was analysed using a two-way ANOVA. Significance was accepted at  $P < 0.05$  and data are presented as mean  $\pm$  SD. **Results** PMS increased ( $P < 0.05$ ) in all conditions immediately, 1 hr and 24 hrs post-exercise. PMS remained elevated in CON at 48 and 72 hours after exercise and in GCS at 48 hrs post-exercise ( $P < 0.05$ ). At 24 hrs PMS was lower in GCS compared to CON ( $3.2 \pm 2.1$  and  $4.6 \pm 2.0$ , respectively;  $P < 0.05$ ) and in NMES ( $2.0 \pm 1.6$ ) compared to GCS ( $P < 0.05$ ). At 48 hrs PMS was lower in NMES than in CON ( $1.3 \pm 1.5$  and  $3.1 \pm 1.8$ , respectively;  $P < 0.05$ ). Serum CK activity increased in all conditions immediately and 1 hr post-exercise ( $P < 0.01$ ). NMES had a tendency to be associated with a lower CK activity at 24 hrs, however, there were no differences between treatments at any time point. **Discussion** The use of a novel NMES technique reduces perceived muscle soreness and is superior to GCS in reducing perceived muscle soreness following intense intermittent exercise. **References** Tucker A, Maass A, Bain D, Chen L H, Azzam M, Dawson H and Johnston A. (2010). *Int J Angiol*, 19, 31-37. Supported by Sky Medical Technology.

### EFFECT OF NEUROMUSCULAR ELECTROSTIMULATION VIA THE PERONEAL NERVE ON ONE-LEGGED PEAK OXYGEN UPTAKE AND PEAK POWER OUTPUT FOLLOWING FOUR WEEKS OF HIGH INTENSITY INTERMITTENT TRAINING

Ferguson, R.A., Dodd, M.J., Thompson, E.B., Taylor, C.W.

*Loughborough University*

**Introduction** Numerous techniques have been suggested to enhance recovery following intense exercise; however, there is evidence that some of these practices, such as cold water immersion, may actually blunt the long term adaptive response to exercise (Yamane et al., 2006). We have previously demonstrated that the use of a novel technique of neuromuscular electrostimulation (NMES) enhances the recovery process following intense intermittent exercise (Ferguson et al., 2013). However, the long term effect of this technique and its impact on the adaptive response to training is not known. The aim of the present study was to examine the effects of NMES immediately following each training session during 4 weeks of high intensity intermittent training (HIIT). **Methods** Seven healthy males (age  $23 \pm 2$  years, height  $177 \pm 8$  cm, body mass  $79 \pm 17$  kg,  $\text{VO}_2\text{max}$   $47 \pm 7$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) completed 12 sessions of HIIT (3 sessions per week), which consisted of 3-7 repetitions of 30 second maximal sprints on a cycle ergometer, each separated by 4 minutes recovery. Immediately after each training session, using a within-subjects design, one leg underwent NMES treatment for an 8 hour period and the contralateral leg did not undergo any treatment (CON). Pre- and post-training measurements were made in each leg of one-legged peak oxygen uptake ( $\text{VO}_2\text{peak}$ ) and peak power output. A two-way (2 x 2) ANOVA with repeated measures was conducted to analyse the within-subject effect of treatment (NMES, CON) and time (pre, post). Significance was accepted at  $P < 0.05$  and data are presented as mean  $\pm$  SD. **Results** Whole body  $\text{VO}_2\text{max}$  increased ( $P < 0.05$ ) following 4 weeks of HIIT ( $47 \pm 7$  vs.  $51 \pm 7$  ml.kg<sup>-1</sup>.min<sup>-1</sup>, pre and post-training, respectively). There was a main effect for time for one-legged  $\text{VO}_2\text{peak}$  ( $P < 0.05$ ), which increased following training in CON from  $37 \pm 8$  to  $40 \pm 8$  ml.kg<sup>-1</sup>.min<sup>-1</sup> and in NMES from  $38 \pm 6$  to  $42 \pm 6$  ml.kg<sup>-1</sup>.min<sup>-1</sup>. There was a main effect for time on one-legged peak power output ( $P < 0.05$ ), which increased following training in CON from  $138 \pm 24$  W to  $157 \pm 32$  W and in NMES from  $142 \pm 36$  W to  $165 \pm 30$  W. There were, however, no differences between CON and NMES for either measure. **Discussion** The use of a novel NMES technique immediately following each training session during 4 weeks of HIIT does not have a detrimental effect on the adaptive response. **References** Ferguson RA, Dodd MJ, Aw Yong XH, Kent HE, Malley AJ, Price SM, and Thorpe BA. (2013). *ECSS, Barcelona*. Yamane M, Teruya H, Nakano M, Ogai R, Ohnishi N and Kosaka M. (2006). *Eur J Appl Physiol*, 96, 572-580. Supported by Sky Medical Technology.

### EFFECT OF CONCENTRIC AND ECCENTRIC EXERCISE ON BREATHING EFFICIENCY

Willems, M.E.T., Myers, S.D., Kelly, J., Cook, M.D.

*University of Chichester*

**Introduction** Ventilatory equivalents for carbon dioxide ( $\text{CO}_2$ ) and oxygen ( $\text{O}_2$ ) are the ratios of minute ventilation and  $\text{CO}_2$  output and  $\text{O}_2$  uptake, respectively, and indicators for breathing efficiency (Cooper and Storer, 2001). During steady-state cycling at 60% of maximal intensity, the ventilatory equivalent for  $\text{O}_2$  was increased 48 hours after eccentric-contraction induced muscle damage (Twist and Eston, 2009). It is not known whether the breathing efficiency differs during non-damaging and damage-inducing exercise. We examined the effect of concentric (non-damaging) and eccentric (damage-inducing) exercise, matched for intensity, on the ventilatory equivalents for  $\text{CO}_2$  and  $\text{O}_2$ . **Methods** Nine men ( $27 \pm 9$  yr,  $179 \pm 7$  cm,  $75 \pm 12$  kg,  $\text{V}'\text{O}_2\text{max}$ :  $52.0 \pm 7.7$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) underwent two 40-min (5x8-min with 2-min inter-bout rest) of concentric (level running, 0%, CON) and eccentric exercise (downhill running, -12%, ECC) on separate days. Running intensity was matched at 60% of maximal metabolic equivalent (MET) by measurements of individual 1 MET, relationship between level and downhill running speeds and MET and maximal MET obtained during a  $\text{V}'\text{O}_2\text{max}$  test. The Douglas bag technique was used for collection of expired gas samples. Maximal isometric force of m.quadriceps femoris of both legs was measured before and after the running protocols. Data were analysed with paired t-tests with significance set at  $P < 0.05$ . **Results** Running speed (CON:  $9.7 \pm 2.3$ , ECC:  $13.5 \pm 3.2$  km.h<sup>-1</sup>) and isometric force deficits (CON:  $-2.0 \pm 6.9\%$ , ECC:  $-17.2 \pm 7.7\%$ ) were higher for downhill running. Level and downhill running bouts had similar  $\text{V}'\text{O}_2$  (CON:  $2.28 \pm 0.51$ , ECC:  $2.20 \pm 0.34$  L.min<sup>-1</sup>), heart rates (CON:  $143 \pm 16$ ; ECC:  $147 \pm 19$  b.min<sup>-1</sup>) and respiratory exchange ratio (CON:  $0.89 \pm 0.03$ , ECC:  $0.89 \pm 0.05$ ) indicating matched intensity and metabolic demands. During downhill running, the ventilatory equivalents for  $\text{O}_2$  (CON:  $27.2 \pm 1.6$ , ECC:  $29.7 \pm 3.3$ ) and  $\text{CO}_2$  (CON:  $30.4 \pm 1.9$ , ECC:  $33.3 \pm 2.7$ ) were 7.1% and 8.3% higher, re-

spectively. Discussion Non-damaging and damage-inducing running exercise, matched at an intensity of 60% of maximal MET, showed a difference in breathing efficiency. Higher breathing efficiency during damage-inducing downhill running exercise may be related to higher impact forces. Because impairment of group III and IV muscle afferents elevated the ventilatory equivalent for CO<sub>2</sub> during steady-state cycling (Amann et al., 2010), damage-inducing downhill running exercise may occur with elevated discharge of group III and IV afferents. Do not insert authors here Introduction Exercise training improves microvascular (MV) function via elevated nitric oxide production and/or via an increase in capillary density (Lash et al. 1992). An acute post exercise cold water immersion (CWI) intervention enhanced the gene expression of vascular endothelial growth factor and nitric oxide (NO) synthase (NOS) (Ihsan et al. unpublished data). However, MV adaptations to regular post exercise CWI have yet to be investigated. The present study aimed to investigate the effect of training and regular post exercise CWI on MV function. Methods Eleven males performed 3 sessions/week of endurance training for 4 weeks. Following each session, subjects immersed one leg in a cold water bath (10°C; CWI) to the level of their gluteal fold for 15 min while the contra-lateral leg served as control (CON). Prior to, and following the training intervention, subjects performed a graded running test to exhaustion to determine their maximal oxygen uptake (VO<sub>2</sub>max) and aerobic speed (MAS). Additionally, MV function of the gastrocnemius was assessed in a randomised and counterbalanced order (i.e. CON & CWI limbs) using near infrared spectroscopy. While resting in a supine position, 5 min of popliteal artery occlusion was applied and upon cuff release, maximal changes in oxyhaemoglobin amplitude (O<sub>2</sub>Hbmax) response time associated with reaching O<sub>2</sub>Hbmax (RT) and 50% of O<sub>2</sub>Hbmax (RT50%), response rate (R-RATE; O<sub>2</sub>Hbmax/RT) and initial R-RATE (R-RATE50%; 50%-O<sub>2</sub>Hbmax/RT50%) were determined. Results Exercise training improved VO<sub>2</sub>max (6.0±7.7%, p=0.026) and MAS (6.4±3.9%, p<0.001). While RT, RT50% and R-RATE were not influenced by training (p>0.05), R-RATE50% increased by 26±47% in the CON limb post training (p=0.037). Furthermore, O<sub>2</sub>Hbmax was increased in both the CON (18±21%, p=0.049) and CWI (20±34%, p=0.018). As a result, when expressed relative to pre O<sub>2</sub>Hbmax, significant training effects were observed in RT (CON; 55±13%, p<0.001, CWI; 49±26%, p<0.001) and R-RATE (CON; 55±13%, p<0.001, CWI; pre=49±26%, p<0.001). Yet, when expressed relative to pre O<sub>2</sub>Hbmax, improvements in RT50% (CON; 23±46%, p=0.003, CWI; pre=14±34%, p=0.263) and R-RATE50% (CON; 23±46%, p=0.045, CWI; pre=14±34%, p=0.407) was only significant in the CON limb. Discussion The present findings suggest that regular post exercise CWI may suppress MV adaptations associated with the initial rate of O<sub>2</sub>Hb resaturation (RT50% and R-RATE50%). Somewhat contradictory to acute exposure (Ihsan et al. unpublished data), it is possible that regular CWI treatment may have attenuated exercise-induced NOS expression and hence flow-mediated MV function. Abstract: Muscle atrophy is linked to reactive oxygen species (ROS) production during hindlimb-unloading due, at least in part, to the activation of xanthine oxidase (XO). The major aim of our study was to determine the mechanism by which ROS cause muscle atrophy and its possible prevention by allopurinol, a well-known inhibitor of XO widely used in clinical practice, and indomethacin, a non-steroidal anti-inflammatory drug. We studied the activation of p38 MAP Kinase and NF-κB pathways, and the expression of two E3 ubiquitin ligases involved in proteolysis, the Muscle atrophy F-Box (MAFb) and Muscle RING Finger-1 (MuRF-1). Male Wistar rats (3 m old) conditioned by 14 days of hindlimb unloading (n=18), with or without the treatment, were compared with freely ambulating controls (n=18). After the experimental intervention, soleus muscles were removed, weighted and analyzed to determine oxidative stress and inflammatory parameters. We found that hindlimb unloading induced a significant increase in XO activity in plasma (39%, p=0.001) and in the protein expression of CuZnSOD and Catalase in skeletal muscle. Inhibition of XO partially prevented protein carbonylation, both in plasma and in soleus muscle, in the unloaded animals. The most relevant new fact reported is that allopurinol prevents soleus muscle atrophy by ~20% after hindlimb unloading. Combining allopurinol and indomethacin we found a further prevention in the atrophy process. This is mediated by the inhibition of the p38 MAPK-MAFbx and NF-κB -MuRF-1 pathways. Our data point out the potential benefit of allopurinol and indomethacin administration for bedridden, astronaut, sarcopenic and cachexic patients. ### **EFFECT OF CONCENTRIC AND ECCENTRIC EXERCISE ON POST-EXERCISE GLUCOSE CLEARANCE**

Willems, M.E.T., Myers, S.D., Kelly, J., Cook, M.D.

*University of Chichester*

Introduction Transient insulin resistance (i.e. a temporary decrease in insulin-mediated glucose clearance) has been demonstrated 48 hours after eccentric exercise (Green et al., 2010; Sherman et al., 1992). However, the acute effect of eccentric exercise on the responses of insulin and glucose to an oral glucose challenge is unknown. We examined the acute effect of concentric and eccentric exercise, matched for intensity, on the responses to an oral glucose tolerance test (OGTT). Methods Ten men (27±9 yr, 178±7 cm, 75±11 kg, V̇O<sub>2</sub>max 52.3±7.3 ml•kg<sup>-1</sup>•min<sup>-1</sup>) underwent three OGTTs after an overnight 12-hr fast: rest (C), 40-min (5 x 8-min with 2-min inter-bout rest) of concentric (level running, 0%, CON) or eccentric exercise (downhill running, -12%, ECC). Running intensity was matched at 60% of maximal metabolic equivalent (MET) by individual determination of 1 MET, relationship for level and downhill running speeds and MET and maximal MET obtained during a V̇O<sub>2</sub>max test. Douglas bag technique was used for expired gas samples. For OGTT, 75-g of glucose in water (Trutol 75, NERL Diagnostics) was consumed with 15-min blood samples for 2-hr and analysed for plasma glucose (YSI 2300 Stat Plus) and insulin (ELISA, IBL International). Maximal isometric force of m.quadriceps femoris of both legs was measured before and

after the running protocols. Data were analysed with ANOVA and t-test with significance set at  $P < 0.05$ . Results Downhill running speed was higher (CON:  $9.7 \pm 2.1$ , ECC:  $13.8 \pm 3.2$  km•h<sup>-1</sup>). Running protocols had similar  $\dot{V}O_2$  (CON:  $2.28 \pm 0.51$ , ECC:  $2.20 \pm 0.34$  L•min<sup>-1</sup>, n=9) and heart rates (CON:  $143 \pm 16$ , ECC:  $147 \pm 19$  b•min<sup>-1</sup>, n=9) indicating matched intensity. Downhill running resulted in higher isometric force deficits (CON:  $-3.0 \pm 6.7$ , ECC:  $-17.1 \pm 7.3\%$ ). During OGTTs, area-under-the-curve for plasma glucose (C:  $724 \pm 97$ , CON:  $710 \pm 77$ , ECC:  $726 \pm 72$  mmol•L<sup>-1</sup>•120 min<sup>-1</sup>) and insulin (C:  $4166 \pm 1882$ , CON:  $3887 \pm 1736$ , ECC:  $3640 \pm 1695$   $\mu$ U•mL<sup>-1</sup>•120 min<sup>-1</sup>), peak glucose (C:  $8.1 \pm 1.3$ , CON:  $7.7 \pm 1.2$ , ECC:  $7.7 \pm 1.1$  mmol•L<sup>-1</sup>) and peak insulin levels (C:  $60.2 \pm 31.4$ , CON:  $53.7 \pm 29.8$ , ECC:  $49.8 \pm 25.3$   $\mu$ U•mL<sup>-1</sup>) were similar. Discussion Post-exercise responses for plasma glucose and insulin to an oral glucose challenge were similar for concentric and eccentric exercise and not different from baseline. Insulin binding, insulin signalling pathways, glucose transporter availability and intracellular glucose disposal pathways do not seem to be affected by the acute effects of unaccustomed eccentric exercise. Post-exercise events in the days following unaccustomed eccentric exercise are required to develop transient insulin resistance. ### POST-EXERCISE COLD WATER IMMERSION ENHANCES GENE EXPRESSIONS RELATED TO MITOCHONDRIAL BIOGENESIS AND VASCULAR REMODELLING

Ihsan, M.1, Watson, G.4, Hui, C.C.1, Lewandowski, P.2, Papazzo, A.2, Cameron-Smith, D.3, Abbiss, C.R.1

*Edith Cowan University, 1: ECU (Perth, Australia), 2: DU (Melbourne, Australia), 3: UA (Auckland, New Zealand)*

Do not insert authors here Introduction Post-exercise cold water immersion (CWI) reduces core and muscle temperatures, muscle metabolic activity and blood perfusion (Ihsan et al., 2013; Peiffer et al., 2009). While these physiological responses may alter acute subsequent exercise capacity, the influence of CWI on muscle oxidative, vascular and metabolic adaptations are unclear. As such, the purpose of this study was to investigate the influence of CWI on post-exercise on vascular, metabolic and mitochondrial-related gene expression. Methods Nine physically active males performed 30 min of continuous running at 70% of their maximal aerobic running speed (MAS), followed by intermittent running to exhaustion at 100% MAS. Following exercise, participants immersed one leg in a cold water bath (10°C; CWI) to the level of their gluteal fold for 15 min. The contra-lateral leg remained outside the water bath and served as control (CON). Core body temperature (T<sub>c</sub>) was monitored throughout the experiment, while muscle biopsies and muscle temperature (T<sub>mus</sub>) measurements were obtained from vastus lateralis prior to exercise (PRE), immediately post exercise (POST-EX; muscle temperature only), immediately following CWI (POST-CWI) and 3 hr post exercise (POST-3HR). Significance was accepted at  $p < 0.05$ . Results The exercise protocol significantly increased T<sub>c</sub> (PRE;  $37.1^\circ\text{C} \pm 0.4$  vs. POST-EX;  $39.3^\circ\text{C} \pm 0.5$ ) and T<sub>mus</sub> (CON;  $38.8^\circ\text{C} \pm 1.0$  vs. CWI;  $39.0^\circ\text{C} \pm 1.4$ ). In contrast, CWI resulted in lower T<sub>mus</sub>, compared with CON ( $28.9^\circ\text{C} \pm 2.3$  vs.  $37.0^\circ\text{C} \pm 0.8$ ). PGC1- $\alpha$  mRNA content was 9-folds higher in CWI, compared with CON at POST-3HR (1792  $\pm$  1374 a.u. vs. 484  $\pm$  402 a.u.). Compared with PRE, mRNA content of VEGF and nNOS were significantly higher at POST-3HR in the CWI (5.3 & 13.4 fold, respectively), but not CON (2.6 & 6.8 fold, respectively). Likewise, a trend towards an increase in iNOS mRNA was observed in the CWI ( $p = 0.055$ ). No changes in gene expression were observed for COX-4, GLUT-4 and eNOS in either CWI or CON. Discussion These data indicate that an acute post exercise CWI intervention may enhance the gene expression of key regulators associated with mitochondrial biogenesis and vascular remodelling. As such, the use of post exercise CWI may enhance favourable adaptations and therefore have implications in both athletic and clinical settings. Further research investigating longer term exercise-induced muscle adaptations with regular CWI interventions is warranted. References Ihsan M, Watson G, Lipski M, Abbiss C. (2013). *Med Sci Sports Exerc*, (in press). Peiffer JJ, Abbiss C, Watson G, Nosaka K, Laursen PB. (2009). *J Sports Sci*, 27(10), 987-93.

### EXERCISE-INDUCED ATGL UPREGULATION INVOLVES AMPK IN SKELETAL MUSCLE

Higashida, K.

*Ritsumeikan University*

Introduction: Endurance exercise training increases lipolytic capacity and fat utilization in skeletal muscles (Hurley et al., 1986). This adaptation results from upregulation of proteins involved in lipolysis, such as adipose tissue triglycerol lipase (ATGL), hormone sensitive lipase (HSL) and MLDP (Alsted et al., 2009, Peters et al., 2012). However, the molecular mechanisms of how exercise modulates lipolysis-associated proteins are unclear. The purpose of this study was to elucidate the mechanisms underlying endurance exercise-induced lipolysis-associated proteins in rat skeletal muscles. Materials and Methods: Male Wistar rats swam for 6 h in two 3-h sessions separated by 45 min of rest. Immediately after or 18 h after the swimming exercise ended, the rats were anesthetized and epitrochlearis and soleus muscles were dissected out. C2C12 Myoblast were cultured in 12-well plates in DMEM supplemented with 10% FBS. Myoblast differentiation was induced by switching to medium containing 2% horse serum when myoblasts were confluent. Four days later differentiation, the myotubes were treated with 50  $\mu$ M 2,4-Dinitrophenol (DNP; an uncoupler of oxidative phosphorylation) for 18 h. Results: A bout of 6-h swimming exercise increased lipolysis-associated proteins (ATGL, MLDP and HSL) in rat epitrochlearis muscle. However, there was no significant increase in these proteins in exercised rat soleus muscle. Phospho-AMPK protein content in epitrochlearis muscle significantly increased immediately after swimming exercise, but not in soleus muscle. Treatment of C2C12 myotubes with 50  $\mu$ M DNP significantly increased phospho-AMPK and ATGL protein content. However, DNP treatment did not affect MLDP and HSL protein contents in C2C12 myotubes. Conclusion: These results suggested that activation of AMPK is involved in exercise-induced increase in ATGL protein content in skeletal muscle. **RELATIONSHIP BETWEEN BREAKFAST AND EXERCISE IN THE MORNING AND THE DAILY RHYTHMS OF PHYSIOLOGICAL PARAMETERS IN HUMANS**

Nishimura, K.1, Nagasaki, K.1, Yamaguchi, H.2, Yoshioka, A.3, Tamari, Y.4, Onodera, S.5, Takamoto, N.1

*1) Hiroshima Institute of Technology, 2) Kibi International University, 3) Kagawa University, 4) Graduate School of Hiroshima Institute of Technology, 5) Kawasaki University of Medical Welfare*

**Purpose:** The purpose of the present study was to determine the relationship between breakfast and exercise in the morning and the daily rhythms of physiological parameters such as oral temperature, heart rate, blood pressure, and cardiac parasympathetic nervous system modulation in humans. **Method:** Ten healthy Japanese men (age,  $21.9 \pm 1.4$  years) volunteered to participate in this study and provided written informed consent before participation. The oral temperature, heart rate, blood pressure, and cardiac autonomic nervous system modulation were first recorded at 0700, and then recorded every 2 h from 0800 to 2200. This study involved 2 conditions, and each condition was simulated on a different day. One was the breakfast and exercise (BE) condition. The BE -condition involved eating breakfast at 0730 and performing cycling exercises for 15 min at 0830. The exercise intensity was adjusted to 40% of maximum oxygen uptake. The other condition was the control (C) condition, in which the subjects did not eat breakfast or perform exercise. Each subject ate lunch at 1230 and dinner at 1830 in both conditions. The peak value and time of each physiological parameter assessed for daily rhythms were calculated by the least squares method. Each parameter was tested using two-way analysis of variance (ANOVA). Post-hoc Bonferroni/Dunn test was performed when a significant difference was observed in ANOVA. **Results and Discussion:** The oral temperature of the C -condition participants changed significantly over 24 h (ANOVA;  $p < 0.05$ ); Natural circadian rhythms were observed in all subjects. The changes in the oral temperature, heart rate, and diastolic blood pressure of participants in the BE -condition were more significant than those in the C -condition (ANOVA;  $p < 0.05$ , respectively). At 0800 and 1400, the ln HF, index of cardiac parasympathetic nervous system modulation, in participants in the BE -condition was significantly lower than that in the C -condition. The peak times of oral temperature, heart rate, cardiac parasympathetic nervous system modulation, and blood pressure of participants in the BE-condition were significantly shorter than those in the C -condition ( $p < 0.05$ , respectively). These data suggested that daily rhythms in humans might be maintained by habitual breakfast and exercise. In conclusion, the daily rhythms of the physiological parameters in humans were accelerated by habitual breakfast and exercise in the morning.

**ALTERATIONS OF NEUROMUSCULAR FUNCTION AFTER THE WORLD MOST CHALLENGING MOUNTAIN ULTRA- MARATHON**

Saugy, J., Place, N., Millet, G.Y., Degache, F., Schena, F., Millet, G.P.

*Lausanne University*

**Introduction** The aim of the present study was to investigate the etiology of neuromuscular fatigue on the most extreme MUM (mountain ultra-marathon) in the world. By using data recorded prior, during and after the event on both runners and control subjects, we aimed to characterize the specificities of such MUM and better describe the underlying mechanisms of extreme fatigue. **Methods** The race supporting this study was the Tor des Géants, 330km and 24000m elevation. 25 male runners took part to the present study and were tested before (Pre-); during (Mid-) and approximately 30 minutes after the run (Post-). A control group ( $n=8$ ) participated to this study, and was tested at Pre- and Post-. Both groups were constrained of the same level of sleep deprivation. MVC force loss of knee extensors (KE) and plantar flexors (PF) was evaluated to provide an index of global fatigue [1]. The voluntary activation ratio of KE and PF was assessed using superimposed high-frequency doublet to detect central fatigue. Finally, evoked stimulations were delivered to determine the extent and type of peripheral fatigue. **Results** Maximal voluntary contraction force declined significantly at Mid- ( $-13 \pm 17\%$  and  $-10 \pm 16\%$ ,  $P < 0.05$  for knee extensor, KE, and plantar flexor muscles, PF, respectively) and further decreased at Post- ( $-24 \pm 13\%$  and  $-26 \pm 19\%$ ,  $P < 0.01$ ) with alteration of the central activation ratio ( $-24 \pm 24\%$  and  $-28 \pm 34\%$ ,  $P < 0.05$ ) in runners whereas these parameters did not change in the control group. Peripheral neuromuscular fatigue markers as 100Hz doublet (KE:  $-18 \pm 18\%$  and PF:  $-20 \pm 15\%$ ,  $P < 0.01$ ) and peak twitch (KE:  $-33 \pm 12\%$ ,  $P < 0.001$  and PF:  $-19 \pm 14\%$ ,  $P < 0.01$ ) were also altered in runners but not in controls. **Discussion** This event induced lesser muscle damages than similar types of event of shorter duration, probably as a result of the very low concentric/eccentric contractions intensity due to the slow pace showing that the amount of neuromuscular fatigue is not necessarily correlated to the difficulty of the event. In addition, a control group allowed us to minimize the effects of sleep deprivation as the main factor of the neuromuscular fatigue in the runners. Beyond the influence of exercise duration on ultra-distance trails, the reduction in maximal force generating capacity seems to be related to other factors such pain in muscles and joints. Paradoxically, such extreme MUM seems to induce relative muscle preservation. **References** 1. Millet GY, Tomazin K, Verges S, Vincent C, Bonnefoy R, et al. (2011) Neuromuscular consequences of an extreme mountain ultra-marathon. *PLoS ONE*

**BENEFICIAL EFFECTS OF NECK COOLING ON EXERCISE CAPACITY AND COGNITIVE PERFORMANCE IN A WARM ENVIRONMENT**

Hasegawa, H., Shimizu, M.

*Hiroshima University*

**Introduction** The increase in core body temperature observed during exercise in hot environments is associated with decreases in prolonged exercise performance. A number of strategies, such as cold water immersion, wearing an ice jacket and cooling the neck region, have been suggested to combat the negative effects of associated high body temperature. The purpose of this study was to investigate the effect of cooling the neck region on endurance exercise capacity and cognitive function in a warm environment. **Methods** Eight male subjects underwent two familiarization trials and two experimental cycling trials. Subjects completed two experimental cycling trials at 65% maximum voluntary exercise to exhaustion with cooling collar at the neck during exercise (COOL) and without cooling collar (CONT)

at 30°C and 80% relative humidity. The modified Stroop color-word test (Stroop, 1935) and executive processing test (Tomprowski, 2007) were conducted to evaluate cognitive function every 10 min during exercise and at the exhaustion. During the cycling session, rectal temperature, skin temperatures, heart rate, ratings of perceived exertion, and thermal sensations were measured. Results In the COOL, time to exhaustion was significantly longer than that for the CON (COOL: 50.2 ± 6.3 min, CON: 43.9 ± 4.1 min,  $p = 0.04$ ). The reaction time of the Stroop color-word test for the CONT tended to long after 40 min exercise, and it was significantly worsened at the exhaustion compared to the COOL. Compared to baseline values, the total reaction time of executive processing test for the COOL was improved during the latter stages of exercise. Rectal temperature and heart rate were increased during exercise, but these physiological responses were not significantly different between the conditions at the same time points. In the COOL, ratings of perceived exertion at 35 and 40 min and thermal sensation from 15 to 45 min exercise were significantly lower than that for the CON trial. Discussion The present findings indicate that practical neck cooling increased the time taken to reach volitional exhaustion and cognitive function by dampening the perceived levels of exercise effort and thermal strain without altering physiological responses in a warm environment. These responses are consistent with the results of practical internal cooling techniques, such as cold drink and ice slurry ingestion during exercise in hot environments (Siegel, 2012). ### POST-EXERCISE HYPOTENSION IS GREATER IN THE MORNING THAN THE EVENING IN PRE-HYPERTENSIVE MEN

Brito, L.1, Rezende, R.1, Silva Jr, N.D.1, Menna-Barreto, L.S.3, Tinucci, T.1, Cipolla-Neto, J.2, Forjaz, C.L.M.1

1: EEFUSP (São Paulo, Brazil), 2: ICBUSP (São Paulo, Brazil), 3: EACHUSP (São Paulo, Brazil).

Introduction: Aerobic exercise is recommended to prevent hypertension in pre-hypertensive individuals. An acute bout of aerobic exercise promotes post-exercise hypotension (PHE). Some studies suggest that PEH is lower when exercise is performed in the morning. However, these studies did not include a control condition (without exercise) for controlling the circadian variations of blood pressure (BP), which limits data interpretation. Therefore, the aim of this study was to compare BP response and its hemodynamic mechanisms after an aerobic exercise bout performed in the morning and evening and corrected by the responses obtained in the control session performed at the same times of day. Methods: 12 young pre-hypertensive men underwent four randomized sessions - two conducted at 9 am and two at 6:30 pm. At each time of day, the subjects underwent a control and an exercise bout (cycle ergometer 45 min, 50% VO<sub>2</sub>peak). Before and after the interventions, BP, cardiac output (CO), stroke volume (SV), peripheral vascular resistance (PVR) and heart rate (HR) were evaluated. The net effects of exercise [(post-pre exercise) - (post-pre control)] were calculated for each time of day and were compared by a paired T-test.  $P < 0.05$  was accepted as significant. Results: Systolic BP decreased significantly, more in the morning than the evening (-8±1 vs -3±1 mmHg), while diastolic and mean BP decreased similarly at both times of day (-3±1 vs -3±1 and -4±1 vs -3±1 mmHg, respectively). CO decreased and PVR increased in the morning, while they did not change in the evening (-0.464±0.158 vs +0.058±0.188 l/min, and +3±1 vs -1±1 mmHg/l, respectively). SV decreased similarly at both times of day, while HR increased less in the morning (-12±3 vs -12±3 ml and +5±1 vs +9±1 bpm, respectively). Discussion: PEH occurred at both times of day, however, the net effect of exercise was greater in the morning than the evening for systolic BP. This difference was observed because CO decreased more in the morning due to a lower increase in HR at this time of day. Even though PVR increased in the morning, this increase was not sufficient to compensate CO reduction and to blunt systolic BP decrease. In conclusion, aerobic exercise has a greater hypotensive effect in the morning, because CO decreases more after exercise at this time of the day. ### THE EFFECTS OF ACUTE EXERCISE ON SLEEP IN CHILDREN

Yukako, I.

National Center of Neurology and Psychiatry

Introduction Sleep is an important component of adolescent growth and development. Laboratory studies using polysomnography in adults have shown that acute exercise results in a small improvements change in the quality of sleep (Kubitz KA et al., 1996). However, most studies with school-aged children have examined sleep duration and/or objective sleepiness by using questionnaires and, therefore, were unable to quantify sleep quality. The purpose of this study was to investigate the effect of acute high-intensity exercise on quality of sleep in children by using polysomnography. Understanding associations of physical activity and/or exercise with sleep quality could shed light on ways to promote sufficient sleep in children. Methods Seven healthy male subjects (mean age ± SD, 12.4 ± 0.5 years) were recruited for this study and underwent two conditions (Rest, Exercise). The exercise condition was performed using a bicycle ergometer for 30-min at 85% of maximal heart rate, 6-7 h prior to bedtime. In the rest condition, subjects rested quietly for 30-min. Polysomnography measurements were performed on two nights in random order at the subject's house. Vigilance test were carried out immediately after waking up. Results Data were analyzed from the five complete samples. The data of two samples could not complete for measurement by the device trouble. Mean total sleep time (TST) was 505.8 ± 31.7 min (Rest) and 495 ± 32.0 min (Exercise). Sleep efficiency was 93.9 ± 4.5% (Rest) and 92.2 ± 7.3% (Exercise). There were no significant differences in the TST, sleep efficiency or the duration of each sleep stage when the rest and exercise conditions were compared. Discussion This is one of the first studies to use polysomnography to obtain estimates of nocturnal sleep quality in response to exercise in children. There was no difference in sleep quality after acute high-intensity exercise in this population. However, ceiling effects for "good sleepers" have also been suggested (Youngstedt et al., 2006). This study may have included "good sleepers," whose age and fitness habits may have affected the results; the lack of differences in sleep quality may suggest that ceiling effects played a role. While this study demonstrated the feasibility of performing polysomnography at a subject's home, in order to estimate sleep quality in children, further research should include larger and/or more varied samples to examine the effects of exercise on sleep patterns. ### PHYSICAL ACTIVITY LEVEL IS DEPENDENT ON EXERCISE TRAINING AMOUNT IN FEMALE ATHLETES

Yoshida, A.1,2, Ishikawa Takata, K.2, Taguchi, M.1, Nakae, S.2, Tanaka, S.1,2, Higuchi, M.1

Waseda University

1: Waseda University (Saitama, Japan), 2: National Institute of Health and Nutrition (Tokyo, Japan) Introduction We have shown previously that there is substantial inter-individual variability in physical activity level (PAL) in female athletes (Yoshida et al., 2012). In ordinary people, PAL is affected by energy expenditure derived from daily physical activity (PA) except for exercise, as lifestyle PA, because of spending no

or short time for exercise. In people who exercise for long periods of time, including exercise training as athletes, it is not clear whether their PAL values depend mainly on exercise or lifestyle PA. This study therefore examined the relationships between PAL values and the amount and duration of exercise and lifestyle PA in female athletes. Methods The study participants included 11 rhythmic gymnasts (RGs) and 11 lacrosse players (LPs). PAL values were calculated by dividing total energy expenditure (TEE) assessed by the 8-day doubly-labeled water method, by resting metabolic rate, measured using an indirect calorimeter. The participants kept an activity diary, with daily PA being classified as training, sleeping, or other PA (lifestyle PA). The intensity of lifestyle PA was assessed using a tri-axial accelerometer. The amount of each PA pattern was calculated as (daily metabolic equivalent value) x (duration) (METs·h), and the amount of training as (daily total amount of PA assessed by TEE and diet induced thermogenesis) - (amount of PA other than training). Results No significant difference in mean PAL was observed between the RGs (2.59±0.63) and LPs (2.43±0.46) groups. The duration and amount of training were higher in the RGs than in the LPs, while mean PA intensity during training was similar in the two groups (RGs, 5.6±2.5 METs; LPs, 6.1±2.5 METs). Although the LPs had longer duration and a smaller amount of lifestyle PA than RGs, the duration and amount of each intensity of lifestyle PA relative to total lifestyle PA were not significantly different between the two groups. In RGs, a higher PAL was associated with a greater amount of training ( $r=0.875$ ,  $p<0.001$ ) and a smaller amount of lifestyle PA ( $r=-0.773$ ,  $p=0.005$ ). In LPs, a higher PAL was associated with a greater amount of training ( $r=0.927$ ,  $p<0.001$ ). Discussion This study showed inter-individual variability in the PAL values was dependent on the amount of training and lifestyle PA in RGs, whereas in LPs, PAL was related only to the amount of training. It is therefore necessary to assess both the amount of lifestyle PA and training using a combination of duration and intensity in order to predict PAL accurately in female athletes, and also take into account different sporting categories. ### THE INFLUENCE OF MORNING AND EVENING ENDURANCE EXERCISE ON METABOLIC RESPONSES AND INFLAMMATORY CYTOKINES IN YOUNG MEN

Kim, H.1, Takahashi, M.1, Numao, S.2,3, Endo, N.1, Konishi, M.3, Suzuki, K.1, Sakamoto, S.1

Introduction Endurance exercise is a potent stimulus that improves cardiovascular fitness and prevents obesity as well as obesity-related diseases. The circadian rhythm influences all aspects of physiological function including endocrine, nervous, immune system. However, the effects of endurance exercise in time of day on metabolic responses and inflammatory cytokines during and after exercise are unclear. Methods Fourteen healthy young men completed two trials in a randomized cross-over design: (1) morning (0900-1000) and (2) evening (1700-1800) trials. In the morning and evening trials, subjects walked for 60 minutes at 60% of maximal oxygen uptake on a treadmill. Pulmonary gas exchange was determined breath-by-breath by a gas analyzer. Blood samples were collected to determine hormones, metabolites, and inflammatory cytokines at pre-exercise, immediately and 2 hour after exercise. Results Plasma adrenaline, interleukin (IL)-6, and serum growth hormone concentrations were significantly higher immediately after exercise in the evening trial than in the morning trial ( $P < 0.01$ ,  $P < 0.05$ , and  $P < 0.001$  respectively). Plasma TNF- $\alpha$  and IL-1 $\beta$  concentrations did not change between trials. Serum free fatty acids concentrations were significantly higher in the evening trial than in the morning trial at 2-hour after exercise ( $P < 0.05$ ). However, there was no significant difference in fat oxidation between the morning and evening trials. Discussion Plasma catecholamines show a circadian rhythm with levels being evening than at morning (Trine and Morgan 1995). Catecholamines are known to play a major role in the regulation of substrate metabolism, affecting glucose production, glycogen mobilization, and lipolysis (Jabbour G et al., 2011). Furthermore, IL-6 is also known to increase hepatic glucose production during exercise or lipolysis in adipose tissue (Pedersen and Fischer, 2007). Therefore, higher catecholamines and IL-6 concentrations in the evening trial may contribute to increase in serum free fatty acids concentrations after exercise in the evening. These findings suggest that acute endurance exercise in the evening induces greater lipolysis than that in the morning and that inflammatory cytokines do not change between morning and evening exercise in young men. ### THE RESPONSE OF PLASMA VOLUME TO OPTIMAL DOSAGE GLYCEROL HYPERHYDRATION

Potter, C.1, Erasmus, B.L.1, Christmas, B.C.R.1, Hillman, A.2, Taylor, L.1

University of Bedfordshire

THE RESPONSE OF PLASMA VOLUME TO OPTIMAL DOSAGE GLYCEROL HYPERHYDRATION 1Institute of Sport and Physical Activity Research, University of Bedfordshire, UK. 2Department of Health and Physical Education, Marywood University, USA. Introduction Previous research has investigated the potential ergogenic effects of in vivo glycerol hyperhydration (G-HH) prior to endurance exercise, typically in a hot environment (>30°C). Glycerol is readily absorbed in vivo; promoting fluid retention in vascular spaces facilitating plasma volume (PV) expansion (although with often equivocal results). Currently no research has observed the effect optimum G-HH dosage (Goulet et al., 2007) has on change in PV (% $\Delta$ PV) in a sedentary state compared to water hyperhydration (W-HH) and the length of time PV expansion transpires for. Method 16 resting males' ingested one of two solutions evenly over a 90 min period (scheduled amount ingested every 15min). Glycerol solution (G-HH) (1.2 g·kg<sup>-1</sup> of body mass (BM) glycerol mixed in 26 ml·kg<sup>-1</sup> of BM of water) or a water solution (W-HH) (26 ml·kg<sup>-1</sup> of BM of water). Urine osmolality was measured prior to ingestion to confirm euhydration. Capillary blood samples were taken every 15 min for 135 min post ingestion to measure haemoglobin (Hb) and haematocrit (Hct) levels. Hb and Hct were used to calculate % $\Delta$ PV (Dill & Costill, 1974). Independent T-Tests and one way ANOVA were performed. Results It was revealed that peak % $\Delta$ PV was significantly higher after G-HH (22.16 ± 3.8%) than W-HH (9.74 ± 5.3%) ( $F_{1,12} = 24.31$ ,  $P < 0.001$ ). Post Hoc analysis illustrated that G-HH increased % $\Delta$ PV significantly higher than W-HH at time points: 0 - 15 min ( $P = 0.002$ ) and 105 - 120 min ( $P = 0.021$ ) post ingestion. Discussion Peak % $\Delta$ PV was 12.4% higher after G-HH compared to W-HH. There were two notable (biphasic) peaks of % $\Delta$ PV during the measured time period; rate of glycerol turnover (rate of appearance of glycerol) may account for this response. With the solution being ingested over 90 min the glycerol turnover could be at a staggered rate (Nelson & Robergs., 2007). The positive % $\Delta$ PV was sustained for 135 min. these results support the use of glycerol as an effective hydrating agent to aid occupational pursuits where dehydration can play a fundamental role in the onset of physiological and cognitive fatigue. It is recommended that occupational pursuits commence immediately post the 90 min ingestion period when PV expansion is highest, to delay the onset of dehydration. References Dill, D.B & Costill, D. ## THE INTRAMYOCYELLULAR LIPID CONTENT IN THE ARMS OF ELITE CROSS COUNTRY SKIERS IS LOWER THAN IN THEIR LEGS

Nielsen, J.1, Holmberg, H.C.2, Schröder, H.D.1, Saltin, B.3, Ørtenblad, N.1,2

1University of Southern Denmark (Odense, Denmark), 2Swedish Winter Sports Research Centre, Mid Sweden University (Östersund, Sweden), 3University of Copenhagen (Copenhagen, Denmark)

**Introduction** Intramyocellular lipid (IMCL) content (Schrauwen-Hinderling et al. 2003) and fat oxidation during exercise (Helge 2010) has been reported to be lower in arm compared with leg muscles, and it has been argued to be due to lower training status in the arm than in the leg muscle of the study populations (Helge 2010). The aim of the present study was to compare IMCL content of arm and leg muscles in elite cross country skiers, who have highly endurance-trained arm and leg muscles. **Methods** Ten male elite cross-country skiers participated in the study. Their mean ( $\pm$ SD) age, and maximum oxygen uptake ( $\dot{V}O_{2max}$ ) was  $22 \pm 1$  years and  $72 \pm 2$  ml  $kg^{-1} min^{-1}$ , respectively. Muscle biopsies were taken from arm (m. triceps brachii) and leg (m. vastus lateralis) muscles. Muscle segments were prepared for transmission electron microscopy and the IMCL content was estimated by point counting on images photographed at  $\times 40,000$  magnification in 9 fibres per biopsy. Values are presented as medians and interquartile range. **Results** The IMCL content of the arms (0.13 (0.09-0.16) % of the total fibre volume) was only 25% of that in the legs (0.52 (0.37-0.85) %) ( $P < 0.0001$ ). Furthermore, examination of intermyofibrillar (IMF) and subsarcolemmal (SS) IMCL revealed that the latter was almost absent from the arms (0.0010 (0.0005-0.0024) volume per fibre surface) and more than 10-fold higher in the legs (0.0108 (0.0078-0.0137)) ( $P < 0.0001$  for the two-way interaction between limb and localization). Consequently, the relative contribution of SS IMCL to total IMCL was lower in the arms (3.6 (2.2-5.2) %) than the legs (10.2 (7.7-13.4) %) ( $P = 0.0001$ ). The proportions of myosin heavy chain (MHC) I and II in legs ( $58 \pm 2\%$  and  $41 \pm 2\%$ ) were higher and lower, respectively, than in the arms ( $40 \pm 3\%$  and  $60 \pm 3\%$ ) ( $P < 0.05$ ). **Discussion** The major finding documented here is that the IMCL content of the arms of elite male cross country skiers, who train both their arm and leg bodies intensively, is nonetheless substantially lower than in their legs. The difference cannot be explained by differences in the relative levels of myosin heavy chain I and II in the arm and leg muscles and is therefore unlikely to be dependent on training status. In addition, in contrast to the legs, the arms exhibit virtually no deposition of IMCL in the subsarcolemmal space, indicating a muscle phenotype-related difference in the subcellular distribution of lipids. **References** Helge JW (2010). *Acta Physiol*, 199,519-528 Schrauwen-Hinderling et al. ## EFFECTS OF HIGH RESISTANCE CIRCUIT TRAINING VS TRADITIONAL STRENGTH TRAINING ON VO2MAX AND BODY COMPOSITION IN SOCCER PLAYERS.

Marín-Pagán, C., Romero-Arenas, S., Martínez-Valencia, M.A., Alcaraz, P.E.

Catholic University San Antonio

**Effects of High Resistance Circuit Training (HRC) vs Traditional Strength Training (TS) on VO<sub>2max</sub> and Body Composition in Soccer Players.** **Introduction** Effects of HRC protocol have been studied in resistance-trained males (1) but no studies that have focused on effects of HRC in soccer populations have been found. Maximal strength training (MS) is a key factor for soccer players, in addition, this training can be applied to achieve endurance improvements and injury prevention (2) in many sports. The aim of this study was to compare cardiorespiratory and body composition changes after 8 weeks of resistance training applying HRC vs. TS protocols in soccer players. **Methods** 18 semiprofessionals soccer players participated in the study (HRC=9; TS=9). Subjects completed an 8-wk training period (1-3 sets: 2 blocks  $\times$  3 exercises at 6 repetition maximum, twice weekly). The difference between protocols was the time of rest between exercises (TS=3'; HRC=35"). Local rest was the same (3') in both protocols. Maximal oxygen uptake normalized to body weight (VO<sub>2maxR</sub>) and body compositions (DEXA) were determinate in pre-post test. **Results** Trend to significant ( $p \leq 0.1$ ) was obtained in VO<sub>2maxR</sub> for the HRC group ( $1.3 \pm 2.5$  ml $\cdot$ kg $^{-1}\cdot$ min $^{-1}$ ) but not in the TS group ( $-0.6 \pm 2.8$  ml $\cdot$ kg $^{-1}\cdot$ min $^{-1}$ ). Time to complete the test was also improved significantly ( $p \leq 0.05$ ) in HRC group ( $16.4 \pm 22.4''$ ) while TS group was worse ( $-9.4 \pm 70.4''$ ) in pre-post test. Fat mass (FM) was reduced significantly in HRC ( $-2.2 \pm 1.0$  kg), TS group reduced FM ( $-0.6 \pm 2.8$  kg) but these different are not statistically significant. Both groups not significantly improve the lean mass (HRC= $0.8 \pm 1.1$ ; TS= $0.9 \pm 1.4$  kg). In %FM, both training protocols groups reduced significantly (HRC= $-2.7 \pm 1.4$ ; TS= $-1.1 \pm 1.1\%$ ) and HRC group obtained significant differences respect to TS group. **Discussion** Recently, one study (3) has reported improvements in VO<sub>2maxR</sub> ( $\sim 5.3$  ml $\cdot$ kg $^{-1}\cdot$ min $^{-1}$ ) after 8-wk of concurrent MS and high-intensity endurance training (ET) in top-level soccer players, in our study we obtained minor cardiorespiratory improvements, probably due to total training volume and additional ET in the Helgerud et al. study (3). Respect body composition parameters, our results in HRC group were higher than those obtained in the other study only for %FM and FM (%FM= $-1.5 \pm 1.6\%$ ; FM= $-1.1 \pm 1.5$  kg; LM= $1.5 \pm 1.9$  kg) (1), which applied the same training protocols, while for TS group were reported similar values (%FM= $-1.1 \pm 1.9\%$ ; FM= $-0.8 \pm 1.8$  kg; LM= $1.2 \pm 1.6$  kg). HRC could be considered as a good tool for applied in soccer players for achieve improvements in maximal strength, VO<sub>2max</sub> and body composition parameters with reduced training time. **References** 1. ## TASK-RELATED THOUGHTS EMERGE SPONTANEOUSLY DURING PROGRESSIVE MAXIMUM EXERCISE

García, S.1, Montesinos, E.1, Anguita, A.1, Morales, J.1, Hristovski, R.2, Balagué, N.

1. INEFC Barcelona (Spain), 2. Ss. Cyril and Methodius University, Skopje

**Introduction** A nonlinear model of attention focus showing the spontaneous emergence and nonlinear dynamics of task-related thoughts (TRT) during constant intensity running has been recently proposed using tools of dynamical systems theory (Balagué, Hristovski, Aragonés & Tenenbaum, 2012). The aim of this study is to test the nonlinear attention focus model under different exercise conditions and reporting methodology. **Methods** Twelve physically active participants previously familiarized with the experimental procedures performed twice a progressive cycling test until exhaustion. The initial load was 20W and increased 20W/min until the required pace (70 rpm) could not be kept for more than 10 s. During the first test their intrinsic dynamics of attention focus was established. During the second they were asked to intentionally maintain a Task-Unrelated Thought (TUT) and report every 30 sec through finger signs (thumb up/thumb down) about the type of thought (TUT or TRT) they had. The dynamics of TUT-TRT were plotted for each participant and divided into 10 non-overlapping temporal windows to obtain TUT-TRT probabilities in each interval. Non-parametric repeated measures Friedman ANOVA was used to compare the different windows. **Results** The 10 exertion time windows repeated-measures Friedman ANOVA ( $N = 12$ ,  $df = 9$ ) revealed a significant effect,  $\chi^2(12, 9) = 70.65$ ,  $p < .0001$ , of exertion time on TUT probabilities. The median probability of finding a TUT state began at 100% in the first half of the test, decreasing around 60% in periods 6,7,8, and to 0% in the last two periods. **Discussion** The time interval probabilities reveal three effort phases coinciding with 3 qualitative different states of the attention focus (i.e.,

stability of the intentionally imposed TUT, spontaneous emergence of TRT intermittently switching with TUT, and stable TRT). The obtained results corroborate the previous nonlinear model of attention focus tested through a different type of exercise and reporting methodology. References Balagué, N., Hristovski, R., Aragonés, D. & Tenenbaum, G. (2012). *Psychology of Sport and Exercise*, 13, 5, 691-697.

### **INFLUENCE OF AGE ON ELECTROMECHANICAL DELAY OF THE KNEE EXTENSOR MUSCLES**

Libardi, C.A.1,2, Souza, T.M.F.2, Conceição, M.S.2, Bonganha, V.2, Chacon-Mikahil, M.P.T.2, Cavaglieri, C.R.2, Moraes, A.C.2, Ugrinowitsch, C.1

1:USP (Brazil), 2:UNICAMP (Brazil)

**Introduction** One of the factors that increase the incidence of falls in the elderly is the impairment of the neuromuscular function of the lower limbs. This impairment can be observed as decreases in rate of torque development (RTD), which is positively associated with functionality and the number of falls in the elderly (1). In addition, the time interval required to occur the excitation-contraction coupling (2) and to take the slack of the muscle-tendon unit (3) may also be important to recovery from a trip, as it reflects how fast the muscle tendon unit would start pulling a bone and move a body's segment. The electrical mechanical delay (EMD) (i.e. the time interval between the electromyographic activity and the onset of the voluntary torque production) is a good candidate to assess the effects of the aging process in the ability to produce torque rapidly. However, there is paucity of data regarding the effects of the aging process on the EMD. The aim of this study was to investigate effects of aging process in the EMD and RTD of the knee extensor muscles. **Methods** The volunteers were assigned to three groups: young group (YG - 23.44 ± 4.74 yrs, 78.14 ± 15.11 kg, 1.72 ± 0.05 m), middle-aged group (MAG - 49.56 ± 6.06 yrs, 72.01 ± 14.07 kg, 1.67 ± 0.06 m) and elderly group (EG- 68.67 ± 9.06 yrs, 67.96 ± 7.60 kg, 1.64 ± 0.07 m). The RTD were obtained through maximal volunteer ballistic isometric contraction (MVBIC) (60°). Muscle electrical activity was recorded by electromyograph (EMG) during MVBIC in the vastus lateralis (VL), vastus medialis (VM) and rectus femoris (RF) muscles. The EMD also was calculated during the MVBIC, taking the time difference between the EMG and torque onsets. **Results** RTD were higher for YG than MAG (P = 0.002) and EG (P = 0.002). There were no significant differences in EMD among the three age groups for VL, VM and RF (P > 0.05). **Discussion** It is known that the RTD decreases with aging (1), what was confirmed in the present study. Previous studies reported greater EMD in middle-age than young subjects (4). However, the present study found no difference between the age groups for the EMD. It is possible to suggest that maintenance of quadriceps muscles EMD with aging are related to a relatively greater recruitment of these muscles in daily activities (such as sitting down and standing up) (5). **Conclusion** Our study indicates that age affect the RTD, but not EMD of VL, VM and RF. **References** 1) Bento et al. ### **THE EFFECTS OF A 6 WEEK ACSM INTERVENTION ON MEASURES OF POWER OUTPUT IN SEDENTARY OLDER MEN.**

Herbert, P.1, Grace, F.2, Ratcliffe, J.2, Baker, J.2, Richards, J.3, Sculthorpe, N.2

University of the West of Scotland

1University of Wales, Trinity Saint Davids, Camarthen Campus, Camarthen SA31 3EP 2 Institute for Clinical Exercise and Health Science, University of the West of Scotland, Hamilton, Scotland ML3 0JB 3 Institute of Sport and Physical Activity Research, University of Bedfordshire, Bedford MK41 9EA **Introduction** Ageing is associated with increased sedentariness and a concomitant decline in absolute and relative maximal power output (Pmax). The American College of Sports Medicine (ACSM) recommends 150 minutes of moderate exercise per week (Garber et al., 2011) for adults to develop and maintain musculoskeletal fitness. However, there is a lack of supporting evidence for the efficacy of these recommendations in improving power output older adults. The present study set out to examine the effect of a 6-week intervention using the ACSM guidelines on measures of muscle power in sedentary older males. **Methods** Participants consisting of untrained older males (UT, n= 22, 62.4±5.4 yrs) underwent 6 weeks of training in accordance with the ACSM's guidelines for the development and maintenance of musculoskeletal fitness (≥30 min.d-1 on ≥5 d.wk-1 for a total of ≥150 min.wk-1). Prior to (Pre) and following (Post) the training intervention participants were assessed for bodymass (BM) and lean body mass (LBM) using standard anthropometric procedures. Additionally maximal lower body power was assessed using a 6 second maximal effort on an air braked cycle ergometer (Wattbike UK). Maximal values were further indexed for bodymass (Pbm) and fat free mass (Pffm). At both time points UT were compared with a group of aerobically trained master athletes (MA, n=17, 60.4±5.2 yrs) who acted as a positive control. Data were analysed using SPSS v20 software using a mixed design ANOVA and post-hoc analyses. The alpha level was set at 0.05. **Results** At Pre UT were not different to MA in terms of Pmax but had significantly lower Pbm and PFFM (p<0.01). Following 6 weeks of intervention, UT did not significantly change Pmax, Pbm or PFFM. Additionally, at Post, UT were again not significantly different from MA in terms of Pmax but were significantly lower than MA for both Pbm and PFFM (p<0.01). **Discussion** These data suggest that the ACSM guidelines are not effective as a short term exercise intervention for improving lower body maximal muscle power. Longer duration or higher intensity interventions may be more beneficial to improve the power profile of ageing muscles. Additionally the data presented here suggest that long term exercise is effective in reducing the age related decline in muscle power relative to body mass and to fat free mass. **References** Garber, C. **AUTO-STABILIZATION PERFORMANCES IN SITTING POSITION: MODIFICATION OF POSTURAL STRATEGIES IN OLDER PEOPLE.**

Mesure, S.1, Duclos, N.C.1, Maynard, L.2

1. ISM UMR 7287 (Marseille, France) 2. CRF Valmante, UGECAM-PACAC, Marseille, France

Human movement and daily activities are performed through adaptive and permanent sensory-motor interactions. In aging subjects, the loop is impaired and the postural stability decreases. Risk of fall becomes a major problem. The medio-lateral (ML) balance is particularly altered in older subjects during quiet standing (Raymakers & al., 2005). We need to focus on the upper part of the body and consider the seated position because lower limbs are implicated in the postural deficit. Our main objective is to highlight specificities of sensory-motor strategies used by elderly people in auto-stabilization paradigm in order to increasing postural adjustment effects. Methods 15 young subjects (Adult Group, 24.8 +/- 4.6 years old) and 12 healthy elderly subjects (Senior Group, 57.9 +/- 2.4 years old) were asked to actively maintain a sitting posture as stable as possible during 12.8 seconds, on a seesaw placed in order to allow roll or pitch oscillation, with or without vision. We determined standard postural parameters and a postural performance index (PI). PI is represented by the area under the curve and is defined with respect to the movement axes (roll: X axis; pitch: Y axis). Appropriate MANOVA and t-Student tests were used, with statistical significance set at  $p < 0.05$ . Results Surface areas and lengths differed with auto-stabilization planes in the "vision" condition, with larger values during roll auto-stabilizations. Concerning surfaces, we found a visual effect during pitch auto-stabilizations. Group effect showed reduced length values for the Senior Group. During roll auto-stabilizations, the variation of X position was larger in the Senior Group. PIx differed between groups during roll auto-stabilizations, with greater values for the Senior Group, whereas no difference was found for Ply during pitch auto-stabilizations. Discussion Postural strategies appear to be modified with aging. Surfaces of CoP displacement are similar whereas lengths decreased with age. Young adult subjects have abilities for a pertinent of multi-sensory and multi-motor integration (Schmid & al., 2008), necessary to perform auto-stabilizations. In contrast, elderly persons seem voluntarily decrease sources of information, trying to diminish the current movement. A specific control is focus on the antero-posterior axis, with less control and more variability on the ML axis. The vision appears stabilizing only during pitch auto-stabilizations. The ML control needs to be specifically involved in an individualized postural training in order to improve balance and preserve the greatest autonomy for motor activities. **TRUNK MUSCLE ENDURANCE AND LOW BACK PAIN IN CONTEMPORARY DANCE STUDENTS**

Swain, C., Redding, E.

*Trinity Laban Conservatoire of Music and Dance*

Trunk muscle endurance and low back pain in contemporary dance students Introduction Low back pain (LBP) is often cited as a common condition in all levels of dance. Evidence suggests that reduced endurance of the trunk muscles can predispose an individual to LBP. The purpose of this study was to examine differences in trunk muscle endurance in a sample of contemporary dance students with and without LBP. Methods Fifteen full-time dance students were divided into four groups: females with LBP (n=6), females without LBP (n=4), males with LBP (n=2), and males without LBP (n=3). All participants provided informed consent, and the study was approved by an institutional ethics review board. Participants performed four isometric tests that assess trunk muscle endurance: the right and left side plank (McGill et al., 1999), double straight leg raise (Arab et al., 2007), and the Sorensen test (Biering-Sorensen, 1984). A modified version of the Osaka City University test (Kazunori et al., 2004) was used to assess the presence of LBP. Results A significant difference ( $p < 0.05$ ) between female dance students with and without LBP was observed in the left side plank. No other significant differences were found. Discussion This study offers some evidence that reduced trunk muscle endurance is present among dancers with LBP, and provides direction for future research into back health among dancers and other athletic populations. **ASSOCIATION BETWEEN LOWER-LIMB MUSCLE STRENGTH AND CLINICAL FEATURES IN JUVENILE DERMATOMYOSITIS**

Solis, M.Y.1, Hayashi, A.P.T.1, Otaduy, M.C.G.1, Kozu, K.T.1, Aikawa, N.E.1, Sallum, A.M.E.1, Pinto, A.L.S.1, Silva, C.A.1, Pinto, A.J.1, Pereira, R.M.R.1, Gualano, B.1

*University of São Paulo*

Introduction Juvenile dermatomyositis (JDM) is a rare idiopathic inflammatory myopathy (also called myositis) characterized by skin rashes, muscle atrophy, myalgia, fatigue, hypoactivity, and poor quality of life. The role of muscle strength in these clinical symptoms has been underexplored. Thus, we aimed to examine the possible relationship between muscle strength and clinical features in JDM patients. Methods This is a cross-sectional study involving 17 JDM patients (14.6 ± 3.4 years old; 12 female). Clinical features (i.e., disease activity, physical function, health-related quality of life) were evaluated by Patient Visual Analogue Scale (P-VAS), Doctor Visual Analogue Scale (D-VAS), Childhood Health Assessment Questionnaire (CHAQ), Childhood Myositis Assessment Scale (CMAS), Disease Activity Score (DAS), Manual Muscle Testing (MMT). For P-VAS, D-VAS, and DAS, higher scores mean worse health/disease activity; for CMAS, MMT and CHAQ, higher scores mean better health/quality of life/physical function. Muscle strength was assessed by leg-press one-repetition maximum test (1-RM). Person's correlations were performed between leg-press 1-RM and the scores obtained from the clinical tests. Results Leg-press 1-RM (32.3 ± 12.7 Kg) was inversely related to D-VAS (-0.55;  $p = 0.02$ ), P-VAS (-0.52;  $p = 0.029$ ), and DAS (-0.52;  $p =$

0.29), and positively associated with CMAS (0.54;  $p = 0.027$ ). No significant correlation was seen between leg-press 1-RM and CHAQ ( $-0.09$ ;  $p = 0.70$ ) and MMT (0.18;  $p = 0.47$ ). Discussion In general, this study demonstrated that lower-limb muscle strength is negatively associated with disease activity (as assessed by DAS) and positively associated with physical function in JDM patients. Exercise has long been proscribed for patients with idiopathic inflammatory myopathies due to the fear that it could worsen disease activity. However, increasing evidence has suggested that exercise is not only safe but also effective in improving some symptoms in myositis. The present data further supports this notion, suggesting that lower-limb muscle strengthening could be of therapeutic relevance in the management of JDM. Future randomized clinical trials involving well-designed physical training programs, namely resistance training, should test this hypothesis. Supported by Fundação de Amparo à pesquisa do Estado de São Paulo (FAPESP) Grant# 2010/187081.

## **INTENSIFIED VS. STANDARDIZED EXERCISE THERAPY IN THE IN-PATIENT REHABILITATION AFTER PRIMARY TOTAL HIP OR AND KNEE REPLACEMENT – A RANDOMIZED CONTROLLED TRIAL**

Pfeifer, K., Hendrich, S., Schmitt, B., Zech, A.

*Friedrich-Alexander University of Erlangen-Nürnberg*

Exercise therapy plays a dominant role in rehabilitation after total hip (THR) or knee replacement (TKR). The objective of this study is to evaluate the effectiveness and sustainability of an intensified compared to a conventional exercise therapy program in rehabilitation after THR and after TKR. Methods: 61 THR patients as well as 61 TKR patients were each randomized to a conventional (control groups/CG) or an intensified (intervention groups/IG) exercise program. In both indications, IGs received an intensified strength training protocol compared to CGs ("usual care"). The programs were standardized in both groups. Exercise therapy dosage was documented via diaries. Joint function (primary outcome - WOMAC), Health related quality of life (HrQoL, SF36), walking speed (Timed 10m walk) and range of motion (neutral-zero method) were tested at beginning and end of in-patient rehabilitation and as two follow-up measurements (three and nine months). Statistics: Repeated measures ANOVA were used to investigate interaction effects and changes across time. Confidence intervals and effect sizes were calculated. Results: In both indications, strength training intensity was significantly higher in the IGs compared to the CGs (THR IG:  $13.4 \pm 0.7$ , CG:  $11.7 \pm 0.6$ ,  $p = 0.000$ ; TKR IG:  $13.4 \pm 0.7$ , CG:  $11.9 \pm 0.8$ ,  $p = 0.000$ ). Perceived pain did not differ between IGs and CGs (THR IG:  $0.3 \pm 0.5$ , CG:  $0.1 \pm 0.3$ ,  $p = 0.109$ ; TKR IG:  $0.4 \pm 0.5$ , CG:  $0.4 \pm 0.7$ ,  $p = 0.897$ ). No interaction effects (group by time) were found in any outcome at any time point of the study period. Joint function significantly improved across time between t1 and t2 (WOMAC THR:  $-35.0\%$ ,  $d = 2.23$ ; TKR:  $-20.0\%$ ,  $d = 1.06$ ) and between t2 and t4 (THR:  $-45.5\%$ ,  $d = 1.57$ ). In HrQoL (SF36; physical component summary = pcs; mental component summary = mcs) participants improved between t1 and t2 (SF36-Score increase THR pcs:  $16.1\%$ ,  $d = 1.37$ ; TKR pcs:  $12.2\%$ ,  $d = 1.08$ ), t2 and t3 (THR pcs:  $24.5\%$ ,  $d = 2.13$ ; TKR pcs:  $16.7\%$ ,  $d = 1.34$ ; TKR mcs:  $9.9\%$ ,  $d = 0.84$ ) as well as t2 and t4 (THR pcs:  $37.8\%$ ,  $d = 2.63$ ; THR mcs:  $0.4\%$ ,  $d = 1.29$ ; TKR pcs:  $30.4\%$ ,  $d = 1.88$ ; TKR mcs:  $7.9\%$ ,  $p = 0.040$ ,  $d = 0.78$ ). Timed 10m walk significantly improved between t1 and t2 (THR: time required has decreased by  $25.7\%$ ,  $p = 0.000$ ,  $d = 2.63$ ; TKR  $30.3\%$ ,  $d = 3.10$ ) as well as active flexion (THR:  $md = 8.5^\circ$ ,  $d = 2.40$ ; TKR:  $md = 18.3^\circ$ ,  $d = 3.20$ ), passive flexion (THR:  $md = 5.8^\circ$ ,  $d = 1.77$ ; TKR:  $md = 17.9^\circ$ ,  $d = 3.06$ ), active extension (THR:  $md = 3.2^\circ$ ,  $d = 1.40$ ), passive extension (THR:  $md = 3.4^\circ$ ,  $p = 0.000$ ,  $d = 1.67$ ), active abduction (THR:  $md = 8.0^\circ$ ,  $d = 2.31$ ) and passive abduction (THR:  $md = 6.4^\circ$ ,  $d = 2.37$ ). Discussion: The strength training intensification has been realized without increase of perceived pain. However, compared to the overall effects of the in-patient rehabilitation no additional gain in function or HrQoL could be achieved. It remains open to what extent an even higher strength training intensity would lead to higher therapy effects in comparison to conventional programs following THR or TKR. Existing training protocols should further be analyzed regarding efficacy and dose-response relationships

## **THE RELATIONSHIPS BETWEEN CORE STABILITY AND LOW BACK PAIN IN WRESTLERS**

Guzel, N.A., Basar, S., Duzgun, I., Cicioglu, I.

*GAZI UNIVERSITY*

Introduction Wrestling includes some lifting techniques from ground that may lead serious low back pain. The aim of this study was to investigate the relationships between core stability and low back pain in young national wrestlers. Methods Eighty-one wrestlers (mean age  $18.60 \pm 0.96$ ) from Turkish young national Greco-Roman (n: 46) and free-style (n:35) wrestling teams participated voluntarily in this study. Low back pain was evaluated by visual analog scale (VAS). Participants were asked to indicate their pain degrees at rest (VASrest), during activities of daily living (VAS-ADL) and sports activities (VAS-sport) on a 10-cm scale. Assessments included in core stability with prone bridge, side-bridge, back extension and trunk flexion tests. Results It was found that  $30.86\%$  of wrestlers have pain at rest,  $29.62\%$  of wrestlers have pain during activities of daily living and  $40.74\%$  of wrestlers have pain during sports activities. Both VASrest ( $r = -0.27$ ,  $p < 0.05$ ) and VAS-ADL ( $r = -0.003$ ,  $p < 0.01$ ) was correlated negatively with back extension test, and VAS-ADL was correlated negatively with back flexion test ( $r = -0.30$ ,  $p < 0.01$ ). Low back pain was not correlated with prone and side bridge tests. Discussion These results showed that low back pain affects core stabilization in wrestlers. Therefore core stability/strength program is suggested to prevent low back pain. References McGuigan MR, Winchester JB, Ericson T. (2006). *J Sports Sci Med*. 5:108-13. ## **ALTER G: AN INNOVATIVE TECHNOLOGY IN PHYSICAL ACTIVE REHABILITATION OF SPINAL STENOSIS**

Landkammer, Y., Bernecker, R., Wicker, A.

*Federal Hospital Salzburg*

Introduction Lumbal spinal stenosis causes back pain spreading as far as the legs and thereby constrains the activities of daily living. By walking in a flexed position patients try to extend the foramina intervertebralia. Claudicatio intermitens/ spinalis forces them to stop walking and sit down, because of pain, parasthesias or paresis (Horst et al., 2012). Loss of physical activity may lead to a decline of physical condition and slowly restrict independence (Schulte et al., 2006). The differential air pressure technology of AlterG treadmills reduces body weight in lower extremity up to 80% and facilitates normal postural control ([www.alterg.com](http://www.alterg.com)). Methods After completing physiotherapy, a 70-year-old left sided lower leg amputated man started extensive endurance training. 250m of walking were challenging. Therefore innovative body weight reducing AlterG treadmill training was initiated in April. Results Early therapy, visual analog scale (VAS) was set at 5.5. At the beginning of AlterG training, body weight was decreased by 40% up to 5% in November (VAS 0). As walking time increased in the air filled chamber (13-35min.), walking distance increased equally from 870m to 2.4km. Discussion One aim of functional rehabilitation is to decrease the pain (Schulte-Frei et al., 2012), keep the patient independent and thereby obtain his physical condition in order to prevent further (cardiorespiratory) diseases. One of the goals of using nearly unknown AlterG treadmills in rehabilitation of orthopedic patients is to restore normal walking mechanics (Chun and Mishra, 2010). The combination of physiotherapy and AlterG training

leads to absence of lower back pain, walking distance increases significantly, the patient feels safer while walking and his independence is ensured. Generally seen AlterG training improves postural control, increase safety while walking as well as economy of movements and thereby affect the lower back pain and needs to be seen as a revolutionary rehabilitation treadmill. ### LONG-TERM EXERCISE REDUCES OXIDATIVE STRESS IN THE HIPPOCAMPUS OF AGING RATS

Nyakas, C., Marosi, K., Radák, Z.

*Semmelweis University Budapest*

**Introduction** Exercise can exert beneficial effects on cognitive functions of older subjects and it can also play an important role in the prevention of neurodegenerative diseases. At the same time limited information is available on the nature of molecular pathways supporting the antioxidant effects of exercise in the brain of aging animals. **Methods** 12-month old, middle-aged female Wistar rats were subjected to daily moderate intensity exercise on a rodent treadmill for a period of 15 weeks which covered the early aging period unmasking already some aging-related molecular disturbances. The levels of reactive oxygen species (ROS), the amount of protein carbonyls, the levels of antioxidant intracellular enzymes superoxide dismutases (SOD-1, SOD-2) and glutathione peroxidase (GPx) were determined in the hippocampus. In addition, to identify the molecular pathways that may be involved in ROS metabolism and mitochondrial biogenesis, the activation of 5'-AMP-activated protein kinase (AMPK), the protein level of peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1a), nuclear respiratory factor 1 (NRF-1) and mitochondrial transcription factor A (mtTFA) were measured. **Results** Our results revealed a lower level of ROS associated with a reduced amount of protein carbonyls in the hippocampus of physically trained rats compared to sedentary controls. Furthermore, exercise induced an up-regulation of SOD-1 and GPx enzymes, p-AMPK and PGC-1a, that can be related to an improved redox balance in the hippocampus. **Conclusion** These results suggest that long-term physical exercise can comprises antioxidant properties and by this way protect neurons against oxidative stress at the early stage of aging, i.e. in the period of life when prevention is the most effective way to assure healthy brain aging.

### ELECTROMYOGRAPHIC AND POSTUROGRAPHIC INVESTIGATION OF PATIENTS WITH NON-SPECIFIC LOW-BACK PAIN

McCaskey, M.A.1,2, Wirth, B.1, Schuster, C.2,3

*1:ETH Zurich (Switzerland); 2:Reha Rheinfelden (Switzerland); 3:Bern University of Applied Sciences (Switzerland)*

**Introduction** Muscle atrophy of stabilising muscles may cause reduced robustness of postural stability (Hodges & Richardson). Compensation of this reduced robustness through superficial muscle recruitment may lead to rigid spinal stabilisation and further postural deficiencies. Consequential overuse of superficial lumbar muscles could be one cause of non-specific low-back pain (NSLBP). Aim of this study was to investigate whether (NSLBP) is accompanied by (1) compensatory increase of superficial lumbar muscles, (2) decrease of hip stabilising muscles' activity, and (3) poorer performance on a labile platform when standing on one leg (OLS). **Methods** 15 patients (PG, mean age: 45y (±13y), 9 females) with NSLBP were compared with 22 healthy controls (CG, mean age: 40y (±15y), 13 females). Based on the oscillation curve recorded from a labile platform (Posturomed®), five posturographic parameters were compared for postural performance: area of surface deflection, damping coefficient, time-to-minimum, curve continuity, and minimal acceleration coefficient. Simultaneous electromyographic (EMG) recordings of three bilateral muscles allowed comparison of relative submaximal voluntary contraction (% sMVC). **Results** (1) Both groups had normal low EMG activity for superficial back muscles with no significant differences. (2) PG exhibited significantly less activity of the contralateral gluteus medius (PG: 0.27% sMVC ± 0.24%, CG: 0.51% sMVC ± 0.36%, p<0.05) while standing on the non-dominant leg, and a tendency of decreased activity of the ipsilateral gluteus medius when standing on the dominant standing leg (PG: 0.85% sMVC ± 0.55%, CG: 1.54% sMVC ± 1.06%, p=0.18). (3) PG and CG performed equally well on the Posturomed® showing no consistent difference in any of the parameters. **Discussion** Results suggest reduced stabilising hip muscle activity with possible asymmetry in PG but no reliance on increased lumbar extensor muscles as compared to CG. The presented setup cannot provide direct information on activity of deep stabilising muscles but allows controlled provocation of the stabilising system to investigate changed motor patterns in NSLBP. Proposed parameters contradict previous findings but should be validated to strengthen their implication. **References** Hodges, P. W., & Richardson, C. A. (1996). Inefficient muscular stabilization of the lumbar spine associated with low back pain. A motor control evaluation of transversus abdominis. Spine (Phila Pa 1976), 21, 2640-2650.

### POSTURAL CONTROL OF ELITE DEAF FOOTBALL PLAYERS

Guzel, N.A., Basar, S., Cinar Medeni, O., Savas, S., Acak, M.

*GAZI UNIVERSITY*

**Introduction** Childhood hearing impairment is a common chronic condition that may have a major impact on postural control. The aim of this study was to determine the postural control of the elite deaf football players and compare football players and sedentary controls. **Methods** Eighteen deaf national football players, 8 third division football players and 9 sedentary controls were evaluated using the Biodex Biosway Portable Balance System. Three adaptation trials and three test evaluations (a 20-second balance test at a stable platform) were applied to the players and controls. Postural stability was tested on two-legged stance with eyes open and closed and on the single limb stance with eyes open. Static postural stability was measured on the basis of three indices: overall, antero-posterior and medio-lateral. The limits of stability test was also performed. Statistical analysis was done using SPSS 15.0 software. Comparison of each parameter between groups was done by using appropriate post hoc test following Kruskal-Wallis test. P value 0.05 was considered as level of statistical significance. **Results** On the two-legged stance test, significant differences were found in overall stability and antero-posterior stability index scores between deaf sportsmen and third division football players (p<0.05). Antero-posterior stability scores were statistically significant different between deaf players and controls (p<0.05). According to limits of stability test, there were significant differences between deaf players and controls (p<0.05). No differences were found among players in single-limb stance test and other parameters of limits of stability test (p>0.05). As a result on two-legged stance test overall stability and antero-posterior stability scores were

better in deaf players compared to third division football players. Also deaf players obtained better antero-posterior stability scores than controls. In addition deaf players were successful compared to controls in the limits of stability test. Discussion These results showed that postural control can be improved by doing regular and systematic exercises in deaf people. References Hinman MR. (2000). Journal of Sport Rehabilitation.9(3):240-252. McGill SM. (2001). Exerc Sport Sci Rev. 29 (1): 26-31.

### PELVIC PAIN MANIFESTATION AND METHODS OF ITS REHABILITATION IN SPORTSWOMEN DURING PHYSICAL ACTIVITY

Kovalenko, T., Suhoruchko, A., Ulyanov, D., Shklyarenko, A.

*Volgograd State University*

**Introduction** Chronic pelvic pain (CPP) is a long-term syndrome, over 6 months, which is difficult to rehabilitate; it disorganizes central regulation mechanisms. Under certain conditions, such as abnormal development of the locomotor system, excessive muscle loading can lead to trauma, inflammation and irradiation and therefore, sports working capacity decrease. Lumbar spine experiences hard muscle loadings which can lead to intervertebral joints and sclerotome inflammation or pelvic organs irradiation, causing CPP. Nowadays, high performance in sport is obtained by dynamic-static muscle loads which basically involve LMS elements (muscles, sheaves, joints). Goal Reevaluation of physical exercise and movements provoking pain, CPP area determination and development of preventive measures for its cutting short. Methods Direct impact on trigger points and functional blocks by means of ischemic compression and post-isometric relaxation of trigger points muscles having; impact on the local area under the trigger chain, reflecting correlation of trigger points with joint damage. Results 60 sportswomen with diagnosed CPP were examined in order to reveal and cure vertebrogenic, orthopedic disorders. Musculoskeletal system diagnosis was based on complaints, neurological, arthologic, manual and X-ray spine examination results which assessed spine, pelvis, shoulders, folds buttocks and joints, active and passive movements, palpation, to determine postural muscle imbalance, seals, trigger points, functional blocks presence. Survey showed that biomechanical disorders of the musculoskeletal system in 83% of athletes in the form of changes in the presence of trigger points and function blocks. The cause of CPP is the existing biomechanical disorders of the musculoskeletal system. 20 sportswomen had CPP complaints during warm-up, training exercises and twisting; 10 cases in spinal column latero-flexion in at L4-L5, L5-S1, and positive tests Pedal, Mennel showed sacroiliac joints blocking. CPP dependence from movements in the lumbar-sacral region was observed in 40 cases indicating its high frequency. Discussion The stable long-term treatment effect is achieved at trigger points alternating manipulation (recognition phenomenon). Manual therapies include three main stages: back and pelvis muscles relaxation; mobilization (passive joints movements within their physiological volume, they are short, fast and impulsive). Manual therapy diagnosis offers new approaches to chronic CPP syndrome differentiation and treatment and increases athletes rehabilitation effectiveness. Thirty examined patients, which is 75 per cent, showed pelvic pain dependence on movement in sacrolumbar region. So this fact reveals the high frequency of CPP.

### EFFECTS OF REHABILITATION TRAINING ON LUMBAR EXTENSION STRENGTH AND PAIN BETWEEN VERTICAL SPINE TRACTION EXERCISE GROUP AND NON-TRACTION EXERCISE GROUP IN KOREAN ADULT PATIENTS OF LOW BACK PAIN

Gun Do, K.

*sports medicine and exercise physiology*

**Introduction** Low back pain is a prevalent condition imposing a large socioeconomic burden(jeffrey et al.2011) and has been investigated in many studies(John,2003). However there is still a lack of knowledge concerning effects of high-tech machines with vertical spine traction exercise machine and pain scores in patients of low back pain. therefore, this study was aimed to assess the effect of rehabilitation training on lumbar extension strength and pain change between vertical spine traction exercise group and non-vertical spine exercise traction group in korean adult patients of Low back pain. Methods Subjects were recruited from KSP hospital and divided into a Vertical Spine Traction Exercise Group(VSTEG)(males: n=14, 62.71+5.1years,170.43+5.1cm, 67.21+10.2kg; females:n=15, 62.80+3.9years, 154.80+2.8cm, 58.07+7.66kg) and Non-Vertical Spine Traction Exercise Group (NVSTEG) (males: n=11, 62.80+3.9 years, 170.36+5.4cm, 69.91+10.6kg; females: n=14, 62.57+28years, 155,86+3.4, 61.07+7.87kg). Both group received resistance training twice a week in Medx lumbar extension machine(Ocala,FL) and SVTEG taken additional training in treadmill walking with Pneu-weight system machine(Pneu max inc). Both groups were tested on a MedX machine at baseline and after 8 weeks for lumbar extension strength at 0°, 12°, 24°, 36°, 48°, 60° and 72°. Statistics were Compiled using spss/windows(15.0). Results There were significant improvement of lumbar extension strength (p<.001) in both VSTEG and NVSTEG. VSTEG increase 65.12% and 53.98% in NVSTEG. VSTEG showed higher improvement than NVSTEG at all degrees except 48°. Both group showed significant decrease on pain rate in VSTEG(70.85%: from 5.73+1.79 to 1.67+1.29) and NVSTEG(47.02%: from 6.38+1.32 to 3.38+1.44) after 8week training. VSTEG appeared more pain decrease(%) than NVSTEG. Discussion Both Group showed improvement of lumbar strength, and differences were found between VSTEG and NVSTEG in strength. VSTEG in Isometric strength was higher(11.17%) than NVSTEG after 8weeks training. These data are in agreement with previous research(grave et al,1990) demonstrating that resistance training of the isolated lumbar extensor muscles can yield isometric torque gains over 8 week training. VSTEG in pain score indicated higher decrease(23.83%) than NVSTEG. This illustrated similar pattern for pain decrease in the two patient group(kim,2008). the morer pain decrease in VSTEG was considered by muscle relaxation in spine traction. Therefore, Resistance training with vertical spine traction machine is a viable alternative to low back pain patients. References Graves JE, Pollock ML, Foster D. (1990). ### ASSOCIATION OF TRUNK MUSCLE PROPERTIES WITH SAGITTAL SPINAL ALIGNMENT IN HEALTHY ELDERLY WOMEN

Tome, I., Nakamura, M., Masaki, M., Ichihashi, N.

*Graduate School of Medicine, Kyoto University*

**Introduction** It is well established that muscle mass decreases with age, which contributes to muscle weakness. Previous studies have reported that skeletal muscle quality, defined as the amount of non-contractile tissue in the muscle and quantified by muscle echo intensity on ultrasound images, also influences strength generation in healthy elderly subjects (Ikezoe et al., 2012; Fukumoto et al., 2012). However, the effect of trunk muscle mass and muscle quality on spinal alignment in healthy, elderly people remains unclear. The aim of this study was to investigate the relationship of trunk muscle properties, obtained from ultrasound images of muscle thickness and mus-

cle echo intensity, with sagittal spinal alignment in healthy elderly women. Methods Twenty healthy elderly women (mean age 85.9 (74-96) years) participated in the study. Standing sagittal spinal alignment, determined from the thoracic kyphosis angle, the lumbar lordosis angle and the sacral inclination angle, was measured using the Spinal Mouse® (Index Ltd.). Muscle thickness, including the rectus abdominis, external oblique, internal oblique, lumbar multifidus and erector spinae muscles was measured using B-mode ultrasound imaging with an 8-MHz transducer. Muscle echo intensity from the ultrasound images represented the muscle quality and an 8 bit gray-scale analysis was used as an index for the amount of non-contractile tissue. Increased echo intensity, related to the presence of non-contractile tissue in the muscle (e.g. increased intramuscular fibrous and adipose tissue) indicated changes in muscle quality. The mean echo intensity was expressed as a value between 0 (black) and 255 (white). Results Pearson correlation coefficient analyses showed that there was a significant negative correlation between thoracic kyphosis angle and rectus abdominis thickness. Lumbar lordosis and sacral inclination angles were significantly associated with lumbar multifidus and erector spinae thickness. No correlation was found between muscle echo intensity and sagittal spinal alignment. Discussion The results suggest that a decrease in rectus abdominis, lumbar multifidus and erector spinae thickness contributes to hyperkyphotic posture in healthy elderly women. In addition, changes in sagittal spinal alignment may be related to muscle mass rather than muscle quality. The findings may help in the development of exercise guidelines for the improvement of spinal alignment and prevention of hyperkyphosis progression in elderly women. ### RESISTANCE TRAINING DECREASES TLR4 EXPRESSION VIA MYELOID DIFFERENTIATION FACTOR 88-DEPENDENT PATHWAY IN ELDERLY SUBJECTS

Rodriguez-Miguelez, P.1, Fernandez-Gonzalo, R.2, Almar, M.1, Collado, P.S.1, González-Gallego, J.1, de Paz, J.A.1, Cuevas, M.J.1

RESISTANCE TRAINING DECREASES TLR4 EXPRESSION VIA MYELOID DIFFERENTIATION FACTOR 88-DEPENDENT PATHWAY IN ELDERLY SUBJECTS Introduction Age and sedentary lifestyle are risk factors implicated in the etiology of diabetes, hypertension, atherosclerosis, and other cardiovascular diseases (Wanderley et al 2013). Several studies have related this effect with the toll-like receptor 4 (TLR4) pathway, that is involved in the expression of inflammatory cytokines through the activation of the nuclear factor kappa-B (NF-kappaB). Regular exercise training induces positive adaptations in heart rate variability, body composition and fitness, as well as a reduction in low-grade chronic inflammation. Therefore, the aim of this study was to investigate the effect of a resistance training programme on the TLR4 pathway and on the production of inflammatory cytokines in the elderly. Methods Twenty subjects, aged 65-87 years, were randomized to either with or without resistance training programme practiced twice per week based on 3 sets of 15-30 repetitions at 40-60% of one repetition maximum (1RM) for the first 6 weeks and 6-12 repetitions by set at 60-80% of 1RM for the last 6. Peripheral blood mononuclear cells were isolated pre- and post-training programme, and used to analyze protein expression of TLR4, tumor necrosis factor-alpha and several interleukins as IL-10 and IL-6. Protein content of myeloid differentiation primary response gene 88 (MyD88), a protein with a central role in mediating signal transduction between TLR4 and NF-kappaB, was also measured. Results Data showed significantly lower TLR4-protein in whole blood samples from older resistance trained, compared to untrained, subjects. Moreover, physically active older adults had also significantly lower MyD88 expression than physically inactive subjects. These changes occurred concomitantly with lower pro-inflammatory cytokine production and higher levels of IL-10. Discussion Previous studies have shown that a period of chronic exercise training decreases both inflammatory cytokine production and the cell-surface expression of TLR4 in monocytes (Gleeson et al 2006). Thus, in resistance-trained older women TLR4 mRNA levels were significantly lower than in sedentary untrained older women (Flynn & McFarlin 2006). Our results confirm that a period of 12-wk of resistance training decreased TLR4 expression as well as reduced low-grade chronic inflammation in elderly subjects. Furthermore, this response seems to be mediated via the MyD88-dependent pathway. References Flynn MG, McFarlin BK. (2006). *Exerc Sport Sci Rev*, 34: 176-181. Gleeson M, McFarlin BK, Flynn M. #### UNSTABLE CHEST PRESS TRAINING DOES NOT MEAN BETTER PERFORMANCE UNDER STABLE CONDITIONS

Zemková, E., Kováčiková, Z., Vilman, T., Hamar, D.

*Faculty of Physical Education and Sport, Comenius University*

Introduction It has been shown [1] that power in concentric phase of chest presses performed on Swiss ball is higher in subjects with than without experience with instability resistance exercises. These differences can be mainly seen in peak and mean power in acceleration phase of lifting with higher weights ( $\geq 60\%$  of 1RM). However, question remains whether better performance under unstable conditions provides some benefits for higher power production on stable surface. The study compares power outputs in concentric phase of chest presses with back supported by either stable bench or unstable Swiss ball in athletes without and with experience with instability resistance training. Methods Subjects of two groups, first having an experience with resistance exercises on unstable surfaces ( $n = 16$ , age  $22.7 \pm 1.9$  y, height  $181.5 \pm 7.2$  cm, weight  $78.1 \pm 10.1$  kg) and second practising only conventional resistance exercises ( $n = 17$ , age  $22.2 \pm 2.2$  y, height  $184.6 \pm 9.7$  cm, weight  $81.3 \pm 8.4$  kg), performed in random order barbell chest presses on the bench and Swiss ball, respectively with previously established weight of  $70\%$  1RM under stable conditions. A system FITRO Dyne Premium based on precise analogue velocity sensor with sampling rate of 100 Hz was used to monitor basic biomechanical parameters involved in exercise. Force is calculated as a product of mass moved and the sum of an instant acceleration and gravitational constant. The acceleration is obtained by derivation of velocity, registered by rotating analogue sensor coupled with the barbell by means of nylon tether. Power is calculated as a product of force and velocity. Peak power ( $P_{peak}$ ) and mean power in acceleration ( $P_{mean acc}$ ) and entire concentric phase of lifting

(Pmean total) were analyzed. Results Power in concentric phase of chest presses on Swiss ball was significantly ( $p < 0.05$ ) higher in group with than without experience with instability resistance exercises (Ppeak:  $646.2 \pm 50.1$  W and  $601.7 \pm 48.2$  W; Pmean total:  $426.7 \pm 42.7$  W and  $386.3 \pm 38.2$  W; Pmean acc:  $495.1 \pm 43.8$  W and  $440.9 \pm 45.0$  W). However, there were no significant differences in power outputs between examined groups when chest presses were performed on the bench (Ppeak:  $657.4 \pm 47.9$  W and  $651.7 \pm 48.2$  W; Pmean total:  $438.1 \pm 39.9$  W and  $430.8 \pm 40.0$  W; Pmean acc:  $508.4 \pm 44.5$  W and  $501.6 \pm 44.7$  W). Discussion The ability to generate high power in concentric phase of unstable chest presses does not mean greater performance benefits on stable support base. These findings support the concept of power training specificity. References Zemková E, Kováčiková Z, Vilman T (2011). 6th International Posture Symposium. Smolenice Castle: 99.

### ENHANCEMENT OF PEAK AND MEAN POWER IN CONCENTRIC PHASE OF SQUATS WITH DIFFERENT WEIGHTS

Zemková, E., Vilman, T., Jeleň, M., Hamar, D.

*Faculty of Physical Education and Sport, Comenius University*

Introduction It has been shown that activation of stretch-shortening cycle during countermovement (CM) weight exercise enhances power production in concentric phase compared to lift from the rest. Such CM enhancement of power depends on weight lifted [1] with some optimal load at which maximal potentiation of power occurs. Usually, peak power is evaluated for this purpose without taking into attention the mean power in acceleration and entire concentric phase of lifting. The study compares the difference in peak and mean power of concentric-only and CM squats while lifting different weights. Methods A group of 16 fit men (age  $22.7 \pm 1.7$  y, height  $183.2 \pm 7.4$  cm, weight  $77.6 \pm 7.5$  kg) performed randomly in different days 3 repetitions of barbell squats without and with CM using maximal effort in concentric phase. Initial weight of 20 kg was increased by 10 kg or 5 kg (at higher loads) up to at least 85 % of previously established 1RM. A system FITRO Dyne Premium based on precise analogue velocity sensor with sampling rate of 100 Hz was used to monitor basic biomechanical parameters involved in exercise. Force is calculated as a product of mass moved and the sum of an instant acceleration and gravitational constant. The acceleration is obtained by derivation of velocity, registered by rotating analogue sensor coupled with the barbell by means of nylon tether. Power is calculated as a product of force and velocity. Peak power and mean power in acceleration and entire concentric phase of lifting were analyzed. The differences in power outputs ( $\Delta P$ ) during squats with and without CM at different weights were calculated. Results As expected, there was higher power output during CM than concentric-only squat. This potentiating effect of mean power in entire concentric phase of lifting was rather modest at lower weights ( $30.1 \pm 8.7$  W at 20 kg) and become more pronounced with increasing weights reaching a maximum of  $125.0 \pm 24.2$  W at 77 % of 1RM. From this point the  $\Delta P$  gradually decreased to  $106.8 \pm 21.4$  W at 100 kg. However, maximal enhancing effect of both peak and mean power in acceleration phase of lifting was achieved at 67 % of 1RM ( $127.7 \pm 23.4$  W) and 69 % of 1RM ( $124.3 \pm 22.1$  W), respectively. Discussion Maximal enhancement of mean power in entire concentric phase of squat occurs at higher weights (about 80 % of 1RM) than peak and mean power in acceleration phase of lifting (about 70 % of 1RM). Nevertheless, the differences in power produced during squats with and without CM (i.e.  $\Delta P$ ) for peak and mean values are rather small. ### IS SKELETAL MUSCLE OXYGEN EXTRACTION MAXIMIZED AT MAXIMAL AEROBIC POWER? A HINT FROM THE 3 MIN ALL-OUT CYCLING TEST.

Lajoie, C., Ziadia, H., Laurencelle, L., Cantin, V.

*Université du Québec à Trois-Rivières*

Background: Cross country competitive mountain biking (MTB) requires several bouts of effort that are well above maximal aerobic power (MAP). At the start of a race, power output is very high until a sustained aerobic pace is established. The 3 min all-out cycling test (3MT) begins with an all-out effort that peaks well over MAP while, on the last 30 seconds of the test, subjects' power drifts slightly under their MAP. Previous researches on 3MT have investigated the pulmonary oxygen kinetics, lactate threshold and critical power. However, the oxygen flow in the skeletal muscle during and after a supra-maximal effort needs yet to be studied. The 3MT could be a valuable laboratory test that mimics the skeletal muscle oxygen behavior at the start of a MTB race. Using near infrared spectroscopy (NIRS) and monitoring deoxyhaemoglobin (HHb) or oxygen extraction, oxyhaemoglobin (HbO<sub>2</sub>), total haemoglobin (THb) or muscle blood flow and tissue saturation index (TSI%), it's possible to better understand oxygen kinetics in the skeletal muscle. Objectives: Determine whether skeletal muscle has during 3MT the ability to extract more oxygen and to use an increased blood flow in comparison with MAP. Also, determine if supra-maximal effort reduces tissue oxygen saturation index (TSI%) in the muscle. Methods: Eight world class elite competitive mountain bikers (age  $21 \pm 2.6$  years;  $VO_{2peak}$ :  $72.01 \pm 3.7$  ml x min<sup>-1</sup> x kg<sup>-1</sup>) conducted a MAP test and a 3MT during a single presence using their own bicycles and a power-measuring rear wheel. Pedaling power,  $VO_2$ , and lactate were measured. Deoxyhaemoglobin (HHb), TSI% and an indirect measurement of muscle blood flow (THb) were monitored by NIRS during both tests. Results:  $VO_{2peak}$  during the 3MT was attained at a test time of  $147.5 \pm 36.6$  sec.  $VO_{2peak}$  measures during the MAP test ( $72.01 \pm 3.68$  ml x min<sup>-1</sup> x kg<sup>-1</sup>) and during the 3MT ( $69.54 \pm 5.46$  ml x min<sup>-1</sup> x kg<sup>-1</sup>) were comparable ( $p = 0.20$ ). During the last 30 sec of the 3MT, pedaling power represented 93.6% ( $p = 0.08$ ) and  $VO_2$  93.3% ( $p < 0.05$ ) of MAP. During the 3MT, peak HHb was significantly lower than the one obtained during the MAP test. However, THb, O<sub>2</sub>Hb and TSI% did not reach higher peak values during the 3MT as compared to the MAP test. In addition, we observed a significant negative correlation between power output and THb during the 3MT ( $r = -0.98$ ,  $p < 0.001$ ), suggesting that skeletal muscle vasoconstriction occurs at higher power outputs. Conclusions: During the 3MT, muscular oxygen transport measured by NIRS never reached a higher peak than those observed during the MAP test. Despite the fact that the average power produced during the 3MT was higher than during the MAP, oxygen saturation of muscle was not lower, suggesting that the muscle cell has a protective mechanism.

### EFFECTS OF DIFFERENT PRESSURE LEVELS IN RESISTANCE EXERCISE WITH BLOOD FLOW RESTRICTION ON GROWTH HORMONE AND INSULIN-LIKE GROWTH FACOR-1 LEVELS IN MIDDLE-AGED WOMEN

Seo, D.I.1, So, W.Y.2, Chang, H.K.2

*1: Dongguk University, 2: Seoul Women's University*

Introduction According to the traditional explanation, muscle hypertrophy occurs primarily due to an overload stimulus produced by a progressive increase in mechanical load using at least 70% of an individual's concentric 1 repetition maximum (1RM) (ACSM, 2009). However, several previous studies have suggested that even low-intensity resistance exercise may have a positive effect, such as improving muscle mass and strength, on skeletal muscles (Loenneke et al. 2011). The purpose of this study was to examine how different between

3% and 5% reducing cuff length in low intensity of blood flow restriction (LI-BFR) exercise on growth hormone (GH) and insulin-like growth factor-1 (IGF-1) levels in middle-aged women. **Methods** Subjects were randomly assigned to 5 groups: a control group (CG; n = 8), a low intensity resistance exercise group (LI; n = 9), a high intensity resistance exercise group (HI; n = 9), a low intensity resistance exercise with 5% reduction in cuff circumference for blood flow restriction group (LI-5%BFR; n = 7), and a low intensity resistance exercise with 3% reduction in cuff circumference for blood flow restriction group (LI-3%BFR; n = 11). Subjects in all training groups completed pre- and post-training assessment of all variables, including GH and IGF-1 levels. **Results** A significant interaction effect ( $p < 0.05$ ) was observed for WHR: WHR was reduced in the HI group compared to the LI group. GH showed a significant interaction effect ( $p < 0.05$ ). Elevated GH was observed in the HI group and the LI-5%BFR group compared to the CG group ( $p < 0.05$ ). In addition, elevated GH was observed in the HI group compared to the LI group ( $p < 0.05$ ). Elevated IGF-1 was observed in the LI, HI, LI-5%BFR, and LI-3%BFR groups compared to the CG group ( $p < 0.05$ ). Moreover, increased IGF-1 was observed in the HI, LI-5%BFR, and LI-3%BFR groups compared to the LI group ( $p < 0.05$ ). For muscle strength, a significant interaction effect ( $p < 0.05$ ) was observed for biceps curls, triceps extensions, leg curls, and leg extensions; muscle strength showed improvement in the HI and LI-5%BFR groups compared to the CG group ( $p < 0.05$ ). Further, biceps curls, triceps extensions, leg curls, and leg extensions were increased in the HI and LI-5%BFR groups compared to the LI group ( $p < 0.05$ ). **Discussion** We demonstrated that use of portable cuffs reducing arm and thigh circumference by 5% was effective in improvement of GH, IGF-1, and muscle strength in middle-aged women. In particular, performance of low-intensity exercise with a 5% reduction of circumference with blood flow restriction resulted in similar increases in GH and IGF-1 levels compared to traditional high-intensity resistance exercise. We also demonstrated that using LI-5%BFR resulted in similar improvement in muscle strength compared to traditional high-intensity resistance exercise.

### **A TEST-DERIVED EQUATION TO ESTIMATE OXYGEN UPTAKE DURING INTERVAL TRAINING SESSIONS USING HEART RATE**

Sanna, I.I, Degortes, N.2, Pinna, M.1, Migliaccio, G.M.2, Tocco, F.1, Concu, A.1, Crisafulli, A.1

*University of Cagliari*

**Introduction.** Heart Rate (HR) monitoring represents a noninvasive tool to evaluate fitness (Strath et al. 2000) since, during incremental effort below the anaerobic threshold (AT), there is a direct relationship between HR and oxygen uptake (VO<sub>2</sub>). Thus, HR can be used to assess energy expenditure. The purpose of this study was to examine in middle distance runners the relationship between HR and VO<sub>2</sub> in (1) an incremental running test and (2) in an interval training (IT) session with the aim to test the validity of estimating of VO<sub>2</sub> from HR data during IT. **Methods.** Thirteen athletes performed an incremental test until exhaustion, and an IT session on a treadmill set at two different intensities: at 80% AT and at 120% AT speed. HR and VO<sub>2</sub> were continuously measured during the two tests (VO<sub>2</sub>real) by a portable gas analyzer. An incremental test-derived equation was used on the IT session to estimate VO<sub>2</sub> from HR data (VO<sub>2</sub>est). Bland and Altman statistics were carried out in order to evaluate the agreement between VO<sub>2</sub>real and VO<sub>2</sub>est. **Results.** The mean correlation between HR and VO<sub>2</sub> was  $r=0.92\pm 0.05$ . The Bland and Altman plot highlighted that limits of agreement of the difference between VO<sub>2</sub>real and VO<sub>2</sub>est were widespread. The limit of agreement at 80% of AT were +1384.33 and -1641.95 mL•min<sup>-1</sup>, while at 120% of AT were +1252.54 and -2411.5 mL•min<sup>-1</sup>. **Conclusion.** This study demonstrates that the use of HR monitoring to assess intensity of exercise during interval training session is unreliable. Indeed, it is known that HR response is affected by several potentially perturbing factors, such as cardiac drift, heat stress and dehydration, as well as CO<sub>2</sub> production (Crisafulli et al. 2006). This fact should be taken into account to correctly estimate energy expenditure by HR during training. **References.** Crisafulli A, Pittau G, Lorrain L, Carcassi AM, Cominu M, Tocco F, Melis F, Concu A. ### **KINEMATIC AND HEART RATE DEMANDS IN 4X4 VS 7X7 SMALL SIDED GAMES IN PROFESSIONAL SOCCER PLAYERS**

Romero Moraleda, B., Paredes, V., Morencos, E., Peinado, A.B., Butragueño, J., Castillo, A., Calderón, F.J.

*Universidad Politécnica de Madrid*

**Introduction** The small sided games (SSG) are one of the most common drills used by coaches for soccer training. In the past, SSG were mainly used for developing technical and tactical abilities. In recent years, there is a growing interest to investigate the effects of the SSG to improve the physical condition of the football player [1-5]. Therefore, the aim of this study was to compare the physiological load, indicated by the response of heart rate (HR) and kinematic variables during exercise SSG 4x4 and 7x7 in professional football players from the Spanish La Liga. **Material and methods** During the season 2011/2012, twenty professional players performed two types of SSG, 4x4 and 7x7, both on the same dimensions (40x25 m.). The response of kinematic variables and HR measured with global positioning system was analyzed using T test for two related samples. **Results** Players performed higher distances in the 4x4 vs 7x7 ( $p < 0.01$ ) but higher values of maximum speed in 7x7 vs 4x4 ( $p < 0.01$ ). On the other hand, the lower the number of players the higher the intensity when it is measured with HR. 7x7 SSG obtained heart rate values upper 85% of maximum HR ( $p < 0.01$ ), while performing 4X4 SSG the predominant intensity measured was 65 -85% of maximum HR ( $p < 0.01$ ). **Conclusion** SSG has shown that the presence of the ball increases the motivation of the players, and allows technical and tactical work simultaneously [6]. Previous studies have shown that this type of training may have a physiological load equal or similar to traditional interval aerobic workouts [1, 7, 8]. The results of this study show that kinematic variables and heart rate obtained significant differences in two small sided games exercises designed as 4x4 vs. 7x7. This is an important issue to consider when planning in terms of training objectives. **References:** 1. Hill-Haas, S. V., Dawson, B., Impellizzeri, F. M., & Coutts, A. J. ## FIELD TESTS TO EVALUATE THE GLIDE ABILITY IN MASTER SWIMMERS

Ciapparelli, C., Scurati, R., Michielon, G., Longo, S., Invernizzi, P.L.

*Università degli Studi di Milano*

**Introduction** Passive drag, which depends on the individual morphology and body position, is a useful parameter to assess the hydrodynamics of the swimmer (Naemi, Easson et al. 2010). A proper streamlined position affects the performance during the glide (Zaïdi, Taïar et al. 2008). This position is associated to sensory-perceptive skills allowing the swimmers to feel the body segments and to assume the best alignment. The aim of this pilot study was to relate the results of two simple field tests generally used for evaluating the glide ability to the swimming performance in the 100 m front crawl and to passive drag in male master swimmers. **Methods** Ten male master swimmers ( $29.6 \pm 2.4$  years,  $69.9 \pm 4.0$  kg,  $178.4 \pm 3.7$  cm,  $22.0 \pm 0.8$  kg·m<sup>-2</sup>) participated to the study. Participants' passive drag (D) was calculated with Splash software (CC, Busto Arsizio, Italy) from speed variations, measured by Speed RT (APLab, Rome, Italy) and by a digital dynamometer, during passive pull with an elastic rope. To evaluate the glide ability, glide after push-off the wall (G) and glide after dive (DG) field tests were then administered, recording the elapsed time in reaching the distance of 8 m. Finally, the performance in 100 m front crawl in a short course pool was timed. Pearson correlation coefficient was then applied to relate the 100 m performance to D, G and DG and to relate D to G and DG. **Results** The performance on the 100 m front crawl is highly related to D ( $r = 0.93$ ,  $p < 0.001$ ), G ( $r = 0.95$ ,  $p < 0.001$ ) and DG ( $r = 0.94$ ,  $p < 0.001$ ). D is highly related both to G ( $r = 0.97$ ,  $p < 0.001$ ) and DG ( $r = 0.98$ ,  $p < 0.001$ ). **Discussion** G and DG field tests can be used as complementary routine to evaluate the technical component enhancement in swimming training. The relationship between the field tests and the passive drag pointed out the role of the swimmers' ability in assuming the best streamlined hydrodynamic position during gliding, independently of the lower limbs component of the push-off the block or the wall. Therefore, considering the simple protocol of administration and measurement, G and DG field tests are shown to be a suitable way for monitoring the development of the sensory-perceptive skills involved in gliding administration in master swimmers, which is particularly relevant for the overall performance during the start and turn phases. **References** Naemi, R., W. ## COMPARATIVE EFFECT OF TWO WHOLE-BODY VIBRATION EXERCISE PROGRAMS ON THE NEUROMUSCULAR FUNCTION AND FITNESS IN YOUNG WOMEN

Raimundo, A., Batalha, N., Tomas-Carus, P., Leal, A., Gusi, N.

*University of Évora*

**Introduction** Vibratory exercises are increasingly used in sport training and physical rehabilitation. This study aims to determine the comparative effects of two vibratory frequencies on the neuromuscular leg function in healthy young active females. **Methods** Twenty-four women (aged  $21.9 \pm 2.6$  years; weight  $59.9 \pm 7.1$  kg) were randomly assigned into 3 groups of 8 subjects: group 25 Hz (G25), group 30Hz (G30), and control group (CG). All intervention programs consisted of 30 training sessions within a 10-week period. The peak torque at 60°/s in concentric and eccentric actions were measured by an isokinetic dynamometer (Biodex System-3, Biodex Corp., Shirley, NY, USA). Fitness tests such Squat Jump, Counter Movement Jump, Stair-Climbing 10-stairs time, 10-m walking time, were also performed. The effects of the interventions were analysed by an adaptation of Analysis of Covariance adjusted by weight. **Results** Vibratory training at 25Hz induced a significant reduction of peak torque in concentric contraction at the velocity of 60°.sec<sup>-1</sup> and improved the stair-climbing capacity. All other variables remained unchanged in the three groups. **Discussion** The results of the present study suggest that 10-weeks of Whole Body Vibration (WBV) programs improved ballistic strength but not isokinetic strength. Some studies with similar frequencies (between 25 Hz and 40 Hz) reported an improvement on vertical jump after 4 and 8 months (Torvinen et al., 2003 Torvinen et al., 2004). Roelants et al., (2004) showed significant improvements of strength measured by isokinetic dynamometer at low (50°/s) and medium velocities (150°/s) in the knee extensors after 24 weeks at 35-40 Hz. Roelants et al., (2004) experimental subjects, were totally untrained whereas ours were female physically active. However, aquatic training (more isoinertial than vibration) improved in isokinetic dynamometry (Gusi et al., 2006). Therefore, young active women could require longer programs to enhance isokinetic dynamometry and the WBV is a non-specific technology to isokinetic strength. **References** 1. **Introduction** The aim of this study was to identify a test assessing the ability of the goalkeeper to repeat high intensity actions (RSA) as well as his ability to repeat it several times without decreasing the execution time. **Methods** 9 participants to regional championship have been recruited in this study. Their average age  $23.7 \pm 7.1$  years, average body mass  $76 \pm 11.7$  kg, and height  $181 \pm 7.3$  cm. The protocol targeted the evaluation of the lower limbs explosive strength before and after the execution of the RSA, with different types of jumps namely: Squat Jump (SJ) Counter Movement Jump (CMJ), and Stiffness (ST). The RSA test consisted of 6 series of 4 technical actions typical of the goalkeeper with an interval of 20s between reps. The following parameters were measured: execution time of each sequence (T1-T6), best (BT) and worst (WT) time, total time (TT), ideal time (IT), decrement index (DSc), average heart rate (HR), and average value of blood lactate (BLa). To carry out the protocol a lactate analyzer (Arkray Lactate Pro) was used along with a heart rate monitor (Polar) and an Accelerometer (FreePower Jump). **Results** Results from the evaluation of the explosive strength before RSA test were: SJ  $0.43 \pm 0.05$ m, CMJ  $0.41 \pm 0.16$ m, ST  $0.34 \pm 0.12$ m. On its hand, post-exercise values were: SJ  $0.48 \pm 0.23$ m, CMJ  $0.40 \pm 0.05$ m, ST  $0.36 \pm 0.08$ m. Finally, values during the RSA test were: BT  $12.1 \pm 0.8$ s, WT  $29.9 \pm 48.8$ s, TT  $97.3 \pm 60.4$ s, DSc  $-7.9 \pm 7.6$ s, HR  $176.5 \pm 9.2$ bpm, BLa  $11.8 \pm 1.9$ mmol / L. **Conclusion** One of the limitations of this study was that it was no conducted in a standardized surface. Instead, several grounds were used: artificial, real grass, and beaten ground. Thus, the difference in terms RSA duration was probably to be of ascribed to this bias. In fact, a big difference between the best and the worst time was found, whereas values of explosive strength showed a less marked difference. BLa and heart rate values are in line with those already found in the scientific literature, thereby confirming the validity of the

test employed in the present investigation. References Evaluation of a specific reaction and action speed (RAS) test for the soccer goal-keeper. Knoop M, Fernandez-Fernandez J, Ferrauti A. ### RELATIONSHIP BETWEEN JAVELIN THROW PERFORMANCE AND ABILITY OF MEDICINE BALL THROW AND MUSCLE OUTPUT IN UPPER LIMB

Aoyama, S., Miki, R., Aoyama, T., Tsunoda, N.

*Kokushikan University*

**Introduction** The training for javelin throw is highly specific and requires precise technical development. Also, Javelin throw is required an explosive ability that elicit a stretch-shortening-cycle (SSC) in the upper limb. It is common SSC training to using medicine ball among the javelin throwers. Therefore, the purpose of this study was to clarify the relationship between javelin throw performance and ability of medicine ball throw and muscle output in upper limb. In addition, it was examine the correct upper limb training way of javelin throw. **Methods** The subjects were eight male javelin throwers (age: 20.8±2.4yrs, height: 177.8±4.6cm, body weight: 78.4±6.6kg, PB: 63.08±7.7m). The subjects performed using medicine ball throw (2kg). The ability of medicine ball throw test (Tauchi et al., 2005) was three concentric throw (CT) and three SSC rebound throw (RT) that was supine position on the bench inclined 30° in the horizontal position to throw the ball as quickly and as far as possible, and farthest throw was adopted from CT and RT respectively. The muscle output in extension and flexion action of elbow and shoulder were measured by using isokinetic dynamometer (Biodex system3) at angular velocity of 60, 120 and 180 deg/s, and highest peak torque was adopted from each angler velocities. In addition, javelin throw performance (JP) values were the total three throw same as competition rule with recorded best throw. **Results** The results were as follows: the ability of RT was significantly higher than CT ( $p < 0.01$ ). There were no significant correlation between JP and muscle output of elbow and shoulder. Similarly JP was not related to the CT and RT. However, significant correlation was observed between CT and muscle output of elbow in extension and flexion. Also RT was closely related to the muscle output of shoulder in flexion. **Discussion** The medicine ball throw was effective in SSC of upper limb for medicine ball training. Even though it was clearly the improvement of muscle output of upper limb, was unaffected of between JP and ability of medicine ball throw in upper limb directly. However, training for improve JP is must be performing the same as release movement. Therefore, the muscle output and correct medicine ball training of upper limb and coaching together is important to depending on the situation, to select the method of training, it is possible to prevent injury of elbow and shoulder joints. In addition, also important to develop javelin throw technique, it can be expectation of better javelin throw performance. **References** Komi PV (1984) Exercise and Sports Sci Reviews. 12, 81-121 Tauchi K, Kudo Y, Ohyama B K, Takamitsu K. ### PHYSICAL FITNESS TEST RESULTS OF MILITARY PILOT APPLICANTS IN FINNISH AIR FORCE: YEAR 1998 VERSUS 2012

Honkanen, T., Mäntysaari, M.J.

*Centre for Military Medicine, Finland*

**Introduction** According to recent empirical evidence the increase in overweight and decline in physical fitness of young men entering military service has become a challenge for the armed forces in Europe. Especially the aerobic fitness has declined during the last ten years among the Finnish conscripts. The aim of this study was to compare physical fitness capacity of military pilot applicants in 1998 and 2012 in Finnish Air Force (FINAF). **Methods** The study group consisted of two cohorts: applicants of 1998 (N = 164) and 2012 (N = 193). The FINAF pilot selection consists of five phases and both cohorts represent applicants who were selected to third phase after psychological and medical tests. All subjects must have reached the minimum level of 3,5 W max<sup>1</sup>/kg in ergometer and 8 points to pass to third phase. FINAF has used the same standardised physical fitness tests to evaluate applicants' physical fitness for 14 years. Aerobic fitness is evaluated with bicycle ergometer test and muscle endurance with five tests. The initial work load of the ergometer test is 20 W and it is increased by 20 W every minute until exhaustion. The work capacity in the ergometer test is measured as the average load (watts per weight) of the last minute (W max<sup>1</sup>/kg). The muscle fitness tests include: standing long jump-, pull-up-, sit-up-, back extension and push-up tests. Each test is valued with a scale from 0-3. Student's t-test was used to compare the levels of these variables between two groups. **Results** The average result of bicycle ergometer test was 4,2 (sd 0,47) W max<sup>1</sup>/kg and average result of muscle test battery was 12 pts in 1998 and 4,1 (0,47) W max<sup>1</sup>/kg and 12 Pts in 2012. The average weight and height of the candidates in 1998 selection were 70,2 (7,8) kg 178,6 (5,1) cm while in 2012 selection the average weight and height were 70,9 (7,8) kg and 178,0 (4,7) kg. No statistically significant differences were found between the two groups. **Discussion** Even though the aerobic fitness capacity has decreased and average weight has increased during the last years among the Finnish conscripts, this change is not seen in the military pilot candidates. **References** Rintala H. ### INTERPRETATION OF TRAINING INTENSITIES BETWEEN ENDURANCE AND SPRINT SWIMMERS IN FRONT CRAWL

Invernizzi, P., Scurati, R., Bosio, A., Longo, S., Michielon, G.

*Università degli studi di Milano*

**Introduction** During a training session coaches often administer the athlete's pacing intensities through instructions such as: "swim slow or moderate or fast". The athletes' experience and perception of speed are crucial for accomplish the given task, which seems not easy to be executed (Stewart & Hopkins, 1997). Moreover, competitive and training background could influence the effort perception and pacing distribution throughout a training session. Therefore, the aim of this study was to assess endurance (EN) and sprint (SP) swimmers' interpretation of slow, moderate and fast intensities during a training session. **Methods** Eight EN (age 19±3 years, height 176±3 cm, body mass 67.5±3.6 kg, 2 females) and 8 SP (age 18±1 years, height 179±5 cm, body mass 70.6±6.8 kg, 1 female) elite front crawl swimmers were recruited. Firstly, the best 50 m performance was assessed. On another day, they were asked to swim three sets of 8 x 50 m front crawl interpreting three different speeds: slow (S), moderate (M) and fast (F). Within each speed, a rest of 2, 3 and 5 s was allowed between each of the 8 trials (S, M and F, respectively). A rest of 3.5 min was observed between sets. Speed (m·s<sup>-1</sup>), normalised speed to the best 50-m performance (%best), stroke frequency (SF, Hz), and stroke length (SL, m) were collected. ANOVA (2x3), Cohen's effect size (ES) and ICC were used to test differences between groups and speeds ( $p < 0.05$ ) and reliability. **Results** No differences between groups were

found at any speed. However, when expressed as %best, significant differences ( $p < 0.01$ ) were present between groups at each speed (S:  $73.5 \pm 2.3$  vs  $66.8 \pm 4.8$ ; M:  $79.5 \pm 3.4$  vs  $73.3 \pm 4.0$ ; F:  $84.9 \pm 4.1$  vs  $79.6 \pm 3.3$ , EN and SP, respectively, ES range: 1.35–6.72). SF was significantly different ( $p < 0.01$ ) between groups (S:  $0.59 \pm 0.06$  vs  $0.55 \pm 0.04$ ; M:  $0.70 \pm 0.08$  vs  $0.63 \pm 0.05$ ; F:  $0.78 \pm 0.04$  vs  $0.72 \pm 0.03$  Hz, EN and SP, respectively; ES range: 0.81–1.54), whereas SL did not differ between groups. Within each speed, ICCs were high (range: 0.89–0.99). Discussion Despite different competitive backgrounds, our swimmers showed similar absolute speed values. However, when normalised to %best, SP swam at slower %best with a lower SF than EN. Probably, our SP perceived that swimming closer to their best performance (that was significantly higher than EN) could have compromised the success of completing the 8x50 m swim at constant pace (especially at F), which was accomplished based on ICCs. Coaches should be aware that different competitive background could lead to different interpretation of intensities instructions. References Stewart AM, & Hopkins WG. Swimmers' compliance with training prescription. *Med Sci Sports Exerc* (1997); 29(10), 1389-1392.

### ANALYSIS OF MUSCULAR IMBALANCES AS INTRINSIC RISK FACTORS OF LOWER LIMB MUSCLE AND LIGAMENT INJURIES IN SPANISH 3RD DIVISION FOOTBALL PLAYERS

Rudé, A., López, J.L.

*University of Vic*

Introduction Muscular imbalances in football appear due to the repeated unilateral actions players execute throughout their career. These muscular imbalances are considered one of the most predictable muscular and ligament injury risk factors. The aim of this study was to analyse the Bilateral Deficit (BLD), the Limb Symmetry Index (LSI) and the Quadriceps to Hamstring Ratio (Q/H) using MuscleLab® Technology (Ergotest, Norway). Methods The tests used were a counter-movement jump test (BLD); a 10 meters unilateral hop test (LSI); and a leg flexion and extension test (Q/H ratio), all monitored using MuscleLab® software (Alkner and Tesch, 2004). To obtain the strength deficits we used three equations: %BLD =  $[(BL - (Unil. Right + Unil. Left)) / BL * 100]$  (Acero et al., 2007) %LSI =  $[(weak\ current\ leg / strong\ current\ leg) * 100]$  (Gaunt and Curd, 2001) %Q/H conventional ratio =  $[(hamstring\ concentric / quadriceps\ concentric)]$  (Yeung et al., 2009) Results The BLD average was  $-9.6 \pm 10.1$ , the LSI average was  $96.6 \pm 2.1$ , and the Q/H ratio average was  $63.3 \pm 0.1$  on both legs. Discussion Overall, 82.4% of the players in our study displayed BLD and only 17.6% did not. Acero et al. (2007) found a BLD of between -21.51 and -23.11 in a study of 258 footballers. In our study, 88.2% of players had a lower BLD while 11.8% displayed a higher deficit than the previous study, the average being  $-9.6 \pm 10.1$ . This strength deficit is considered to indicate a risk of muscular injuries (Howard and Enoka, 1991). Regarding LSI, if the index is more than 90%, there is considered to be no injury risk (Anderson et al., 2006). The average with our players was 96.6, all of them being above 90%. Consequently, they exhibited no muscular injury risk. The strength difference between the two legs could be balanced because the non-dominant leg is used for balance in football. The Q/H ratio of each leg should be at least 75% for the risk of muscular and ligament injury to be ruled out (Dintiman et al., 2001). Overall, the average data of our players was  $63.3 \pm 0.1$  in both legs. Specifically, 82.4% were below 75% on their right leg, and 70.6% on their left leg. ### EXUBERANT INFLAMMATORY REACTION AFTER AN INFILTRATION OF PLATELET-RICH PLASMA

Kaux, J.F., Croisier, J.L., Léonard, P., Le Goff, C., Crielaard, J.M.

*University of Liège*

Background : PRP, obtained from centrifuged autologous blood, contains a large quantity of growth factors, which may enhance tissue healing processes. Local infiltration of PRP represents a relatively new treatment for tendinopathies. To date, no side effects have been reported after infiltration of PRP to treat tendinopathy. Case report : A 35-year-old patient had a right upper patellar tendinopathy which was resistant to all of the conservative treatments for more than 6 months. The patient was a type 1 diabetic (well controlled). He benefited from an intratendinous infiltration of 6 mL of PRP ( $8.105$  platelets/ $mm^3$ , almost no red or white blood cells) without local anaesthetic. Immediately following the infiltration, local cryotherapy was performed for 15 minutes. NSAIDs were avoided, but class-1 or -2 pain-killers were authorised if necessary. A standardised sub-maximal eccentric rehabilitation should be started 1 week after. However, the patient experienced local swelling with erythema, increased heating and pain which appeared just underneath the patella, but without biological inflammatory syndrome. A great Doppler signal in a thicker patellar tendon was observed by US, but there was no sign of local infectious disease demonstrated by either CT or MRI. However, the local inflammation did not decrease after a progressive 3-week treatment of local cryotherapy, local and oral NSAIDs and colchicine 1 mg. Thus, an insidious infection was suspected, even though there was neither evidence of biological inflammatory syndrome or sign of infectious lesion on imagery examination. An antibiotic therapy (rifampicine 600 mg + minocycline 100 mg) was initiated for 3 months. Finally, a 3-phase bone scintigraphy suggested the presence of a complex regional pain syndrome type 1 treated by a classical physical therapy and concomitant class-2 pain killers. The evolution was favourable after 6 months of symptomatic treatment, and the pain decreased to a level similar to that before the infiltration of PRP. Discussion/ Conclusions: This case report calls attention to potential side effects that are linked to this new therapy by infiltration of platelet rich plasma in case of tendinopathy, in particular when used in patients with type 1 diabetes. Thus, the balance between benefits and risks must be carefully evaluated before using this treatment in patients with type 1 diabetes. References: Platelet-rich plasma application in the management of chronic tendinopathies. *Acta Orthop Belg* 2013; 79: in press

### EXERCISES TO PREVENT THE SUSPENSION TRAUMA IN WORKERS USING HARNESS.

Pollastri, L., Lanfranconi, F., Bartesaghi, M., Vergani, H., Molteni, C., Scotti, V., Novarina, M., Miserocchi, M.

*University of Milano-Bicocca, Health Science Department, Laboratory of Clinical Physiology and Sport*

**Introduction** Workers involved in tasks that need harness could face an unexpected fall that is barely not the major adverse effect: indeed, a prolonged orthostasis during work in harness may drive to a chain of events including unconsciousness known as "suspension trauma" (ST). Purpose of this study is to evaluate cardiovascular changes during work in harness and to evaluate whether a strategy based on specific exercises could prevent ST. **Methods** The SOSPEI project consisted of 2 experimental phases: on day 1, we evaluated the cardiovascular response to simulated working tasks being suspended in a full body harness (phase1); on day 2 we estimated the impact of the introduction of specific exercises (phase2) aimed to favor the venous return during the working session, in order to contrast the factors leading to ST. Forty volunteers were tested up to a maximum of 3 hours of suspension or until subjective distress of developing ST. We measured oxygen uptake (VO<sub>2</sub>), heart rate (HR) and by near-infrared spectroscopy (NIRS) muscle oxygenation ( $\Delta$ [HHb]) of the vastus lateralis muscle and cerebral O<sub>2</sub> saturation. Furthermore we evaluated the cognitive status and the neuro-muscular coordination. **Results** During phase1, 47,3% of volunteers showed hypertensive values for diastolic and systolic blood pressure. Moreover, despite a mild energy expenditure ( $34,8 \pm 9,56$  %VO<sub>2</sub>max) during work in harness, the individual perception of fatigue (evaluated by BORG's scale) was compatible with a work rate corresponding to 80% VO<sub>2</sub>max as during an incremental test on treadmill. In phase2, specific exercises aimed to improve the venous return were carried out while subjects were performing their work load in harness. Compared to the work tasks of phase1, the exercise strategy caused an increase of cerebral blood flow and a lower utilization of the cardiac reserve (6,2% Vs 10,3%). Furthermore the introduction of the exercises strategy led to a significant lengthening of the suspension time before subjective distress feeling. **Discussion** Exercise strategy to improve venous return alleviates the tolerance of work in harness but does not eliminate neither the fatigue distress nor hypertension, likely reflecting a stable increase in peripheral vascular resistances. This point represent a cardiovascular risk factor for workers in harness. **References** Seddon P. Harness suspension: review and evaluation of existing information. Contract Research Report (for the Health and Safety Executive), 2002 Jiskoot J, Clarys JP (1975).

### NEW APPROACH FOR CRITICAL PREVENTION OF OSGOOD-SCHLATTER DISEASE IN SOCCER

Kawakita, H., Ishii, H., Kato, H., Amano, Y.

*Rikkyo University*

**Introduction** The Osgood-Schlatter disease (OSD) is known as a typical sports injury at the period of growth. Repeated strong contraction of the large patellar tendon may cause softening and partial avulsion of the developing secondary ossification center of tibia tuberosity. Some researchers reported about the risk factors of OSD, for instance abnormal lower limbs alignment. Now it is impossible to prevent OSD with these risk factors. It is obvious that frequent huge contraction forces of patellar tendon induce OSD. Soccer coaches should have controlled the contraction force of patellar tendon with young soccer players in training. Accordingly, if one day a young soccer player has huge contraction forces of patellar tendon, the same training program should be avoided in a few days because of recovery from the damage of tibia tuberosity. It is important to reveal the extent of the contraction force in motion of soccer. The contraction forces must be associated with a knee extension torque. It was investigated the knee extension torque for each motion of soccer training. The purpose of this study was to reveal the risk motion that onset of OSD during soccer activity. **Methods** The subjects of the present experiment were 8 healthy adult males soccer players. Nine typical motions were performed in soccer. Motion data were collected three-dimensionally by a motion analysis system consisting of eight cameras at 200Hz, and ground reaction force data were collected using a force plate at 1000Hz. Knee extension torques were obtained by using an inverse dynamic technique. **Results** As for the peak value of knee extension torque, single leg drop landing ( $3.45 \pm 0.65$  Nm/kg) showed high value. This was followed by, stop motion ( $3.19 \pm 0.23$  Nm/kg), cutting ( $3.05 \pm 0.58$  Nm/kg), kick motion ( $2.91 \pm 0.40$  Nm/kg), double legs drop landing ( $2.75 \pm 0.93$  Nm/kg), approach ( $2.48 \pm 0.37$  Nm/kg), sprint ( $2.30 \pm 0.50$  Nm/kg), turn ( $2.12 \pm 0.41$  Nm/kg), squat ( $0.75 \pm 0.14$  Nm/kg). **Discussion** The knee extension torque of single leg drop landing is significantly higher than these soccer motions of approach, sprint, and turn. It was revealed that the motions of single leg drop landing, stop motion and cutting induce strong contraction of the patellar tendon, compared with approach, sprint, and turn. Classifying motion according to the knee extension torque value, and making the training program that considered the loading dose thought it was profitable for the prevention of the OSD. In this case, balance of intensity to become the point. For the early teens, perform the high intensity training that load hangs for a cardiopulmonary function because the growth of respiratory and circulatory systems becomes active, and it is thought that it becomes important that such a training of the load reduces it to the body of the period of growth. The future examination subject, pursue data and an approach method to be able to make use of on the field. **References** M. S. TURNER et al. (1981). J Bone Joint Surg, 63-B, 396-398

### A META-ANALYSIS OF INJURIES IN SENIOR MEN'S PROFESSIONAL RUGBY UNION

Williams, S., Trewartha, G., Kemp, S.P.T., Stokes, K.A.

*University of Bath*

**Introduction:** Rugby union has one of the highest reported incidences of match injuries amongst all professional team sports (e.g. Brooks et al., 2005). The majority of research within this field has focused on elite male cohorts; here we present the first meta-analytic review of these data. The aim of this study was to summarise the incidence and severity of injuries in senior men's professional rugby union, and determine overall effects of: Level of play; new versus recurrent injuries; playing position; type of injuries; location of injuries; severity of injuries; period of match; and mechanism of injuries. **Methods:** Electronic databases were searched using key words 'rugby union' and 'inj\*'. Fifteen papers addressing injuries in senior men's professional rugby union (1995 through to September 2012) were included in the review. A maximum of 10 of these papers provided incidence data that could be modelled via a Poisson mixed-effects generalised linear model, while up to nine studies provided severity data that could be modelled via a general linear mixed model. Magnitude based inferences were used to assess differences between factors. **Results:** The overall incidence of injuries in senior men's professional rugby union matches was 81 per 1000 player h (95% confidence interval [CI]: 63-105), and 4 per 1000 player h (95% CI: 3-5) during training. Estimated mean severity for match injuries was 20 d (95% CI: 14-27), and 22 d (95% CI: 19-24) for training injuries. A higher level of play was associated with a greater incidence of injuries in matches, with no clear difference in severity. New injuries occurred substantially more often than recurrent injuries, while the severity of recurrent injuries was, on average, 10 d (95% CI: 4-17) greater than new injuries. Trivial differences were found in injury incidence and severity between forwards and backs. Muscle/tendon and joint (non-bone)/ligament injuries were the two most prevalent injury groups, whereas fractures and bone stress injuries had the highest average severity. The lower limb was the body region with the highest injury incidence, while upper limb injuries were most severe. The third

quarter of matches had the highest injury rate, and injuries most commonly occurred as a result of being tackled. Discussion: This meta-analysis confirms match injury incidence rates in professional rugby union can be considered high in comparison to other team sports but similar to other collision sports. In order to markedly reduce overall injury burden, efforts should target lower limb injury prevention strategies and technique during contact, as these may render the largest effect. References Brooks et al. (2005). *Br J Sports Med*, 39, 757-66. Acknowledgement Funded by the Rugby Football Union

### EPIDEMIOLOGY OF MATCH INJURIES IN ELITE ENGLISH WOMEN'S RUGBY UNION – INITIAL FINDINGS.

Gabb, N., Trewartha, G., Collins, H.F., Kemp, S., Stokes, K.A.

*University of Bath*

Introduction Participation in women's rugby has seen huge growth in recent years, but little evidence is available relating to the risk of injury. We conducted a longitudinal analysis of match injuries sustained by elite female rugby players. Methods A cohort design was employed to study match injuries sustained by adult female rugby union players during 166 matches (2320 player hours) in the English Premiership competition and separately whilst competing internationally for England (21 matches; 420 player hours) during the 2011/12 and 2012/13 seasons. Team medics reported all match time-loss (>24 hours) injuries on a weekly basis, detailing severity, location, diagnosis and injury mechanism. Incidence rates were calculated using match exposure details. Significant differences were assumed if the 95% confidence intervals (CI) did not overlap. Results Injury incidence in Premiership matches was 39 injuries per 1000 player hours (95% CI: 32, 48) with a mean severity of 44 days (median=15 days). Injury incidence in England international matches was 74 injuries per 1000 player hours (95% CI: 52, 105) with a mean severity of 81 days (median=39 days). In both cases, the tackle was the event resulting in the greatest proportion of injuries (Premiership=53%; England=42%) and the most days lost (Premiership=61%; England=59%). The lower limb was the body region most commonly injured and ligament injuries the most common type of injury in both Premiership and England matches. Discussion Injury incidence rate for female players during Premiership matches is significantly lower than their male counterparts (39 v 93 injuries per 1000 player hours [Kemp et al., 2011]); this might be because sex is a risk factor for injury or due to the amateur status of the women's game. In contrast, the overall incidence of injuries for England's women and men during international matches was very similar (74 v 78 injuries per 1000 player hours, respectively); however, total days absence was significantly higher for England women compared to men (5969 v 1789 days absence per 1000 player hours [Kemp et al., 2011]). The greater severity in women's rugby may be due to players sustaining more serious injuries; however, it may also be due to limited medical support and players balancing full-time careers with rehabilitation programmes. The tackle was associated with the greatest proportion of injuries and the lower limbs were most frequently injured. Consequently, if the injury burden is to be reduced then both the technique in the tackle and lower limb injury prevention/rehabilitation strategies should be targeted. References Kemp SPT et al. (2011). *England Rugby Premiership Injury and Training Audit 2010-2011 Season Report*. Acknowledgement Research funded by the Rugby Football Union.

### PREVENTION OF FALL-RELATED INJURIES IN 7-12 YEAR OLD CHILDREN: A CLUSTER RANDOMIZED CONTROLLED TRIAL

Nauta, J., Knol, D.L., Adriaensens, L., Klein Wolt, K., van Mechelen, W., Verhagen, E.A.L.M.

*VU University Medical Center*

Introduction To counteract the recently observed increase in forearm fractures in children worldwide, an educational program to improve fall skills was developed. In this eight week during program children learned basic judo techniques in their physical education (PE) classes. In this study the effectiveness of this educational program in decreasing the number and severity of fall-related injuries was studied. Methods A cluster randomized controlled trial was conducted in 33 primary schools. The intervention group received the educational program to improve falling skills during their PE classes while the control group received their regular PE curriculum. At baseline (October 2009) and follow-up (May 2010), a questionnaire was completed by the children about their physical activity behaviors. Furthermore, fall-related injuries were registered continuously during a school year. Differences between groups were analyzed using a generalized linear mixed model, adjusting for cluster effects and confounding. Results After receiving the intervention, children showed a reduced number of fall-related injuries per 1.000 hours of physical activity compared to children that did not receive the program (injury incidence density intervention group 0.14 [95% CI 0.09 – 0.18] vs control group 0.26 [95%CI 0.21 – 0.32]). However, because of major cluster effects the difference in injury incidence was not significant. Including habitual physical activity into the model revealed a trend suggesting that the educational program to improve fall skills was effective in decreasing falling-related injury risk, but only in the least active children. For injury severity, no differences were found between study groups. Discussion/Conclusion(s) The present study is one of few intervention studies on physical activity related injuries in children, and to our knowledge the first to target fall-related injuries in a school based setting. Our finding that the least active children might benefit most from this type of injury prevention is in line with findings of Collard et al who, in a comparable study, reported that their physical activity related injury prevention program showed larger effects for those children with low habitual physical activity levels. This is arguably due to the increased injury risk in the low active group as found in the current and previous research. While injury risk is high due to reasons yet to be established, preventive effects of a school-based injury prevention approach may have a large impact. This dilutes the overall effect when adjusting the analyses for the clustered design.

### PROSPECTIVE INJURY SURVEILLANCE OF WOMEN'S LACROSSE: A 2-YEAR STUDY

Sanomura, M.1,2, Hosokawa, Y.3, Hoshiba, T.1, Saho, Y.1, Miyamura, T.2, Nakamura, C.1, Fukubayashi, T.1

1: *Waseda University (Tokyo, Japan)*, 2: *Tokoha University (Shizuoka, Japan)*, 3: *University of Arkansas (Arkansas, USA)*

Introduction Lacrosse is a fast-paced game that involves running, cutting, and jumping maneuvers while a cross (stick) is used to pass, catch, and shoot a ball (Lincoln et al., 2007). In the National Collegiate Athletic Association Injury Surveillance System data for women's lacrosse (Dick et al., 2007), the most frequently injured body part was the ankle, the most common type of injury was sprain, and the most common mechanism of injury was non-contact. There is not much literature with respect to injury characteristics in Japanese women lacrosse players. The purpose of this prospective study was to examine the specific injury characteristics in collegiate women's lacrosse for a 2-year season in Japan. Methods Injury data were collected from the Division I collegiate women's lacrosse team over a 2-year period (April 2010 to March 2012). The individual injury data items gathered were the number and incidence of injuries, the injured body part, the type and mechanism of injury, injury recurrence, and the days that elapsed until full participation in practice. The injury incidence rate was indicated as 1000 athlete-hours and 1000 athlete-exposures (1000 AHs and 1000 AEs, respectively). An injury was defined as an incident that occurred during practice and/or games and resulted in the player missing 1 day or more of participation in practice and/or games. Results The total AHs and AEs over the 2-year period were 27,621 and 13,437, respectively. The total number and incidence rate

of injury was 309 injuries and 11.19 injuries per 1000 AHs and 23.00 injuries per 1000 AEs, respectively. The most frequently injured body part was the ankle, followed by the knee and the thigh (2.24, 1.63, and 1.20 injuries per 1000 AHs, respectively). The proportion of lower extremity injuries was approximately 74% of all injuries. Sprains and muscle cramps/spasms (24.9% and 24.6%, respectively) were the two most common types of injury. The most frequent mechanism of injury was overuse (39.1%), contact (e.g., other players, the cross, and the ball; 24.9%), and non-contact (17.2%). Non-contact ankle sprain was found to be the most frequent injury pattern in women lacrosse players. Injury recurrence accounted for 26.1% of all injuries, and the most number of days required for the player to return to practice and/or games was between 3 and 7 days. Discussion An understanding of the specific injury characteristics of women lacrosse players may facilitate the development of an injury prevention program, which is 1 component of the comprehensive strategy for injury prevention based on the 4-step injury prevention model proposed by van Mechelen et al. (1992). References Lincoln AE et al. (2007). *Am J Sports Med*, 35, 207-215. Dick R et al. (2007). *J Athl Train*, 42, 262-269. van Mechelen W et al. (1992). *Sports Med*, 14, 82-99.

### JOGGERS OVER 40 YEARS: INCIDENCE OF INJURIES BY ANATOMIC REGION

Sesboüé, B.1, Guillaume, V.1, Clarys, J.P.2, Hulet, C.1

1: INSERM-UCBN, U1075, Caen F-14000, France, 2: Experimentale Anatomie, Bruxelles, Belgium

Introduction Jogging is gaining popularity without interruption since the seventies and runners older than 40 are increasing with it. PURPOSE: Verify if injuries over 40 are similar to those within a younger sample of joggers. Methods A questionnaire including 23 issues was submitted to more than 1000 registered joggers of a particular region in France. The majority of questions related to injury and personal approach of their running frequency over the last year. Results 597 valid responses, divided as 233 subjects (183 male; 50 female) under 40 and as 364 subjects (277 male; 87 female) over 40 were received (overall BMI  $22.78 \pm 2.38$  kg.m<sup>2</sup>). In the -40 sample more subjects perform less than 20 km/week compared to the +40 sample ( $P < 0.05$ ) and -40 runners are equally lesser involved in competition than the older group. The choice of underground and the level and frequency of warming-up are identical in both groups. The +40 group, however, will pay more attention to muscle elongation practice and hydration ( $P < 0.05$ ). That same group will use its running shoes for more than 1500 km while almost 99% of the -40 group will change earlier. 83.4% of all subjects were injured in the preceding year (NS between groups). Regardless the age the knee was the most occurring injury type (50.5%-40; 38.9% +40) followed by ankle strains, in majority (18.9%) in the younger group and by the pedis region in the older group (24.8%). Muscular lesions occurred most in the +40 group (26.1% versus 16.7%;  $P < 0.02$ ). Discussion Injuries in our sample are more frequent than in other studies (Macera et al., 1989; Rochongar et al., 1995) but in accordance with McKean et al. (2006) related to the knee in particular. In the +40 group, the foot ranked second and is ranked fifth localization in the -40 group. In accordance with Rochongar et al., we found no relation between lesions and the choice of underground. Conclusions The combination of more distance/week, more competition and longer use of shoes may be at the origin of the increase of foot lesions in the +40 group. ### CAN THE FUNCTIONAL MOVEMENT SCREEN™ PREDICT INJURIES IN VETERAN SOCCER PLAYERS?

Hammes, D., aus der Fünten, K., Meyer, T.

Saarland University

Introduction The Functional Movement Screen™ (FMS™) consists of seven tests and aims to assess the quality of fundamental human movements. Its application is widely used to predict injuries. Despite the frequent practical use of the FMS™, only few studies have examined a possible relationship between the test result and the injury risk and none with regards to veteran soccer players. Therefore, the purpose of this study was to determine whether the FMS™ can be used to predict injuries in veteran soccer players. Methods 18 veteran soccer teams ( $n = 238$ ) were recruited for a prospective 9 months follow-up (1 season). The players (age:  $44 \pm 7$  years; weight:  $84 \pm 11$  kg, height:  $178 \pm 6$  cm) performed the FMS™ at the start of the study period. Player exposure hours and injuries were recorded according to the FIFA/UEFA consensus statement (Fuller et al., 2006). Only time-loss injuries were considered. Results The median FMS™-score was 12 (25th percentile: 10, 75th percentile: 14). No FMS™ Cut-off-score could be detected by using Receiver Operating Characteristic (ROC) curves (area under the curve [AUC]: 0.56,  $p = 0.17$ ). Univariate logistic regression, with "injured/non-injured" as the dependent and FMS™-Score as the independent variable, did not reveal a significant relationship ( $R^2 = 0.01$ ,  $p = 0.15$ ) as well. Taking injury incidences (injuries per 1000 h) into account and dichotomizing the group using the median FMS™-score (LOW:  $\leq 12$ ; HIGH:  $>12$ ) as cut point, no significant differences were found either (15.3; 95% confidence interval [CI]: [11.1 - 19.5] vs. 10.8 [7.3 - 14.3]; incidence rate ratio [IRR]: 1.41 [0.92 - 2.15];  $p = 0.11$ ). There is a tendency if the injury incidences of the 25th percentile (LOW25: FMS™-score  $\leq 10$ ) and the 75th percentile (HIGH75:  $\geq 14$ ) are compared (19.2 [13.1 - 25.2] vs. 11.9 [7.3 - 16.4]; IRR: 1.62 [0.98 - 2.66];  $p = 0.06$ ). The results did not differ if contact and non-contact injuries were analyzed separately. Discussion: The findings of this study suggest that the FMS™ is not able to predict injuries in veteran soccer players. However, the results of the comparisons of injury incidences indicate that there might be a tendency towards a higher injury risk associated with lower FMS™ score. Reasons for this results might be too sports unspecific tests or a too imprecise scoring system. References Fuller, C. W., Ekstrand, J., Junge, A., Andersen, T. E., Bahr, R., Dvorak, J., . . . ### RADIOLOGICAL EVIDENCE OF THE CAM DEFORMITY IN ELITE MALE WATER POLO PLAYERS

Melville, P.

University of Queensland

Introduction Symptomatic cam type femoroacetabular impingement (FAI) is a source of hip and/or groin pain & injury for the male athlete [1]. This study utilised Magnetic Resonance Imaging (MRI) to assess the evidence of the cam deformity in a cohort of elite male Water Polo players. Methods 3D weDESS MR images of both hip joints using a 3T system were obtained in thirty elite male Water Polo players (24 + 4.2, 17-38). Images were reformatted into a radial plane sequence to accurately visualise the femoral head neck junction (FHNJ). Alpha angle (AA) measures were performed at the superior (S), anterosuperior (A-S), anterior (A) regions of the FHNJ; AA  $> 60^\circ$  was deemed to indicate a cam deformity [2]. The AS FHNJ junction was also graded using a three point grading scale (1- no cam deformity, 2- minor cam deformity, 3- prominent cam deformity). Results The intra-rater reliability of the AA and grading scale were shown to be excellent (ICC 0.986) and good (Kappa 0.674). The mean + SD for AA's at the S, AS, and A regions were  $44.0 + 4.60$ ,  $65.2 + 12.90$  &  $60.4 + 9.40$ . AS

AA's were significantly ( $p > 0.05$ ) greater than AA's at the S and A regions. Overall, 62% (37/60) of the hips were shown to have the cam deformity (AS AA>600); 22/30 athletes were shown to have a cam deformity in one or both hips. Finally, a strong positive Pearson's correlation of 0.817 was recorded between the AS AA and grading scores. Discussion In agreement with previous research [3-6], this study found that the cam deformity was commonly bilateral, most pronounced at the AS FHJ and present around 60% of hips amongst young male athletes. This study highlights the relevance of cam type FAI as a potential source of hip and/or groin pain in the male Water Polo player. References 1. ### **KNEE JOINT POSITION SENSE IN SUBJECTS AFTER ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION: A PRELIMINARY REPORT OF A LONGITUDINAL STUDY**

Hoshiya, T., Sanomura, M., Fukubayashi, T.

*Waseda University*

**Introduction** ACL injury and/or reconstruction can affect both the reconstructed and intact knees in terms of a patient's joint position sense and quadriceps muscle activation. However, the changes actually caused by ACL reconstruction and their associated behavioural characteristics are unclear. This longitudinal study aimed at observing the behavioural changes in a year after reconstruction and at assessing the sensorimotor system at the knee joint. **Methods** We included 7 subjects (2 men and 5 women; mean age,  $20 \pm 1.4$  years; mean height,  $162.9 \pm 7.8$  cm; mean body weight,  $57.6 \pm 8.8$  kg) who underwent double-bundle ACL reconstruction surgery with a semitendinosus graft. In this study, we reproduced knee joint position and bilateral position-matching tasks to assess knee joint position sense at 6 and 12 months after ACL reconstruction. We used an electronic goniometer to acquire the knee joint angle during each task performed thrice, and the angles of deviation from the target angle/reference leg were determined as the reproducing/matching errors. **Results** In subjects who underwent ACL reconstruction of the right knee, the mean reproducing errors (Standard Deviation) at 6 and 12 months were  $0.8^\circ$  (2.3) and  $2.1^\circ$  (0.7), respectively, in the reconstructed knee and  $3.7^\circ$  (0.1) and  $1.6^\circ$  (0.0), respectively, in the other leg. In subjects who underwent ACL reconstruction of the left knee, the mean reproducing errors at 6 and 12 months were  $5.1^\circ$  (3.3) and  $4.6^\circ$  (2.3), respectively, in the reconstructed knee and  $3.5^\circ$  (0.5) and  $3.0^\circ$  (3.6), respectively, in the other leg. In subjects who underwent ACL reconstruction of the right knee, the mean matching errors at 6 and 12 months were  $7.6^\circ$  (0.5) and  $2.4^\circ$  (0.2), respectively, in the right reference leg and  $-1.4^\circ$  (6.2) and  $0.9^\circ$  (0.2), respectively, in the left reference leg. In subjects who underwent ACL reconstruction of the left knee, the mean matching errors at 6 and 12 months were  $0.8^\circ$  (3.4) and  $5.6^\circ$  (3.7), respectively, in the right leg and  $3.6^\circ$  (2.3) and  $2.5^\circ$  (3.2), respectively, in the left leg. **Discussion** The levels of the reproducing errors at 6 months and 12 months in both reconstructed and intact knees tended to remain the same in regardless of right- or left-knee reconstruction. As for the position-matching task, the reference limb seemed to change the results at 6 months, implying that the matching process may correlate between the 2 limbs. This effect tends to be lacking at 12 months, but it is plausible that both the reconstructed and the intact knees must be taken into account at the same time 1 year after the reconstruction. ### **ASSOCIATION BETWEEN THE STRESS FRACTURE AND BONE METABOLISM MARKERS IN FEMALE COLLEGIATE ATHLETES -FOCUS ON 'TRACP-5B' AS A NEW BONE METABOLISM MARKER-**

Wakamatsu, K., Sakuraba, K., Fujita, S., Kubota, A.

*Juntendo University*

**ASSOCIATION BETWEEN THE STRESS FRACTURE AND BONE METABOLISM MARKERS IN FEMALE COLLEGIATE ATHLETES — FOCUS ON 'TRACP-5b' AS A NEW BONE METABOLISM MARKER—** **Introduction** Many female athletes are indefinitely benched from competitions because of the 'female athlete triad' of amenorrhea (menstrual abnormality), stress fractures and bone loss (osteoporosis), and eating disorders. In general, women who suffer from amenorrhea and have low bone mineral density (BMD) (an indicator of bone strength) are at the highest risk for overuse injury of bone that leads to stress fractures (Louis et al., 1991). However, some athletes have achieved superior results in competitions without experiencing stress fractures despite low BMD, suggesting that it is difficult to predict the occurrence of stress fractures based on BMD alone. Recently, the importance of bone metabolism is increasingly being recognized as a factor influencing bone strength (Banfi et al., 2010). Therefore, we hypothesized that bone metabolism markers are important in predicting overuse injury of bone. The purpose of this study was to examine the usability of some bone metabolism markers, especially TRACP-5b, for prevention of overuse injury of bone. **Methods** The subjects were Japanese 142 elite female collegiate athletes who were divided into a stress fracture group and control group. After the measurement of BMD, bone alkaline phosphatase (BAP), N-telopeptide cross-link of type I collagen (NTx), and bone specific tartrate-resistant acid phosphatase (TRACP-5b) in blood samples were measured in the both groups. **Results** No significant differences were observed in the levels of BAP and NTx between the stress fracture group and control group. In contrast, the TRACP-5b levels were  $381.5 \pm 130.7$  mU/dL and  $324.1 \pm 99.9$  mU/dL in the both groups, respectively. A significant increase in TRACP-5b in female collegiate athletes levels was observed in the stress fracture group ( $p < 0.01$ ). **Discussion** Previous studies have demonstrated that TRACP-5b is particularly useful in understanding the physical condition of top-level female skiers (Lombardi et al., 2011). In our study, we conclude that TRACP-5b is a reliable bone metabolism marker compared with other markers, and our results demonstrate that TRACP-5b may be a useful bone metabolism marker for monitoring bone condition in female collegiate athletes. **THE EPIDEMIOLOGY OF TIME-LOSS INJURIES IN ENGLISH COMMUNITY LEVEL RUGBY UNION**

Roberts, S.P.1, Trewartha, G.1, England, M.1,2, Shaddick, G.1, Stokes, K.A.1

1: University of Bath, (UK), 2: Rugby Football Union, (UK)

Introduction Research conducted to date on injuries to rugby union players has focussed primarily on elite and youth level. The majority of male senior players participate at community level, yet there is limited information on this group. Therefore, the aim of this study was to establish the incidence and nature of time-loss injuries in English community rugby and to assess differences between different levels of play. Methods Using a prospective cohort study design, injury information was collected from 46 and 67 and 76 English community clubs during rugby seasons 2009/10, 2010/11 and 2011/12, respectively. Club medical staff reported injury information for time-loss injuries occurring during match play and causing a player to miss at least one match. Clubs were subdivided into groups A (levels 3 and 4; mostly semi-professional), B (5 and 6; mostly amateur clubs) and C (7, 8 and 9; social and recreational clubs) for analysis. Logistic regression was used to obtain rates of injuries, together with 95% confidence intervals (CI). Significant differences in the rates of injuries were assessed by comparing the fit (via changes in deviance) of a series of models. Differences were deemed to be statistically significant if  $p \leq 0.05$ . Results The overall injury incidence was 16.9 injuries per 1000 player match hours with a higher incidence for group A (21.7; 95% CI 19.8 to 23.6) compared with group B (16.6; 95% CI 15.2 to 17.9) and C (14.2; 95% CI 13.0 to 15.5, both  $p < 0.001$ ) and a higher incidence in group B compared with C ( $p = 0.011$ ). There was no difference between forwards and backs. The mean time-loss was 6.6 matches absence, with knee and shoulder injuries resulting in a mean of 10.6 and 8.3 matches absence, respectively. Half of all time-loss injuries occurred to the lower limb, with knee and ankle joint/ligament injuries the most common diagnoses. Shoulder joint/ligament injuries were the most common and severe upper limb injuries. Contact events accounted for 80% of all injuries and tackle events accounted for 50%. Running was the most common non-contact injury event, of which 56% were hamstring injuries, and these injuries were predominantly sustained by backs (1.4; 95% CI 1.1 to 1.8) rather than forwards (0.5; 95% CI 0.3 to 0.7;  $p < 0.001$ ). There was a significantly higher injury rate in September and October (early season) compared with all other months ( $p < 0.001$ ). Discussion More time-loss injuries occur at higher levels of community rugby. Injury prevention strategies should focus on player education around the tackle event and exercises which strengthen the muscles in the shoulder, knee and ankle. **Mini-Orals****PP-PM17 Health and Fitness [HF] 11****A 16-WEEK AEROBIC INTERVAL TRAINING PROGRAM IMPROVES HEALTH RELATED QUALITY OF LIFE IN METABOLIC SYNDROME PATIENTS.**

Cruces, C., Fernández-Elías, V.E., Ortega, J.F., Hamouti, N., Mora-Rodriguez, R.

Universidad de Castilla-La Mancha

Introduction and Purpose: The SF-12 [1] is a short form survey with 12 questions all selected from the SF-36 Health Survey. This survey provides an overview of a person's perceived mental and physical health as well as their overall health-related quality of life perception. Some studies have used combined strength and endurance training to improve health-related quality of life in a healthy population [2]. The purpose of this study was to assess the effects of 16 weeks of aerobic interval training on health related quality of life (HRQoL) in people with metabolic syndrome. Methods: Forty-eight sedentary metabolic syndrome men ( $n=22$ ) and women ( $n=26$ ),  $52 \pm 9$  years old participated in a 16-week supervised cycle-ergometer high intensity interval training program (45 min, 3 times-week). Their HRQoL was assessed monthly using the SF-12 questionnaire. Two main component scores, mental (MCS) and physical (PCS) were differentiated in this cohort. Results: The scores progressively increased with the duration of the training program. After 16-weeks of aerobic interval training the Physical Component increased by 4.1 units while the Mental Component by 2.3 units compared to pre-training values (9% and 17%; respectively,  $P < 0.05$ ). The overall HRQoL score increased by (8%). The improvement in the metabolic syndrome factors (Z score changes) was highly correlated with the improvements in overall HRQoL ( $P=0.0024$ ). Conclusion: According to the SF-12 survey results a 16-week aerobic interval training program increased by (8%) the health related quality of life (HRQoL) in people with metabolic syndrome. The increase is more marked in the physical component and highly correlated with the biological improvement in the participant's health (Z score). This data suggest that the individual interpretation of the HRQoL is a good index of their biological health. References: 1. **FOOD GROUP PREFERENCES AND ENERGY BALANCE IN MODERATELY OBESE POSTMENOPAUSAL WOMEN SUBJECT-ED TO A BRISK WALKING PROGRAM**

Garnier, S.1, Vallée, K.2, Lemoine, S.3, Joffroy, S.1, Gaubert, I.4, Drapeau, V.2, Tremblay, A.2, Auneau, G.1, Mauriège, P.1

(1) Université Paul Sabatier, Toulouse, France; (2) Laval University, Québec, Canada; (3) Université de Rennes, France; (4) FFEPGV, Paris, France.

The main objective of this study was to examine the effects of a 16-week walking program on food group preferences and energy balance of 156 sedentary postmenopausal women, 50 to 65 years-old, whose body mass index ranged from 29 to 35 kg/m<sup>2</sup>. Women were subjected to 3 sessions/week of 45 min-walking at 60 % of heart rate reserve. Total energy intake, TEI and food groups preferences (3-day dietary record), total energy expenditure, TEE (3-day physical activity diary), cardiorespiratory fitness, CRF (2-km walking test), anthropometry and body composition (bioimpedance) were measured before and after our walking program. The modest increase in TEE of  $151 \pm 24$  kcal/day (mean  $\pm$  SD) ( $p < 0.0001$ ) leads to body weight and fat mass losses as well as to waist girth reduction ( $p < 0.0001$ ). However, TEI remained unchanged despite a slight decrease in carbohydrate intake ( $-1.0 \pm 0.5$  % TEI;  $p < 0.05$ ) vs. a minor increase in protein intake ( $0.7 \pm 0.3$  % TEI;  $p < 0.05$ ). Analysis of food records revealed a decreased consumption of fruits ( $-0.18 \pm 0.08$  servings/day;  $p < 0.05$ ),

sweet and fatty foods ( $-0.23 \pm 0.09$  servings/day;  $p < 0.01$ ), but an increased oil consumption ( $0.32 \pm 0.08$  servings/day;  $p < 0.0001$ ) after walking. Women with the highest body weight loss showed the greatest reduction in fruits ( $-0.43 \pm 0.16$  servings/day;  $p < 0.05$ ), sugar and sweet foods ( $-0.098 \pm 0.22$  servings/day;  $p \leq 0.05$ ) as well as fatty foods ( $-0.31 \pm 0.21$  servings/day;  $p < 0.05$ ). Women characterized by the greatest fat mass loss showed the highest decrease in fatty food consumption ( $-0.20 \pm 0.19$  servings/day;  $p < 0.05$ ). A similar analysis taking into account tertiles of waist girth or CRF changes did not reveal changes in food group preferences. Our data indicate that moderate physical activity leads to minor changes in food group consumption but does not modify TEI, thus maintaining a negative energy balance in obese postmenopausal women.

### **NO DIFFERENCES IN ACUTE BLOOD PRESSURE AND HEART RATE RESPONSE BETWEEN HIGH INTENSIVE RESISTANCE TRAINING AND TRADITIONAL TRAINING.**

Moro, T., Bianco, A., Paoli, A.

*University of Padova*

**Introduction** Regular practise of physical activity would contrast obesity and several related disease<sup>1</sup>, but exercise should be enjoyable and useful to be part of person's lifestyle<sup>2</sup>. It has been recently demonstrated that High Intensity Resistance Training (HIRT) may increase resting energy expenditure after exercise and may reduce Respiratory Ratio hence improving fat oxidation<sup>3</sup>. The shorter exercise time commitment may help to reduce one major barrier to exercise that is the lack of time. The aim of this study was to verify the safety of High Intensity Resistance Training by the monitoring Blood Pressure (BP) and Heart Rate (HR) during one session of HIRT and compare it to the resistance protocols propose by ACSM Guidelines<sup>1</sup> (TT). **Methods** Twenty healthy volunteers performed one session of both type of RT: HIRT technique consists of 6 repetitions, 20" rest, 2/3 repetitions, 20" rest, 2/3 repetitions with 2'30" rest between sets<sup>2</sup>; TT consisted of 3 sets of 15 repetitions with 1'15" rest between sets. We measured Blood Pressure and Heart Rate during exercise and basal lactate after each session. **Results** Subjects shown similar HR response to both training (HIRT= $128,20 \pm 15,64$ ; TT=  $116,29 \pm 14,78$ ), also minimal and maximal value weren't significant different (HIRT=  $89,50 \pm 18,39$  and  $149,33 \pm 16,26$ ; TT= $84,33 \pm 15,23$  and  $150,00 \pm 16,12$ ). No difference was detected also in SBP (HIRT= $134,82 \pm 13,90$ ; TT=  $128,87 \pm 12,46$ ) or DBP (HIRT= $73,38 \pm 10,90$ ; TT= $73,94 \pm 9,66$ ). Interesting during HIRT session DBP reach lower peak than during TT ( $p < 0.05$ ). **Discussion** Different intensity of resistance training elicit similar cardiovascular response in our subjects young healthy subjctets. Furthermore, DBP, the most important BP parameter, reached lower level during HIRT than during TT. The results of this study suggest that HIRT could be a safe type of training. Further studies are needed to evaluate the efficacy and safety of HIRT in overweight subjects. **References** <sup>1</sup>Willis LH. *J Appl Physiol.* 2012 Dec 15;113(12):1831-7. <sup>2</sup>Garber CE. *Med Sci Sports Exerc.* 2011 Jul;43(7):1334-59. <sup>3</sup>Paoli A. *J Transl Med.* 2012 Nov 24;10:237.

### **WALK@WORKSPAIN: IMPACT OF "SITTING LESS AND MOVE MORE AT WORK" ON EMPLOYEES' CARDIOVASCULAR RISK FACTORS**

Bort-Roig, J.1, Puig-Ribera, A.1, González-Suárez, A.M.2, Martínez-Lemos, I.3, Giné-Garriga, M.4, Fortuño, J.4, Gilson, N.D.5

*1. Universitat de Vic, 2. Universidad del País Vasco, 3. Universidad de Vigo, 4. Universitat Ramon Llull-Blanquerna,(Spain) 5. The University of Queensland (Australia)*

**Introduction:** Sitting time represents an independent preventable risk factor for cardiovascular disease (CVD), even among individuals who meet physical activity recommendations (Katzmarzyk et al., 2009). However, approximately 80% of adults work in sedentary and light activity occupations (Tudor-Locke et al., 2011). This study investigated the impact a "sit less and move more" program had on employees' major CVD risk factors. **Methods:** Office employees from four Spanish universities engaged in the program over 19 weeks ( $n=264$ ; age  $42 \pm 10$  years; 171 women). The intervention group (IG,  $n=129$ ) used a pedometer, a diary and a website which provided strategies, motivational materials and interactive features to increase step counts and reduce sitting time at work. Following baseline measures, the intervention consisted of a (i) ramping phase to progressively increase baseline step counts to 10,000 by integrating active working tasks, short and long walking routes at work, (ii) a maintenance phase to sustain the increased volume of step counts through researcher support. An additional campus in each university acted as a control group (CG,  $n=135$ ). Outcome measures were completed at baseline, post-intervention and two months follow-up. Measures included waist circumference, body mass index (BMI) and, systolic and diastolic blood pressure. ANOVA was used to analyse differences within and between groups. **Results:** The IG significantly decreased waist circumference at post-intervention ( $-1.7$ cms,  $p < .05$ ) and two months follow-up ( $-2.1$ cms,  $p < .05$ ). When compared to controls, the IG showed a significant higher decrease on waist circumference post intervention and at follow up ( $-1.0$ cms,  $p < .05$ ;  $-0.7$ cms,  $p < .01$  respectively). There were no significant changes for blood pressure and BMI, but average BMI values did decrease relative to the controls at post intervention, with these decreases maintained at follow-up ( $-0.09$  kg/m<sup>2</sup>). **Discussion:** A workplace program aiming to reduce sitting time and increase step counts successfully reduced abdominal fat and showed a trend towards reducing BMI. Walk@WorkSpain may be an effective intervention strategy for improving some CVD risk factors in office workers. **References:** Tudor-Locke C, Leonardi C, Johnson WD, Katzmarzyk PT. ### **THE EFFECT OF 8-WEEKS AEROBIC TRAINING ON QUALITATIVE AND QUANTITATIVE PARAMETERS OF STROKE VOLUME**

Pustivšek, S., Auersperger, I., Škof, B.

*University of Ljubljana, Faculty of Sport*

**Introduction** During the increase of exercise intensity the stroke volume (SV) is changing. It increases until the plateau is reached. Data published about this issue are controversy and there is a lack of researches on recreational sports participants. The aim of this study was to analyse changes of the dynamic in SV after 8- weeks of aerobic training and to estimate the changes in some quantitative parameters. **Methods** Sample consists of 18 female recreational sports participants ( $32.3 \pm 5.3$  years). Participants had an intermediate training three times per week on 85% of their VO<sub>2</sub>max with an exercise to rest ratio of 1:1. Once a week, a continues exercise of 8 to 12 km run on 70 – 87 % of their maximal heart rate (HRmax) was performed. Exercise sessions were monitored with Polar (RS400sd, Finland), VO<sub>2</sub>max was measured with on line breath by breath technology (CosmedK4b2). Intensity was calculated using Edwards methodology (Janssen, Dallmeijer, & van der Woude, 2001) and stroke volume was calculated with Stringers formula (Stringer, Hansen, & Wasserman, 1997). **Results** There was an increase of stroke volume in first and second minute of test ( $p < 0.05$ ). HR at SVmax decreased. SV dynamic did not

show any changes. A significant final speed increase was found ( $4.41 \pm 4.62\%$ ;  $p < 0.01$ ). Discussion There were no qualitative changes in stroke volume after 8-weeks of endurance training. This was a consequence of non-significance of the changes in dynamic of SV. This results agree with literature (Astrand, et al., 1964; T. Rowland, 2009), showing a dynamic of plateau in stroke volume. There was an increase of SV in first two minutes of the test ( $p < 0.05$ ) what may reveal quantitative changes. An increase of endurance abilities was found, what can be a consequence of the training intensity. Speed, time and distance were significantly higher on the end compared to first test, as was concluded by Škof & Milić (2010). Low increase of aerobic abilities can be explained by the high endurance capacity of the participants. It seems that 8-weeks aerobic training can induce quantitative changes but not qualitative changes. Further investigations should include also sedentary population. References Astrand P. O, Cuddy T. ### STAIR CLIMBING TO PROMOTE BALANCE, GAIT, STRENGTH, RESTING HEART RATE AND SUBMAXIMAL ENDURANCE IN HEALTHY COMMUNITY-DWELLING SENIORS

Zahner, L., Donath, L., Roth, R., Faude, O.

*Institute of Exercise and Health Sciences, Univ of Basel*

Introduction Stair climbing has been shown to induce a health-related additional energy expenditure and increase leg strength as well as maximal oxygen uptake in young adults (Gottschall et al., 2010). Data on effects of regular stair climbing on selected fall-risk factors and cardio-circulatory outcomes in seniors are lacking. Thus, the present study aimed at examining the effects of a guided stair-climbing intervention on resting heart rate and submaximal endurance as well as strength, balance and gait in seniors with particular emphasis on differences between the 1- and 2-step ascending strategies. Methods 48 healthy seniors were randomly assigned (strata: age, gender, BMI) to either a 1-step strategy (INT1), a 2-step strategy (INT2) or a control group (CON). Nine seniors dropped out (health complaints, insufficient training compliance). Thus, 39 seniors (females: n=22, males: n=17; age: 70.5 (SD 5.1) y; BMI: 25.8 (3.1) kg/m<sup>2</sup>) completed the 8-week training intervention (3 sessions per week, attendance 83%). The amount of stairs climbed per session progressively increased from 256 to 640 stairs. The overall climbed altitude (INT1: 1659 (349) m, INT2: 1556 (235) m,  $p=0.38$ ) and total vertical work (INT1: 1144 (290) kJ, INT2: 1126 (201) kJ,  $p=0.85$ ) was similar for both groups. We assessed standing balance, spatio-temporal gait, maximal and explosive strength as well as submaximal endurance before and after the training period. Results We found relevant decreases in heart rate ( $p=0.04$ ,  $\eta^2=0.16$ ; INT1: -8 min<sup>-1</sup>, INT2: -10 min<sup>-1</sup>, CON: -1 min<sup>-1</sup>), perceived exertion ( $p=0.01$ ,  $\eta^2=0.22$ ; INT1: -1.2 (10-point Borg scale), INT2: -2.5, CON: +0.2) and lactate concentration ( $p=0.06$ ,  $\eta^2=0.14$ ; INT1: -0.4 mmol/L, INT2: -0.5 mmol/L, CON: +0.1 mmol/L) during submaximal uphill (8% inclination) walking. Moreover, resting heart rate was significantly reduced in INT2 (-8min<sup>-1</sup>,  $p=0.02$ ,  $\eta^2=0.20$ ). A large effect for center-of-pressure path length displacement during right leg stance ( $\eta^2=0.14$ ,  $p=0.10$ , INT1: -14%, INT2: -9%, CON: +1%) was found. Spatio-temporal gait parameters did not relevantly change. Large effects in favor of INT1 and INT2 were present for peak force during leg press ( $\eta^2=0.16$ ,  $p=0.04$ ) as well as rate of torque development during right leg plantar flexion ( $\eta^2=0.14$ ,  $p=0.06$ ). Conclusion Independent of the ascending strategy, a guided stair climbing intervention beneficially affects cardio-circulatory endurance, resting heart rates and selected strength parameters. The transfer to standing balance and gait characteristics seems restricted. References Gottschall JS et al. (2010) *J Strength Cond Res*, 24, 2558-2563.

### EFFECTS OF WHOLE BODY VIBRATION TREATMENT AFTER ECCENTRIC TRAINING ON PHYSIOLOGICAL "DOMS" MARKERS AND PAIN PERCEPTION

Brazo-Sayavera, J.I, Tejero, J.I, Adsuar, J.C.I, Del Pozo, B.2, Olcina, G.I, Timón, R.I

*1. University of Extremadura; 2. University of Sevilla*

Introduction Unusual physical exercise or eccentric training may cause damage onset muscle soreness (DOMS) between the next 24-72 hours following exercise. This muscle damage could impair physical performance. The aim of this study was to analyze the use of a whole body vibration platform (WBMV) as a new recovery method after eccentric training. Methods Moderate trained participants (n=20) were randomly divided in two groups: control group (CG) and experimental group (EG). Both groups performed a lower limb eccentric strength training session with 4 exercises (quads and hamstrings) performing 4x5rep / rec2' 120% 1RM. EG group used after training a tilting WBV platform (Galileo Fitness Novotec Medical, Germany), that oscillates through the medial axis. The WBV treatment was as follows: 3x1min / rec 30sec at 14,5Hz, 16,5Hz and 22,5 Hz respectively. Amplitude was 4mm and knee flexion was 90 degrees. Before, after training (or vibratory treatment), 24h and 72h, pain perception (VASpain scale), and blood samples were taken. Urea, CK and GOT (Coulter CPA) were determined. SPSS 19.0 was used to perform statistical analysis. ANOVA test was carried out to determine differences between groups. Results EG showed at 72h lower urea (ml/gr) values than CG ( $32,00 \pm 12,72$  vs  $59,50 \pm 6,13$ )  $p < 0.05$ , as well as in pain perception (0-100 units) ( $34,00 \pm 11,40$  vs  $65,00 \pm 21,21$ )  $p < 0.05$ . Not significant differences were found in other parameters or measuring times. Discussion These new findings may attribute the use of a WBV platform as a recovery method after eccentric training, with significant impact especially after 72h after finishing exercise. Urea plasma values decreases can be explained by an increase in local blood flow as consequence of WBV treatment (Di Loreto, C., et al., 2004). With blood flow increased, athletes are able to eliminate waste product faster and reduce recovery time and muscle soreness. (Verschuere et al., 2004). This way pain perception is also reduced (Dawson, A et al., 2012). ### WALK@WORKSPAIN: DOES IT IMPROVE JOB PRODUCTIVITY IN OFFICE EMPLOYEES?

Puig-Ribera, A., Bort, J., González, A.M., Martínez, I., Giné, M., Fortuño, J., Muñoz, L., Gilson, N.D.

*Universitat de Vic, Barcelona, Spain*

Introduction Presenteeism (time of impaired performance while at work due to health reasons) is highly prevalent due to increasing chronic health problems (Goetzal et al, 2004). Lack of physical activity (PA) is a risk factor for presenteeism (Cancelliere et al, 2011) but

evidence on the effectiveness of workplace PA programs to decrease health-related productivity losses is scarce. We evaluated the impact a 'sit less and move more' program (Work@WorkSpain) had on employees' job productivity. Methods A sample of 264 employees (age 42±10 years; 171 women) from four universities engaged the program (19 weeks). The intervention group (IG, n=129) used a pedometer, a diary and a website that provided strategies, motivational materials and interactive features to increase step counts and reduce sitting time at work. An additional Campus in each University acted as a control group (CG, n=135), maintaining habitual behaviour. Measures of work performance (Work Limitations Questionnaire, WLQ) were completed at baseline, post-intervention and two months follow-up. The WLQ identified three subscales, reflecting ability to meet job demands for (i) output, (ii) time management and (iii) mental-interpersonal skills. Resulting scale scores were transformed to a 0-100 continuum that represented the rate of difficulty in performing job demands (from low to high). An estimated percent of productivity loss (WLQ Index) was calculated. Paired and independent samples t-tests evaluated differences within and between groups at pre, post-intervention and follow-up. Results Job productivity significantly decreased in both groups, but the IG showed a significant less rate of decline ( $p < .05$ ). The IG perceived less difficulty than controls in performing (i) job's time and scheduling demands (-10;95%CI: [-17;-2]), (ii) cognitive and interpersonal tasks (-9;95%CI: [-16;-2]) and (iii) meeting demands for quantity, quality and timelessness of completed work (-6;95%CI: [-11;-1]). This effect significantly increased at two months follow-up (-11;95%CI: [-19;-3]; -10;95%CI: [-17;-3]; -8;95%CI: [-14;-2] respectively). As a result, the IG enhanced job productivity at post-intervention and follow-up by 1.7% and 2% when compared to controls ( $p < .05$ ). Conclusion Office employees engaging in Walk@WorkSpain showed less health-related productivity losses than controls. Workplace programs to reduce sedentary behaviour may be effective at decreasing presenteeism costs. References Goetzl RZ, Long SR, Ozminkowski RJ, et al. *J Occu Environ Med* 2004; 46:398-412 Cancelliere C, Cassidy JD, Ammendolia C, et al. *BMC Public Health* 2011;11:395

### PSYCHO-PHYSIOLOGICAL RESPONSES TO A STANDARDIZED EXERCISE PROGRAM INDOORS VS. NATURAL ENVIRONMENT: PRELIMINARY RESULTS FROM A PILOT STUDY. PART II: MOTIVATION TO EXERCISE

Calogiuri, G., Nordtug, H.2, Weydahl, A.3, Patil, G.1

*Norwegian University of Life Sciences; 2: Tromsø University, Tromsø, Norway; 3: Finnmark University College*

**Introduction** Environmental setting can influence psychological responses and motivation to exercise (Marsh et al., 2006). Being outdoors in natural environments has been associated with vitalization (Ryan et al., 2010), which may improve individuals' attitude towards physical activity and elicit active lifestyles. As a pilot study, we have investigated the impact of a standardized exercise program in two different environmental settings (indoors vs. outdoors in a natural environment) on explicit and implicit cognitions towards physical activity. **Methods** Healthy adults, 7 males and 7 females (age 48.5±7.3 yr; BMI 25.4±2.5; VO<sub>2</sub>max 39.8±7.7 ml/min/kg), undertook two exercise sessions within 1-week, each consisting in 25-min biking (60.1±7.9 %HRR) followed by 20-min circuit strength training with rubber bands (49.7±9.6 %HRR). The subjects were randomized to the indoor or the outdoor group. Connectedness with nature scale (CNS), an adjusted version of the leisure time exercise questionnaire (LTEQ) and an implicit association test (IAT) were administered before the intervention. Enjoyment, perceived restorativeness of the environment, affect and intention to exercise in the following 10-weeks were measured in concomitance with each exercise session, along with ratings of perceived exertion and heart rate values. Two- and ten-weeks after the intervention, the subjects were asked to complete the LTEQ and IAT again. Statistics consisted of bivariate correlation and linear mixed model. Results CNS was positively correlated ( $p < .05$ ) with the individuals' fitness and initial LTEQ (preliminary measurements). During the exercise sessions, the outdoor group reported higher ratings of enjoyment, perceived restorativeness of the environment and positive affect (all  $p < .01$ ), as compared to the indoor group. When adjusted for the LTEQ values, a significant main effect of 'group' was found for intention ( $p < .05$ ), in favor of the outdoor group. No significant changes in the LTEQ and the IAT over the follow-up period were found, but this might be imputed to a sensitive drop-off. **Discussion** The results indicate that experiences of exercise in natural environments may improve motivation to be physical active. Though, more studies on larger samples are needed. **References** Marsh, A.P., Katula, J.A., Paccchia, C.F., Johnson, L.C., Koury, K.L., & Rejeski, W.J. ### PSYCHO-PHYSIOLOGICAL RESPONSES TO A STANDARDIZED EXERCISE PROGRAM INDOORS VS. NATURAL ENVIRONMENT: PRELIMINARY RESULTS FROM A PILOT STUDY. PART I: AFFECT & PERCEIVED RESTORATIVENESS OF THE ENVIRONMENT

Calogiuri, G.1, Evensen, K.1, Patil, G.1, Ihlebæk, C.M.1, Raanaas, R.K.1, Weydahl, A.2

*1: Norwegian University of Life Sciences; 2: Finnmark University College*

**Introduction** Physical activities in contact with nature, such as walking in green areas, have been associated to positive mental states. Anyway, the effects of 'green exercise' on mental health are still debated (Thompson Coon et al., 2011). Especially, experimental studies investigating complex exercise programs comparing indoor vs. outdoor-natural settings are missing. As a pilot study, we investigated psychological responses in individuals undertaking a standardized exercise program indoors (gym-hall) vs. outdoors in natural environment. **Methods** Healthy adults, 7 males and 7 females (age 48.5±7.3 yr; BMI 25.4±2.45; VO<sub>2</sub>max 39.8±7.7 ml/min/kg), undertook two exercise sessions within 1-week, each consisting in 25-min biking (60.1±7.9 %HRR) followed by 20-min circuit strength training with rubber bands (49.7±9.6 %HRR). The subjects exercised at 15:30, randomized to the indoor or the outdoor group. Mood was measured one week before the intervention (BASELINE; no exercise for at least 48-hours) by Physical Activity Affect Scale (PAAS). Affect was then measured by PAAS before (PRE) and after (POST) each exercise session. Ratings of perceived exertion (RPE) and enjoyment were measured after both the biking and the strength bouts. Perceived restorativeness of the environment (fascination and being away) was measured after completion of each exercise session. A linear mixed model was used to investigate possible PRE-POST effects and differences across groups (indoor vs. outdoors) for the four components of affect (positive affect, negative affect, fatigue, and tranquility). The individuals' mood ratings at BASELINE were set as a covariate in the model. Correlation between affect and the other exercise parameters (enjoyment, RPE, fascination and being away) was eventually studied. Results A significant main effect of 'group' was found for positive affect ( $p < .01$ ), with higher values reported by the outdoor group. No difference was found for RPE across the groups. On the other hand, the outdoor group reported higher ratings of enjoyment, perceived fascination and being away, which on turn were correlated with positive affect ( $p = .05$ ,  $p = .05$ , and  $p = .01$ , respectively). **Discussion** These results provide further confirms on the positive effects of exercising in natural environments on people's mental states, as compared to indoor settings. More studies on larger sample and including different environmental variables are recommended. **References** Thompson Coon J, Boddy K, Stein K, Whear R, Barton J, & Depledge MH (2011). *Environ sci technol*, 45(5), 1761-1772

### VITALITY BEACH- HEALTH PROMOTION IN THE SAND

Wollesen, B., Geissel, T., Hansen, D., Mattes, K.

*University of Hamburg*

**Introduction** A variety of health promotion programs to recreate from work related stresses are supported by German health insurances. Own pilot studies led to the conclusion, that prevention programs conducted in the sand or at the beach will show positive effects on different physical dimensions e.g. cardiovascular fitness. In addition results of Davies & Mackinnon (2006) indicated higher energy exposures when walking in sand compared to other surfaces. However, up to now there is no intervention which examined effects of training in the sand to gain health related effects on physical fitness and to reduce occupational stresses. Therefore, the aim of this randomized controlled trial was to analyze health benefits of an indoor beach prevention program for middle aged employees. **Methods** N= 49 people (24 men; 25 woman; 38.3 ± 10.3 y) were randomized into two training groups (n=33) and a control group (n=16). The intervention (12\* 90 min sessions; once a week) includes strength, endurance, balance and coordination training following a standardized protocol. A standardized running course was used to evaluate coordination and endurance (time and heart rate); a spine check was done with a Medi-Mouse®; a short version of the Star Execution Balance Test (SEBT) analyzed balance performance and flexibility and the SF12-questionnaire examined physical and psychological well-being. The collected data were analysed by using a 3-way ANOVA (group, variable, repeated measurement) within common limits of significance ( $p \leq .05$ ). **Results** The training group improved their strength in the spine check whereas the control group did not ( $p=.002$ ,  $F=11.7$ , partial eta square =.295). In addition they improved balance and mobility in all measured directions of the SEBT ( $p \leq .01$ ) and decreased the running time (t1: 44.8 ± 8.9 sec; t2: 35.7 ± 5.9 sec;  $p=.000$ ,  $F= 54.9$ , partial eta square=.764) of the running course with a constant heart rate. Moreover the women of the intervention group increased their psychological well-being ( $p=.000$ ,  $F=14.9$ , partial eta square =.304). **Discussion** The program showed health related benefits in different dimensions. The main outcomes are improved physical fitness for back strength, improved flexibility and balance. We suppose that the decreased running time of the course indicates improved coordination under cardio vascular stress. In addition the program was well accepted by the participants. Therefore the intervention should be integrated into the health promotion catalogues of the health insurances. However, the limitations of this study are that there were no measurements of lasting effects and if the improved fitness is able to compensate work related stresses. **References** Davies, S. E. H. & Mackinnon, S. N. (2006). The energetics of walking on sand and grass at various speeds. *Ergonomics*, 49:7, 651-660.

### INFLUENCE OF DIFFERENT PHYSICAL INTERVENTIONS IN BIOCHEMICAL VARIABLES OF WOMEN PARTICIPANT OF HEALTH UNITS IN RIO CLARO – SP – BRAZIL.

Zorzetto, L.P., Papini, C.B., Nakamura, P.M., Kokubun, E.

*Universidade Estadual Paulista*

**Introduction** Physical exercise (PE) is important in promoting health and preventing some diseases. Among other pathologies benefited by the PE practice is dyslipidemia, which is a disorder in the lipid metabolism that can affect the levels of lipoproteins into the bloodstream. **Objective** Analyze the effect of two PE interventions on the participants rates of glucose, cholesterol, HDL, LDL and triglycerides. **Methods** Both interventions were realized on health units in the city of Rio Claro: a) Group 2 days weekly (G2; n=14; 58.71 ± 9.71 years), with duration of 60 minutes/day composed by aerobic exercise (AE) (25 minutes) and resistance exercise (RE) (15 minutes), and an advice to perform PE on other days of the week; b) Group 3 days weekly (G3; n=14; 57.93 ± 8.78 years), with duration of 90 minutes/day also composed by AE (50 minutes) and RE (15 minutes), without any kind of advice in the end of class. In both groups the remaining time was used to warm-up and stretching exercises. For biochemical variables analysis it was collected 5 mL of blood, with participants fasted for at least 12 hours, pre and post six months of intervention. All samples were collected by nursing techniques and data analyzed by laboratory technicians (UNESP). Statistical analysis used a t Test for paired-samples ( $p < 0.05$ ). **Results** It was found significant difference in G2 for the variables: Cholesterol Pre: 171.14 ± 18.70 mg/dL, Post: 141.71 ± 18.54 mg/dL;  $p=0.002$ , HDL Pre: 47.57 ± 13.08 mg/dL, Post: 56.14 ± 10.69 mg/dL;  $p=0.046$ , LDL Pre: 132.78 ± 19.86 mg/dL, Post: 93.58 ± 12.83 mg/dL;  $p<0.001$ . The G3 showed significant difference for the variables: Glucose Pre: 106.00 ± 33.86 mg/dL, Post: 89.57 ± 28.47 mg/dL;  $p=0.005$ , LDL Pre: 134.85 ± 31.58 mg/dL, Post: 105.42 ± 28.19 mg/dL;  $p<0.001$ . **Discussion** Both interventions promoted benefits to participants, agreeing with other studies (Monteiro et al., 2007; Yoshida et al., 2010). Worth noting that even G2, that used a lower daily duration and weekly frequency than G3, also promoted significant improvements in the variables. The lack of control of participant's diet may have influenced the results, especially in variables that were not found significant improvements. Thus, the results demonstrate the effectiveness of a physical program, with two or three days/week, in the control and reduction of lipid profile. In terms of public health, that can represent savings in the spending on population health. **References** Monteiro HL, Rolim LMC, Squinca DA, Silva FC, Ticianeli CCC, Amaral SL. ### ASSOCIATIONS OF MUSCULAR AND CARDIORESPIRATORY FITNESS WITH C-REACTIVE PROTEIN CONCENTRATION IN YOUNG ADULT MEN

Vaara, J.P.1,2, Vasankari, T.3, Fogelholm, M.4, Häkkinen, K.2, Santtila, M.5, Kyröläinen, H.1,2

1: National Defence University, Finland, 2: University of Jyväskylä 3: The UKK Institute for Health Promotion Research 4: University of Helsinki 5: Personnel Division of Defence Command, Finland

**Introduction** Serum high sensitive C-reactive protein (CRP) is an inflammatory marker, which is associated with the pathogenesis of atherosclerosis (Gonzalez et al. 2003). Cardiorespiratory fitness (CRF) is inversely associated with CRP (Kuo et al. 2007). However, little is known on the association of muscular fitness and CRP. Therefore, the aim of the present study was to assess the relationships of muscular and cardiorespiratory fitness with CRP in young adult men. **Methods** 686 men (25.5±5.0 yrs.) participated. Muscular endurance (MEI) consisted of push-ups, sit-ups and repeated squats (repetitions in one minute) and maximal strength (MSI) in leg extension and bench press (N). The muscular fitness test scores were divided by body weight. CRF was determined by a cycle ergometer test until exhaustion (predicted  $\dot{V}O_{2max}$ ) and waist circumference (WC) was measured. CRP was analyzed from blood samples after an overnight fast and log transformation was used in the analysis. Pearson correlation coefficient and multinomial regression models with  $\beta$ -coefficients were used. **Results** CRP was inversely correlated with CRF ( $r=-0.47$ ), MEI ( $r=-0.46$ ), MSI ( $r=-0.29$ ), and positively with WC ( $r=0.46$ ) ( $p<0.001$ ). In the multinomial regression model, after adjustments for age and smoking CRP was inversely associated with CRF ( $\beta= -0.25$ ,  $p<0.001$ ), MEI ( $\beta= -0.14$ ,  $p<0.05$ ) and positively with WC ( $\beta=0.22$ ,  $p<0.001$ ). No significant association between CRP and maximal strength was observed. **Discussion** In addition to aerobic fitness and waist circumference, muscular endurance was beneficially associated with serum high

sensitivity c-reactive protein. Similar association was not, however, evident for maximal strength. These findings indicate that also muscular endurance training may be advantageous in order to prevent low-grade systemic inflammation. References Gonzalez MA, Selwyn AP. #### THE RELATIONSHIP BETWEEN DIETARY HABITS, BODY MASS INDEX, AND PHYSICAL FITNESS AMONG JAPANESE PRESCHOOL CHILDREN

Takami, K.1, Egawa, K.2, Kato, T.3

1) HOSEI UNIVERSITY, (TOKYO JAPAN), 2) GRADUATE SCHOOL OF SPORT SCIENCES, WASEDA UNIVERSITY (TOKYO JAPAN), 3) SUZUKA UNIVERSITY OF MEDICAL SCIENCE, (SUZUKA JAPAN)

**Introduction:** Studies have shown that children's physical fitness levels have declined because of a decrease in amount of physical activities. It has also been reported that thinner children tend to be in less favorable physical condition. A close link has been found between fitness levels and dietary habits, which is relevant to obesity and thinness. The purpose of this cross-sectional study is to examine the relationship of dietary habits, body mass index, and physical fitness among Japanese preschool children. **Method:** 144 Japanese preschoolers (70 boys and 74 girls, aged 4 to 6 years old) were given our fitness tests. Their parents were also asked to answer six questions regarding their children's dietary habits. **Results:** 138 subjects completed all the tasks, which provided the necessary data for this study. Based on their body mass indexes, the subjects were classified into five categories as follows: 1 very thin, 39 thin, 95 average, 3 overweight, and 0 obese. They were also graded into five categories, A through E, according to the norm-referenced criteria of physical fitness: 1 A, 8 B, 23 C, 70 D, and 36 E. **Discussion:** No connection was observed between physical fitness and body mass index. Those who were graded into the upper three categories (A, B and C) were grouped into one as the upper level group. The comparison of three groups (A-B-C, D, and E) indicated that lower fitness levels tend to be related to poorer dietary habits. On the other hand, the children in the upper level group demonstrated better eating habits. They tend to eat a variety of food, including a wide range of vegetables. They enjoy helping out in meal preparation and also liked dinner time at the table. Skipping breakfast was not common in any group. Many parents, however, were aware of some other problems in their eating habits. The children who were more physically fit were those who had a better attitude toward meal time, and whose parents work together to achieve better dietary habits in their children.

#### POSTURE OF BOYS AS A RESULT OF WATER GYMNASTICS AND SWIMMING

Torlakovic, A., Muftic, M.2, Talovic, M.3, Radjo, I.3, Kebat, R.1

Olympic Swimming Pool Center-Sarajevo; Faculty of Health Studies, University of Sarajevo; Faculty of Sport and Physical Education, University of Sarajevo

**BACKGROUND** Based on an analysis of habits of children aged 12-14, it has been found that they spend 56% of their time sitting and during this time, their backs are bent forward more than 20° and/or rotated by more than 45° (Saarni, 2007). Body posture is treated as a dynamic stereotype formed in the process of individual development, physical education and exercise (Shklyarenko et al., 2011). The goal of the research was to identify changes in body posture of boys as a result of the water gymnastics and swimming program. **METHODS** The research was conducted based on a sample of 35 boys aged 11.4 ± 2.2. Their posture was assessed in compliance with the Napoleon Wolanski method. An expert assessment of the following regions was conducted prior to and after the exercise program: head posture, shoulder posture, shoulder blade posture, chest posture, spinal column posture, stomach posture, leg and feet posture. The combined program of water gymnastics and swimming was implemented during a period of 24 weeks, three times per week, with sessions lasting for 60 minutes. For the analysis of the initial and final testing, a T-test for dependent samples has been used/ marked differences are significant at  $p < .0500$ . **RESULTS** The analysis of research findings showed that significant changes in posture assessment occurred: assessment of head posture (AOHP  $p = .000$ ), assessment of shoulder posture (AOSP  $p = .000$ ), assessment of shoulder blade posture (AOSBP  $p = .000$ ), assessment of chest posture (AOCP  $p = .000$ ), assessment of spinal column posture (AOSCP  $p = .000$ ), assessment of stomach posture (AOSTP  $p = .000$ ), assessment of leg posture (AOLP  $p = .000$ ), assessment of feet posture (AOFPP  $p = .000$ ) and general assessment of posture (GAOPW  $p = .000$ ). **CONCLUSIONS** The problem of poor posture of children is one of the more important problems of the modern way of life. Based on the research findings it may be concluded that the continued combined water gymnastics and swimming program does have a significant impact on improvement of posture of boys of this age. **REFERENCES** Saarni, L. #### PHYSICAL SELF-PERCEPTION OF CHILDREN FOLLOWING A 12-WEEK RESISTANCE EXERCISE PROGRAM

Jones, M.T., Skidmore, B., Passon, B.

\*George Mason University, ^Springfield College

**Introduction** Psychological benefits of regular cardiovascular (CV) exercise, resistance training (RT) exercise, or a combined (CV+RT) program have been regularly studied in adults. A combined program of CV and RT exercise has been shown to increase self-efficacy in preadolescent girls (Annesi et al., 2005). An exercise program of only RT improved self-concept in adolescent males and females (Velez et al., 2010). Middle childhood (8-10 yr) remains relatively understudied in this area. Therefore, the aim of the current study was to analyse whether or not physical self-perceptions of children would change following a 12-week (wk) resistance exercise program. **Methods** Twenty-four children from an after school program participated in the 12-wk study. Pre-testing in wk1 consisted of the Physical Self-Perception Profile for Children (PSPPC), which contains 6 subscales: general self-worth (GSW), physical self-worth (PSW), perceived sport

competence (SPORT), perceived bodily attractiveness (BODY), perceived physical strength (STRENGTH), perceived level of physical conditioning (CONDITION). Boys ( $n=11$ ,  $9.0 \pm 0.9$  yr) and girls ( $n=13$ ,  $9.3 \pm 0.7$  yr) were randomly assigned by sex into control (CON,  $n=12$ ) or experimental (EXP,  $n=12$ ) groups. After a familiarization session with the child-sized resistance training equipment, the EXP received 12-wk of resistance exercise 2 d/wk. Training sessions were 45 min and consisted of 5-min warm up followed by 2 sets x 15 repetitions of 7 exercises performed at a 3:0:2 tempo concluding with 5-min cool down. Child to instructor ratio was 4:1. Post-testing of PSPP-C for CON and EXP occurred in wk12 after completion of the exercise program. A  $2 \times 2$  repeated measures analyses of variance (ANOVA) was used to analyze PSPP-C. Bonferroni pairwise post hoc analyses examined differences in the subscales of the PSPP-C. Alpha level was set at  $p < 0.05$ . Results There was no difference ( $p > 0.05$ ) between CON and EXP pretests of PSPP-C. A significant interaction ( $p = 0.37$ ) existed between CON and EXP groups. Post hoc analyses showed significant gains ( $p < 0.05$ ) for EXP in all 6 subscales from pre to post. Only the SPORT subscale improved for the CON group ( $p = 0.02$ ). Discussion Children who participate in a 12-wk resistance exercise program display enhanced physical self-perception compared to a control group. The CON and EXP began the program with similar PSPP levels. Regular resistance exercise improved all 6 subscale scores, not just STRENGTH, in the EXP. Children who participate in regular resistance exercise may have an increased awareness of their own levels of physical conditioning and strength. References Annesi, JJ, et al. ## DEVELOPMENTAL PATHWAYS OF FITNESS, AND NOT BASELINE, PREDICT FITNESS STATUS AT THE END OF CHILDHOOD.

Rodrigues, L.P.1, Lopes, V.P.2

[1] Instituto Politécnico de Viana do Castelo; [2] Instituto Politécnico de Bragança

Introduction It is generally described that children fitness levels increase along childhood. Complementary to this idea is the notion that the tracking of children's fitness is good to moderate during this developmental time, and that baseline (initial values) of fitness are determinant on fitness development. The importance of developmental pathways has been recently reinforced by a theoretical argument that predicts that healthy lifestyle trajectories will evolve through either a positive or negative spiral of engagement or disengagement, respectively, in various physical activity behaviors across childhood that are reciprocally linked to motor skill, perceived competence and fitness development (Stodden et al., 2008). The main goal of this study is to test the hypothesis that different developmental pathways of physical fitness do occur during childhood (6-to-9 years-old), and to test their correlation with baseline fitness status. Methods This longitudinal study design included 507 primary school children who were assessed annually for four years on seven physical fitness tests. Childhood individual trajectories (baseline and slope values) on each of the fitness tests were determined along the four years of the study. Participants were divided into three groups according to individual fitness trajectories over time: Slow Rate of Change (Slow RC Change), Average Rate of Change (Average RC), and High Rate of Change (High RC). An ANOVA  $3 \times 2$  (Group x Sex) with Bonferroni post hoc tests was used to test for the differences on rate of change between the constituted groups, and sex. Correlations between slope and test values were used to analyze the possibility of fitness performance prediction along the four years of the study. Results Results showed (1) significant differences on the rate of change between all groups ( $p < .001$ ) for all variables tested (Slow RC < Average RC < High RC); (2) no effect from sex differentiation ( $p > .15$  for all cases); and no positive correlation between baseline values and final values on physical fitness. Discussion The fact that differential pathways of fitness development were found throughout childhood adds to the established knowledge, and can be used as fundament for children's fitness programs. The level of fitness, even if not satisfactory early in childhood, can be changed, and it is the pathway, not the baseline, that shows to be of major importance for children to achieve a fit state. In conclusion, children show different rates of change in fitness development over childhood; and having a positive developmental trajectory of fitness predicts a fitter state at the end of childhood, independent of the initial values at 6-years-of-age. References Stodden, D. F., Goodway, J. D., Langendorfer, S. J., Robertson, M. A., Rudisill, M. E., Garcia, C., et al. (2008). ## ADIPOSIY INDICATORS IN YOUTH FROM A LOW SOCIOECONOMIC REGION

Matsudo, V.K.R.1, Rezende, L.F.M.1,4, Matsudo, S.M.1, Raso, V.2,3

1: CELAFISCS; 2: UNOESTE - Medicine and Physical Educatio School; 3: UNIBAN - Masters Program in Rehabilitation and Social Inclusion ; 4: FMUSP - Masters Program in Preventive Medicine

Introduction BMI has been often used as an adiposity indicator in population-based studies (GONZALEZ et al. 2010). However, studies with children and women recommended that BMI should be used in conjunction with other estimates of body composition (i.e. skinfolds) in order to maximize the adiposity estimation in children. (WILSON et al. 2011) Purpose To analyze the power of different skinfolds to predict adiposity in youth with low socioeconomic status. Methods We measured body mass (BM), body mass index (BMI), waist circumference (WC), body fat (FAT) and skinfold at subscapular (SB), suprailiac (SI), middle axillary (MA), abdominal (ABD), biceps (BI), triceps (TRI) and middle calf (MC) regions in 232 youth aged 10-15 living in a low socioeconomic status island in Brazil. In addition, we calculated trunk adiposity (TrkA: SB + SI + MA + ABD divided by four), peripheral adiposity (PA: BI + TRI + MC divided by three) and total adiposity (TA: SB + SI + MA + ABD + BI + TRI + MC divided by seven). Results All skinfolds were subjected to principal component analysis (PCA). That revealed only abdominal skinfold with an eigenvalue exceeding 1, which explained 87% of the variance. This variance has increased by 95% when we added the next two components, i.e., supra-iliac and middle axillary skinfolds. The second PCA was constituted by TrkA, TA, PA, BMI, WC, BM and FAT, but it was explained only by TrkA (77% of the variance). Discussion Skinfold thickness is cheap and more direct measure of adiposity in children than BMI (OLDS, 2009). Our results recommend abdominal, supra-iliac and middle axillary, as well as trunk adiposity (i.e., mean of subscapular, suprailiac, middle axillary, abdominal) as the best body adiposity indicators in boys and girls from a low-socioeconomic region. ## DEMOGRAPHIC CHARACTERISTICS, OBESITY INDICES AND PHYSICAL FITNESS OF OVERWEIGHT/OBESE ELEMENTARY SCHOOL AGED CHILDREN IN CYPRUS

Panayiotou, G.1, Douda, H.2, Makris, A.1, Tokmakidis, S.P.2

1:European University of Cyprus (Cyprus), 2:Democritus University of Thrace (Greece)

**Introduction** Childhood obesity has reached epidemic levels in developed countries (Manus et al., 2012). Environmental factors, lifestyle preferences, and cultural environment play essential roles in the rising prevalence of obesity worldwide (Leal & Chaix, 2011). The aim of the present study was to assess the correlations among demographic characteristics, obesity indices and physical fitness level of elementary school children in Cyprus, aged 6 to 12 years old. **Methods** A cohort of 763 healthy pupils, aged  $10.21 \pm 1.59$  yrs, participated in the study and were divided according to their gender (372 boys, 391 girls) and their obesity level (normal, overweight, obese) as defined by IOTF criteria (Cole et al., 2000). Demographics characteristics were collected and anthropometrical and physical fitness measurements were obtained. Results 72.9% of pupils presented normal values of body weight, 18.9% were overweight and 8.3% obese. Pearson correlation revealed negative correlations among BMI and Multistage-Fitness Test ( $r = -.182$ ,  $p < .001$ ), Flexed Arm-Hang Test ( $r = -.342$ ,  $p < .001$ ), Standing Long-Jump test ( $r = -.129$ ,  $p < .001$ ), Handgrip-strength test ( $r = .440$ ,  $p < .001$ ), Sit-Ups test ( $r = -.165$ ,  $p < .001$ ) and Sit-and-reach test ( $r = .110$ ,  $p < .01$ ). Percent body fat presented negative correlation with cardiovascular endurance ( $r = -.325$ ,  $p < .001$ ), muscle strength ( $r = -.452$ ,  $p < .001$ ) and abdominal strength ( $r = -.245$ ,  $p < .001$ ) while significant correlation observed between lean body mass and handgrip test ( $r = .753$ ,  $p < .001$ ). Students who live in an apartment presented 68.5% normal weight, 20.5% were overweight and 11% obese versus 73.3%, 18.6% and 8.1% respectively of those living in a detached house. **Discussion** The results of this study revealed the prevalence of obesity in Cyprus and support that elevated body mass makes obese children less active with reduced cardiorespiratory fitness in any demographic environment they live. Indeed, the increased body mass with the negative correlations of BMI and body fat percentage with physical fitness, leading obese children be less active with reduced cardiovascular endurance as compared to the non-obese children (Sallis et al., 2000; Christodoulos et al., 2004). Thus, the promotion of lifelong physical activity and healthy eating habits are essential to school age yet to ensure the physical health in adulthood. **References** Christodoulos AD, Douda HT, Polykratis M, Tokmakidis SP. ## HABITUAL PHYSICAL ACTIVITY IS ASSOCIATED WITH ACE I/D GENOTYPE IN 12 YEAR OLD BOYS

Mäestu, J.1, Lätt, E.1, Rääsk, T.1, Laas, K.1, Jürimäe, T.1, Sak, K.2, Jürimäe, J.1

1: University of Tartu, 2:ASPER

**Introduction** There is only very limited data on specific gene interactions with habitual physical activity levels. Most studies in the field have considered physical activity rather as a covariate for the gene effects on other phenotypes, rather than the dependent variable itself. The aim of was to investigate the association between ACE I/D polymorphism and physical activity in 12 year old boys. **Methods** In total, 265 boys (calendar age  $12.04 \pm 0.77$  years) were investigated. Body composition and cardiovascular fitness on cycle ergometer were measured in addition to 7-day accelerometry based physical activity (PA). Also, several possible cofactors (screen time, participating in sport clubs) that might have association with PA were considered. Results Sedentary PA was significantly lower in DD subjects compared to I allele carriers, while light PA was significantly higher in DD subjects compared to II subjects. Using the model with three genotypes, there was a trendline effect on light PA ( $F(2,256)=2.49$ ;  $p=0.085$ ;  $\eta^2=0.015$ ). A significant main effect of the D allele was found on total PA ( $F(1,256)=5.453$ ;  $p=0.020$ ;  $\eta^2=0.021$ ). Adding screen time as a covariate did not change ACE I/D polymorphism effect on total PA levels ( $F(2,256) = 3.326$ ;  $p=0.041$ ;  $\eta^2=0.025$ ). Carriers of the D allele had significantly higher light PA ( $F(1,256)=4.710$ ;  $p=0.031$ ;  $\eta^2= 0.20$ ), with screen time as covariate. **Discussion** No association with ACE genotype or allele effect were found on higher PA levels (ie. moderate and vigorous PA) that are considered as most positive for the decrease of cardiovascular health risks in children. However, carrying the D allele of the ACE I/D genotype had a main effect on total PA with screen time as covariate. PA and sedentary activity predict independently chronic disease risk and mortality, and should therefore be considered as separate constructs (Ekelund et al. 2012). It should be considered that studying the effects of PA on health not only moderate to vigorous activities are important, but the full range of activity range should be taken into account (Pate et al. 2008). As we were able to demonstrate ACE genotype effect on the amount of sedentary, light and total PA, the prevention strategies focused at this period of life should take into account that sedentary lifestyle in children is related to gene effects. In conclusion, ACE I/D polymorphism is associated with different levels of PA in healthy boys, accounting with confounding factor screen time. **References** Ekelund U, Luan J, Sherar LB, Esliger DW, Griew P, Cooper A (2012). *JAMA*, 307, 704-712 Pate RR, O'Neill JR, Lobelo F (2008). *Exerc Sport Sci Rev*, 36, 173-178

## THE RELATIONSHIP BETWEEN BODY IMAGE SATISFACTION, BODY COMPOSITION AND METHODS IN CONTROLLING WEIGHT

Bezerra, P., Venancio, C.

Viana do Castelo Polytechnic Institute

**Introduction** Body image dissatisfaction is common in adolescent. Studies have shown that female adolescents believe they are fat even though their BMI is normal. The engaging in methods to control weight may promote harmful behaviors that often result in unhealthy physical appearance. The physical activity performed in an excessive and intensive manner has been identified as one of the most relevant behaviors in controlling weight. The aim of this study was to investigate the differences in body fat percentage and also the methods used in controlling weight in different aged adolescent females. Relationships between the variables of interest were also investigated. **Methods** 624 (218 group-15y, 211 group-16y and 195 group-17y) adolescent female ( $15.96 \pm 0.81$ , weight =  $57.7 \pm 9.9$  Kg, height =  $1.61 \pm 0.05$  m, BMI =  $22.1 \pm 3.7$ ; no significant differences between groups) were recruited from Viana do Castelo student population. The subjects were accessed on both body weight and composition (Tanita BC-418), and were asked to complete a physical activity questionnaire. ANOVA with Bonferroni adjustment was performed to detect group differences. Spearman coefficient of correlation was used to assess the relationship between body image satisfaction (BIS), body weight and composition, and methods used in controlling weight. Significance was set at  $p < 0.05$ . Results Significant differences were found between groups in percent of fat in both left and right leg [ $F(2, 617) = 28.761$  and  $21.981$ ,  $p < 0.001$ ], and left and right arm [ $F(2, 617) = 41.138$  and  $72.666$ ,  $p < 0.001$ ], but not in whole body percent of fat and trunk percent of fat. Post-hoc analysis with Bonferroni adjustment indicated that the younger group has higher percent of fat in segments ( $p < 0.001$ ) than their counterparts. No significant differences were found between groups in relation to methods used

in controlling weight. However, adjusting the sample to BMI level (<19; 19–24; >24), it was found significant differences between groups in such parameters IF (2, 616) = 36.097 and 15.205,  $p < 0.001$ , for Diet and exercise]. The Diet and Exercise were mainly used by the group BMI>24. Moderate to strong negative correlation were found between BIS and both body weight and composition ( $r = -0.49$  to  $-0.65$ ,  $p < 0.05$ ). Also moderate negative correlations were found between BIS and Diet and Exercise ( $r = -0.39$  and  $-0.23$ ,  $p < 0.05$ ) as methods used in controlling weight. Conclusion The group-15y showed higher percent of body segments fat than their counterparts. Age differences were found to affect BIS. However, BIS seems to be influenced by both BMI and percent of fat in body segments. Findings also show that the principal methods in controlling weight, diet and exercise, are mainly used by overweight adolescents (BMI > 24), independently of age.

### EFFICACY OF A PAEDIATRIC HOME-BASED PHYSICAL ACTIVITY PROGRAM ACCORDING TO 2008 GUIDELINES

Galvani, C.1,2, Rossi, M.2, Magnoni, D.3, Casolo, F.2, Faina, M.1,4

*Applied Exercise Physiology Laboratory, Catholic University of the Sacred Heart*

1Laboratorio di Fisiologia, Università Cattolica del Sacro Cuore, Milano, Italia; 2Scienze Motorie, Università Cattolica del Sacro Cuore, Milano, Italia; 3Medico Pediatra, Varese, Italia; 4Istituto di medicina e scienza dello sport, CONI, Roma, Italia Introduction Participation in vigorous physical activity (VPA) during childhood should be encouraged as it is superior to moderate physical activity (MPA) for attenuating cardiometabolic risk factors in youth (1). As the home environment is closely associated with reduced levels of physical activity (PA) (2), the aim of this study was to objectively measure PA behaviour in a sample of 6 to 11 yr-old children in order to investigate if they fulfilled PA guidelines (3) following a home-based PA program. Methods 14 healthy children (age,  $9.5 \pm 2$  yr; BMI,  $19.4 \pm 1$  kg/m<sup>2</sup>) were monitored during a whole week in winter with a Actiheart (AH) monitor (Cambridge Neurotechnology, UK). The AH is able to measure acceleration and heart rate, for objectively measuring time spent in sedentary or light (SLPA, <3 METS) to moderate (3-6 METS) and vigorous (>6 METS) PA. Children were asked to comply with a 90 min of daily PA program with at least 60 min of MPA per day. Activities were chosen from the play and chores categories of the Compendium of PA for youth (4). Compliance was assessed by asking the mothers directly about children degree of adherence to instructions. A one-way ANOVA was used to compare compliant (CD) and non-compliant days (NCD) and significance was set at  $p < 0.05$ . Results Data analysed through the Branched model showed that children significantly exceeded 60 min of moderate-to-vigorous PA (MVPA) (MVPA  $144.7 \pm 106.2$  min/day,  $p < 0.0001$ ). However, the between intensity comparison revealed a significant higher amount of time spent in MPA than in VPA (MPA  $130.1 \pm 91.5$  min/day; VPA  $14.6 \pm 23.5$  min/day,  $p < 0.0001$ ). Besides, a significant difference was detected between CD and NCD for time spent in VPA (VPA: CD  $20 \pm 27.7$  min/day; NCD  $8.2 \pm 15.7$  min/day,  $p < 0.05$ ). No differences were detected for SLPA (SLPA: CD  $1276.6 \pm 90$  min/day; NCD  $1316.8 \pm 119.9$  min/day, ns) and for MPA (MPA: CD  $143.4 \pm 74.2$  min/day; NCD  $114.9 \pm 107$  min/day, ns). Discussion This study's data indicate that i) children significantly exceed 60 min of MVPA per day, ii) they spent a higher amount of time in MPA than in VPA and iii) the developed home-based PA program allows a significant increase in VPA. Getting children to make VPA part of their daily routines is important, especially considering that there is a marked reduction in PA over the adolescent years (5). ### DEVELOPMENT OF PHYSICAL FITNESS AND THE RELATIONSHIP WITH EXECUTIVE FUNCTIONING IN CHILDREN WITH INTELLECTUAL DISABILITIES.

Hartman, E., Smith, J., Westendorp, M., Visscher, C.

*Center for Human Movement Sciences*

Introduction The relationship between physical fitness (PF) and cognition has been studied in several populations such as typically developing children (TD children), and elderly with or without cognitive impairments (e.g Colcombe & Kramer, 2003). In TD children, positive relationships between aerobic fitness and executive functioning (EF) were found (Chaddock et al., 2012), an important predictor for academic achievement. The aim of this study was to examine the development of physical fitness in children with intellectual disabilities (ID), aged 8-12, as well as the possible relationship between PF (aerobic fitness and strength) and EF. Methods From 2009 until 2012, 61 children with ID (45 boys, 16 girls; age range 8-11 in the year of enrollment; IQ range=56-79) participated in a longitudinal study. Items of the Eurofit including aerobic fitness (shuttle run, 10x5m shuttle run) and strength (handgrip, standing broad jump) were measured annually. In 2012, EF was assessed with the Stroop test (inhibition), Self-ordered pointing task (working memory), the Trailmaking test (set-shifting) and the Tower of London (planning). The development of the children's PF was modeled in MLwiN by comparing the likelihood ratio test statistic of a model with and a model without age. To examine the relationships between PF and EF, regression analyses were conducted controlling for age and sex. Results Multilevel models showed a positive development of physical fitness between age 8 and age 12 ( $p < .01$ ), with developmental accelerations between 8-9 for running speed (2.3 s), between 11-12 for aerobic endurance (.7 stages) and explosive strength (6.8 cm), whereas the development of handgrip strength was linear (2 kg/y). Significant positive relationships were found between one or two of the aerobic fitness items and several domains of EF: planning, set-shifting, working memory and inhibition ( $p = .018$  to  $p = .048$ ,  $R^2 = .12$  to  $.18$ ). For strength, only a significant relationship was found between handgrip and planning ( $p = .004$ ,  $R^2 = .22$ ). Discussion Children with ID develop PF in a positive way, including developmental accelerations. Mainly aerobic components of PF were related to EF, which underlines that boosting children's aerobic fitness will not only be beneficial for their health, but it might be important for their cognitive development as well. ### MEASUREMENT OF PHYSICAL ACTIVITY IN YOUNGSTERS: INFLUENCE OF OBESITY AND ACCELEROMETER PLACEMENT

Tanha, T., Wollmer, P., Dencker, M., Flodmark, C.E.

*Clinical Sciences*

Aim To evaluate the effect of obesity and accelerometer placement on measurement of physical activity. Method A total of 36 youths, 18 girls and 22 boys, were included (mean age  $17.9 \pm 1.2$  years). They were stratified as normal weight if BMI<25 and as obese if BMI>25. A treadmill test (4km/h, 6km/h and 8km/h) was performed with accelerometers positioned around the waist and on the ankle. Accelerometer (Actigraph model 7164) data were compared between the groups using Mann-Whitney's test for both waist and ankle accelerometer data output for all speeds. Results Mann-Whitney's test results were non-significant between the two groups when the accelerometer was placed around the ankle and around the waist for 4km/h and 6km/h. Accelerometer data output when placed around the waist

during 8km/h showed significant differences ( $p < 0.0001$ ) between the groups with mean values  $\pm$ SD of  $164 \pm 92$  (BMI < 25) and  $342 \pm 157$  (BMI > 25). Conclusion In this pilot study we showed that level of obesity influence data output during jogging when the accelerometer is placed around the waist. No differences were shown when the accelerometer was placed around the ankle. Placement of the accelerometer around the ankle may provide more reliable measurements of physical activity when lean and obese youngsters are compared.

### **ASSESSMENT OF MUSCULOSKELETAL CONDITIONS AND THEIR IMPACTS IN THE ADOLESCENT POPULATION: ADAPTATION AND VALIDATION OF THE NORDIC MUSCULOSKELETAL QUESTIONNAIRE**

Legault, E., Cantin, V., Descarreaux, M.

*University of Quebec in Trois-Rivières*

**INTRODUCTION** Valid and reliable instruments measuring injury prevalence and their impacts in the adolescent population are scarce. The Extended Nordic Musculoskeletal Questionnaire (NMQ-E) is a reliable 99-item instrument that measures the point, 6-month and life prevalence and impacts of musculoskeletal symptoms over 9 body regions (Dawson and al. 2009). An adapted version of the NMQ-E would be a useful tool to assess the prevalence of disorders in the adolescent population. The purpose of this study was: (1) to adapt the NMQ-E to the adolescent population and (2) to assess the validity and reliability of the adapted version of the instrument. **METHODS** Based on the results of a translated (French) and adapted NMQ-E administered to 61 adolescents, a final 27-item dichotomous questionnaire was developed. The questionnaire measured the 6-month prevalence of musculoskeletal symptoms and the impact of these symptoms on school and work attendance and on sports and leisure activities. Among the adolescents who agreed to participate; thirty-nine (mean age:  $13.7 \pm 1.8$ ) formed the reliability cohort and thirty-four (mean age:  $14.2 \pm 2.3$ ) formed the criterion validity cohort. Reliability was measured by test-retest with a mean time interval of  $28 \pm 8$  hours. Criterion validity was assessed by comparing the adapted NMQ-E answers to the participants' clinical records. Validity and reliability were calculated using proportions of observed agreement (Po) and the Cohen kappa statistic (k). **RESULTS** The mean Po for the test-retest was 0.92 for the 6-month symptom prevalence items, 0.99 for the impact of symptoms on school and work items and 0.96 for the impact on sports and leisure activities items. Kappa values for the reliability assessment ranged between 0.82 and 1.00 for the 27 dichotomous variables. The criterion validity kappa obtained for the agreement between participants' clinical records and questionnaires was  $k = 0.72$ . **DISCUSSION** Kappa values for the reliability and the criterion validity are considered of moderate to perfect agreement beyond chance (Viera and al. 2005), indicating that there is only minor variations between tests and good agreement between questionnaire items and clinical records. Finally, the present results indicate that the adapted version of the NMQ-E is an appropriate self-administered musculoskeletal disorder screening tool for the adolescent population. However, items related to the impacts of symptoms would benefit from additional validation using school and sport attendance records. **REFERENCES** Dawson A, Steele E, Hodges P and Stewart S. ### **MULTIDISCIPLINARY INTERVENTION TO PROMOTE A PHYSICALLY ACTIVE BEHAVIOUR AND HEALTHY NUTRITION FOR THE MANAGEMENT OF CHILDHOOD OBESITY**

Serra, N.1, Ensenyat, A.1, Sagarra, L.1, Rotger, A.2, Castro, I.2, Mur, J.M.2

*1: INEFC Lleida (Lleida, Spain), 2: Nereus Association. Food and healthy physical exercise. Health Region of Lleida (Lleida, Spain)*

**Introduction** Obesity is attributed mainly to environmental factors, and authors (Davison & Birch, 2002) indicate that due to changes in physical activity behaviour. In developed countries time spent on physical activity tasks decreases, whereas that devoted to sedentary behaviours (Agarwal 2008). The aim of this study was to determine whether physical exercise training, associated with a family nutrition and physical activity education programme could induce changes in indices of adiposity (BMI z score and fat distribution) in sedentary overweight children. **Methods** The intervention design is a longitudinal prospective study with post-test at 9 months. A total of 86 (56 boys and 30 girls, range 8-14 years) sedentary and overweight children, as defined by the International Obesity Task Force Criteria, and their parents participated in the study. Consisting of physical activity training for children and nutrition and physical activity behaviour, that involves parents and child participation. **Results** At the end of the program, BMI z score was significantly reduced in  $0.2 \pm 0.29$  units ( $p < 0.001$ ). Fat percentage was modified only in boys' lower extremities ( $P < 0.01$ ). **Discussion** This intervention shows that a 9 months children and family intervention, of the treatment of childhood obesity based on friendly uncompetitive physical activity, can induce a positive change in the reduction of BMI z score in sedentary obese children. In terms of fat percentage results are less encouraging and it is suggested that a more intense children and family dietary habits approach should be introduced, and to increase its effectiveness a more individually-tailored exercise. Whether or not these changes can be maintained in the future remains to be analyzed one year after the intervention period ends. **References** Agarwal, RK. (2008). *Indian Pediatrics*, 45, 443-445. #### **OBESITY IN CHILDREN AND ADOLESCENTS WITH DOWN SYNDROME: AGREEMENT BETWEEN BODY MASS INDEX AND BIOELECTRICAL IMPEDANCE ANALYSIS**

Samur-San Martin, J.E., Bertapelli, F., Ramalho, L.C.B., Goncalves, E.M., Barbeto, V.J.O., Krahenbuhl, T., Mendes, R.T., Hessel, G., Guerra-Junior, G.

*University of Campinas (UNICAMP)*

**Introduction** The prevalence of obesity in children and adolescents has increased, causing various problems health in children and adolescents. In individuals with Down syndrome (DS) the same has been observed (Murray e Ryan-Krause, 2010; van Gamen-

Oosterom et al., 2012; Loveday et al., 2012). However, there is a not criterion widely accepted to classify obesity in DS. The aim of this study was to verify the agreement of the prevalence of obesity classified by body mass index (BMI) and excess body fat determined by bioelectrical impedance analysis (BIA) in children and adolescents with DS. Methods The BMI was assessed in 41 children and adolescents with DS, aged from 5 to 20 years and obesity were classified according to the criteria of Cole and Lobstein (2012). The percentage of body fat (%BF) was estimated by BIA (BIA 310 Bioimpedance Analyzer) and excess fat was classified according to Williams et al. (1992). Results Using the criteria of BMI 65.9% were classified as obese, and by %BF measured by BIA 31.7%. A moderated (Kappa = 0.452 for girls) and regular (Kappa = 0.333 for boys) agreement were found between BMI groups and %BF. Discussion Some authors report that the use of BMI in individuals with SD may have a limitation in the classification of obesity (Bandini et al., 2012). Regarding to the BIA it can be used, however, Loveloy et al. (2012) highlights that there is lack of an equation for best results. Although, BMI and BIA are useful tools for epidemiological studies, currently there is no consensus regarding to the reference values to identify the risks associated with obesity in children and adolescents with DS. Therefore, the lack of reference values for the correct analysis of the results by the method of BIA is difficult in its applicability, especially for DS. This suggests that other assessment techniques are applied to determine more adequate the results. References Murray J, Ryan-Krause. (2010). *Pediatr Nurs*;36(6):314-319. Introduction: Obesity is associated with cardiovascular and metabolic complications in children with Down Syndrome (DS). However, the criteria's for obesity classification in this population remains unclear. The aim of this study was to verify the agreement between established criteria for obesity classification by body mass index (BMI) and percentage of body fat (%BF) estimated by model based in skinfold thickness in children and adolescents with DS. Methods: The sample consisted of 76 individuals with DS with age from 6 to 18 years. Measures of weight and height were done for BMI (kg/m<sup>2</sup>). Triceps and subscapular skinfolds to estimate the body fat percentage (%BF) predicted by equation developed by Slaughter et al. (1988). BMI was classified according Cole & Lobstein (2012) and the %BF was classified according to Williams et al. (1992). The classifications were compared by contingency table 2 x 2 and the agreement was verified by Kappa index, according to the criteria of Svanholm et al. (1989). Results: The obesity prevalence estimated by BMI was 60.5% and %BF was 40.8%. A moderated agreement was found between BMI groups and %BF (Kappa = 0.591 and 0.467 for boys and girls, respectively). Discussion: Anthropometry is widely used to assess obesity, because it is easy and inexpensive. The results between the cutoffs of BMI and %BF were discrepant regarding the diagnosis of obesity. Among individuals with DS, studies shows limitations in the use of BMI (Bandini et al., 2012) and of %BF estimated by skinfolds method (González-Agüero et al., 2011). The preliminaries results of this study demonstrated that BMI and %BF should be used with care to identify the prevalence of obesity in children with DS. Introduction Adolescents with Down syndrome (DS) have lower levels of bone and lean body mass and higher levels of fat mass than their counterparts without disabilities(1). Whole Body Vibration training (WBV) has showed increments in the cross-sectional muscle area of females with low bone mineral density(2). Therefore, the aim was to elucidate the effects of 20-week of WBV on cross-sectional muscle and subcutaneous fat at tibia and radius in adolescents with DS. Methods Twenty-six adolescents with DS (12 to 19 years) and twenty-five sex-age-matched controls were randomly assigned to WBV (15 DS; 13 non-DS) or control (11 DS and 12 non-DS) groups. WBV was performed squatting on the platform in sets for a total duration of 10 min 3 days per week with a vibration dose from 1.8 to 2.6 g and for a total of 20 weeks. Peripheral quantitative computed tomography scans were taken at 66% of the length of the tibia and the radius; cross-sectional muscle and fat areas were registred (mm<sup>2</sup>). Repeated measures of ANOVA adjusting by height, weight and Tanner stage were used to analyze possible group by time interactions on these variables. Adjusted values at pre- and post-training moments were recorded and percentages of change were calculated. Student's t tests for independent variables were used to evaluate the differences in percentages of change between WBV and control groups within each condition group. Results No significant group by time interactions were found for any of the studied variables after the training period. In the non-DS group, WBV group showed a higher percentage increase in cross-sectional muscle area of the tibia and in cross-sectional fat area of the radio than the control group. Within the DS, the WBV group showed a higher percent declination in cross-sectional muscle area and a higher percent increase in fat cross-sectional area of the tibia than the control group (all p>0.05). Discussion A 20-week WBV might not be enough by itself to achieve significant improvements on cross-sectional muscle or fat areas at tibia and radius in adolescents with DS. However, some improvements towards increases in muscle and decreases in fat areas were observed in non-DS group against the observed in DS group. Other important factors such as possible changes on diet and/or physical activity patterns during the training period should be taken into account before stating strong conclusion on this regard. **EFFECTS OF AN EXERCISE PROGRAM IN ADOLESCENTS WITH DOWN SYNDROME**

Greguol, M., Seron, B.B., Reis, E.L., Carraro, A.

*State University of Londrina; University of Padua*

**Introduction** Obesity and low cardio respiratory fitness are present in most adolescents with Down syndrome, which can be explained by the combined sedentary behavior and the characteristics of the disability, such as hypotonia, low HRmax and cardiovascular disease (Balic et al., 2000; Dodd & Shields, 2005). **Objective** To investigate the effects of a training program on maximal oxygen consumption (VO<sub>2</sub>max - ml/kg/min), test duration (TD - seconds) and percentage body fat (% FAT). **Methods** The study included 41 adolescents (25 boys and 16 girls), mean age 15.4 (± 2.9) years, divided into 3 groups: AT (aerobic training, n = 16), RT (resistance training, n = 15), CON (control group, n = 10). Evaluations were performed before and after training: maximal exercise test on a treadmill using the spirometer K4b<sup>2</sup> (Cosmed) with protocol validated by Fernhall et al. (1990), and assessment of %FAT by plethysmography with the equipment Bod Pod® (Life Measurement Inc., Concord, CA). Training consisted of 12 weeks (3 X week for AT group and 2 X week for RT group), with 40 minutes per session, preceded by 10min of warm-up. The AT performed treadmill/cycling exercise at 50-70% of reserve HR monitored by hearth rate monitors. The resistance training consisted of 9 exercises with 2 sets of 12 RM. Descriptive statistics and t test were used (level of significance p <0.05). **Results** AT and RT showed no significant changes before and after training in VO<sub>2</sub>max values (AT: 30.5 ± 6.2 and 30.0 ± 5.8, p = 0.4; and RT: 31.6 ± 5.9 and 31.9 ± 5.3, p = 0.74) and % FAT (AT: 29.2 ± 11.0 and 29.3 ± 10.4, p = 0.99; and RT: 22.9 ± 10.9 and 22.1 ± 12.2, p = 0.28), while CON reduced VO<sub>2</sub>max values (28.1 ± 3.8 and 21.3 ± 4.3, p <0.01) and increased % FAT (31.3 ± 7.2 and 34.3 ± 8.3, p = 0.04). TD only showed improvement for AT (815.9 ± 139.4 and 901.5 ± 61.1, p <0.01). **Conclusion** The 12-week training program did not cause significant changes in VO<sub>2</sub>max and % FAT, however showed improvement in TD for AT. Adolescents who did not participate in the program had significant decreases in VO<sub>2</sub>max values and increased the percentage of body fat, showing that exercise seems to maintain the fitness of adolescents with Down syndrome. **References** Balic M, Mateos E, Blasco C. **EFFORT TO INCREASE PHYSICAL ACTIVITY AMONG COMMUNITY WORKERS IN HORNAFJORDUR, ICELAND**

Asmundardottir, M.1, Sveinsson, T.2

*1: HSSA (Hornafjordur, Iceland); 2: UI (Reykjavik, Iceland)*

**Introduction** Sedentary lifestyle is common in the world today and at the same time the prevalence of obesity and diabetes type 2 is increasing. This may lead to poorer public health and a greater risk of lifestyle diseases. Employers are concerned about rising costs related to the health of their employee. Health promotion can lower health related costs, as studies have shown that interventions emphasizing physical activity (PA) can be effective in increasing or maintaining levels of PA. The aim of the study was to examine the effectiveness of two different types of health promotion in increasing PA and improve health among community workers in the town Hornafjörður in Iceland. **Methods** Community workers were invited to participate and 125 accepted, where 103 completed the study. Baseline measurements took place at the beginning of the study period. Participants were reevaluated after a 6 month intervention and again 6 months after the intervention ended. Outcome measures included measurements of body composition (BMI, waist circumference and skinfolds), endurance (6 min submax bicycle test), resting blood pressure, blood parameters (total cholesterol, HDL and LDL cholesterol, triglyceride, blood sugar), quality of life (questionnaire), and PA (accelerometer). After the first measurements, the participants were randomly divided into three groups: two intervention groups and a control group. Both interventions emphasized PA. One research group received individual-based intervention with regular reminding and the other group received group-based intervention with standardized counselling once every month. **Results** No significant difference was found between groups in any of the changes in the outcomes variables. The blood pressure lowered significantly during the study period for all three groups; systole from 127 to 121 mmHg (p=0.01) and diastole from 77 to 71 mmHg (p<0.001), whereas LDL cholesterol levels increased; 2,9 to 3,1 mmól/L (p=0.01). PA decreased over time for all three groups; moderate-to-vigorous PA from 37 to 32 min/day (p=0.03). Other parameters did not change significantly. **Discussion** It is clear that neither intervention was effective in changing PA of the employees or health indicators. In order to affect participants an intervention may need to include a component based on theories of behavioural changes, be more holistic and a clear part on the workplace's culture (Marshall, 2004; Pelletier, 2009; Griffin et al 2010). **References** Marshall, A. L. (2004). *Journal of Science and Medicine in Sport*, 7(Suppl. 1), 60-66. Pelletier, K. R. (2009). *Journal of Occupational and Environmental Medicine*, 51(7), 822-837. Griffin, S. F., Wilcox, S., Ory, M. G., Lattimore, D., Leviton, L., Castro, C., o.fl.. (2010). *Health Education Research*, 25(2), 325-342.

**DOES WHOLE BODY VIBRATION TRAINING AFFECT BONE STRENGTH INDEXES IN ADOLESCENT WITH DOWN SYNDROME?**

Matute-Llorente, A.1,2, González-Agüero, A.1,3, Gómez-Cabello, A.1,2, Julián-Almárcegui, C.1, Gómez-Bruton, A.1,2, Vicente-Rodríguez, G.1,2, Casajús, J.A.1,2

*1 GENUD Research Group, Universidad de Zaragoza, Spain 2 Universidad de Zaragoza, Spain 3 Aberystwyth University, Ceredigion*

**Introduction** Adolescents with Down syndrome (DS) are characterized by low bone mineral density, a non-regular bone acquisition during growth (González-Agüero et al., 2011) and higher risk of suffering bone fractures (González-Agüero et al., 2012). Whole Body Vibration (WBV) training has showed improvements in bone mass in children with disabling conditions (Ward et al., 2004). Therefore, the aim of this study was to elucidate the effects of 20 weeks of WBV training on bone strength indexes in adolescents with and without DS. **Methods** Twenty-six male and female adolescents with DS (12 to 19 years) and twenty-five sex-age-matched controls were randomly assigned to WBV (15 DS; 13 non-DS) or control (11 DS and 12 non-DS) groups. Peripheral quantitative computed tomography (pQCT) scans were taken at tibia and radius; cortical thickness (CRT\_THK; mm), resistance to fracture load (FRC\_LD; N) in X and Y axes, stress strain index (SSI; mm<sup>3</sup>) in X and Y axes, bone strength index (BSI; mg<sup>2</sup>/mm<sup>4</sup>) and polar strength strain index (SSIPol; mm<sup>3</sup>), were calculated from these measurements. WBV was performed squatting on the platform in sets for a total duration of 10 min 3 days per week for a total of 20 weeks (from 1.8 to 2.6 g). Repetead measures of ANOVA adjusting by height, weight and Tanner stage were used to analyze possible group by time interactions on bone strength indexes. **Results** No significant group by time interactions were found for any of the studied variables after 20 weeks of training (all p>0.05). **Discussion** A 20-week WBV training 10 min 3 times per week with a vibration dose from 1.8 to 2.6 g might not be enough to provoke a significant improvement on bone strength indexes at tibia and radius in adolescents with and without

DS. This suggests that the protocol used was not effective to achieve improvements in bone strength indexes in adolescents. Further studies with longer trainings and different intensities should be performed in order to elucidate the effects that WBV may have at different training intensities. References González-Agüero, A. et al. (2011). Osteoporos Int, 22(7): 2151-2157. González-Agüero, A. et al. (2012). Osteoporos Int. Ward, K. et al. (2004) J Bone Miner Res, 19(3): 360-369

### EXERCISE VS. RELAXATION - A NEUROCOGNITIVE PERSPECTIVE IN INTELLECTUAL DISABILITY

Vogt, T.1, Schneider, S.1, Anneken, V.2, Strüder, H.K.1

1German Sport University Cologne, 2Research Institute for Inclusion through Physical Activity and Sport

Introduction Today, exercise is well accepted to promote health. Recent neurophysiological and behavioural studies emphasise the benefits of exercise on cognitive performance. Although, neurocognitive processes are well identified (e.g. transient hypofrontality theory [1]) these studies were mainly set up for healthy individuals. Within intellectual disability, underlying neurocognitive processes remain widely unclear and thus characterize the primary aim of this study. Method Comparing 10 min moderate cycling ( $61.82 \pm 7.83$  W at  $70.09 \pm 5.83$  rpm) to 10 min familiar relaxation ('snoezelen' [2]), 11 right-handed adolescent ( $16 \pm 1.34$  years,  $167.27 \pm 10.01$  cm,  $69.36 \pm 7.80$  kg) volunteered to participate. According to the American Association on Intellectual and Developmental Disabilities, participants were characterized as intellectually disabled with the ability to distinguish between colours and shapes. Both, the exercising and relaxation condition were embedded in ability-modified cognitive performance assessments. Randomly flashing lights served as stimulus source. Reaction times and equivalent neurophysiological parameters were recorded. A 32 active electrode EEG enabled analyses of low-resolution brain electromagnetic tomography (LORETA) and event-related potential waveforms, in particular the N2 component. Results Moderate cycling revealed a decrease in fronto-electro cortical activity, that was most pronounced in the medial frontal gyrus ( $p < 0.001$ ). In addition, reaction time decreased ( $p < 0.01$ ) and was mirrored in decreased N2 latency ( $p < 0.01$ ) after exercise. However, relaxation revealed no significant changes. Discussion Based on the transient hypofrontality theory, decreased fronto-electro cortical activity is suggested to display a rearrangement of cortical resources, associated with cognitive states. A decrease in reaction time, mirrored in decreased N2 latency indicates immediate control of action. Taken together, the findings of this study support exercise programs in intellectually disabled adolescent to positively influence neurocognitive performance. References [1] Dietrich A. Transient hypofrontality as a mechanism for the psychological effects of exercise. Psychiatry Res 2006; 145(1):79-83. [2] Hogg J, Caveat J, Lambe L, Smeddle M. ### COMPARATIVE STUDY OF FOOTPRINTS IN YOUNG PEOPLE WITH DOWN SYNDROME

Gutiérrez, L., Massó, N., Costa, L., Guerra, M.

1Blanquerna Faculty of Health Sciences, Ramon Llull University, Barcelona, Spain. 2 Blanquerna Faculty of Psychology and Educational and Sports Sciences, Ramon Llull University, Barcelona. Spain.

Introduction: Musculoskeletal disorders of the locomotive apparatus are common in young people with Down syndrome, especially in the feet (Miller, 1995; Mik, 2008). Early diagnosis by examination of podiatric footprints can help prevent orthopedic manifestations (Galli, 2012). Calculating podiatric indexes through the footprint allows classification according to foot type (Razeghi, 2002). Our objective was to analyze, measure and classify footprints on the basis of podiatric indices (gold standard) in young people with Down syndrome. Methods: In this cross-sectional comparative study we analyzed 86 footprints from two groups, 21 healthy subjects, 11 men ( $20.45 \pm 2.16$ ) and 10 women ( $20.00 \pm 1.70$ ), and 22 young people with Down's syndrome, 11 men ( $23.82 \pm 3.12$ ) and 11 females ( $24.82 \pm 6.81$ ). Footprints were recorded in standing position using an optical pedoscope and a digital camera system. We calculated the Hernández-Corvo index, the Chippaux-Smirak index, Clarke's angle and the Stahelli index using the program Photoshop CS5 (Stahelli, 1997). We then compared the results of both samples and analyzed the concordance between types of feet and right and left feet by Chi-square test. Results: Footprints in individuals with Down syndrome showed flatfoot and/or pronated Hernández-Corvo index: 38.6%, Chippaux-Smirak: 50%; Stahelli: 70.4% and Clarke's angle 59.1%. In healthy subjects showed cavus feet Hernández-Corvo index 57.1%; Chippaux-Smirak index 59.5%; Stahelli index 81%; and Clarke's angle 57.1% showed normal foot. Difference between the two groups were statistically significant ( $p < 0.01$ ) in Chippaux-Smirak index, Stahelli index, and Clarke's angle, whereas the Hernández-Corvo index does not meet the conditions of applicability for Chi-square test. The correlation between the right and left foot was not significant. Conclusions: Young people with Down Syndrome had a higher percentage of pronation and lower percentage of cavus feet than the control group. References Galli PM. 2012. #### THE EFFECT OF THREE WEEKS OF SHORT-TERM SPRINT INTERVAL VERSUS CONTINUOUS ENDURANCE TRAINING ON PERIPHERAL FATIGUE FOLLOWING MATCHED-WORK HIGH INTENSITY EXERCISE

Ross, E.Z.1, Twomey, R.1, Carter, H.1, Sansom, J.1, Dekerle, J.1,2

1: University of Brighton (United Kingdom), 2: University of Lille 2 (France)

Introduction A short period of sprint interval training (SIT) improves performance comparable to that observed in continuous endurance training (ET). Both elicit rapid oxidative muscular adaptations (Burgomaster et al., 2005), but adaptations of contractile muscle function at

rest and during fatigue following SIT have yet to be established. The aim of this study was to examine the effects of 3 weeks of a low volume (SIT) and high volume (ET) regime on aerobic performance, muscle function and muscular fatigue. Methods Thirty-one men were pair matched (peak VO<sub>2</sub>), assigned to SIT (n=15, 21±1 years, 80±11 kg) or ET (n=16, 22 ± 2 years, 78±7 kg), and performed 9 (SIT) or 15 (ET) training sessions over 21 days. Each session consisted of either four or five repeats of 30 s 'all out' cycling with 4 min recovery (SIT) or 40 to 50 min continuous cycling at ~62% peak VO<sub>2</sub> (ET). Total training volume (in kJ) was significantly lower in SIT (~11% of ET). Participants performed a time to exhaustion trial (80% peak power) pre and post training (TTE<sub>pre</sub> and TTE<sub>post</sub>, respectively), and a trial of equal work to that achieved in TTE<sub>pre</sub> (ISO). Maximal isometric knee extension (MVC) and potentiated twitch force of the quadriceps (POT) in response to supramaximal electrical stimulation of the femoral nerve were assessed pre- and post-exercise for two trials (TTE<sub>pre</sub> and ISO). Results A comparable improvement in peak VO<sub>2</sub> (~7%) and TTE (~56%) was found in both groups (P>0.05). In the unfatigued state, neither training regime increased MVC (P>0.05). Both SIT and ET attenuated fatigue, measured as the exercise-induced reduction in MVC (SIT -26±10% to -12±12%; ET -34±8% to -19±10%, P<0.05) and POT (SIT -37±14% to -33±18%; ET -49±13% to -41±16%, P<0.05), with no difference between the two training regimes. Maximal rate of force development during POT slowed following the exercise trials, but less so after both training regimes (TTE<sub>pre</sub> -51±19 % vs. ISO -41±26%, P<0.05). Discussion Both training regimes improved aerobic exercise performance and fatigue resistance during a matched work exercise trial. These data suggest that the previously reported comparable improvements in muscle oxidative capacity and metabolism elicited by SIT and ET have physiological relevance to muscular performance and fatigability. Given the substantially lower training volume performed in SIT, this study provides further evidence that it is a time-efficient strategy to induce exercise performance improvements. ### MUSCLE METABOLIC DETERMINANTS OF EXERCISE TOLERANCE ABOVE AND BELOW CRITICAL POWER

Chidnok, W., Fulford, J., Bailey, S.J., Skiba, P.F., Vanhatalo, A., Jones, A.M.

*UNIVERSITY OF EXETER*

**Introduction** The *W'* represents a fixed amount of work that can be completed above the critical power (CP) and is depleted at the point of task-failure during severe-intensity exercise. When severe-intensity exercise is interspersed with recovery intervals, *W'* is reconstituted at a rate dependent upon the intensity of the recovery interval (Chidnok et al., 2012: *Med Sci Sports Exerc*, 44: 996-76); however, the intramuscular bases for this intensity-dependent *W'* recovery have yet to be investigated. We tested the hypotheses that: 1) muscle metabolites linked to the fatigue process would recover after exhaustion during recovery exercise performed CP, and 2) that these changes would influence the capacity to continue exercise. **Methods** Eight male subjects participated in this investigation. Initially, subjects completed four constant-work-rate single-leg knee-extension exercise bouts until the limit of tolerance to establish the parameters of the power-duration relationship (i.e., CP and *W'*). In three subsequent visits, subjects completed an exercise bout predicted to lead to exhaustion in 180 s followed by a work-rate reduction to either severe intensity exercise (above CP), heavy intensity exercise (below CP), or a 10 min passive recovery period, in a random order. The muscle metabolic responses to exercise were assessed using 31P magnetic resonance spectroscopy (31P-MRS). Data were analyzed using two-way repeated measures ANOVA. **Results** The tolerable duration of exercise during the recovery from exhaustive exercise was significantly greater in CP conditions (600 ± 0 s vs. 39 ± 31 s, respectively) (P<0.05). During passive recovery and CP recovery exercise, muscle [PCr] and pH did not recover, remaining at ~37 ± 8% of the initial baseline and 6.6 ± 0.2, respectively. **Discussion** These results indicate that the recovery of intramuscular metabolites in the recovery from exhaustive severe intensity exercise can be differentiated according to whether the recovery exercise is performed below or above the CP. The CP therefore represents an important intramuscular metabolic threshold which dictates the ability to maintain intramuscular homeostasis and the capacity to tolerate high-intensity exercise. **References** Chidnok W, DiMenna FJ, Bailey SJ, Vanhatalo A, Morton RH, Wilkerson DP, Jones AM (2012). *Med Sci Sports Exerc*, 44, 966-76.

### EFFECTS OF ENDURANCE EXERCISE ON MUSCULAR SIZE AND NEUROTROPHIN IN SENESCENCE-ACCELERATED MICE

Maekawa, T., Nakada, S., Ishii, N.

*Tokyo University*

**Introduction** Aging-related decline in muscular function (sarcopenia) is characterized by decreases in muscular size, strength and velocity. Many factors have been thought to be involved in the aging related muscular atrophy, and the decrease in the number of motor neurons would be one of the important factors, because the innervation greatly affects the survival of muscle fibers (Larson et al., 1995). It has been reported that endurance exercise effectively prevents the loss of motor neuron during aging (Kanda et al., 1998), and also causes increased expressions of neurotrophins in skeletal muscle, serum, and other tissues (Cuppini et al., 2007). Although neurotrophins have been regarded as important in the function and survival of neurons, their roles in the progress and prevention of aging related muscular atrophy remain unclear. The present study investigated the effects of endurance exercise on muscular size, number of motor neurons and protein expressions of a neurotrophin, brain-derived neurotrophic factor (BDNF) and its receptor, during aging of senescence-accelerated mice (SAMP8). **Method** SAMP8 mice were randomly assigned to pre-exercise (PE), exercise (E) and sedentary (S) groups. At the age of 35 wk, the mice in PE were sacrificed and the specimens of the gastrocnemius muscle and spinal cord were obtained. The mice in E were endurance-exercised (5-degree inclined treadmill running; 20 m/s; 30 min; 3 sessions/wk) until the age of 51 wk. Thereafter, the mice in both E and S groups were sacrificed and the tissues were excised. The number of motor neurons innervating the muscle was measured by using a retrograde-transported fluorescent marker. The protein expressions of BDNF and its receptor TrkB were quantified with Western blotting. **Results** Muscle-fiber cross sectional area was significantly (P<0.05) larger in E group than in other groups. The expression level of BDNF within the muscle tended to be higher (P=0.068) in E than in S group. However, muscle-fiber composition (%ST), number of motor neurons, expression of BDNF within neurons and that of TrkB in both the muscle and neurons showed no significant differences between groups. **Discussion** The present results suggest that endurance exercise has partial effect in preventing the aging-related muscular atrophy and this effect is independent of the number and function of motor neurons. Exercise with much higher intensity, e.g., resistance exercise, may be required to cause bigger effects on both muscles and motor neurons. However, the interpretation of the present results would be limited by the use of senescence-accelerated mice. **References** Larsson L, Ansved T. *Prog. ### INFLAMMATORY RESPONSES AFTER DIFFERENT VELOCITIES OF ECCENTRIC EXERCISE

Conceição, M., Libardi, C.A., Chacon-Mikahil, M.P.T.C., Nogueira, F.R.D., Vechin, F.C., Bonganha, V., Cavaglieri, C.R.  
*University of Campinas – UNICAMP*

**Introduction** Eccentric exercise (ECC) induces muscle damage (MD), mainly when fast ECC is executed (Chapman, et al., 2006). After MD, is initiated a cascade of inflammatory events, including increases in concentrations of pro- and anti-inflammatory cytokines (Peake et al., 2005). Thus it is possible that the superior magnitude of MD may also induce a greater systemic inflammatory response. A study showed that women presented differences in inflammatory response compared to men (Stupka et al, 2000), since the estrogen (17 $\beta$ -estradiol) could promote a protective effect, attenuating the inflammatory response (Tiidus, 2003). No previous studies compared the inflammatory responses after different velocities of ECC in women. The present study aimed to verify MD and inflammatory response following different velocities of ECC in women. **Methods** Nine women (Ecc30, 23.8 $\pm$ 2.0 years; 57.8 $\pm$ 7.0 Kg; 1.6 $\pm$ 0.5 m) performed 30 maximal eccentric actions at 30°/s. Another ten women (Ecc210, 22.2 $\pm$ 3.9 years; 56.4 $\pm$ 6.0 Kg; 1.6 $\pm$ 0.5 m) performed the ECC at 210°/s. Changes in maximal voluntary isometric contraction (MVIC), range of motion (ROM), muscle soreness and creatine kinase (CK) and concentrations of tumor necrosis factor-alpha (TNF- $\alpha$ ), interleukin-6 (IL-6) and interleukin-10 (IL-10) were compared by a mixed model analysis of variance with repeated measures. Results It was found a group vs. time interaction for CK with greater values for Ecc30 (P< 0.001). A group effect (with greater decreases for Ecc30) for ROM (P< 0.001) and a time effect for ROM (P= 0.004), soreness (P< 0.001), TNF- $\alpha$  (P= 0.004), IL-6 (P=0.001) and IL-10 (P= 0.041) were found. **Discussion** Our results showed that slow ECC demonstrated higher serum CK compared with fast ECC. This is divergent compared to Chapman, et al., (2006). Also, all cytokines enhanced after both velocities of ECC. Although previous studies suggested that voluntary ECC does not cause inflammation (Malm & Yu, 2012); our results indicate that ECC induced changes in MD markers and promoted both pro- and anti-inflammatory systemic cytokines responses in women independent of ECC velocity. **Conclusion** In conclusion, the ECC induced MD and promoted both pro- and anti-inflammatory response; however, the responses are similar between fast and slow ECC. **References** Chapman, D., et al (2006). *Int J Sports Med*, 27(8), 591-598. ### COMPARISON IN ECCENTRIC EXERCISE-INDUCED MUSCLE DAMAGE OF THE ELBOW FLEXORS AMONG 9-10 AND 14-15 YEARS OLD BOYS AND 20-25 YEARS OLD MEN

Nosaka, K., Chen, H.L., Chen, T.C.

*Edith Cowan University, National Chiayi University*

**Introduction** Many studies have examined eccentric exercise-induced muscle damage, but little is known about the muscle damage in children. To the best of our knowledge, only two studies compared muscle damage between preadolescent boys and adult men. Marginson et al. (1) reported that decreases in maximal voluntary contraction torque of the knee extensors and jump height, and increases in muscle soreness after 8 sets of 10 plyometric jumps were significantly smaller for boys (9-10 y) than adult men (20-29 y). Gorianovas et al. (2) reported similar findings after 100 drop jumps; however, no previous studies have used arm eccentric exercise to investigate muscle damage in children. The present study compared changes in several indirect markers of muscle damage after maximal eccentric exercise of the elbow flexors among pre-adolescent and adolescent boys, and adult men after two exercise bouts separated by 3 weeks. **Methods** Untrained pre-adolescent (9-10 y) and adolescent (14-15 y) boys, and adult (20-25 y) men (n=13/group) performed two bouts of 5 sets of 6 maximal isokinetic (90°/s) eccentric contractions of the elbow flexors of the non-dominant arm on a dynamometer, in which the elbow joint was forcibly extended from 90° to 0° (full extension). Changes in maximal voluntary isokinetic (60°/s) concentric contraction torque (MVC-CON), optimum angle, range of motion, upper arm circumference (CIR), visual analog scale for muscle soreness, plasma creatine kinase activity and myoglobin concentration, and ultrasound echo-intensity before, immediately after and 1-5 days after the first and second exercise bouts were compared among the groups by a two-way repeated measures ANOVA. Results MVC-CON before exercise was smaller (P<0.05) for 9-10 y (8.9  $\pm$  1.9 Nm) compared with 14-15 y (25.1  $\pm$  3.9 Nm) and 20-25 y (35.3  $\pm$  4.6 Nm). Changes in all variables after the first bout were smaller (P<0.05) for 9-10 y than 20-25 y as well as for 14-15 y than 20-25 y, and all changes except CIR were also smaller (P<0.05) for 9-10 y than 14-15 y. After the second bout, changes in all variables were smaller (P<0.05) than those after the first bout for all groups, but the changes were significantly (P<0.05) different among the groups in the same way as that of the first bout. No significant difference in the magnitude of the repeated bout effect was evident among the groups. **Discussion** These results indicate that the magnitude of muscle damage is significantly less for pre-adolescent than adolescent boys and adult men, and for adolescent boys than adult men after the first and second eccentric exercise. It appears that the magnitude of eccentric exercise-induced muscle damage increases with development of muscles, and changes in muscle characteristic with development account for the difference in the muscle damage. **Reference** 1) Marginson et al. *J Appl Physiol*. 99:1174-81, 2005. 2) Gorianovas et al. *BioMed Res Int*. 218970, 2013.

### EFFECT OF A PRE-EXERCISE GLYCOGEN REDUCTION PROTOCOL ON THE RECOVERY OF NEUROMUSCULAR FUNCTION FOLLOWING MILD EXERCISE-INDUCED MUSCLE DAMAGE

Gavin, J.P., Myers, S.D., Willems, M.E.T.

*University of Chichester*

**Introduction** High-intensity exercise is associated with glycogen depletion and short-term neuromuscular fatigue. In contrast, eccentric contractions cause exercise-induced muscle damage (EIMD) and delayed neuromuscular recovery. Temporal neuromuscular responses for those with EIMD and lowered glycogen are unclear. Therefore we examined the effect of muscle glycogen reduction on the recovery of neuromuscular function during mild EIMD. **Method** Fifteen men (22 $\pm$ 4 yr, 179 $\pm$ 7 cm, 76 $\pm$ 15 kg) performed a single-leg glycogen depleting cycling protocol (Pilegaard et al., 2002) the evening before a maximal isokinetic eccentric bout. Neuromuscular function was measured by isometric maximal voluntary contraction (MVC) and electrical stimulation (resting twitch, 20 and 50 Hz): at baseline; post-cycling; and post-eccentric upto 48-h. Cycling began with the control leg supported, whilst the glycogen reduction (GR) leg undertook: 20-min cycling at ~75% VO<sub>2</sub>max power; eight 90-s sprints, with 90-s rests (5% steps from 90 to 55% VO<sub>2</sub>max); and an all-out cycle at ~85% VO<sub>2</sub>max power. Next morning, 100 single-leg, maximal eccentric knee extensions (1.57 rad range of motion at 1.57 rad/s) were completed for the GR, and then control. Two-way, repeated measures ANOVA compared recovery of neuromuscular function between conditions from baseline, with differences located using Bonferonni paired t-tests. Results Glycogen reduction cycling reduced MVC force by: -23.2% (GR: P=0.0001), and -5.4% (control: P=0.002). Post eccentric exercise, MVC loss was similar between legs at: 0- (GR: -23.9%; control: -

19.4%), 12-h (GR: -10.6%; control: -9.7%) and 24-h (GR: -15.8; control: -13.5%;  $P>0.05$ ). By 48-h MVC remained impaired in the GR leg only (-7.4%,  $P=0.003$ ). Cycling decreased resting twitch force in the GR (-46.7%,  $P=0.001$ ), whilst potentiating force for the control (20.9%,  $P=0.05$ ). Eccentric exercise lowered twitch force more for GR (-41.3%), than the control leg (-13.7%,  $P=0.02$ ). At 12-h twitch force was recovered in both legs. Similarly, eccentric exercise reduced 20- (GR: -28.3%; control: -29.1%) and 50 Hz forces (GR: -16.2%; control: -19.25%), with full recovery by 12-h. Discussion Reduced muscle glycogen delayed the recovery of voluntary force, but not neuromuscular responses, during mild EIMD. Prolonged voluntary force loss, coupled with preserved twitch contractile capacity, suggests peripheral fatigue mechanisms. As greater immediate neuromuscular decline was associated with reduced glycogen in mild EIMD, more severe eccentric protocols may expand insight upon glycogen state and neuromuscular responses. References Pilegaard H, Keller C, Steensberg A, Helge J, Pedersen BK, Saltin B, Neufer D. (2002). *J Physiol*, 541(1), 261-271.

## THE REDUCTION IN MAXIMAL FORCE CAPACITY CAN LIMIT THE TIME TO TASK FAILURE OF A SUSTAINED CONTRACTION

Abdelmoula, A., Baudry, S., Duchateau, J.

*faculté des sciences de la motricité*

The reduction in maximal force capacity can limit the time to task failure of a sustained contraction Introduction A common manifestation of muscle fatigue is a decrease in the force capacity assessed by maximal voluntary contraction (MVC) performed within a few seconds after failure of a sustained contraction (Enoka et al. 2011). Nonetheless, MVC force after failure remains generally greater than the target force of the sustained contraction, suggesting that task failure was not related to the decrease in maximal force capacity (Booghs et al. 2012). However, the short rest period between the end of the fatiguing task and the subsequent MVC likely allows some recovery of the maximal force capacity. The aim of this study was to evaluate the decrease in maximal force capacity at failure and a few seconds after a submaximal sustained voluntary contraction performed at two contraction intensities. Methods Seven subjects performed isometric contractions with the abductor pollicis brevis muscle until failure at an intensity of 25% and 50% of MVC force, in separate sessions. The fatigue task ended when subject was unable to maintain the required force level for 5s. Before, at failure (without stopping the sustained contraction), and after 5s of rest, subjects performed a MVC during which a train of 3 stimuli (100 Hz) was applied to the median nerve to calculate the central activation ratio (CAR). Results The time to failure was longer for the task performed at 25% ( $282\pm 72$ s) than at 50% MVC ( $117\pm 30$ s;  $p<0.05$ ). The MVC force decreased ( $p<0.05$ ) by  $53.5\pm 13.5\%$  and  $47.5\pm 10.1\%$  at failure for the 25% and 50% MVC tasks, respectively, but had partially recovered (about 70% of initial values) 5s after failure. The CAR reached 100% before fatigue, decreased to  $95.4\pm 5.2\%$  and  $94.2\pm 5.0\%$  ( $p<0.05$ ) at failure for the 25% and 50% MVC tasks, respectively, and fully recovered after 5s. Discussion At failure, MVC force decreased by about 50% for both contraction intensities, indicating that the decrease in maximal force capacity likely contributed to task failure for the 50% but not the 25% MVC task, the remaining force capacity being greater than the target force in the latter case. However, MVC force had recovered to 70% of initial values and central fatigue (assessed by CAR) had completely disappeared 5s after failure, masking the influence of the force deficit on task failure for the higher intensity. These results indicate that assessing maximal force capacity at the end of a fatiguing contraction without rest may provide more relevant information on mechanisms responsible for task failure, and further support that mechanisms underlying task failure vary with the intensity of the sustained contraction. ## IS SPASTICITY EXACERBATED WITH ACUTE NEUROMUSCULAR FATIGUE IN STROKE PATIENTS?

Bouardham, J., Roche, N.1, Teixeira, M.1, Hameau, S.1, Bensmail, D.1, Zory, R.1

*GRCTH, EA4497 (Garches, France)*

Introduction Spasticity and fatigue are two disabling and persistent symptoms affecting many stroke survivors. However, the effects of neuromuscular fatigue on spasticity have never been studied on a population of hemiparetic patients. This question is particularly relevant since in the clinical context, patients, who exhibit spasticity of rectus femoris, frequently report some difficulties to flex their knee during swing phase of the gait cycle, when they are tired. Therefore, the main aim of this study was to assess the effects of neuromuscular fatigue on stretch reflex-related torque and EMG of spastic knee extensors in hemiparetic patients. We hypothesized that repetitive concentric contractions of knee extensor muscles and the resulting fatigue would increase hyper-excitability of the stretch reflex. Methods Eighteen patients performed passive (stretch reflex) and dynamic (voluntary strength) evaluations before (PRE) and immediately after (POST) a fatigue protocol using an isokinetic dynamometer. Electromyographic activity of rectus femoris, vastus lateralis and biceps femoris was simultaneously recorded. PRE and POST test consisted of i) passive evaluation at three different velocities, ii) isometric and iii) concentric maximal voluntary contractions (MVCs) of the knee extensor muscles. The voluntary isokinetic fatigue protocol consisted of 40 maximal repetitive concentric contractions of knee extensor muscles at  $60^\circ/\text{sec}$ . Immediately after the fatigue protocol, subjects reproduced the initial assessment for the passive and dynamic trials. Results During the fatigue protocol, the mean normalized peak torque and the neuromuscular efficiency of the knee extensors muscles significantly decreased. The torque developed by the knee extensors muscles during isometric contractions decreased in the fatigued state. The peak resistive torque and the normalized RMS values of VL and RF during passive stretching movements were not modified by the fatigue protocol during all stretching velocity. Discussion Results showed that fatigue induced by isokinetic repetitive maximal knee extension do not influence spasticity of quadriceps muscle in patients after stroke. They also highlighted that although patients exhibited decline in strength development after localized muscle fatigue, mainly produced by excitation-contraction coupling failure (Remaud et al., 2005), the modifications in muscles properties following stroke seem preserve stretch reflex components (Knorr et al., 2012). References Remaud A, Cornu C, Gue A. (2005). *J Athl Train*, 40, 281-287. Knorr S, Rice CL, Garland SJ. (2012). *Disabil Rehabil*, 34, 2291-2299.

## EFFECTS OF A ONE-MONTH MUSCLE OVERLOAD ON THE MEDIAL GASTROCNEMIUS MOTONEURONS

Haluszka, A., Baczyk, M., Celichowski, J., Krutki, P.

*University School of Physical Education, Poznan*

Introduction Various models of chronic neuromuscular activity, as workload training, tendon transfer, or paresis and peripheral nerve damage lead to muscle overload. Chronic increases or decreases in the activation of motor units mostly induce biochemical changes, especially in muscle fibers and innervating them alpha-motoneurons. Less knowledge is available on adaptation in electrophysiological properties of motoneurons. The aim of this study in adult rats was to investigate whether 5 weeks of the functional muscle overload

results in alterations of electrophysiological properties of motoneurons (MNs). Methods Rats were subjected to chronic overload of the medial gastrocnemius (MG) muscle by bilateral tenotomy of its synergists (lateral gastrocnemius and soleus (LGS), and plantaris). As the result of this operation, only the MG muscle was able to evoke a foot plantar flexion during daily locomotor activity. To assure that the operated MG muscles were regularly voluntarily activated, rats were subjected to extensive voluntary activity on a running wheel and additionally to a training program on a treadmill for 5 weeks, 5 days a week. The intracellular recordings from spinal MNs were made in deeply anesthetized animals. The MG or LGS MNs were identified by antidromic stimulation of the respective nerve branches. Results The basic electrophysiological properties of MNs were considerably modified by the muscle overload, mostly in fast-type MNs. 5 weeks of the compensatory muscle overload evoked substantial changes in membrane and rhythmic properties primarily of fast-type MNs innervating the MG muscle (a decrease in rheobase current and a spike generation threshold, as well as a leftward shift of the frequency-current relationship). The measured properties of slow-type MNs remained unaltered. Motoneurons innervating the unloaded muscles exhibited reverse modifications of their membrane properties, but adaptations in overloaded MG MNs were more pronounced than in unloaded LGS MNs. Discussion Either voluntary wheel running or endurance treadmill training produce adaptations in the electrophysiological properties of MNs pools that involve alterations in membrane properties resulting in increased excitability. It has been revealed that the functional muscle overload by removal of its major synergists has no effect on the size of the cell body of MNs and the level of their oxidative potential, but results in an increase in the muscle fiber size, a shift toward "slower" physiological properties. Our data point on higher excitability of fast-type MNs and are in line with the above observations. Alterations in MNs' electrophysiological properties lead to changes in discharge patterns of MUs, what in turn may influence force developed by muscle fibers.

### MUSCLE FATIGUE FOLLOWING SUSTAINED CONTRACTIONS WITH IDENTICAL TORQUE-TIME INTEGRAL

Rozand, V., Cattagni, T., Theurel, J., Martin, A., Lepers, R.

*INSERM 1093*

Introduction Central and peripheral mechanisms of neuromuscular fatigue are intensity-dependent. In most of studies on muscle fatigue, the intensity of the submaximal fatiguing contractions is fixed, while the duration is determined by the time to exhaustion (Smolander et al., 1998). It has been shown that low intensity prolonged contractions induced central fatigue, contrary to high intensity contractions (Yoon et al., 2007). In contrast, other studies found greater peripheral fatigue for low intensity contractions (Fuglevand et al., 1993). However, in these studies the intensity-duration combination, quantified by the force- or torque-time integral, was not controlled and could in part explain the diversity of the results. Therefore, the aim of this study was to compare neuromuscular alterations following isometric sub-maximal contractions at different intensities and durations, but with a similar torque-time integral. Methods Sixteen participants performed three isometric sustained contractions at different intensities (25 %, 50 %, and 75 % of Maximal Voluntary Contraction (MVC) torque in knee extension) with different durations but similar torque-time integral value. MVC torque, maximal voluntary activation level (VAL), M-wave amplitude and potentiated doublet amplitude were assessed before and immediately after the sustained contractions. EMG activities of the vastus lateralis (VL) and rectus femoris (RF) muscles were recorded during the sustained contractions. Results MVC torque reduction after the exercise was similar in the three conditions (-23.4 ± 2.7 %). VAL decreased significantly in a similar extent (on average: -3.1 ± 1.3 %) after the three sustained contractions. Potentiated doublet amplitude was similarly reduced in the three conditions (-19.7 ± 1.5 %), but VL and RF M-wave amplitudes remained unchanged. EMG activity of VL and RF muscles increased during the three contractions (VL: 54.5 ± 40.4 %; RF: 53.1 ± 48.7 %). Discussion The three submaximal isometric contractions of the knee extensor muscles with different intensity-duration combinations but with similar torque-time integral induced a similar level of fatigue with identical central and peripheral alterations. Further studies are required to determine whether the level of fatigue is dependent on the value of torque-time integral of the contraction. References Fuglevand AJ, Zackowski KM, Huey KA, Enoka RM. ### MUSCLE DAMAGE INDUCED BY AN ULTRA-ENDURANCE TRIATHLON AFFECTS SLOW FIBRES AND IS RELATED TO DEHYDRATION

Barrero, A.1, Cadefau, J.A.1, Irujo, A.1, Chaverri, D.1, Guerrero, M.2, Carmona, G.2, Cussó, R.2, Iglesias, X.1, Rodríguez, F.A.1

*1: INEFC-Barcelona Sport Sciences Research Group, Institut Nacional d'Educació Física de Catalunya, Universitat de Barcelona, 2: Faculty of Medicine, Universitat de Barcelona (Barcelona, Spain)*

Introduction Ultra-endurance triathlon (UET) races (3.8-km swim, 180-km cycle, 42.2-km run) induce muscle damage (Neubauer et al., 2008). Fast (FM) and slow myosin (SM) assessment in blood 48 h after exercise is a useful marker for the detection of skeletal muscle damage (Guerrero et al., 2008). This study aimed to assess muscle damage after an UET race as indicated by FM, SM and creatine kinase (CK) serum levels and to relate them to the hydration status. Methods 11 well-trained non-professional ultra-endurance triathletes (mean ± SD: age 37.2 ± 4.6 years, body mass 74.3 ± 6.7 kg, height 174 ± 6 cm, BMI 24.5 ± 1.9 kg/m<sup>2</sup>, VO<sub>2</sub>max 67.5 ± 4.2 mL/(kg•min)) competed in the Extreme Man Salou-Costa Daurada UET 2011. Venous blood samples were collected up to 30 min before and 48 h after finishing the race. ELISA method was used to determine myosin concentration in serum. Body mass (BM) and bioimpedance (BIA) bioelectrical variables (Z-Metrix®, Biopar-Hom Co, France) were obtained before, 30 min post-race, and 48 h after. Total (TBW), intracellular (ICW), and extracellular body water (ECW) content was estimated using the instrument software. Results Race time was 759±SD 64 min. Initial SM levels (1016±228 •g/l), FM levels (1091±374 •g/l), and CK activity (202±87 U/l) largely increased post-race (170±93%, 16±37% and 600±476%, respectively, p<0.001). SM increase was closely related to the increase in CK (r=0.72, p=0.013). BM (74.0±6.8 kg) decreased post-race (-5.8±1.9%) and 48 h after (-1.4±1.2%) (ANOVA, p<0.001), as well as TBW, ECW and ICW (-8.5±2.9%, -10.8±3.7% and -7.0±2.8, respectively, p<0.001), with no further changes 48 h after. BM decrease was closely related to the reduction in TBW, ECW, and ICW (r=0.98, 0.95, and 0.85, respectively, p≤0.001). The increase in SM levels was related with the decrease in TBW (r=0.71, p=0.014) and ICW (r=0.74, p=0.01), but not in ECW (r=0.56, p=0.08). Discussion While CK increased activity is believed to be a reliable marker of muscle damage, elevated SM levels suggest specific damage in slow muscle fibres, which are largely predominant in ultra-endurance athletes. Our results, beyond confirming fibre muscle damage induced by an UET race, strongly suggest that cellular structural damage predominantly affects slow fibres, and that muscle damage is influenced by hydration status. ## HOW TO MEASURE CARDIORESPIRATORY FITNESS IN CHILDHOOD AND ADOLESCENCE

Schlenker, L., Schmidt, S., Albrecht, C., Woll, A., Bös, K.

*Karlsruhe Institute of Technology (KIT)*

**Introduction** Cardiorespiratory fitness is considered as the most important health related physical ability and it is a powerful marker of health (Ortega et al., 2008). Therefore it is important to measure the cardiorespiratory fitness accurately. Field tests offer a feasible alternative to expensive labor procedures. In this study we compared three different commonly used field-based endurance tests for children and adolescences, using maximal oxygen uptake (VO<sub>2</sub>max) as criterion reference. **Methods** A sample of 23 boys from 11 to 14 years ( $m = 12,31$ ) performed three endurance tests. 1. The 6-minute-endurance-run (6-MR) around a volleyball court. Total distance (m) was recorded (Bös & Wohlmann, 1987). 2. The 20m Shuttle Run Test (20m SR), where the children had to run back and forth on a indoor 20 m course. The starting speed of 8.5 km/h was increased each minute with 0,5 km/h. Test duration (sec) was recorded (Leger et al., 1988). 3. A bicycle ergometer test on a SRM system. The initial workload of 25 W was increased every 2 minutes by 25 W. The physical work capacity (watt/kg) at the heart rate of 170 bpm (PWC 170) was assessed. In addition VO<sub>2</sub>max was determined via Cortex Metamax 3B gas analysis system. Pearson correlation coefficients were calculated. **Results** The children achieved a mean distance of 1288 (+/- 101) meters in the 6-MR, the mean test duration in the 20m SR was 510 (+/- 99) seconds and the mean result of the PWC 170 test was 2,61 (+/-0,64) W/kg. The results of the 6-MR showed the highest correlations with VO<sub>2</sub>max ( $r=0.81$ ;  $p<0.01$ ) followed by the results of the 20m SR ( $r=0.66$ ;  $p<.01$ ) and the PWC 170 ( $r=0.63$ ;  $p<.05$ ). **Discussion** When using VO<sub>2</sub>max as criterion reference, the 6-MR appears to be the most appropriate method for assessing cardiorespiratory fitness for the group of 11 to 14 year old boys. The 20m SR seems to be a less suitable method. Due to its complex test protocol, it seems to be more appropriate for older participants. As a submaximal test, the great benefit of the PWC 170 test is its independence from personal motivation. Yet, on the negative side, the test results are influenced by the widely differing individual heart rates. Thus, the PWC 170 test renders itself useful only in terms of a rough assessment of cardiorespiratory fitness. **References** Bös, K. & Wohlmann, R. ### IMPAIRED IMMUNE FUNCTION AFTER MILD HYPOTHERMIA AND PROLONGED COLD EXPOSURE

Dolci, A.1, Brierley, J.1, Fortes, M.1, Lloyd-Jones, E.2, Walsh, N.1, Oliver, S.1

*1Extremes Research Group, College of Health and Behavioural Sciences, Bangor University, UK, 2 Department of Haematology, Ysbyty Gwynedd, Betsi Cadwaladr University Health Board, UK*

The aim was to assess the effect of mild hypothermia and prolonged cold exposure on immune function of healthy humans. As cold exposure is known to activate the sympathetic nervous system and HPA axis, which are known to have immunosuppressive effects, we hypothesized that mild hypothermia would impair immune function, as assessed by clinically relevant immune measures, which included saliva flow rate and IgA secretion rate, bacterial-stimulated neutrophil degranulation and vaccine-stimulated cytokine production (IFN- $\gamma$  and IL4). In a repeated measures design 19 males completed a cold trial and a thermal neutral control trial in a random order. During the cold trial they were immersed in 13°C water until rectal core temperature reached 36°C. Following this they completed a seated and semi-nude cold air exposure (0°C) for up to 3 hours or until core temperature reached 35°C. Core temperature was lowest 21 (31) minutes into the cold air exposure (35.17 (0.33)°C (mean (SD))). Immediately after the lowest core temperature there was an increase in circulating leukocytes (30%,  $P < 0.001$ ), neutrophils (42%,  $P = 0.002$ ), lymphocytes (22%,  $P = 0.008$ ) and monocytes (35%,  $P < 0.001$ ). After 3-hour cold-air exposure the general leukocyte mobilization was followed by divergent changes in leukocyte subpopulations, where circulating neutrophils increased further (97%,  $P < 0.01$ ), monocytes returned to control values and circulating lymphocytes were lower than control values (-16%,  $P < 0.01$ ) until 3 hours after cold exposure. Bacterial-stimulated neutrophil degranulation and vaccine-stimulated IL4 were unchanged after cold exposure. In contrast, immediately after the lowest core temperature there were decreases in vaccine-stimulated IFN- $\gamma$  production (-44%,  $P = 0.04$ ), saliva flow rate (-59%,  $P = 0.06$ ) and IgA secretion rate (-52%,  $P = 0.01$ ), which suggest temporary immune suppression. Moreover, despite rewarming and feeding, vaccine-stimulated IFN- $\gamma$  production did not return to control values within the 3-hour recovery, which suggests more prolonged immune suppression, specifically, impaired antimicrobial capacity. As cortisol (39%  $P = 0.05$ ), adrenaline (150%  $P = 0.04$ ) and noradrenaline (357%  $P < 0.001$ ) were all increased on the cold trial it is plausible that these stress hormones are responsible for the alterations in circulating leukocytes and immune suppression observed. In conclusion this study shows that mild hypothermia causes immune suppression in healthy individuals, which might explain the increased incidence of infection reported after cold exposure.

### WHOLE BODY CRYOSTIMULATION AS A DAILY RECOVERY STRATEGY DURING INTENSIFIED TRAINING IN ELITE-LEVEL SYNCHRONIZED SWIMMING

Schaal, K., Le Meur, Y., Rebeyrol, J., Louis, J., Petit, O., Hellard, P., Casazza, G., Hausswirth, C.

*National Institute of Sport, Expertise and Performance*

**INTRODUCTION:** Elite athletes frequently undergo periods of intensified training (IT) within their normal training program. Optimizing recovery during IT is particularly important in order to avoid excess fatigue that could undermine the intended training adaptations of IT. After demonstrating the effectiveness of whole body cryostimulation (WBC) as a short term recovery aid between two exhaustive exercises (1), we investigated whether daily WBC during IT influenced key factors to speed-up recovery (sleep and food intake) and whether it could prevent early physiological signs of an overreached state (2,3). **METHODS:** After 1 week of normal training (BASE), 10 elite synchronized swimmers performed two 12-day IT periods in randomized order, using WBC daily (ITWBC), or not (ITCON). The IT were separated by 9 days of light training. 3 exercise test sessions were performed: at BASE and after each IT. After obtaining resting heart rate variability

(HRV) samples, swimmers performed a 400m time trial to quantify the lactate ([La-b]), heart rate (HR400), salivary alpha amylase [AAs]400 (as an indicator of sympathetic activity) and cortisol ([Cs]400) response to maximal exercise. Swimmers wore a wrist actigraph nightly to monitor sleep patterns throughout the experiment. Energy intake (EI) was measured during each period. Fasted, waking saliva samples were obtained on the first and last day of BASE and each IT to measure [Cs] and leptin ([Ls]) concentrations. Results: ITCON resulted in significantly increased HRV indices of parasympathetic activity (R-to-R interval, SD1, HFnu), and decreased sympathetic activity (LFnu) while this did not occur with ITWBC. Significant decreases in mean swim speed ( $-1.1 \pm 0.5\%$ ), [La-b]400 ( $-11 \pm 6\%$ ) and [AAs]400 ( $-25 \pm 16\%$ ) were observed from BASE to ITCON, while no significant changes were found after ITWBC. Change in swim speed was inversely correlated with changes in HRpeak, [La-b]peak and [Cs]peak ( $r = -0.95, -0.65$  and  $-0.81$ ). Sleep fragmentation index increased with both IT, suggesting decreased sleep quality, but actual sleep quantity was preserved with ITWBC and decreased with ITCON ( $435 \pm 7$  and  $413 \pm 9$  vs  $433 \pm 10$  min for BASE). No changes in EI were observed during either IT despite a 25% increase in exercise energy expenditure ( $2244 \pm 162$ , ITWBC:  $2250 \pm 262$ , ITCON:  $2273 \pm 371$  kcal/day); body fat mass and [Ls] decreased during the study. CONCLUSIONS: Daily WBC during IT effectively prevented the appearance of several signs of fatigue accumulation, including parasympathetic hyperactivity at rest, suppressed sympathetic activation during exercise and decreased performance. WBC also helped maintain sleep quantity, but did not help increase food intake in response to intensified training in elite synchronized swimmers. 1 Schaal K et al (2013) Appl Physiol Nutr Metab. doi: 10.1139/apnm-2012-0155 2 Le Meur Y et al (2013) J Appl Physiol. doi: 10.1152/jappphysiol.01254.2012 3 Le Meur Y et al (under review, Med Sci Sport Exerc)

## 6 WEEKS OF HIGH INTENSE INTERVAL TRAINING IMPROVES MITOCHONDRIAL RESPIRATORY CAPACITY BUT NOT VO2MAX

Dohlmann, T., Hindsø, M., Larsen, S., Dela, F., Helge, J.W.

*University of Copenhagen*

**Introduction** Alteration in mitochondrial respiratory capacity has been linked to several conditions that are associated with a sedentary lifestyle, such as obesity and insulin resistance. It is well known that endurance training can diminish these conditions, but some high intensity interval training (HIIT) protocols have shown similar improvements in insulin sensitivity, in spite of the reduced training volume. However it is sparse with literature regarding HIIT and the effect on mitochondrial respiratory capacity. The aim of this study was to investigate the effects of a low volume HIIT protocol on mitochondrial respiratory capacity and VO<sub>2</sub>max in sedentary overweight adults. **Methods** 8 healthy sedentary men (n=2) and women (n=6) (age  $40 \pm 3$  yrs, BMI  $32 \pm 2$ , VO<sub>2</sub>max  $2383 \pm 115$  ml·min<sup>-1</sup>) were recruited for this study. They underwent 6 weeks of supervised HIIT on a cycle ergometer (18 sessions of 7x1min exercise bouts interspersed with 1min rest periods). Muscle biopsies were taken from m. vastus lateralis before and after training. Mitochondrial respiratory capacity was measured ex vivo in permeabilized muscle fibers using high resolution respirometry (Oxygraph-2k, Oroboros, Innsbruck, Austria). The respiratory protocol investigated maximal coupled state 3 respiration (complex I + II linked substrates) with the following substrates (malate, glutamate, octanoyl carnitine, succinate and ADP; GMSO3), as well as state 4o (oligomycin; LEAK). Body composition was measured by DXA and VO<sub>2</sub>max using an incremental cycle test to exhaustion. **Results** Mitochondrial respiratory capacity increased significantly following training; GMSO3 respiration increased by 13% ( $57 \pm 4$  to  $64 \pm 5$  pmol O<sub>2</sub>·mg<sup>-1</sup>·s<sup>-1</sup>) and LEAK respiration increased by 24% ( $21 \pm 2$  to  $25 \pm 2$  pmol O<sub>2</sub>·mg<sup>-1</sup>·s<sup>-1</sup>). The present training protocol didn't elicit a significant improvement in VO<sub>2</sub>max (4%,  $P = 0.37$ ), but time to fatigue during the VO<sub>2</sub>max test was significantly increased by 18% post training ( $P < 0.001$ ). BMI and body composition were not changed following training. **Discussion** Interestingly the present training protocol induced a significant improvement in mitochondrial respiratory capacity, but not in whole body VO<sub>2</sub>max, thus implying that the training stimulus was adequate to improve the respiratory capacity locally. The observed improvement in mitochondrial function and time to fatigue suggest that the HIIT training may induce positive metabolic effects that can attenuate the development of lifestyle diseases, independently of VO<sub>2</sub>max. The project is funded by the EU FP7 program

## MITOCHONDRIAL RESPIRATORY CAPACITY IN SKELETAL MUSCLE DOES NOT CHANGE AFTER HIGH INTENSITY INTERVAL TRAINING IN PATIENTS WITH TYPE 2 DIABETES

Bjerre Andersen, N., Skaaby, S., Pedersen, H.P., Nielsen, M.B., Petersen, H.H.H., Helge, J.W., Dela, F.

*University of Copenhagen*

**Introduction:** High intensity interval training (HIIT) has been shown to effectively increase biomarkers (citrate synthase (CS) activity) of mitochondrial content in skeletal muscle in healthy subjects (1). Whether this finding also translates into increased oxidative respiratory capacity remains to be shown. In addition, the effect of HIIT in insulin resistant muscle has never been elucidated. **Methods:** Eight patients with type 2 diabetes (T2DM) (age  $58 \pm 2$  yrs; BMI  $32 \pm 1$  kg/m<sup>2</sup>; HbA1C  $7.2 \pm 0.3\%$ ; maximal oxygen uptake (VO<sub>2</sub>max):  $27 \pm 1$  ml/min/kg) and four healthy controls (CON) (age  $53 \pm 2$  yrs; BMI  $29 \pm 1$  kg/m<sup>2</sup>; HbA1C  $5.5 \pm 0.1\%$ ; VO<sub>2</sub>max:  $31 \pm 3$  ml/min/kg) performed 8 supervised one-legged training sessions on a bicycle ergometer (10 x 1 minute HIIT alternating with 1 min rest; workload > 60% of one-legged VO<sub>2</sub>-peak; heart rate > 80 % of maximal heart rate). This protocol significantly improved skeletal muscle insulin sensitivity (2). 40 hrs after last training session a muscle biopsy from v. lateralis was taken. Mitochondrial respiratory capacity was measured (Oroboros 2k, Innsbruck, Austria) in freshly prepared permeabilized fibers, and O<sub>2</sub> flux was recorded during state 2 (using Glutamate and Malate for complex I respiration (GM2)), state 3 (addition of ADP (GM3) and finally with further addition of Succinate for respiration with dual electron input to complex I+II as substrates (GMS3)). Differences were tested by 2 way ANOVA for repeated measures. **Results:** Mitochondrial respiration was similar ( $P > 0.05$ ) in trained (T) vs. untrained (UT) muscle at all three respiratory states in T2DM (GM2:  $9 \pm 3$  vs.  $9 \pm 2$ ; GM3:  $48 \pm 7$  vs.  $43 \pm 5$ ; GMS3:  $82 \pm 8$  vs.  $79 \pm 6$  pmol O<sub>2</sub>/sec/mg muscle, respectively) and in CON (GM2:  $9 \pm 1$  vs.  $8 \pm 1$ ; GM3:  $49 \pm 5$  vs.  $47 \pm 7$ ; GMS3:  $97 \pm 9$  vs.  $94 \pm 14$  pmol O<sub>2</sub>/sec/mg muscle, respectively). Likewise, respiratory rates were similar ( $P > 0.05$ ) between T2DM and CON. **Conclusion:** We confirm that mitochondrial respiration is similar in T2DM and CON. The accumulated 80 minutes of effective exercise cannot improve mitochondrial respiratory capacity. There is an apparent discrepancy between literature reports on HIIT induced CS activity and mitochondrial respiratory capacity. 1. Hood, M.S., et al. ### MITOCHONDRIAL RESPIRATION CHANGING AFTER REPEATED-CYCLING-SPRINTS PERFORMED UNDER CLASSIC ACIDOSIS AND INDUCED-ALKALOSIS.

Delfour-Peyrethon, R.1,2, Thomas, C.1,4, Hanon, C.1, Granata, C.3, Bishop, D.3

*INSEP*

1 INSEP, (Paris-France) 2 MIP, (Nantes-France) 3 ISEAL, (Melbourne-Australia) 4 University of Evry Val d'Essonne, (Evry-France) Introduction It has previously been demonstrated, in humans, that three maximal cycling bouts were sufficient to increase maximal stimulated respiration in human mitochondria after 110min of recovery (Tonkonogi et al.). In line of this result, we aimed to specifically investigate the role of acidosis on different mitochondrial respiration state alterations. Methods On two separate weeks, height active males performed a 3x30sec Wingate Test either under acidosis, after placebo ingestion, or 90min after sodium bicarbonate ingestion (0.3g.kg<sup>-1</sup> NaHCO<sub>3</sub>; randomized, double-blind fashion). Each sprint was separated by 20min of passive recovery. Blood samples were taken before exercise and during recovery for pH and bicarbonate concentrations ([HCO<sub>3</sub><sup>-</sup>]). Mitochondrial respiration was recorded by Oroboros systems using permeabilized fibers from muscle biopsies, performed on the Vastus Lateralis at rest and 24h after exercise (Pesta and Gnaiger). Results NaHCO<sub>3</sub> supplementation was effective to increase pH and [HCO<sub>3</sub><sup>-</sup>] pre-exercise and until the end of the sprints compared to placebo (pHend 7.27±0.1 vs 7.14±0.1; [HCO<sub>3</sub><sup>-</sup>]end 14.1±4.8 vs 9.9±3.6 respectively). There were no performance differences (maximal power, mean power, fatigue index) between acidosis and alkalosis conditions. Maximal respiration (Vmax) was significantly lower (-32.5%; P<0.01) 24h after exercise in alkalosis condition, whereas Vmax was maintained with placebo. Furthermore, submaximal respiration state 2 and 4 were not impaired in both conditions after 6h and 24h of recovery. Discussion In conclusion, our results suggested that Vmax was significantly decreased 24h after an acute repetition of all-out cycling sprints performed under induced alkalosis in humans, but not under classic acidosis. These difference responses could be due to an inhibition of activating mitochondrial respiration signal(s), such as Reactive Oxygen Species, under alkalosis conditions. References M. Tonkonogi, B. Walsh, T. Tiivel, V. Saks, K. Sahlin. (1999) Eur J Physiol 437:562–568. Pesta D. and Gnaiger E. (2011) Mitochondrial Bioenergetics: Methods and Protocols. rt authors here

### BRACHIAL ARTERY CHARACTERISTICS IN WELL-TRAINED ROCK CLIMBERS

Thompson, E.B., Farrow, L., Hunt, J.E.A., Lewis, M.P., Ferguson, R.A.

*Loughborough University*

Introduction Rock climbers represent a trained cohort in which high-force intermittent isometric forearm muscle contractions are performed. Subsequently the forearm vasculature is subjected to repeated ischaemia and distorted haemodynamic signals. Adaptation of the peripheral vasculature, such as an augmented post occlusion reactive hyperaemia has previously been observed in rock climbers (Ferguson and Brown, 1997), however the effects within upstream conduit arteries is unknown. Therefore, the aim of this study was to investigate brachial artery function and structure in well-trained rock climbers in comparison to age-matched sedentary control participants. Methods 8 well-trained rock climbers (CLIMB) (age; 24 ± 3 yrs, height; 180 ± 11 cm, body mass; 72 ± 8 kg, isometric handgrip strength; 46 ± 8 kg) with a minimum of 3 years climbing experience were compared against 8 controls (CON) (age; 23 ± 2 yrs, height; 175 ± 7 cm, body mass; 73 ± 12 kg, isometric handgrip strength; 37 ± 9 kg). Brachial artery characteristics were assessed using Doppler ultrasound. Artery diameter and blood flow were measured at rest and following 5-mins of ischemia (peak diameter) and ischemic exercise (maximal dilation) to calculate flow mediated dilation (FMD; i.e. function) and dilatatory capacity (DC; i.e. structure). Independent t-tests were used to compare the differences between the two groups and significance was accepted at P < 0.05. Data are presented as mean ± SD. Results Resting (4.30 ± 0.26 vs. 3.79 ± 0.39 mm), peak (after 5 minutes ischaemia; 4.67 ± 0.31 vs. 4.12 ± 0.45 mm) and maximal (after ischaemic exercise; 5.14 ± 0.42 vs. 4.35 ± 0.47 mm) diameters were greater (P < 0.05) in CLIMB than CON, respectively, despite no difference in FMD (9.2 ± 2.6 vs. 8.7 ± 2.9 %). Peak reactive hyperaemic blood flow (1136 ± 504 vs. 651 ± 221 ml/min) was greater (P < 0.05) in CLIMB compared to CON. Discussion These data demonstrate that well-trained rock climbers exhibit greater arterial diameters compared to sedentary control participants. Moreover, there was no difference in FMD between groups. These results are in accordance with the 'athlete's artery' paradigm (Green et al., 2012) of an enlarged arterial lumen despite being functionally 'normal'. The present data, together with the observations of resistance vessel adaptations (Ferguson and Brown, 1997) clearly demonstrate an enhanced peripheral vasculature in rock climbers and offer a unique insight into vascular adaptation with chronic training in intermittent blood flow restricted conditions. References Ferguson R A and Brown M D. (1997). Eur J Appl Physiol, 76, 174-180. Green D J, Spence A, Rowley N, Thijsen D H J and Naylor L H. (2012). Exp Physiol, 97(3), 295-304.

### GHRELIN LEU72MET POLYMORPHISM AFFECTS A RELATIONSHIP BETWEEN HDL CHOLESTEROL AND CARDIORESPIRATORY FITNESS LEVEL IN MIDDLE AND OLDER ADULTS.

Kono, S.1, Iemitsu, M.1, Murakami, H.2, Fujie, S.1, Sanada, K.1, Kawano, H.3, Gando, Y.3, Kawakami, R.2, Tanaka, N.2, Miyachi, M.2

*1) Faculty of Sport and Health Science, Ritsumeikan University 2) Health Promotion and Exercise Program, National Institute of Health and Nutrition 3) Waseda University*

BACKGROUND Ghrelin (GHRL) Leu72Met polymorphism is associated with metabolic syndrome risk factors, such as body fat, fasting blood glucose, and HDL cholesterol level. Habitual exercise brings higher cardiorespiratory fitness and results in improvement of metabolic syndrome risk factors. However, the effect of GHRL Leu72Met on the relationship between cardiorespiratory fitness level and metabolic syndrome risk factors remains unclear. PURPOSE The aim of present study was to clarify whether GHRL Leu72Met polymorphism affects change in metabolic syndrome risk factors that is associated with cardiorespiratory fitness level in the healthy Japanese adults. METHODS Healthy 829 Japanese men and women participated in this study. As an index of cardiorespiratory fitness, we measured peak oxygen uptake (VO<sub>2peak</sub>) during an incremental cycle ergometer exercise test. The study subjects were divided into 4 groups according to fitness level and age, younger High-Fit and Low-Fit groups (age < 40 yr) and middle-aged/older High-Fit and Low-Fit (age ≥ 40 yr), that the division of fitness groups based on the median value of VO<sub>2peak</sub> in each sex and decade. GHRL Leu72Met polymorphism was determined by real-time PCR with Taqman probe. All subjects measured body composition by using DXA, blood pressure and blood profiles, as the metabolic syndrome factor risks. RESULTS Body mass index, body weight, % body fat, triglycerides, fasting glucose and HbA<sub>1c</sub> were lower and HDL cholesterol and VO<sub>2peak</sub> were higher in High-Fit subjects compared with in Low-Fit subjects. However, there were no significant differences in metabolic syndrome parameters between LeuLeu and LeuMet+MetMet genotypes in GHRL Leu72Met polymorphism. In the middle and older age subjects, HDL cholesterol level in the LeuLeu genotype is significantly higher than that in the LeuMet+MetMet genotype (P<0.05) in the High-Fit group. However, in the Low-Fit group, there was no significant difference between two

genotypes. Additionally, in the younger subjects, there were no significant differences between ghrelin genotype and fitness levels. CONCLUSION These results suggest that GHRL Leu72Met polymorphism affects the change in HDL cholesterol that is associated with higher cardiorespiratory fitness level in the healthy middle and older adults. ### THE ERGOGENIC EFFECT OF OXYGENATION ON HYPOXIA-INDUCED CENTRAL FATIGUE DEPENDS LINEARLY ON THE PIO<sub>2</sub> AND THE IMPROVEMENT IN SAO<sub>2</sub>

Losa-Reyna, J.1, Torres-Peralta, R.1, Ponce-González, J.G.1, Morales-Alamo, D.1, Perez-Suarez, I.1, Calle-Herrero, J.1, Lundby, C.2, Calbet, J.A.1

*1University of Las Palmas, 2University of Zürich*

Introduction Rapid oxygenation relieves fatigue during maximal exercise in severe hypoxia. The ergogenic effect of re-oxygenation has been observed when the level of hypoxia during exercise is high (inspiratory PO<sub>2</sub> (PIO<sub>2</sub>)<86 mmHg) but not in moderate hypoxia (PIO<sub>2</sub>=104 mmHg). Thus there must be threshold values for PIO<sub>2</sub>, P<sub>ET</sub>O<sub>2</sub> and SaO<sub>2</sub> at which oxygenation relieves fatigue. Methods To determine if such thresholds exist and to explore if re-oxygenation at exhaustion in hypoxia restores VO<sub>2</sub>max, ten healthy young men (age = 21.0 ± 2.0 yr, VO<sub>2</sub>peak = 3.6 ± 0.3 L/min; mean ± SD) performed six incremental exercise test to exhaustion (20W/min). The first two test were performed in random order in normoxia or hypoxia (PIO<sub>2</sub>=74 mmHg) and femoral venous and arterial blood gases were determined. The next four incremental exercise tests were composed of an initial incremental phase in severe hypoxia (PIO<sub>2</sub>=74 mmHg) (HYP1) until exhaustion (Exh1). At Exh1, subjects were strongly encouraged to continue the exercise (HYP2) when at the same time PIO<sub>2</sub> was changed swiftly to either 74 (placebo), 82, 91 or 99 mmHg. After 2 min the load was increased by 20 W/min until exhaustion (Exh2). At Exh2, the PIO<sub>2</sub> was increased to 142 mmHg (normoxia; NX3) and after 2 min of additional exercise, the load was increased by 20 W/min until exhaustion (Exh3). Results In HYP1, VO<sub>2</sub>peak was uniformly reduced by 33% (P<0.05). There was a placebo effect, i.e., an ergogenic effect of a sham increase in PIO<sub>2</sub> (42±20; range 16-88 seconds). Exercise performance (W<sub>peak</sub>, time to exhaustion and work performed) was increased significantly when at Exh1 the PIO<sub>2</sub> was increased from 74 to 99 and 142 mmHg, respectively. The improvement in work (ΔW) was predicted by the equation ΔW= (1.76\*ΔSaO<sub>2</sub>) + (0.16\*P<sub>ET</sub>O<sub>2</sub>) -11.04 KJ (R<sup>2</sup>=0.99, P<0.001), where the change in SaO<sub>2</sub> and the level of P<sub>ET</sub>O<sub>2</sub>, explained 97% and 2% of the variance in work added at exhaustion in hypoxia with oxygenation, respectively. Increasing PIO<sub>2</sub> at exhaustion transiently reduced pulmonary ventilation and increased P<sub>ET</sub>CO<sub>2</sub>, but this effect was only significant for the highest PIO<sub>2</sub> (142 mmHg). Conclusions Fatigue is caused by a predominantly centrally mediated mechanism during exercise in hypoxia as demonstrated by the existence of a placebo effect. The ergogenic effect of re-oxygenation depends linearly on the improvements elicited on SaO<sub>2</sub> and PaO<sub>2</sub>. Regardless of the level of hypoxia at exhaustion, re-oxygenation allows restoring VO<sub>2</sub>peak and the ability to continue exercising. The gain in exercise capacity following re-oxygenation depends on the severity of peripheral fatigue, such that when the level of hypoxia is moderate, oxygenation does relieve fatigue but the gain in exercise capacity is small since peripheral fatigue will be the predominant source for terminating the exercise task. ### AN EXPLORATION OF AFTERLOAD DEPENDENT RELAXATION AS A COMPONENT OF VENTRICULAR ARTERIAL INTERACTION USING SPECKLE TRACKING ECHOCARDIOGRAPHY AND PULSE WAVE ANALYSIS AT REST AND DURING EXERCISE

Kearney, M., Stöhr, E., Black, J., Backx, K., Yousef, Z., Cockcroft, J., Shave, R.

*Cardiff Metropolitan University, Wales Heart Research Institute, University Hospital Wales*

Introduction Optimal LV relaxation is essential for exercise performance. The onset of LV relaxation is dependent on the timing of the arterial load and is termed 'afterload-dependent relaxation' (ADR). ADR requires effective ventricular-arterial interaction (VAI). However, the classic measure of VAI, the ratio of arterial (E<sub>a</sub>) and ventricular (E<sub>es</sub>) elastances, may not reflect ADR as E<sub>es</sub> is a global measure of LV systolic function and E<sub>a</sub> does not take into account the timing of arterial load. Speckle tracking echocardiography (STE) allows for regional quantification of LV mechanics throughout the cardiac cycle and pulse wave analysis (PWA) provides the timings associated with the arterial pressure waveform. We hypothesise that the combination of STE and PWA will be a better method to capture ADR compared to E<sub>a</sub>/E<sub>es</sub>. In order to test this hypothesis, STE, PWA and E<sub>a</sub>/E<sub>es</sub> were measured at rest and during exercise. Methods 11 (8 male) healthy participants (28±9yrs) underwent simultaneous STE and PWA at rest and during sub-maximal exercise on a supine cycle ergometer. E<sub>es</sub> was derived using a single beat method which employs a normalised elastance value at end diastole that is adjusted for individual hemodynamics. E<sub>a</sub> was calculated by the ratio of end-systolic pressure to stroke volume. Results During exercise there were significant increases in heart rate (54±7 vs 86±11 bpm, p<0.000), end diastolic volume (115±31 vs 125±31 ml, p<0.04) and ejection fraction (57±4 vs 62±4 %, p<0.003). While there was a significant decrease in E<sub>a</sub>/E<sub>es</sub> (0.59±0.95 vs 0.41±0.45 mmHg/ml, p<0.000), it was not accompanied by significant changes to E<sub>a</sub> or E<sub>es</sub>. However, the timing of the reflected wave (Tr) was shortened from 159±19 to 142±9 ms (p<0.002) and this was paralleled by reductions in time to peak (TTP) in diastolic; apical rotational velocity (517±94 vs 384±73 ms, p<0.000); basal circumferential strain rate (507±54 vs 444±69 ms, p<0.01); apical circumferential strain rate (543±44 vs 466±43 ms, p<0.000) and longitudinal strain rate (518±37 vs 436±33 ms, p<0.000). Discussion In line with our hypothesis, STE and PWA captured significant changes in arterial and LV diastolic function that were not reflected in E<sub>a</sub> or E<sub>es</sub>. A shortened Tr accompanied by reductions in TTP of key diastolic LV mechanical variables may suggest that early arrival of arterial systolic load is beneficial for LV relaxation. Consequently, STE and PWA have the potential to be able to quantify ADR and if used in conjunction with E<sub>a</sub>/E<sub>es</sub>, may provide a comprehensive analysis of VAI throughout the cardiac cycle.

### THE CLINICAL UTILITY OF AN ACCELEROMETER FOR MEASURING HABITUAL PHYSICAL ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: A LONGITUDINAL STUDY.

Prioreschi, A., Hodkinson, B., Avidon, I., Tikly, M., McVeigh, J.

*University of the Witwatersrand*

This study aimed to assess changes in disease activity, as well as changes in objectively measured physical activity levels (using actigraphy) in response to commencement of Disease Modifying Anti Rheumatic Drug (DMARD) therapy in drug-naïve patients with rheumatoid arthritis (RA). Eighteen RA patients completed this study as did 18 age, sex and body mass index matched healthy control participants. At baseline, and again after three months, Actical accelerometers were fitted on the dominant hip of each participant for two weeks; and RA patients completed disease activity and functionality questionnaires. After three months of drug therapy, patients had significant improvements in disease activity as assessed by the clinical disease activity index (p<0.001) and functional ability as assessed

by the health assessment questionnaire ( $p < 0.001$ ). In parallel with these changes, the average activity counts in sedentary thresholds decreased after three months in the RA patients ( $p = 0.010$ ), while average activity counts within higher intensity thresholds increased. At baseline, RA patients showed diurnal differences in physical activity compared with healthy controls. RA patients were less physically active than control participants in the morning ( $p = 0.048$ ), and in the late afternoon ( $p = 0.016$ ), yet these diurnal patterns were no longer different after the DMARD intervention. Multiple regression showed that the change in the level of moderate activity between baseline and follow up was most highly associated with a change in C-reactive protein ( $\beta = -0.922$ ,  $p = 0.026$ ). The decreases in sedentary activity and increases in moderate activity were most strongly associated with decreased morning stiffness of the joints ( $\beta = 0.694$ ,  $p = 0.035$  and  $\beta = -0.927$ ,  $p = 0.024$  respectively). In conclusion, DMARD therapy significantly improved disease activity in patients with RA, and these improvements were paralleled by improvements in physical activity. Actigraphy data were also significantly correlated with multiple, well-validated disease activity measures showing the validity of actigraphy as an objective outcome measure of RA.

### OXYGENATION AND NEUROMUSCULAR RESPONSES DURING SIMULATED UPWIND SAILING EXERCISE ON A LASER ERGOMETER

Callewaert, M.1, Geerts, S.3, Lataire, E.3, Boone, J.1,2, Celie, B.1, De Clercq, D.1, Vantorre, M.3, Bourgois, J.G.1,2  
Ghent University

**Introduction** During upwind sailing, Laser sailors place their feet under a hiking strap and the middle of the thigh on the edge of the boat in order to increase up-righting moment by extending parts of the upper body further outside the boat (i.e. hiking). Our study aims to explore muscle oxygen extraction and muscle activation pattern by combining Near-infrared Spectroscopy (NIRS) and Electromyography (EMG) measurements from the M. Vastus Lateralis during an upwind sailing test (UST) on a sailing ergometer. The sailing ergometer, which measures hiking moment accompanied with a computerized biofeedback-system allows us to impose a certain quasi-isometric UST. **Methods** Ten male high-level Laser sailors ( $18.5 \pm 2.0$  yrs;  $180.9 \pm 4.7$  cm;  $72.3 \pm 4.8$  kg) performed a left (IsomQL) and right (IsomQR) leg maximal voluntary isometric knee-extensor strength test at  $120^\circ$  knee angle as well as an UST (18 bouts of 90s hiking at constantly varying intensity interspersed with 10s to tack). Deoxygenated hemo- and myoglobin concentration (deoxy[Hb+Mb]) and reoxygenated [Hb+Mb] (reoxy[Hb+Mb]) were expressed relative to occlusion amplitude performed before protocol (NIRS). Mean Power Frequency (MPF) and Root Mean Square (RMS) were calculated for each bout as mean of the final 10 s and expressed relative to the MPF or RMS value during the first bout (EMG). Repeated measures ANOVA was conducted to investigate significant changes in deoxy[Hb+Mb], reoxy[Hb+Mb], MPF and RMS throughout bout 1, 5, 10, 15 and 18. Pearson correlation coefficient was used to test the relationship between MPF at bout 18 (MPF18) and maximal voluntary isometric knee-extensor strength. **Results** Muscular responses to UST can be divided into 3 phases: (1) a significant initial increase in deoxy[Hb+Mb] and RMS as well as a decrease in reoxy[Hb+Mb] and MPF (bout 1-10;  $p < 0.01$ ); (2) a significant steady state phase (bout 10-15;  $p < 0.01$ ); (3) a clearly visible, though not significant, increase in deoxy[Hb+Mb] and RMS and decrease in reoxy[Hb+Mb] and MPF (bout 15-18). Significant correlation were found between MPF18 on the one hand and IsomQL ( $R = 0.727$ ;  $p = 0.027$ ) and IsomQR ( $R = 0.809$ ;  $p = 0.008$ ) on the other hand. **Discussion** Sailors show three distinct phases in muscle oxygen extraction and muscle activation pattern during UST. Quick muscle oxygen restoration during tacking, changes in muscle activation pattern (i.e. more accurate recruitment of slow-twitch fibres) and maximal voluntary isometric knee-extensor strength seems to be crucial determinants which delay muscle fatigue during hiking in upwind sailing.

### SAMPLING TIME INFLUENCES THE DETERMINATION OF MUSCLE WATER AND ELECTROLYTE CHANGES AFTER DEHYDRATING EXERCISE

Fernández-Elías, V.E., Hamouti, N., Ortega, J.F., Mora-Rodriguez, R.  
Universidad de Castilla-La Mancha

During prolonged dehydrating exercise contracting skeletal muscle is highly perfused maintaining intracellular water content whereas intravascular water content (i.e., blood) markedly declines. After exercise, osmotic forces shift fluid from the intracellular space (i.e., muscle) to defend the intravascular fluid space; (1)). Thus, it is possible that sampling muscle before fluid re-equilibration may lead to the conclusion that water in previously active muscle is preserved (2) to aid on substrate recovery or waste product elimination despite whole body dehydration. **Purpose:** To determine if sampling time (i.e., by muscle biopsy) affects the measurement of muscle water content and electrolytes (i.e. sodium and potassium) of previous active muscle after whole body dehydration. **Methods:** Seven aerobically-trained cyclists ( $VO_{2max}$ :  $53 \pm 3$  ml/kg/min) exercised during 150 minutes ( $65\% VO_{2max}$ ) in a hot-dry environment ( $33^\circ\text{C}$ ; 30% rh, 2.5 m/s air flow) dehydrating by  $4.6 \pm 0.3\%$ . Blood samples were drawn at baseline and after 15, 60, 120 and 150 min of exercise to calculate plasma volume (PV) changes. Muscle samples were taken before exercise, right after dehydrating exercise, 1 hour and 4 hours after exercise to measure muscle water content (i.e.,  $H_2O_m$ ) and electrolytes. **Results:** At the end of exercise, PV declined by  $-18\%$  ( $P < 0.05$ ) whereas it was progressively recovered after 60 min of supine rest ( $-10\%$ ;  $P < 0.05$ ) and 4 h of rest (i.e.,  $-3\%$ ;  $P < 0.05$ ). Muscle water content and electrolytes concentration right after exercise were similar to pre-exercise. However, after 60 min of supine rest, muscle water content decreased from  $398$  to  $354$  mL/100g dm ( $P < 0.05$ ) remaining low after 4 hours of rest ( $357$  mL/100g dm). Muscle sodium and potassium concentration increased after 60 min of supine rest ( $9.4$  to  $11.1$  and  $46.1$  to  $47.2$  mmol/L respectively;  $P < 0.05$ ) remaining at those concentrations after 4 hours of rest ( $11.6$  and  $47.5$  mmol/L, respectively). **Conclusion:** Exercise-induced whole body dehydration also results in water deficit in contracting skeletal muscle. For accurate assessment of the effects of dehydration on muscle water content and electrolyte concentration, supine recovery for at least one hour is required to reach fluid re-equilibration. **References** 1. ### THERMOREGULATORY RESPONSES AND FLUID BALANCE DURING MEDICAL RESPONSE FORCE DEPLOYMENT

Ang, W.H.1, Teo, Y.S.1, Ong, C.C.2, Lee, K.W.1,3,4

1: DSO National Laboratories, Singapore, 2: Medical Response Force, Singapore, 3: National University of Singapore, Singapore, 4: Nanyang Technological University, Singapore

**INTRODUCTION** Physical activity undertaken in uncompensable heat stress imposes risk of heat injuries and compromises work tolerance (Taylor, 2006, Cheung et al, 2000). Many past studies on uncompensable heat stress were done in laboratories. This study evaluated the thermoregulatory responses and fluid balance of Medical Response Force deployment during day and night. **METHODS** Sixty-two male

military personnel (Mean $\pm$ SD; 21 $\pm$ 1 years; 1.71 $\pm$ 0.06 m; 68.6 $\pm$ 11.7 kg; BMI: 23.3 $\pm$ 3.6; body surface area: 1.79 $\pm$ 0.16 m<sup>2</sup>) participated in day and night trials wearing different protective suits: semi-permeable Paul Boyle suit (NT) and impermeable Tyvek suit (T). Each trial was over two 1 h work-rest cycles (Day: 35 min work/25 min rest; Night: 45 min work/15 min rest). Core temperature (Tc), skin temperature (Tsk) and heart rate (HR) were measured continuously. Sweat loss was calculated based on change in nude body mass before and after each trial, fluid intake and urine output. RESULTS WBGT for day and night trials were 31.0 $\pm$ 0.3 °C and 25.7 $\pm$ 0.2 °C respectively (p<0.001). There was no difference in mean Tc (38.0 $\pm$ 0.3 °C), Tsk (35.5 $\pm$ 0.8 °C) and HR (119 $\pm$ 16 bpm) between the day and night trials, and between the two suits (p>0.05). NT resulted in higher mean Tsk compared to T in the day trial (NT: 36.3 $\pm$ 0.5 °C; T: 35.4 $\pm$ 0.8 °C; p<0.001). Mean HR was higher in NT compared to T during the 2nd work-rest cycle in both the day (NT: 128 $\pm$ 17 bpm; T: 111 $\pm$ 19 bpm; p<0.05) and night trials (NT: 113 $\pm$ 15 bpm; T: 103 $\pm$ 15 bpm; p<0.001). Mean sweat loss rate was also higher for NT as compared to T in both day (NT: 0.77 $\pm$ 0.27 L/h; T: 0.56 $\pm$ 0.35 L/h; p<0.05) and night trials (NT: 0.62 $\pm$ 0.25 L/h; T: 0.38 $\pm$ 0.13 L/h; p<0.001). NT replaced higher % of the sweat loss with fluid intake as compared to T in both the day (NT: 43 $\pm$ 22 %; T: 29 $\pm$ 22 %; p<0.05) and night trials (NT: 38 $\pm$ 24 %; T: 22 $\pm$ 23 %; p<0.05). CONCLUSION This study validated that the Medical Response Force work-rest cycle was safe in both day and night deployments. Higher Tsk and sweat rate of NT compared to T during the day was due to higher work rate during the 2nd work-rest cycle, as supported by the HR data. Therefore, it was metabolic heat production that contributed more to heat strain when working under uncompensable heat stress rather than the heat dissipation properties of the suits studied. Fluid replacement was impractical and inadequate when wearing the two suits. Thus, a fluid replacement regime should be implemented to prevent risk of excessive dehydration, especially during extended training or operation. ### SYSTEMATIC REVIEW AND META-ANALYSIS OF TRAINING MODE, IMAGING MODALITY AND BODY SIZE INFLUENCES ON THE MORPHOLOGY AND FUNCTION OF THE MALE ATHLETE'S HEART

Utomi, V., Oxborough, D., Whyte, G., Somauroo, J., Sharma, S., Shave, R., Atkinson, G., George, K.

*Liverpool johnmoores university*

**Introduction** The athlete's heart (AH) remains a popular topic of study. Controversy related to training-specific cardiac adaptation and continuing developments in imaging technology and scaling prompted this systematic review and meta-analysis. **Methods** A systematic review and mixed-random effect meta-analysis of the means of left (LV) and right (RV) ventricular structures and function as well as left atrial diameter (LAD) was conducted on 92 records. Using inverse-variance pooled mean estimates, the impact of endurance vs. resistance training and echocardiography vs. cardiac magnetic resonance (CMR) imaging were explored between groups. The relationships between LV, RV and LAD with body surface area (BSA) were assessed via multiple meta-regression models. **Results** All LV structural parameters were higher in athletes compared with controls. LV end-diastolic dimension and volume were higher in endurance compared to resistance athletes 54.8mm (54.1-55.6) vs. 52.4mm (51.2-53.6) & 171ml (157-185) vs. 131ml (120-142). RV end-diastolic volume, mass and LAD were higher in endurance athletes than controls. LV end-diastolic volume was larger when using CMR than echocardiography 171ml (157-185) vs. 131ml (120-142). Meta-analysis regression models demonstrated positive and significant associations between BSA and LV mass, RV mass and LAD. **Discussion** Both athlete groups present with a similar qualitative cardiac adaptation on a continuum, with greater cardiac dimensions in endurance athletes reflecting a greater overall training volume. The use of CMR resulted in a higher LVEDV than echocardiography and this agrees with previous comparative studies (Prakken et al 2008 & LaGerche et al 2011). Our research was limited by lack of proper allometric scaling in most studies. Nevertheless the positive correlation between BSA and measures of cardiac structure highlights the need to take account of individual variability in body size at individual study level (Dewey et al 2008). Morphological features of the male AH were noted in both athlete groups. The previously described training-specific pattern of concentric hypertrophy was not discerned in resistance athletes. These data should inform current knowledge of the AH and prompt ongoing research. **References** Lagerche A, Heidbuchel H et al. 2011. *Med Sci Sports Exerc*, 43, 974-81. ### EFFECTS OF REMOTE ISCHEMIC PRECONDITIONING ON HIGH-INTENSITY CYCLE PERFORMANCE

Kilding, A.E., Sequira, G., Wood, M.R.

*AUT University*

**Introduction** Sport-specific warm-ups are a standard component of most athletes' pre-competition routines. However, additional 'priming' methods may exist that may serve to optimize subsequent performance. Remote ischemic pre-conditioning (RIPC) is a passive intervention that involves brief periods of ischemia and reperfusion to induce a local and systemic effect that may serve to enhance physical performance. We aimed to determine the effect of RIPC on VO<sub>2</sub>max and 4 km laboratory time trial (TT) cycling performance. **Methods** An acute, single-blind, crossover design was adopted. After familiarization, 8 well-trained cyclists (age: 27.0  $\pm$  7.0 yrs) completed two incremental VO<sub>2</sub>max tests and two 4 km TT's, on a cycle ergometer, on separate days. Prior to each test, participants underwent RIPC or sham-IPC. RIPC involved 3 x 5 min bouts of thigh blood flow occlusion, interspersed with 5 min of reperfusion. Sham-IPC involved negligible occlusion for the same duration. To make inferences about true (population) values of the effect of RIPC on physiology and performance, the uncertainty in the effect was expressed as 90% confidence limits (CL) and as likelihoods that the true value of the effect represents substantial change. **Results** There was no substantial difference in VO<sub>2</sub>max between RIPC and sham-RIPC trials (-0.1  $\pm$  1.9%). However, there was a tendency for mean power output during the RIPC 4 km TT to be higher than during the sham-RIPC TT (2.2  $\pm$  2.0%; effect size: 0.18  $\pm$  0.15). **Discussion** While acute RIPC prior to incremental cycling appears to have minimal effect on aerobic capacity, the observed tendency for improved TT performance, albeit small, suggests that RIPC has potential to be a performance enhancer for well-trained athletes prior to high-intensity exercise.

**THE RELIABILITY OF TWO DIFFERENT SPRINT TESTS PERFORMED ON A NON-MOTORIZED TREADMILL**

Kirbschus, K., Fernandez-Fernandez, J., Wiewelhoeve, T., Raeder, C., Ferrauti, A.

*Ruhr-University Bochum*

**Introduction** The non-motorized treadmill (NMT) system initially reported by Lakomy (1984) has been used extensively to assess sprinting performance. However, there has been limited research into the reliability of different sprint tests (i.e., single or repeated sprint (RS) tests) using such systems. Therefore, the aim of this study was to determine the reliability of two different sprint tests on a NMT. **Methods** 17 male sport students (age:  $27.3 \pm 5.5$  yrs; height:  $1.78 \pm 0.05$  m; BMI:  $24.2 \pm 2.1$ ) participated in the study. After a standardized 10 min warm-up, subjects performed two non-randomized consecutive testing sessions separated by one week: a 10 s all-out sprint and 2 h later, a RS test consisted of 6 X 4 s all-out sprints, with 20 s passive recovery, on a NMT. Parameters analyzed included velocity, power output, step length and frequency and heart rate (HR). Additionally, blood lactate (La) values and oxygen uptake (VO<sub>2</sub>) were analyzed in eleven subjects. Reliability was obtained using intraclass correlation coefficient (ICC). **Results** The 10-s sprint showed moderate to high reliability for all the values analyzed (velocity: 0.911 (0.772-0.967); peak power: 0.881 (0.723-0.955); mean power: 0.855 (0.453-0.954); step length: 0.853 (0.644- 0.944), and step frequency: 0.823 (0.577-0.932)). The RS test also showed moderate to high reliability values (mean velocity: 0.963 (0.903-0.986); peak power 0.936 (0.835-0.976); mean power: 0.939 (0.771-0.980). Moreover, we found a moderate to high intraday reliability between velocity in the 10-s sprint and the first sprint of the RS on day one (0.927 (0.728-0.976)) and day two (0.895 (0.739-0.961)). **Results** also showed significantly higher ( $p < 0.01$ ) physiological load (i.e., VO<sub>2</sub>, La and HR) during the RS test compared to the 10-s sprint. **Discussion** and **conclusions** The present study showed that both tests, 10-s and RS, seem to be reliable in a group of sport students. We can suggest that because of its specificity (i.e., sprint) and laboratory conditions, the NMT could be a useful tool for testing and training. Regarding the differences between tests, the RS test is more demanding than the 10-s, but also seems to be more reliable. **References** Lakomy, H.K.A. (1984). **TRUNK MUSCLE ACTIVITIES DURING ABDOMINAL BRACING: COMPARISON AMONG MUSCLES AND EXERCISES**

Maeo, S., Takahashi, T., Takai, Y., Kanehisa, H.

*National Institute of Fitness and Sports in Kanoya*

**Introduction** Abdominal bracing is considered an effective exercise technique for spine stabilization training, and is often adopted in rehabilitation and/or fitness programs (Monfort-Panego et al. 2009). However, there is little information on how muscular activities during the task differ among the muscle groups located in the trunk and from those during other trunk exercises. The present study aimed to clarify muscular activity levels during abdominal bracing with respect to muscle- and exercise-related differences. **Methods** Ten healthy young adult men performed five static (abdominal bracing, abdominal hollowing, prone, side, and supine plank) and five dynamic (V-sit, curl-up, sit-up, and back extensions on the floor and on a bench) exercises. Surface electromyogram (EMG) activities of the rectus abdominis (RA), external oblique (EO), internal oblique (IO), and erector spinae (ES) muscles were recorded in each of the exercises. The EMG data were normalized to those obtained during maximal voluntary contraction of each muscle (% EMGmax). **Results** The % EMGmax value during abdominal bracing was significantly higher in IO ( $60 \pm 11\%$ ) than in the other muscles (RA:  $16 \pm 1\%$ , EO:  $28 \pm 4\%$ , ES:  $19 \pm 2\%$ ). In comparison to other exercises, the % EMGmax values for RA, EO, and ES were significantly lower in the abdominal bracing than in the V-sit and sit-up for RA and EO and back extension for ES muscle. However, the % EMGmax value for IO during the abdominal bracing was significantly higher than those in most of the other exercises including dynamic movements. **Discussion** Dynamic exercises involving spine flexion and extension are usually preferred for strengthening the trunk muscles (Hibbs et al. 2008). For non-athletes or patients with lower back pain, however, these are considered as advanced exercises which induce high loads to the lumbar spine. From a clinical point of view, therefore, static exercises are usually recommended for rehabilitation and/or fitness programs at the expense of muscular activity (Monfort-Panego et al. 2009). In IO muscle, nevertheless, abdominal bracing showed greater activity than most of the other exercises including dynamic ones. These results indicate that abdominal bracing is one of the most effective techniques for inducing a higher activation level in IO muscle even compared to dynamic exercises involving trunk flexion/extension movements. **References** Hibbs AE, Thompson KG, French D, Wrigley A, Spears I (2008). *Sports Med* 38: 995-1008 Monfort-Panego M, Vera-Garcia FJ, Sanchez-Zuriaga D, Sarti-Martinez MA (2009). *J Manipulative Physiol Ther* 32: 232-244

**SWIMMING ECONOMY ASSESSMENT AROUND THE MAXIMAL LACTATE STEADY STATE**

Pelarigo, J.G.1,2, Figueiredo, P.1,3, Ribeiro, J.1, Sousa, A.C.1, Pimenta, R.A.1, Padilha, M.B.1, Denadai, B.S.4, Fernandes, R.J.1,2, Greco, C.C.4, Vilas-Boas, J.P.1,2

**Introduction** Parameters related to swimming economy such as energy cost of locomotion (C, Kcal.kg<sup>-1</sup>.km<sup>-1</sup>) are not widely used to evaluate long-distance swim tests. However, C may be more sensitive to changes in speed as compared with more traditionally used parameters, such the measurement of oxygen uptake (Fletcher et al., 2009). Therefore, the objective of this study was to analyze swimming economy along the 97.5%, 100% and 102.5% of the maximal lactate steady state intensity (MLSS). **Methods** Ten female long-distance swimmers ( $17.5 \pm 1.8$  yrs,  $61.1 \pm 5.6$  kg,  $1.69 \pm 0.06$  m) performed, in different days, three to five 30min sub-maximal continuous tests to determine velocity, caloric equivalent (kcal.L<sup>-1</sup>) and oxygen uptake (VO<sub>2</sub>) corresponding to the 97.5%, 100% and 102.5%MLSS (Pelarigo et al., 2011). The VO<sub>2</sub> and the C values were analyzed along the continuous tests in seven moments (4thmin and 25, 33, 50, 66, 75 and 100% of the test duration) and compared between the different intensities by ANOVA repeated measures. The C was calculated as = VO<sub>2</sub> (L.min<sup>-1</sup>) \* caloric equivalent (Kcal.L<sup>-1</sup>) \* velocity<sup>-1</sup> (m.min<sup>-1</sup>) \* body mass<sup>-1</sup> (Kg) \* K<sup>-1</sup> (1000m.Km<sup>-1</sup>). **Results** The C values showed

similar adjustments in relation to the effect of time at intensities correspondent to 97.5% (mean:  $2.89 \pm 0.03$ ), 100% (mean:  $3.04 \pm 0.04$ ) and 102.5%MLSS (mean:  $3.18 \pm 0.03$ ). In relation to the effect of intensity, there were significant difference between 97.5% and 102.5%MLSS in all moments of the test, representing an increase of 8.5 to 11.7% among the values of C. Discussion Although swimming economy showed to be stable along the test at the three swimming intensities, when comparing the different intensities the swimming C was higher with increasing velocity, which suggests to be one of the fatigue determinant factors. ### CAN STRENGTH TRAINING ALTER THE PACING STRATEGY DURING A 10-KM RUNNING RACE?

Damasceno, M.V.1, Pasqua, L.A.1, Silva-Cavalcante, M.D.1, Correia-Oliveira, C.R.1, Santos, V.G.F.1, Lima-Silva, A.E.2, Bishop, D.J.3, Bertuzzi, R.1

1: USP (São Paulo, Brazil), 2: UFAL (Maceió, Brazil), 3: ISEAL (Melbourne, Australia)

**Introduction** Previous studies have indicated that the pacing strategy (PS) has a significant impact on endurance performance. It has been hypothesised that PS is centrally-controlled in order to protect the athletes from harmful changes to homeostasis and to prevent premature fatigue. In turn, current research indicates that endurance performance may also be improved by the addition of strength training (ST). However, the influence of ST on PS remains unknown. Therefore, the aim of this study was to investigate the impact of ST on PS during a 10-km running race. **Methods** Sixteen male, endurance runners were allocated to an experimental (EG, n=8) or control group (CG, n=8). The EG performed an 8-wk ST. Before and after the experimental period, the subjects performed: a) a maximal incremental treadmill test to determine the maximal oxygen uptake (VO<sub>2</sub>max) and peak treadmill velocity (PTV); b) a maximum dynamic strength test for the half-squat exercise (IRM), and c) a 10-km running race on a 400-m outdoor track to determine PS. Dependent variables were compared using 2-way ANOVA (group and moment as factors). A 2-way ANOVA with repeated measures (distance × moment) followed by a LSD post hoc was used to compare the running speed each 400 m within groups. The level set for significance was  $\alpha = 0.05$ . Results IRM and PTV were increased after training ( $p < 0.05$ ). However, there were no differences for VO<sub>2</sub>max ( $p > 0.05$ ). After the ST period, all athletes completed the 10-km time trial in shorter times ( $43:31 \pm 05:25$  vs  $42:22 \pm 04:36$ min:s); this approached statistical significance ( $p = 0.061$ ). An U-shaped profile of the speed vs distance curve pre and post training for both the groups was observed. However, for the post-training curve in EG there was a smaller reduction ( $p < 0.05$ ) and a large increase in speed during middle and last part (end spurt) of the race, respectively, compared to pre training. **Discussion** Our data revealed that IRM and PTV were improved after ST, while VO<sub>2</sub>max maintained unchanged. These mechanical variables have been associated with neuromuscular characteristics and so-called "muscle power factors", respectively. Interestingly, IRM and PTV gain were accompanied by a more sustainable PS, with a smaller speed reduction throughout the race and a more pronounced end spurt after ST. It seems reasonable to hypothesize that increased IRM and PTV could allow runners to sustain higher intensities by reducing the relative force generated at the same absolute running intensity. These findings clearly show that peripheral system has a crucial role on PS adopted during a long-distance running. **Acknowledgments** FAPESP (2011/02769-4)

### EFFICACY OF THE INJURY PREVENTION PROGRAM '11 +' ON ANTERIOR CRUCIATE LIGAMENT INJURY RISK FOR ADOLESCENT FEMALE SOCCER PLAYERS.

Saho, Y.1,2, Tsuda, M.1, Nakamura, C.2, Makoshi, H.2, Sanomura, M.2,3, Otomo, M.2, Fukubayashi, T.2

1: Teikyo University (Tokyo, Japan), 2: Waseda University (Tokyo, JAPAN), 3: Tokoha University (Shizuoka, Japan)

**Introduction** Anterior cruciate ligament (ACL) injury is one of the most severe injuries. To reduce these injuries, FIFA recommended the injury prevention program '11 +'. This program is useful in the prevention of injuries (Soligard et al.). However, it is unclear how this program helps reduce injuries. Recently, Myer et al. suggested the non-contact ACL injury risk prediction algorithm (Nomogram). This method employs the clinically obtainable measures of knee valgus motion, knee flexion range of motion, body mass, tibia length and quadriceps-to-hamstrings (Q/H) ratio. This predicts high knee adduction moment (KAM). So, the aim of this study was to examine that the '11 +' program could reduce risk of ACL injury using clinical based measurement. **Methods** Sixteen adolescent female soccer players participated (Age; 12-14 years). The players performed '11 +' every training session for 4 months. Before and after the intervention, two-dimensional (frontal and sagittal plane) knee kinematics data during drop vertical jump (DVJ) were captured with digital video camera (Myer et al.). Knee valgus motion and knee flexion range of motion were calculated from video frame at the initial contact, and the video frame at maximum knee valgus motion and maximum knee flexion. Body mass, tibia length and Q/H ratio were measured. Using these parameters, the points of the predicts high KAM were calculated by Nomogram in both knees. A paired t-test were used to determine the effect of the intervention ( $p < 0.05$ ). **Results** Total points of Nomogram were significantly higher after intervention than before intervention in both knees (before vs. after intervention in right and left knees; 71.9 and 68.8 points vs. 79.7 and 76.4 points,  $p < 0.05$ , this indicated the prediction of high KAM was increased). Analyzing the contents of total point, the points of tibia length were significantly higher after intervention than before intervention in both knees (31.9 and 41.4 vs. 31.5 and 42.2,  $p < 0.05$ ). The points of knee valgus motion was low after intervention comparing to before intervention, but not significantly in both knees (18.5 and 14.1 vs. 15.6 and 10.0). **Discussion** The results of this study, predicts risk of ACL injury rose after intervention. The reason of this results caused by lengthening the tibia, because the subjects of this study was adolescent. Otherwise, noting to knee motion, knee valgus motion were reduced. Knee valgus motion is one of the risk factor of ACL injury. This suggests that 11 + has possibility of prevention ACL injury. **References** Soligard T et al. (2008). *BJM*, 337, a2469. ### VALIDITY OF A VIDEO-BASED JUMP ASSESSMENT ON THE SAND IN BEACH VOLLEYBALL

Buscà, B.1, Peña, J.2,3, Alique, D.3, Hileno, R.3, Salas, C.3,1, Morales, J.1, Bantulà, J.1

1: Psychology, Education and Sport sciences Faculty of Blanquerna. Ramon Llull University (Barcelona), 2: University of Vic (Barcelona), 3: INEFC Lleida (University of Lleida)

**Introduction** Quick actions and different jumping abilities are the most important conditioning factors in beach volley. Blocking and attacking actions required a specific jump patterns on the sand. Hence, jumps and other movement are different from its indoor counterparts because the compliance and friction of the surface. Bishop (2003) found a 5% decrease of performance in block jump in comparison to rigid surface (but  $r = 0.93$ ;  $p < 0.01$ ) and Giatsis et al. (2004) a 13.9% of decrease in SJ (but  $r = 0.89$ ;  $p < 0.01$ ). Difficulties to display a contact

mat or a force platform on the sand are evident. The aim of the study was to test the validity of a video-based protocol to assess the jump in blocking actions on the sand. Methods 17 national-standard beach volleyball players (12 male and 5 female) performed 3 trials of CMJ and block jump on a rigid surface (BJR), and a block jump on the sand (BJS). Chronojump Bosco System was used to assess flight time in jumps on a rigid surface. High-speed video camera was used to assess flight time in jumps on the sand. A frame by frame video analysis was carried out by two expert observers. Intra- and interobserver reliability was assessed using the percentage of error method. Coefficient of variation (CV) was calculated to assess the stability of measures. Pearson product-moment correlation was calculated to assess the relationship between the different jump protocols. Results The average of CV for BJS, CMJ and BJR was 3.25%, 3.85% and 2.22%, and mean flight times were  $0.56 \pm 0.06$ ,  $0.55 \pm 0.15$  and  $0.61 \pm 0.05$ , respectively. Players jumped 8,2% less on the sand on average. We found a significant relationship between BJS and CMJ ( $r=0.58$ ;  $p<0.05$ ), between BJS and BJR ( $r=0.83$ ;  $p<0.01$ ), and between BJR and CMJ ( $r=0.92$ ;  $p<0.01$ ). Discussion Intra- and interobserver reliability was  $<5\%$  and considered acceptable (James, Taylor and Stanley, 2007). Reliability of BJS attending CV value is considered between moderate and large (Hopkins et al., 1999). According to the findings of Bishop (2003), around 5% decrease, and Giatsis et al. (2004), around 13% of decrease, players jumped less on the sand. However, Bishop tested the same action with another methodology with some reliability missing data. Observing the correlation between BJS and BJR on different surfaces, we could conclude that this is an easy, accessible, reliable and valid test to assess the jump flight time on the sand. ## EFFECT OF WALL INCLINATION AND CLIMBING ABILITY ON PHYSIOLOGICAL RESPONSE IN FEMALE CLIMBERS

Panackova, M., Balas, J., Bunc, V.

*Charles University*

Introduction Watts (2004) counts sport climbing among activities with moderate energy expenditure. The average oxygen consumption ( $\dot{V}O_2$ ) is around  $20-34 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$  and maximum oxygen uptake is around  $30-45 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ . The wall inclination, the climbing speed and the climbing ability are considered as main determinants of the oxygen consumption (Mermier et al., 1997; Watts and Drobish, 1998; Bertuzzi et al., 2007). The aim of the study was to compare the effect of wall inclination and climbing ability on physiological response during climbing with a determined speed in female climbers. Methods Eleven female climbers ( $24.9 \pm 4.1$  years,  $56.7 \pm 5.8$  kg,  $164.5 \pm 5.8$  cm) volunteered to participate in the study. The females were divided according to their actual climbing ability on recreational ( $n=6$ ) and elite ( $n=5$ ) climbers. The physiological response on the same route configuration at three different wall inclinations - positively angled ( $100^\circ$ ), vertical ( $90^\circ$ ) and overhanging ( $80^\circ$ ) was tested at a determined speed ( $25 \text{ steps}\cdot\text{min}^{-1}$ ). The portable gas analyser was used to assess physiological response during climbing. Results We found a significant effect ( $p < 0.01$ ) of the wall inclination on the oxygen consumption ( $100^\circ - 31.5 \pm 2.4 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ;  $90^\circ - 33.5 \pm 2.4 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ;  $80^\circ - 34.6 \pm 2.3 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ) and significant difference ( $p < 0.01$ ) between recreational and performance climbers. There was not found any interaction between the inclination and the climbing ability. The average difference in oxygen consumption between recreational and elite climbers was  $3.3 \pm 0.6 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ . Discussion We confirmed that the wall inclination and the climbing ability are main determinants of oxygen consumption during climbing when the climbing speed is held constant. Therefore, we agree with Mermier et al. (1997) that the climbing in steeper inclination is more energy demanding. The lower climbing ability was associated with higher oxygen consumption which might be connected with a worse economy of movement in recreational climbers. Oxygen consumption can, thus, be used as a parameter for quantitative evaluation of climbing technique. References Bertuzzi M.C.R., Franchini E, Kokubun E, Kiss M. D. P. A. M. ## INFLUENCE OF REGRESSION MODEL ON THE RELATIONSHIP BETWEEN LACTATE THRESHOLD USING THE MAXIMAL-DEVIATION METHOD AND PERFORMANCE WELL-TRAINED ATHLETES

Santos-Concejero, J., Granados, C., Bidaurrazaga-Letona, I., Zabala-Lili, J., Irazusta, J., Gil, S.M.

*UCT/MRC Research Unit for Exercise Science and Sports Medicine, University of Cape Town; University of the Basque Country UPV/EHU*

Introduction The lactate threshold calculated by the maximal-deviation method (LTD<sub>max</sub>) has been suggested to be more highly correlated with performance than the lactate threshold values determined by other methods (Machado et al, 2011). However, the influence of the choice of the regression model on the LTD<sub>max</sub> method in well-trained athletes remains unclear. Therefore, the aim of this study was to investigate the relationships between endurance performance and the LTD<sub>max</sub> calculated by an exponential-plus-constant and a third-order polynomial model. Methods 20 well-trained male runners participated in this study (age:  $29.1 \pm 6.6$  years; 10-km race time:  $31.5 \pm 1.2$  km/h). All subjects completed a maximal incremental running test at 1% slope on a treadmill, starting at 9 km/h without previous warm up. The velocity increased by 1.5 km/h every 4 minutes with 1 minute between the stages used for blood lactate determination. Lactate-speed data were fitted by an exponential-plus-constant and a third-order polynomial equation. The LTD<sub>max</sub> was determined for both regression equations. Results The exponentially-derived and the polynomially derived LTD<sub>max</sub> were  $17.4 \pm 0.9$  and  $17.2 \pm 0.9$  km/h, respectively. Exponentially-derived LTD<sub>max</sub> had a higher correlation ( $r=0.71$ ) and smaller standard error of estimate (SEE) ( $0.22$  km/h) with performance than the polynomially-derived equivalent ( $r=0.61$ ;  $SEE=0.26$ ). Discussion These results suggest that the exponentially-derived LTD<sub>max</sub> is a better performance predictor than the polynomial equivalent in well-trained male athletes, in agreement with the results reported by Machado et al. (2012) in recreational female runners. Therefore, the exponential regression should be used when calculate the lactate threshold by the maximal-deviation method in well-trained male athletes. ## INTENSITY DOSE-RESPONSE EFFECTS ON BONE MINERAL DENSITY AND ISOKINETIC STRENGTH IN MIDDLE-AGED AND ELDERLY ADULTS

Lin, L.

*National Cheng Kung University*

**INTENSITY DOSE-RESPONSE EFFECTS ON BONE MINERAL DENSITY AND ISOKINETIC STRENGTH IN MIDDLE-AGED AND ELDERLY ADULTS** Linda L. Lin<sup>1</sup>, Michael S. Lo<sup>2</sup>, Min- Hwei Hsieh<sup>3</sup>, Yi-Ju Chen<sup>4</sup>, 1:National Cheng Kung University, (Taiwan); 2:Kun Shan University, (Taiwan); 3:Chang Gung Medical Foundation, (Taiwan); 4: Chi-Mei Medical Center(Taiwan) Introduction Physical activity and exercise have been recommended as a strategic intervention to promote optimal bone mineral density (BMD), muscle mass and to decline the risks of bone loss during middle and later life. Recent studies focused on the influences with different dose of exercise. The purpose of this study was to explore the effects of resistance training on bone mineral density and lean body mass with same training volume but different intensities in middle-aged and elderly adults. Methods Participants were 23 men and 37 women (52-68-year-old) volunteers, assigned to 6 groups (male of control group, n=8, 64.3±3.4yrs; male of moderate-intensity group, n=8, 64.1±3yrs; male of high- intensity group, n=7, 63.8±2.3yrs; female control group, n=10, 58.7±2.5yrs; female of moderate-intensity group, n=13, 60.4±5.9yrs and female of high- intensity group, n=14, 57.5±2.4yrs). The training program consisted of gradual increase in weight-resistance exercise 2 sessions per week under supervision, and the pre-test (0 week) and the post-test (25 weeks) data, including bone mineral density and body composition and elbow, knee extensors and flexors isokinetic strength's peak torque were measured by dual-energy X-ray absorptiometry (DXA) and Biodex System 4 PRO. Results The leg BMD had significant difference between gender (men showed significantly higher than women), the arm lean mass had significant difference among groups (high and moderate groups showed significantly higher than control group) (p<.05). Most of the upper body strength ( biceps, triceps) and the lower body strength ( quadriceps, hamstring) had shown significant differences between gender, among groups, like the antagonist muscle: triceps' peak torque at 180°/s: high- intensity group improved 22.9%, moderate-intensity group increased 22.2%, then control group decreased 5.2%(p<.05), high speed velocity of quadriceps at 180°/s, high- intensity group improved 12.7%, moderate-intensity group increased 9%, and control group was 0.2%(p<.05). There were no significant differences between exercise groups. Discussion The high and moderate intensity programs were designed to produce similar total workloads in subjects with similar strength values. After 24 weeks of training leg bone mineral density and arm lean mass were increased. The high speed isokinetic strength of the antagonist muscle of limbs improved more. Furthermore, it had also shown the similar responded and effect of bone mineral density and isokinetic strength between middle-intensity with high repetitions and high-intensity with low repetitions but male show a greater response at the depend variable than female.

## EFFECTS OF PARTIAL REDUCTION IN STRENGTH TRAINING REGIMEN ON PERFORMANCE AND MUSCLE MASS

Tricoli, V.1, Tavares, L.1, De Souza, E.1, Laurentino, G.1, Aihara, A.2, Ugrinowitsch, C.1

1: EFFE-USP (São Paulo, BRAZIL), 2: DASA (São Paulo, BRAZIL)

**Introduction** The maintenance of strength and power performance and muscle mass is important for sports and daily physical activities. However, sometimes we have to interrupt (detraining, DE) or reduce strength training (ST) stimuli due to injuries or training schedule. It has been shown that DE causes a progressive loss of previous adaptations (Henwood and Taaffe, 2008; Tokmakidis et al., 2009). Nevertheless, the effects of a reduction in ST are still scarce (Tucci et al., 1992; Garcia-Pallares et al., 2010). The magnitude of these effects may depend on training volume and frequency (Fleck, 1994). Therefore, the aim of the study was to investigate the effects of reduced ST programs and DE on maximum strength (1RM), vertical jump (VJ) performance, and muscle cross sectional area (CSA). **Methods** Thirty three males (23.1±2.8 yr, 1.73±0.06 m, 71.9±6.2 kg) were divided into 3 groups: reduced training volume (RTV, 2x6-8RM, 2x/wk), reduced training frequency (RTF, 4x6-8RM, 1x/wk), and DE. Initially, all groups were submitted to an 8-wk ST program (3-5x6-15RM, 2-3x/wk). After the ST, the RTV and RTF groups reduced volume and frequency; respectively, over the next 8 weeks of training while the DE group detrained. Half-squat 1RM, VJ height, and quadriceps CSA (MRI) were measured before and after ST and after the reduced training period. A mixed models analysis was used to compare 1RM, VJ, and CSA changes between groups pre-ST, post-ST and post-reduced training. **Results** Pre-ST there were no significant differences between groups. After 8 wk of ST, we found significant (p<0.01) increases of 27.9±10.7%, 26.7±7.8%, and 28.4±6.0% in lower limbs 1RM for RTV, RTF, and DE groups, respectively. VJ (4.5±1.4%, 4.8±1.9%, and 4.2±1.3%) and CSA (6.9±3.9%, 6.1±3.6%, and 5.8±5.5%) also increased similarly between RTV, RTF, and DE; respectively. After the reduced training period, there was a small increase in 1RM for RTV (3.0±3.4%) and RTF (3.5±2.7%) while DE showed a decrease (17.1±14.0%) in strength (p<0.001). VJ performance (-0.5±1.5%; +0.5±0.9%) and CSA (-2.2±4.1%; -1.3±1.8%) did not change significantly for RTV and RTF but only for DE (VJ -4.0±0.9%; CSA -4.7±7.0%). **Discussion** According to our results, after 8 wk of ST, a partial reduction in training volume or frequency associated with moderate to high intensity stimulus was able to maintain lower limbs performance and muscle mass. On the other hand, a similar period of detraining resulted in significant losses in these variables. **References** Fleck SJ *Streng Cond J*, 16(1), 22-28. ## LOW VOLUME WEIGHTED STEPPING IMPROVES LOWER LIMB MUSCLE STRENGTH, POWER AND FUNCTIONAL ABILITY IN OLDER FEMALES.

Mair, J.L., De Vito, G., Boreham, C.A.

*University College Dublin*

**Introduction.** Lower limb muscle power independently predicts functional status in elderly women (Foldvari et al., 2000). Weighted stair climbing has been shown to improve muscle power and functional ability in older adults, in a practical, time-efficient manner (Bean et al., 2002). However older adults present a high risk of falling on staircases (Studenski et al., 1994). Weighted stepping, on and off a single step, may be a safer alternative in older cohorts, yet little is known about the training effects of such an intervention. Thus, the aim of this study was to evaluate the effects of a six-week weighted step intervention on aerobic fitness, muscular strength and power, and functional ability in sedentary older women. **Methods.** Eleven healthy older females (mean, SD; age: 67.4, 3.53 years, stature: 1.59, 0.05m, body mass: 67.64, 10.89kg) completed baseline testing (TS1), a six-week control period followed by re-test (TS2), and a six-week individually prescribed weighted step intervention followed by post-test (TS3). Training consisted of 54 exercise sessions, divided into three sessions/day on three days/week. Participants performed four sets of 10 step-up repetitions as quickly as possible, wearing a weighted vest with progressively increasing load from 0% to 10% body mass. Aerobic fitness (submaximal cycle test), power output (modified Wingate test), quadriceps muscle strength (maximum isometric voluntary contraction), and functional fitness (stair climb, chair rise, 4m walk) were

assessed. Results. Repeated measures ANOVA did not detect any changes in body mass, chair rise time, 4-m walk time or aerobic fitness. Significant improvement in stair climb time (12.3%  $p < 0.001$ ), stair climb power (10.4%,  $p = 0.024$ ), peak power output (12.3%,  $p = 0.001$ ) and quadriceps muscle strength (13.2%,  $p = 0.007$ ) were observed as a result of the training. Conclusion. These results show, for the first time, that short-term stepping exercise with an external load can significantly improve lower limb muscle strength, power and functional ability in older females by 10-13%. Since ageing is associated with declines in muscle strength and power by 12-15% per decade after 50 years of age (Macaluso & De Vito, 2004), the observed training improvements suggest that a weighted stepping intervention could potentially prolong independence by at least 10 years. ### EFFECTS OF A PRE-EXERCISE GLYCOGEN REDUCTION PROTOCOL ON NEUROMUSCULAR RESPONSES DURING MAXIMAL ECCENTRIC KNEE EXTENSIONS

Gavin, J.P., Myers, S.D., Willems, M.E.T.

*University of Chichester*

**Introduction** Eccentric exercise is followed by a transient loss of force, muscle soreness and impaired muscle glycogen homeostasis (Widrick et al., 1992). Where concentric exercise may reduce muscle glycogen, it does not induce muscle damage. Glycogen repletion is crucial for the recovery of muscle function in subsequent bouts; yet the neuromuscular consequences of performing eccentric exercise in a glycogen reduced state are less clear. **Method** Thirteen men ( $22 \pm 3$  yr,  $179 \pm 6$  cm,  $76 \pm 15$  kg) completed a single-leg glycogen depleting cycling protocol with dietary manipulation (Pilegaard et al., 2002), the evening before a bout of maximal eccentric contractions. The control leg was supported whilst the glycogen reduction (GR) leg completed: 20-min cycling at a  $\sim 75\%$   $VO_{2max}$  power; eight 90-s sprints at a 1:1 work-to-rest ratio (5% decrements from 90 to 55%  $VO_{2max}$ ); and exhaustive cycling at  $\sim 85\%$   $VO_{2max}$  power. Early the following morning, single-leg eccentric exercise was performed for the GR, then control condition. The bout involved 100 maximal eccentric knee extensions at 1.57 rad/s. Peak torque and electromyography (EMG) were recorded through each 1.57 rad range of motion, with EMG processed for root-mean square (RMS) and median frequency (MDF). To ensure analysis at constant angular velocity, measures were averaged for each contraction as three, 0.26 rad epochs mid-range of motion. Epochs corresponded to short (first), medium (second) and long (third) muscle lengths. Paired samples t-tests were used to compare: peak torque, work done, RMS and MDF during contraction one and one-hundred. Results Torque decreased at short muscle length in both conditions (GR: -19.3%,  $P = 0.02$ ; control: -18.4%,  $P = 0.01$ ), and at medium (-15%,  $P = 0.08$ ) and long muscle lengths (-21.7%,  $P = 0.02$ ) for GR. GR resulted in a -11.2% decrement in work done ( $P = 0.002$ ), yet was sustained from repetition one to one-hundred in the control condition. There was a trend towards decreased RMS in the GR (-9.6%,  $P = 0.07$ ), without change in the control. However, MDF increased at short (13.2%,  $P = 0.01$ ) and long lengths (17.9%,  $P = 0.016$ ) in the GR leg. **Discussion** These findings suggest neuromuscular modulation to maximal eccentric knee extensions may be altered according to muscle glycogen availability. Similar amplitude, but higher signal frequency, suggests increased motor unit firing rates to compensate for torque loss when performing eccentric contractions with GR. It appears neuromuscular mechanisms are sensitive to glycogen state in the knee extensors. References Pilegaard H, Keller C, Steensberg A, Helge J, Pedersen BK, Saltin B, Neuffer D. ### PROJECT ACE : REFINEMENT OF A VOLUNTEER-LED ACTIVE AGEING INTERVENTION USING QUALITATIVE METHODS

de Koning, J., Stathi, A., Withall, J.

*University of Bath*

**Introduction** Interventions to stimulate physical and social activity by older adults are of great public health value for the growing, inactive and often socially isolated older population. Project ACE emerged from the AVON Network for the Promotion of Active Ageing in the Community programme (AVONet; Stathi et al., 2012; Life Long Health and Wellbeing-Phase 2) which synthesised existing evidence and identified the potential physical and psychological benefits of volunteering initiatives and of staying engaged and socially connected in the neighbourhood. The ACE programme uses paid coordinators to support older volunteers ('Activators') to engage older adults who are not socially integrated ('Participants') into physical and social activities in their communities. This pilot study aimed to refine the ACE programme and highlight possible challenges and recommendations for its successful implementation. **Methods** Qualitative data was gathered from older volunteers ( $n = 9$ ), managers of volunteers ( $n = 4$ ) and older receivers of social volunteering services ( $n = 28$ ) who live in the city where the ACE programme will be implemented. Interview topics included the feasibility and attractiveness of the ACE programme, possible challenges and recommendations for successful implementation. Framework analysis was used to analyse and interpret the data, and practical considerations drawn. **Results** The ACE programme was generally praised for its potential to meet older people's needs of feeling competent, socially involved and independent. However, a number of challenges, recruitment in particular, were raised. Specific recommendations were offered which were considered to refine the intervention programme content, recruitment strategies and implementation plan. **Conclusions** The ACE programme offers a timely, accepted and needed initiative for older adult physical activity promotion. The most prominent challenge, that of adequate recruitment of Participants, might be minimised through the use of local media and a focus on 'out and about', rather than 'physical activity'. Activator training using manuals and certificates, and support through peer meetings are highly important. The structure of meetings between Activators and Participants must be flexible and should ideally be matched for interests. Discretion must be used to judge readiness for Participants to come together in small groups. Finally, as well as organising the Participant-Activator meetings and groups, coordinators should be available to be contacted by telephone by Activators desiring to discuss Participant issues and in need of extra motivation. ### CAN THE BPAQ PREDICT BONE MINERAL DENSITY IN MIDDLE-AGED AND OLDER MEN?

Bolam, K., Beck, B., Adlard, K., Skinner, T., Cormie, P., Galvão, D., Spry, N., Newton, R., Taaffe, D.

*The University of Queensland, Australia; Griffith University, Australia; Edith Cowan University, Australia; Sir Charles Gairdner Hospital, Australia; University of Newcastle, Australia.*

**Introduction** Regular physical activity plays an important role in the regulation of bone mass and is therefore a vital element in the prevention of osteoporosis. A limitation of traditional measures to assess the role of physical activity has been the inability to account for critical

bone-specific loading. As a result, the Bone-specific Physical Activity Questionnaire (BPAQ) [1] was developed to account for this loading and is a useful tool to predict indices of bone strength in young adult adults. However, its ability to predict bone strength in middle-aged and older adults, a population at increased risk for the development of osteoporosis, as well as in clinical populations where bone is adversely affected by treatment is unknown. Therefore, the purpose of this study was to evaluate the ability of the BPAQ to predict bone mineral density (BMD) in healthy middle-aged and older men, and men with prostate cancer (PCa) undergoing androgen suppression therapy (AST), which has well established negative effects on BMD. Methods Participants were 110 men from two distinct groups: group 1 comprised 36 community-dwelling men aged 50 years and over, while group 2 comprised 71 men with PCa receiving AST. The BPAQ was self-administered. Values were entered into the on-line calculator so that past (pBPAQ - all activities since 1 year of age), current (cBPAQ - activities in the previous 12 months only), and total BPAQ score (tBPAQ - average of pBPAQ and cBPAQ scores) could be calculated. BMD (g/cm<sup>2</sup>) of the whole body (WB), hip (total hip and femoral neck-FN), and lumbar spine (L2-4) were assessed by DXA (Hologic, QDR4500). Results In healthy men, relationships were found between tBPAQ and pBPAQ with hip and WB BMD ( $r = 0.28-0.45$ ,  $p < 0.05$ ), whereas in men with PCa only pBPAQ was associated WB BMD ( $r = 0.24$ ,  $p = 0.044$ ). In stepwise regression analysis, body mass and tBPAQ predicted 30% of the variance in hip BMD of healthy men ( $p = 0.003$ ), cBPAQ predicted 25% of the variance at FN ( $p = 0.002$ ), and body mass, age and tBPAQ predicted 47% of the variance in WB BMD ( $p < 0.001$ ). In men with PCa, BPAQ was not an independent predictor of BMD. Discussion We found that current and total physical activity as indicated by the BPAQ predicted BMD at the hip and whole body in healthy middle-aged and older men but not men on AST. As a result, although the BPAQ appears to be a useful predictor of bone status in healthy men, adverse effects of treatments such as AST on bone may override the clinical utility of physical activity measures such as the BPAQ. ## COMPARABILITY OF ACCELEROMETER- AND IPAQ-DERIVED PHYSICAL ACTIVITY AND SEDENTARY TIME IN SOUTH ASIAN WOMEN

Babakus, W.S., Thompson, J.L., Duda, J.L.

*University of Birmingham*

Introduction Accurate measurement of physical activity (PA) and sedentary time (ST) is essential in developing effective intervention strategies to improve health outcomes. There is no generally accepted standardised method of assessing PA and ST, although self-report questionnaires and objective methods (e.g., accelerometry) are widely used (Kurtze et al., 2008). There is limited research documenting objectively measured PA/ST in South Asian (SA) women and no published evidence of the validity of self-report methods of PA/ST assessment of SA in the United Kingdom (UK) (Babakus & Thompson, 2013). The purpose of the study is to assess the comparability of accelerometer and IPAQ derived PA/ST measures among SA women in the UK. Methods 140 SA women wore an ActiGraph accelerometer for 7 consecutive days; a sub-sample ( $n = 51$ ) completed the IPAQ-Short form (IPAQ-SF) and a brief structured interview to determine ease of use, understanding of terms used in the IPAQ-SF, and cultural contextualisations of PA/ST in daily life. Metabolic equivalent minutes per week (METminwk) were calculated for accelerometer and IPAQ-SF derived moderate-to-vigorous PA (MVPA) and ST. Interview data were analysed using content analysis (Kondracki et al., 2002). Results Mean age and BMI for the full sample were  $46.5 \pm 14.3$  yr and  $28.3 \pm 5.0$  kg/m<sup>2</sup>, respectively. Accelerometer and IPAQ-SF derived mean METminwk for MVPA were  $397.0 \pm 259.7$  and  $367.1 \pm 1102.2$ , respectively. Accelerometer and IPAQ-SF derived mean METminwk for ST was  $530.0 \pm 86.7$  and  $370.5 \pm 228.8$ , respectively. Mann-Whitney U tests indicate no significant difference ( $p > 0.05$ ) between the full and sub-sample in age, BMI, or accelerometer and IPAQ-SF derived MVPA and ST. Spearman correlations indicated no significant associations between accelerometer and IPAQ-SF mean METminwk for MVPA ( $r_s = -.332$ ,  $p = .113$ ), or ST ( $r_s = .096$ ,  $p = .649$ ). Major themes from the interview included: 1) lack of cultural context and terminology for participation in leisure-based PA; 2) inability of participants to equate their own PA with examples of intensity levels from the IPAQ-SF; 3) inability to recall sitting time; and 4) limited general knowledge of real-life examples of activities that are of moderate or vigorous intensity. Discussion Results indicate that the IPAQ-SF may not accurately measure PA/ST in UK SA women. These findings are supported by qualitative evidence indicating several issues with interpretation and recall of PA/ST. Further validation of the IPAQ-SF with a larger sample is needed to determine its suitability within this population. References Babakus & Thompson (2012). Int J Behav Nutr Phys Act, 9:150. ### PP-PM80 Training and Testing [TT] 15

#### EVALUATION OF A NEW FORCE/VELOCITY TEST AND ITS RELATION TO MUSCLE MASS AND AGE CATEGORY IN HANDBALL.

Sánchez, A., Mónico, M., Romero, R., Drobnic, F.

*INEFC*

Introduction The capacity to support a level of work of high intensity for short periods of time is one of the most successful physiology characteristics in sport activities and is not easy to evaluate in the training with modifies the maximum level realized in the first phases of the test. A new evaluation model is proposed of the maximum potency and its relation with the fatigue that the condition of physical maturation allows us to establish as regards the category or with the corporal composition measured by means of corporal densitometry or conventional anthropometry by external measurements. A relation is established between this measurement in 4 age categories, <17 to, <16 to, <15 y <14 in handball teams of Fc Barcelona, each one of them with 17 athletes. Method The designed test consists of four sprints in the Monark LE cycloergometer of 10 seconds of duration (life) followed (consecutively) by 50 seconds of rest. The loads of displacement corresponds to 75 g/kg first period, 50 g/kg second, 25 g/kg and 500 g fourth. Before the exercise a warm up of at least 5 minutes is performed to a variable rate. Determine the maximum RPM reached on each series in which the maximum power achieved is established and a work area under the curve of strength/speed. Lactate removal is obtained from the lobe of the ear after 5 minutes of the test. To evaluate the corporal composition by means of densitometry a Lunar System iDXA is used. The Drinkwater formula is used to establish the muscular and fat percentage of every subject. Results The values of Maximal Power Developed (MPD) in watts correspond

to the categories of <14, <15, <16 y <17, years to 600(123), 802(183), 904(300) and 1105(344), work area to 602(125), 744(149), 819(150) y 900(125). The muscle percentage according to Drinkwater is of 43,9(3), 43,3(2,5), 42,6(4,6) and 46,3(3,2) and the fat percentage is of 8,0(3,5), 7,8(1,5), 9,6(3,5) and 8,1(2,3) while the fat percentage according to Yuhász is 10,4(3,9), 9,5(1,7), 11,0(3,5), 9,0(2,4) and through IDXA 17,6(4,2), 17,4(3,1), 19,5(7,7) y 15,9(4,2). The R between the values of power and work area in relation to the muscle mass as the Drinkwater (0.815 and 0.839) or the upper extremities or lower extremities mass alone (0.840 and 0.900). Lactate levels do not discriminate the groups being the average of all of them of 7.3 (2.3). Discussion Test easy and practical to perform. Subjects are involved during all the periods of exercise. Results discriminate the categories by the work area under the shape F/V. Data correlates well with muscular values by the standard anthropometrics or by IDXA. ### TRANSMISSION OF PLATFORM VIBRATIONS THROUGH CABLES AND ITS EFFECT ON UPPER-BODY MUSCLE ACTIVITY

Tankisheva, E.1, Boonen, S.2, Druyts, H.1, Verschuere, S.1

1: KUL (Leuven, Belgium), 2: UZ Leuven (Leuven, Belgium)

**Introduction** Vibration acts on the human body by transmitting mechanical loading from different vibration sources. Vibration has been reported to stimulate the activity of lower-limb muscles (Cardinale and Lim, 2003). Only a few studies have reported low or no effects on upper body muscle performance during vibration stimulation (Hazell et al., 2007). We tested a new vibration device with a cable-pulley resistance system attached to a vibration platform, in an attempt to channel the vibration indirectly from the platform to the upper body and potentially broaden the impact of training to the whole body. The aim of the study was to evaluate the vibration transmission through the cables to the upper body and the relationship between vibration parameters and muscle activation during different static and dynamic arm exercises. **Methods** Fifteen clinically healthy participants performed 3 different arm exercises – biceps curl, triceps curl, and lateral raise. Vibration transmission to the upper body was assessed over a wide range of accelerations (from 1.90 to 5.98 g) and frequencies (25 to 40 Hz). Additionally, muscular activity of biceps brachii, triceps brachii, deltoid, upper and lower trapezius was recorded. **Results** The results showed a significant attenuation of the platform accelerations transmitted through the vectran cables to the upper body. Handle vibration ranged between 27 – 44 % of the acceleration delivered by the platform. Vibration increased the muscle activity of biceps brachii, triceps brachii, deltoid and upper trapezius muscles significantly only during biceps curl exercises. No frequency and/or acceleration effect was found on the size of the muscle response. **Discussion** The outcome of this study indicates the potential of a whole body vibration platform with a cable-pulley resistance system to stimulate the muscle activity of some arm muscles. The vibration delivered by the platform that reached the handle ranged between 27 % – 44 % and might be affected by the different angles of the cables, the orientation and the distance of the handle with respect to the platform. The subjects performed commonly used exercise as biceps curl which resulted in a significant increase in arm muscle activity during vibration stimulation. Different vibration parameters delivered by the platform did not evoke different muscle response probably because of the different vibration approach, the limited vibration transmission at the handle and the high variance in the EMG response. The specific vibration parameters used in the present study seem safe and suitable for the specific arm exercises. References Cardinale M, Lim, J. (2003), *J Strength Cond Res*, 17(3), 621-624 Hazell TJ, Jakobi JM, Kenno KA. (2007), *Appl Physiol Nutr Metab*, 32(6), 1156-1163

### THE CMJ AS A MEASURE OF CONTROL FOR INDOOR TRAINING ON HIGH-LEVEL MIDDLE AND LONG DISTANCE RUNNERS

Balsalobre-Fernández, C., Tejero-González, C.M., del Campo-Vecino, J.

*Autonomous University of Madrid*

**Introduction** The counter movement jump (CMJ) has been used for monitoring the training process in track&field sprinters because of its ability to identify states of peak performance and fatigue (Jiménez-Reyes & González-Badillo, 2011). However, its use for controlling the training process of high-level middle and long distance runners is poorly studied. **Purpose** Compare the value of the CMJ measured at the start of the indoor season with the value of the CMJ measured during the preparatory period in a group of high-level middle and long distance runners. **Methods** Sample The sample consists of a group of 15 middle and long distance runners (3 women), average age 24.9 years (SD = 5.1), with personal bests ranging from 1:48 to 1:54 min (men) / 2:02 to 2:06 min (women) (800m), 3:39 to 4:04 min (1500), 8:03 to 8:36 min (3000m) and 14:09 to 15:03 min (men) / 15:58 (women) (5000). Variables CMJ height was measured in cm once a week during the preparatory period (November 2012-January 15th 2013) and at the beginning of the indoor competitive period (January 15th-31st 2013). **Instrumental** To measure the CMJ, an Optojump infrared platform (Microgate, Italy) was used. **Procedure** The CMJ vertical jump was measured once a week. This jump was always performed the same day of the week, at the same time of the day and under the same conditions. 3 trials were executed and the best was recorded. In total, 540 CMJ were analyzed. **Statistical Analysis** We proceeded with nonparametric statistics, Wilcoxon test (one-sided), using the statistical software IBM SPSS Statistics 20 (IBM Corp., USA). **Results** The Wilcoxon test found statistically significant differences ( $Z = -2.05$ ,  $p = 0.020$ ) between the average CMJ at the beginning of the indoor competitive period ( $29.7 \pm 4.6$ ) and the average CMJ during the preparatory period ( $29.0 \pm 3.9$ ). The CMJ average was 2.4% higher at the beginning of the indoor competitive period than during the preparatory period. **Conclusion** Our results indicate that one of the consequences of the preparatory training for the indoor season of high-level middle and long distance runners is the significant improvement of the CMJ. Its assessment may be very useful to control the training process for the indoor season of such athletes. References Jiménez-Reyes, P., & Gonzalez-Badillo, J. J. (2011). Monitoring training load through the CMJ in sprints and jump events for Optimizing performance in athletics. *Culture, Science and Sport*, 7 (18), 207-217.

### REPRODUCIBILITY OF AN ALL-OUT TETHERED FIELD TEST FOR ANAEROBIC PARAMETERS DETERMINATION IN SLALOM KAYAK

Manchado-Gobatto, F.B., Ferrari, H.G., Messias, L.H.D., Reis, I.G.M., Terezani, D.R., Gobatto, C.A.

*University of Campinas - UNICAMP*

**Introduction** The slalom kayak is performed in down water course designated by gate placement, magnitude of waves, velocity of water flow (Shephard, 1982) and requires important participation of anaerobic metabolism (Zamparo et al., 2006). The aims of this study were to present an all-out tethered field test analyzing their reproducibility for anaerobic parameters determination of slalom kayakers. **Methods** Six well trained athletes (national Brazilian team level, K1 category,  $23 \pm 2$  yrs) were submitted to two 30 seconds all-out tethered

specific test performed on a lake, separated for 24hrs between them. The kayakers paddled tied using an elastic cord attached to the kayak and a load cell coupled in a wood structure at the border of lake connected to the data acquisition system with signs collection at 1000hz, aimed the measurement of the paddling force. Blood samples were collected at the end of the test (1 to 10 min) for quantify the blood lactate. The peak force (PF), mean force (MF), time to peak force (TPF), peak lactate (PLac) and time to peak lactate (TPLac) were obtained. The reproducibility was tested by paired t-Student test and Pearson product-moment ( $P \leq 0.05$ ). Data are showed as mean  $\pm$  standard error of mean. Results There was not statistical difference between the 1st and 2nd test for all parameters evaluated (PF=147.4 $\pm$ 10.3N and 134.1 $\pm$ 9.4N; MF=105.5 $\pm$ 8.6N and 95.8 $\pm$ 6.9N; TPF=9.5 $\pm$ 0.5s and 9.8 $\pm$ 0.4s; PLac=7.3 $\pm$ 0.1mM and 6.8 $\pm$ 1.1mM and TPLac=7 $\pm$ 1min and 6 $\pm$ 1min). Significant correlations between PF ( $r=0.87$ ), MF ( $r=0.85$ ) and PLac ( $r=0.95$ ) were observed. The coefficient of variation between tests for PF, MF, TPF, PLac were respectively 6.6%, 8.1%, 9.1% and 8.9%. Discussion Field tests have less control of the experimental conditions than laboratory tests, on the other hand their ecological validity is greater. Tethered field tests have been purposed in different sports modality to anaerobic evaluation (Papoti et al., 2008; Lima et al., 2011), but not yet tested in slalom kayak. Despite the field conditions, the parameters obtained by all-out kayak tethered test in two efforts showed similar values and high relationship. Furthermore, low coefficient of variation (<10%) were observed for all measurements. Thus, we conclude that the specific all-out tethered test can determine anaerobic parameters of slalom kayakers and was reproductive for the group of high performance athletes evaluated. ### GAS EXCHANGE AND OXYGEN UPTAKE KINETICS DURING SUB-MAXIMAL EXERCISE IN SWIMMING

Almeida, T., Espada, M., Reis, J., Vleck, V., Alves, F.

*Faculty of Human Kinetics, Technical University of Lisbon*

**Introduction** The heavy exercise intensity domain includes the exercise intensities between ventilatory threshold (VT) and maximal lactate steady state (MLSS). Oxygen uptake (VO<sub>2</sub>) is an important determinant of exercise performance and the dynamic transition of VO<sub>2</sub> kinetics provides a unique window into understanding metabolic control (Poole et al. 2008). Recently, Reis et al (2012) indicated that VO<sub>2</sub> kinetics of the primary phase is associated with performance during high-intensity swimming. The aim of this study was to determine the relationship between VO<sub>2</sub> kinetics in heavy-intensity swimming, aerobic parameters and swimming performance. **Methods** Twelve male swimmers completed an incremental test composed by 5x250 and 1x200 m front crawl for VT, respiratory compensation point (RCP) and maximal oxygen uptake (VO<sub>2</sub>max) determination, as well as the respective swimming velocities. For MLSSv estimation, athletes performed 30-min at constant velocity at 87.5, 90 and 92.5% of vVO<sub>2</sub>max. In two complementary days, 6-min bouts were performed separated by one hour of passive rest between each repetition, two in one day 2.5% below MLSSv and the other two in another day 2.5% above MLSSv. All tests were completed with aquatrainer swimming snorkel®. Best 400 and 800 m races were recorded (respectively, T400 and T800). Results VT (45.9  $\pm$  7.0 ml.kg<sup>-1</sup>.min<sup>-1</sup>) and RCP (51.3  $\pm$  7.6 ml.kg<sup>-1</sup>.min<sup>-1</sup>) were significantly different than VO<sub>2</sub>max (58.04  $\pm$  7.0 ml.kg<sup>-1</sup>.min<sup>-1</sup>). Mean VO<sub>2</sub> at MLSSv (49.3  $\pm$  9.2 ml.kg<sup>-1</sup>.min<sup>-1</sup>) was not significantly different from RCP ( $p < 0.01$ ). MLSSv (1.30  $\pm$  0.04 m.s<sup>-1</sup>) and RCPv (1.31  $\pm$  0.08 m.s<sup>-1</sup>) were also not significantly different. T400 was correlated with VO<sub>2</sub> time constant of the primary phase (tp) at infra MLSSv ( $r = 0.64$ ,  $p < 0.03$ ). T800 was also correlated with tp in both 97.5% and 102.5% of MLSSv (respectively  $r = 0.75$ ,  $p < 0.01$  and  $r = 0.58$ ,  $p < 0.05$ ). vVO<sub>2</sub>max was significantly correlated both with T400 and T800 ( $r = -0.70$  and  $r = -0.72$ ,  $p < 0.01$ ). **Discussion** Our results are in line with Deckerle et al. (2003) study which evidenced that MLSS and RCP are physiologically related. The correlations between tp below and above MLSSv and performance show that the primary phase of VO<sub>2</sub> kinetics presents a clear relation with performance and aerobic capacity. vVO<sub>2</sub>max seems to be a good predictor of middle and long-distance swimming performance. ### THE EFFECTS OF FLOAT-EQUIPPED AQUA TRAINING SWIMWEAR ON WATER JOGGING.

Akiharu, S.1, Kenji, Y.1, Saori, S.2, Nozomu, S.2, Yumiko, T.2, Takahiro, K.2, Makoto, O.2

*\*/Graduate school of sports system, Kokushikan University\*\*/( HUMAN SCIENCE RESEARCH CENTER, WACOAL CORP)*

**Introduction** It is widely reported that water exercise is an effective form of continuous exercise therapy for sufferers of knee joint pains and lower back pains. In addition, there are also reports of the effectiveness of water exercise performed in the comparatively greater buoyancy of deep-sea water (which has a relative weight of 1.05 times). This research was carried out with the aim of revealing what kind of physiological effects can be observed when aqua training swimwear with 60g floats attached to both sides of the chest (hereafter referred to as Swimwear X) was worn during aqua walking exercise. **Methods** The subjects were 12 healthy adult females (aged 43.9years). For the measurements, we used Swimwear X, and swimwear without floats attached (hereafter referred to as Swimwear C). The water walking was performed in an indoor pool 16m in length, at a rate of about 27m/min, over two round trips. Heart rate was measured during standing rest, submerged rest, and immediately after the water walking was finished. Walking times, muscle activity, and oxygen absorption amount were also measured. Additionally, forward tilt of the body immediately prior to foot landing was calculated from a video taken during the exercise. Results There was no significant statistical difference observed between Swimsuit X and Swimsuit C in terms of walking speed in the water, step/pace, or heart rate immediately after the exercise. Swimsuit X showed a tendency of not assuming a forward bent posture during the period prior to foot landing. Additionally, Swimsuit X showed less muscle activity of the biceps femoris muscle group. **Discussion** It is thought that Swimwear X was worn during aqua walking is an effective form of continuous exercise therapy for sufferers of knee joint pains and lower back pains. ## RELIABILITY OF DIFFERENT JUMP AND MAXIMAL STRENGTH TESTS

Westphal, M., Raeder, C., Fernandez Fernandez, J., Wiewelhoeve, T., Ferrauti, A.

*Ruhr-University Bochum*

**Introduction** Vertical jump and maximal strength tests are well established measurement tools for the assessment of performance in athletes. However, the reliability of drop jump (DJ), countermovement jump (CMJ), multiple rebound jumps (MRJ), repeated countermovement jumps (RCMJ), maximal voluntary isometric contraction (MVIC) and one repetition maximum (1RM) might be questioned in population with a lower level of performance (i.e., recreational athletes). Therefore the 1st aim of this study was to analyze the reliability of different jump and maximal strength tests in sport students. Moreover, we examined the correlation between two major reactive strength indices in vertical drop jumps (i.e., the jump efficiency coefficient (EKA) and the reactive strength index (RSI)). **Methods** Thirty-eight sport students participated in two non-randomized consecutive testing sessions within one week: DJ, CMJ, MRJ, RCMJ, MVIC and 1RM. Reliability was obtained using intraclass correlation coefficient (ICC), standard error of measurement (SEM) and systematic bias ( $\Delta$ ). Correlation analyses were conducted by Pearson's correlation coefficient. Results All tests showed moderate to high reliability, with CMJ (0.917 (0.840-0.957)), MRJ (0.903 (0.813-0.950)), RCMJ (0.949 (0.894-0.974)), MVIC (0.916 (0.838-0.956)), 1RM (0.959 (0.921-0.979)), EKA for MRJ (0.926 (0.858-0.961)) and RSI for MRJ (0.914 (0.836-0.955)) showing high values. On the other hand, DJ (0.891 (0.791-0.943)), EKA for DJ (0.876 (0.762-0.935)) and RSI for DJ (0.861 (0.734-0.928)) showed moderate values. The correlation analyses between EKA and RSI in the DJ showed values of 0.995 and 0.993, for testing day 1 and 2, respectively. Correlation between EKA and RSI of MRJ showed values of 0.994 and 0.998 for testing day 1 and 2, respectively. **Discussion** The test battery conducted in the present study illustrates a reliable method for jump and strength performance assessment. However, results also showed that the use of the DJ seems not to be appropriate for non-highly trained population. If the aim is to test reactive strength performance, the use of the MRJ should be recommended. In addition, if the aim is to measure jump efficiency, both reactive strength indices, EKA and RSI, seem to be practical as were highly correlated. Nevertheless, the present results are based on non-highly trained subjects. We can speculate that differences can be expected when testing other populations. **References** Ball, N. B. & Zanetti, S. ## ARE CHANGES IN BODY COMPOSITION ASSOCIATED WITH JUMPING HEIGHT AND STRENGTH OVER A SEASON IN NATIONAL LEVEL BASKETBALL, HANDBALL, AND VOLLEYBALL PLAYERS?

Silva, A.M., Matias, C.N., Santos, D.A., Rocha, P.M., Sardinha, L.B.

*Faculty Human Kinetics, Technical University Lisbon*

**Introduction** Body composition assessment throughout the season in team sports is crucial, though the extent to which total fat (FM) and fat-free mass, including total-body water (TBW) and fluid distribution, predicts power and strength, remains unclear. Additionally, most of the studies investigated body composition changes at the whole body level, such as height and weight, skinfolds, or other anthropometric indicators. Therefore we aimed to analyze the relationship between changes in molecular and tissue-level body components with jumping height and strength in national level players over a season. **Methods** At the beginning and at the competitive periods, measures of total FM, lean-soft tissue (LST), and bone mineral (Mo) estimated by dual energy X-ray absorptiometry were obtained in 63 basketball, handball, and volleyball players (20±5yrs), 40 males and 23 females. Skeletal muscle (SM) was estimated from appendicular LST using Kim et al. model (2004). TBW and extracellular water (ECW) were assessed by deuterium and bromide dilution, respectively, and intracellular water (ICW) was calculated as TBW minus ECW. A refractometer was used to test urine specific gravity (USG). Jumping height was assessed with a squat (SJ), countermovement (CMJ), and countermovement Abalakov (CMJA) jumps while maximal lower strength was tested in a leg press. Changes were expressed as a percentage from the baseline values. Comparison of means and multiple regression analysis were performed. Results Jumping height improved ( $p < 0.05$ ) by 8.3±13.9%, 6.3±8.5% and 7.5±12.0%, respectively for the SJ, CMJ, and CMJA and maximal strength increased by 12.5±20.8%. Weight, Mo, LST, SM, TBW, and ECW increased (1.8±2.9%; 2.4±3.5%; 3.0±2.7%; 3.2 ±4.0%; 1.7±5.5%; 3.0±8.6%, correspondingly) while %FM decreased (3.6±2.2%) but no changes were found in ICW (-1.5±7.9%). Among the changes in the several body components, only ICW was related with differences in SJ ( $r = 0.282$ ;  $p = 0.033$ ), CMJ ( $r = 0.401$ ;  $p = 0.013$ ), and maximal strength ( $r = 0.303$ ;  $p = 0.016$ ). These associations remained significant after adjusting for gender, age, and changes in USG (strength:  $\beta = 72.030$ ,  $p = 0.045$ ; SJ:  $\beta = 0.371$ ,  $p = 0.033$ ; CMJ:  $\beta = 0.383$ ,  $p = 0.012$ ). **Discussion** This observational study with a follow-up from the beginning to the main stage of a season revealed that players improved body composition, maximal strength, and jumping height. Though no mean differences were observed in intracellular water, changes in this body component explained improvements in strength and jumping height, regardless of age, gender, and hydration status. If these findings are confirmed through well-design experimental studies in highly-trained athletes, a regular assessment and tracking of the intracellular water compartment should be incorporated throughout a season to avoid reductions in this water pool. **References** Kim J, Heshka S, Gallagher D, Kotler DP, Mayer L, Albu J, Shen W, Freda PU, Heymsfield SB. *J Appl Physiol* 2004; 97: 655-660.

## SPRINT AND AGILITY PERFORMANCE IN YOUNG FEMALE SOCCER PLAYERS

Mathisen, G.

*University of Tromsø*

**Introduction** Linear sprint and agility performance are important skills in soccer, and the amount of sprinting may be of vital importance in soccer matches. Studies have revealed that elite players perform better in linear sprint and agility than sub-elite players, and fitness testing of youth soccer players may provide important information for coaches. However, there are few studies in young female soccer players on linear sprint and agility performance. Thus, the purpose of this study was to test these abilities in 14-16 year-old female soccer players, and compare the results with male soccer players at the corresponding age. **Methods** 46 young local soccer players, 24 female with mean age ( $\pm$  SD) 15,4 ( $\pm$  0,73), and 22 males with mean age 15,2 ( $\pm$  0,87) were tested in linear sprint and agility performance. The linear sprint-test was a 20 m track with 10 m split time recording (Brower Timing System, UT, USA). The agility test was a 20 m standardized course. Results Results for the female players shows mean 1,91 s ( $\pm$  0,10) (min 1,75 s, max 2,11 s) in 10 m linear sprint, and mean 3,41 s ( $\pm$  0,17) (min 3,08 s, max 3,82 s) in 20 m linear sprint for female players. Mean results on linear sprint for males was 1,84 s ( $\pm$  0,12) (min 1,62 s, max 2,04 s), and 3,22 s ( $\pm$  0,23) (min 2,86 s, max 3,72 s). Mean results for agility test was 8,10 s ( $\pm$  0,32) (min 7,51 s, max 8,81 s) for females, and 7,61 s ( $\pm$  0,39) (min 6,90 s, max 8,41) for males. **Discussion** Findings from the study showed difference in linear sprint and agility performance as shown in earlier studies. Difference between gender was 3,5 % in 10 m linear sprint,

6,4 % in 20 m linear sprint, and 6,1 % in agility performance. However, individual results show that the best results from female players are on approximately the same level or even higher than mean results from the male players. Results from the present study may be of interest for coaches in youth female soccer, and studies on sprint and agility training among youth female soccer players has to be followed up. ### **THE RELATIVE AGE EFFECT IN ENGLISH LOWER-LEAGUE YOUTH SOCCER PLAYERS: A PRELIMINARY CROSS-SECTIONAL STUDY**

Lovell, R., Parkin, G., Vaeyens, R., Portas, M.

*The University of Western Sydney*

The relative age effect (RAE) is a phenomenon characterised by a higher propensity of player birth dates in the early months of the selection year. This preliminary study examined the birth date distribution in a large sample of U9-U18 soccer players representing teams in the English professional leagues. We also examined if the players' birth date resulted in any anthropometrical or physical differences. Birth dates of 767 players representing teams from 13 lower-league clubs were collected from chronologically-grouped squads, and categorised into quartiles from the start of the selection year (Q1 = Sep-Nov; Q2 = Dec-Feb; Q3 = Mar-May; Q4 = Jun-Aug). 542 players' somatic maturation was estimated (age at peak height velocity: APHV), together with endurance (Multi-stage fitness Test), sprint (20m), repeated sprint (10 x 20m), agility (T-Test), and counter-movement jump assessments. A greater proportion of players with Q1 birth dates ( $p < 0.01$ ) was observed in all age-groups (U18: 48.4%; U16: 44.8%; U15: 58.6%; U14: 46.2%; U13: 42.9%; U12: 44.9%; U11: 36.2%; U10: 37.2%; U9: 54.3%). Due to the low frequency of Q3 and Q4 birth dates, players were categorised into semesters to examine if relative age resulted in any physical advantages. There were few differences in anthropometric and physical fitness measures between players born in the first (S1) and second (S2) semesters of the selection year. Although not statistically significant, U9, U10, and U12 players born in S2 tended to have a lower APHV (effects size [ES]: 0.6-0.7). In some squads, S2 players tended to have lower sprint (U9; ES: 0.54), agility (U12; ES: 0.77), and repeated sprint capacities (U9; ES: 0.91), and a lower body mass (U9 & U13; ES: 0.65). There were no between-semester differences in the physical fitness and APHV measures of the U14-U18 players. The RAE demonstrated in this population supports previous work in elite-youth soccer. We also observed a strong RAE as early as U9, although this should be interpreted with caution given the smaller sample in younger age groups ( $n=35-65$ ). We observed few between-semester differences in physical attributes, but pre-pubescent players born in S2 were likely to mature earlier. However, the birth date bias did not result in any physical advantages in adolescent and post-adolescent players. Longitudinal research is required to determine if the relative age of elite-youth players provides a physical advantage during development.

### **OPTIMISATION OF THE STIMULATION PARAMETERS FOR FES TRAINING: A PRELIMINARY STUDY ON ABLE-BODIED SUBJECTS**

Deley, G., Deneziller, J., Babault, N.

*Faculty of Sport Sciences*

Introduction Aerobic exercise can be broadly beneficial to health and quality of life in humans with spinal cord injury (SCI) (Jacobs et al. 2001, Ditor et al. 2003). However, exercise must meet certain criteria to induce significant benefits. One solution for SCI patients is Functional Electrical Stimulation (FES) during rowing, that couples volitional arm and electrically controlled leg exercise. Despite its beneficial effects, FES has not gained widespread clinical popularity because of the rapid muscle fatigue that it can engender (Peckham and Knutson 2005). The stimulation pattern needs to be adequately adapted to produce high force while minimizing fatigue. Hence, our aim was to explore the differences between two stimulation programs on torque production and fatigue. This preliminary study has been performed in healthy subjects. Methods 15 subjects regularly involved in a physical activity were included in this study, composed of two experimental sessions interspersed with at least 72 hours. Each session corresponded to a stimulation program applied during 30 minutes. The first program, called "constant-frequency trains" (CFTs), consisted in 6 seconds ON – 6 seconds OFF stimulation trains (450  $\mu$ s, 40 Hz, no ramp) during 30 minutes. The second program, "variable-frequency trains" (VFTs), consisted in 10 minutes of CFTs followed by 20 minutes of 6 seconds ON – 6 seconds OFF (frequency: 20 Hz, pulse width: 450  $\mu$ s, no ramp but preceded by a 80-Hz doublet). The torque evoked by each contraction was recorded. Results Our results showed significantly greater decreases in evoked torque after the CFTs program in comparison with VFTs (-71•7.3 % and -36•5.5 % respectively,  $P < 0.05$ ). MVC was also more decreased after CFTs (-36•7.4% vs. -32•6.9%). Total work during the 30 minutes was greater when VFTs were applied. Discussion The present results have shown that a stimulation program with VFTs reduces fatigue allows for higher force contractions during the entire session compared to CFTs. This might be explained by the "catch-like" phenomenon, i.e. the tension enhancement observed after an initial brief interpulse interval is added to the beginning of a subtetanic train of pulses (Burke et al. 1970). Therefore, this experimental VFTs program might provide a more optimal stimulus for FES-row training and thereby result in greater exercise-induced adaptations. It now has to be tested on SCI FES-rowers. References 1. Jacobs PL, Nash MS, Rusinowski JW (2001) *Med Sci Sports Exerc.* 33: 711-717. 2. ### **THE INFLUENCE OF UNILATERAL TRAINING ON CROSS EDUCATION AND ASYMMETRY IN USE OF LIMBS IN YOUNG BASKETBALL PLAYERS**

Cvorovic, A., Kocic, M., Beric, D.

*University of Nis*

Introduction Cross education and functional asymmetry in limbs use are phenomena that are based on neurological responses at the CNS level affected by external stimuli. Primary aim of this study was to analyze how the unilateral training affects on trained and untrained limb and to which extent leads to a reduction of asymmetry determined in the initial testing. Methods The study included 15 male basketball players in age category U15 by FIBA regulations. Explosive strength of the arm extensors was measured by modified Throwing Gate Test using Newtest Powerlimer 300 device (Tossavainen, 2003). For vertical jump is used modified run-up vertical jump test (Young et al. 1999). Each limb was tested with three attempts in tests. It was conducted 24 training sessions in the time period of 8 weeks, with

the focus on the weaker limb in initial testing. Every workout has treated each of tested variables with one exercise for three sets and with similar movement tasks like in tests. For data analysis are used Mixed Design ANOVA, asymmetry index (AI% Chavet et al. 1997), and % differences between same limbs on initial and final testing. Results Effects of unilateral training on trained upper limb were 15.05% and for untrained 10.36%. Improvement for trained lower limb was 12.54% and 8.69% for untrained. AI in initial testing for upper limbs was 6.42%, and for lower - 10.73%, and AI in final testing for upper limbs was 2.52% and for lower - 6.69%. Discussion In accordance with the primary aim of the research it was found that unilateral training except that significantly affect on the trained limb, also significantly affects on untrained limb for arm extensors and for run-up jumping ability with positive influence on decreasing of asymmetry. The results are consistent with research in the area of cross education and asymmetry in limb use (Zhou 2003; Chavet et al. 1997), but most studies differ in methodology and test conditions, so that any comparison should be taken with a certain amount of restraint. This study offered a possible model approach in solving practical problems in practice and where competition requires more bimanual and bipedal efficiency as is the case in basketball. Existing research does not intend to deal with the physiological causes of these phenomena, but only for the purpose of practical application in specific sport training. ### ENERGY COST AT VO<sub>2</sub>MAX SWIMMING INTENSITY: COMPARISON BETWEEN METHODS

Fernandes, R.J.1,2,3, Sousa, A.1,2, Ribeiro, J.1,2, Pelarigo, J.G.1,2, de Jesus, K.1, Vilas-Boas, J.P.1,2,3, Figueiredo, P.4

1: Faculty of Sport, University of Porto, 2: CIFI2D, 3: LABIOMEPE, 4: Higher Education Institute of Maia

Introduction Energy cost (C) has been described as a bioenergetical predictor of human locomotion (di Prampero, 1986), and considered a fundamental parameter applied to swimming training (Fernandes et al., 2006). However, C has been traditionally assessed through the oxygen consumption (VO<sub>2</sub>) (sometimes including the blood lactate concentrations - [La-] – contribution), and scarcely considering other ventilatory parameters. The purpose of this study was to compare C at maximal oxygen consumption (VO<sub>2</sub>max) swimming intensity by means of two methods. Methods Ten male senior swimmers (17.9±3.1yrs, 69.3±6.1kg and 1.8±4.8m) performed a 7x200m front crawl incremental protocol until exhaustion (cf. Fernandes et al., 2006). Capillary blood samples for [La-] analysis were collected from the ear-lobe at 3 and 5min after the last step. Gas exchange parameters were assessed breath by breath (averaged 5s) using a portable and telemetric gas analyzer (K4b2, Cosmed, Italy). C was calculated in the last step by means of two methods: (i) using the net VO<sub>2</sub> and [La-] values, by considering the ratio between energy expenditure and correspondent velocity (VLmethod); and (ii) through the calorific unit cost (CUCmethod) (Kcal.kg<sup>-1</sup>.km<sup>-1</sup>) = VO<sub>2</sub> (L.min<sup>-1</sup>) \* calorific equivalent (Kcal.L<sup>-1</sup>) \* velocity<sup>-1</sup> (m.min<sup>-1</sup>) \* body mass<sup>-1</sup> (kg) \* K<sup>-1</sup> (1000m.Km<sup>-1</sup>) (Fletcher et al., 2009). Comparison between groups was done using Paired T-Test (p≤0.05). The method agreement was assessed by the Bland-Altman plot. Results Mean (±SD) values for VLmethod and CUCmethod were significantly different: 87±0.08 and 0.94±0.10kJ/m, respectively (p<0.05). The Bland-Altman plot showed that the mean difference was close to zero (0.05), and the corresponding limits of agreement (average ± 1.96 SD) ranged between -0.05 and 0.166, indicating a small difference (in 95% of the subjects) between the two methods. Discussion The main finding of this study was that expressing C corresponding to a very high swimming intensity differs accordingly to the method used. The CUCmethod, by taking into consideration the respiratory exchange ratio, is more variable and influenced by other factors (such as pre-exercise diet, resting muscle glycogen content and muscle fibre composition, Fletcher et al., 2009). Still, the VLmethod, by reflecting only the quantity of ATP used in the exercise, already considering the error associated with [La-] analysis, seems to be less sensitive to external factors. ### PP-BN01 Biomechanics [BM] 1

#### SPECIFIC MUSCLE-TENDON ARCHITECTURE IN ELITE KENYAN DISTANCE RUNNERS

Kunimasa, Y., Sano, K., Oda, T., Nicol, C., Komi, P.V., Locatteli, E., Ito, A., Ishikawa, M.

Graduate school of Sport and Exercise Sciences

Introduction The superior success of Kenyan endurance runners has stimulated large amount of interest to explore valid reasons for their performance. Reliable physiological studies conducted on the Kenyan runners have not shown any superior genetic make-up and biochemical advantages in Kenyan runners (Saltin 2003). Consequently, Saltin (2003) suggested that one of the possible reasons for their high mechanical efficiency could be the special biomechanical make-up of these runners in their structures and function of muscle-tendon complex (MTC). More concretely, the question could be asked and answered, partially at least, if elite Kenyan runners possess a particular type of MTC and especially its Achilles tendon (AT), to store and utilize elastic energy during running. Therefore, the purpose of this study was to examine the lower-leg muscle-tendon architecture in elite Kenyan distance runners. Methods 13-elite Kenyan (KENYANS) and Japanese (JAPANESE) distance runners participated in this study. The achievement rates of their personal best record to the world records were calculated (Kenyan 97.0±2.3%, Japanese 88.1±2.3%). The following parameters were measured at a standing position by ultrasonography and caliper: AT length to gastrocnemius muscles (LAT\_GAS), AT length to soleus muscles (LAT\_SOL), AT cross-sectional area (CSA), AT moment arm and the length of lateral malleolus to metatarsale fibulare for foot gear ratio. The relative LAT\_GAS and LAT\_SOL were calculated by dividing each tendon length by shank length. Results/ Discussion The absolute LAT\_GAS and LAT\_SOL were significantly greater in KENYANS than in JAPANESE but not relative values. As compared to Japanese runners, AT moment arm was greater and foot gear ratio was smaller in KENYANS significantly. These results are in disagreement with previous studies which reported that the shorter AT moment arm is, the better the running economy and greater AT stretching (Scholz et al, 2008; Raichlen et al, 2011). However, the ankle joint stiffness was greater and less AT stretching during hopping (Sano et al, 2013) and running (Sano et al, in press)

for KENYANS. Longer AT moment arm can be advantageous for the lever ratio of the force production and might be related to the energy consumption of running. References Scholz MN et al. ### INFLUENCE OF GENDER ON CORE STABILITY STRATEGIES DURING LATERAL REACTIVE JUMPS

Weltin, E., Gollhofer, A., Mornieux, G.

*Albert-Ludwigs University Freiburg*

**Introduction** Insufficient function of the core seems to occur more often in females resulting in higher injury incidences among female athletes. Additionally recent literature suggests that deficits in trunk proprioception in the frontal plane (Zazulak et al., 2007) and increased lateral trunk lean are associated with increased knee abduction loading (Jamison et al., 2012). Frontal plane biomechanics seem to be important regarding lower limb injury and a better understanding of the role of the core during lateral movements is needed. Thus the aim of the present study was to assess the differences in pelvic and trunk control between male and females in response to perturbations during lateral movements. **Methods** 3D full body kinematics were recorded (Vicon) for 12 men and 12 women performing lateral reactive jumps (LRJ) with their right leg on a motor driven plate. The lateral jump was performed under three different conditions, either without any perturbation (stable), or with a 10 cm perturbation to the right (sliding) or to the left (counteracting) at the time of landing. Trunk, hip, pelvis and knee kinematics at the time of the maximal pelvis abduction angle occurring in the first 50% of stance were compared between males and females by means of an analysis of variance with conditions treated as a repeated measure. Results Male athletes demonstrated greater pelvic tilt to the left ( $-5.9 \pm 5.0^\circ$  vs.  $-0.3 \pm 7.3^\circ$ ,  $p=0.011$ ) and hip internal rotation ( $6.3 \pm 6.2^\circ$  vs.  $-4.5 \pm 7.8^\circ$ ,  $p=0.001$ ). Females showed more trunk rotation to the left ( $-2.4 \pm 7.7^\circ$  vs.  $4.0 \pm 7.4^\circ$ ,  $p=0.039$ ) as well as greater knee abduction ( $4.7 \pm 6.5^\circ$  vs.  $-7.7 \pm 6.4^\circ$ ,  $p<0.001$ ). Additionally the comparison of the time curve of lateral trunk lean revealed that females move their trunk in the new movement direction after weight acceptance (lateral trunk lean at toe off:  $-1.7 \pm 3.4^\circ$  vs.  $1.8 \pm 3.6^\circ$ ,  $p=0.025$ ). **Discussion** Results suggested that perturbation during LRJ is compensated differently between genders. Male athletes adjust their pelvic tilt with respect to the new movement direction (Houck et al., 2006) and thus seemed to initiate push off more efficiently. The data suggests that female athletes relied on a strategy that resulted in greater trunk rotation and an active motion of the trunk in the frontal plane after weight acceptance. In addition the greater knee abduction angle displayed by the females is known as a risk factor for lower limb injuries. From a core stability perspective different control strategies are applied by males and females and with respect to lower limb injury females might be at a disadvantage. ### TRANSTIBIAL AMPUTEES FAVOUR THE INTACT LIMB WHEN LANDING FROM A COUNTERMOVEMENT JUMP

Strike, S., Diss, C.E.I., Schoeman, M.2

*1. University of Roehampton (London UK); University of the Free State (Bloemfontein, SA).*

**Introduction** Transtibial amputees (TTA) are encouraged by health professionals to engage in recreational sports to gain from the health and mechanical benefits associated with exercise. However they may be prone to injury and long-term joint damage if bilateral strength differences and asymmetrical loading patterns are evident in dynamic movements. Therefore, symmetry during vertical jump landings between amputees' intact and prosthetic limbs was assessed to determine the role of each limb in controlling the downward momentum of the centre of mass. **Method** Six unilateral TTA and ten nondisabled (ND) participants completed 10 maximal vertical jumps the highest of which was analyzed. Data were collected using 2 Kistler force platforms synchronized with a 9-camera Vicon motion analysis system. Thirty four reflective markers were attached to anatomical landmarks. Joint moments and powers were calculated using standard inverse dynamics. Symmetry between the limbs was assessed through the symmetry index (SI) (Herzog et al., 1989). Results Quasi-unilateral landings onto the intact limbs were performed at touch-down. Individual asymmetries were evident in the peak vertical force magnitudes (SI=51-140%); duration from touch-down to peak vertical force (SI=52-157%); ankle joint angles at touch-down (SI=100-538%) and range of motion (SI=147-200%); knee (SI=66-179%) and hip (SI=87-132%) extensor moments and work done at the ankle (SI=155-199%) and hip (SI=83-204%). High peak vertical forces experienced by both limbs (mean  $25.25 \pm 4.89 \text{ N} \cdot \text{kg}^{-1}$  intact,  $14.61 \pm 8.28 \text{ N} \cdot \text{kg}^{-1}$  prosthetic) relative to the low landing heights compared to the ND participants indicate a potential risk of injury during landing. **Discussion** Although the exact force threshold which induces injury is unknown, the higher forces and moments experienced on the intact side indicated that jump landings may potentially lead to injury or progressive joint degeneration, especially considering that TTAs are predisposed to osteoarthritis at the intact knee and hip (Melzer et al., 2001). The peak vertical forces occurred almost simultaneously despite a delay in touch-down on the prosthetic side. From an injury perspective, the integrity of biological material is subject to both the magnitude of an external perturbation and the time over which it is applied. Therefore, the shorter durations to the peak vertical force due to limited prosthetic ankle's range of motion and absent plantarflexors may potentially increase the risk for injury and skin breakdown on the prosthetic side. ### CHANGES IN THE LENGTH-RATE OF FORCE DEVELOPMENT RELATIONSHIP AFTER ISOMETRIC EXERCISE AT A LONG MUSCLE LENGTH

Philippou, A.1, Koutsilieris, M.1, Maridaki, M.2

*National & Kapodistrian University of Athens*

**Introduction** Maximal isometric exercise at a long length has been shown to cause muscle damage and a disproportionately larger drop in maximal force at short versus long muscle lengths (Philippou et al., 2003). This disproportionate loss of strength results in a shift of the length (angle)-force relationship towards longer lengths (Brockett et al., 2001). We hypothesized that this shift could have a detrimental effect on muscle's ability for maximum rate of force development (RFD) at short muscle lengths. Therefore, the aim of this study was to investigate whether there is a muscle-length dependent impairment of RFD following this type of exercise. **Methods** Seven non-weight trained male volunteers (age:  $27.0 \pm 2$  yrs, height:  $174.7 \pm 2$  cm, mass:  $74.4 \pm 4$  kg) performed 50 maximal isometric contractions of the elbow flexors at a lengthened position (i.e., with the shoulder held at  $45^\circ$  of extension from the neutral position and the elbow joint at  $40^\circ$  of flexion), on an isokinetic dynamometer. Peak isometric force (PIF) and time to peak isometric force (TPIF) of the elbow flexors were measured at five different elbow flexion angles, i.e.,  $20^\circ$ ,  $40^\circ$ ,  $90^\circ$ ,  $110^\circ$  and  $130^\circ$ , in random order, and maximum RFD was determined as the PIF/TPIF ratio. Measurements were done before and for 4 consecutive days post-exercise, and included also creatine kinase (CK)

activity, muscle soreness (DOMS) and elbow joint range of motion (ROM). Analyses of variance were used for statistics. Results Isometric exercise at a long muscle length induced significant changes in the indirect indicators of muscle damage; Serum CK activity was increased on day 1 post exercise ( $P<0.01$ ), DOMS ratings were peaked on day 2 post exercise ( $P<0.05$ ) and ROM declined and remained significantly decreased for the whole testing period ( $P<0.01$ ). Before exercise, maximum RFD was higher at the elbow angle of 40° compared with 110° and 130° ( $P<0.001$ ). During the post-exercise period, maximum RFD was significantly decreased at all the angles tested ( $P<0.05-0.001$ ). The percent changes in RFD post-exercise were also significant over time but not between angles ( $P<0.05-0.001$ ). Discussion This study demonstrated that RFD following isometric exercise-induced muscle damage was affected proportionately at the various lengths measured. This finding suggests that RFD impairment is not muscle-length dependent and that contributing factors, other than the shift of the length-force relationship (Prasartwuth et al., 2006), may play a major role for the impairment of length-RFD relationship after muscle damaging isometric exercise. ## EVALUATION OF ACL INJURY RISK FACTORS IN YOUNG FEMALE HANDBALL PLAYERS

Domínguez-Castrillo, Ó.1,2, Turmo, A.1,3, Linde, X.3, Ferrer-Roca, V.1

1: GRSANE Centre Alt Rendiment (CAR) (Barcelona, Spain), 2: INEFC-Barcelona (Barcelona, Spain), 3: RCD Espanyol (Barcelona, Spain)

Introduction The anterior cruciate ligament (ACL) injury is one of the most severe and costly. Women athletes have a higher propensity to ACL injury. The goal of this pilot study was to detect the risk of injury in a youth female handball players using kinetic and kinematical parameters. Methods 14 players of the youth regional level draft participated in the study. Landing was monitored in two Drop Jump from a height of 40 cm. The system used for this purpose combined a 4-camera ViconMotus 9.1 equipment and two Kistler force platforms. Collected data included tibia length, knee medial-lateral displacement, knee flexion ROM and asymmetry of vertical impulse between both lower limb. The QuadHam ratio was obtained in isokinetic knee extension/flexion movements at 240°/s. The algorithm proposed by Myer et al. in 2010 was used for the prediction of probability of dynamic knee valgus during landing. Results Shapiro-Wilk test ( $p>0.05$ ) showed a normal distribution of kinetic and kinematical variables. Players presented higher impulse forces of dominant leg compared to non-dominant during eccentric phase of jump ( $p<0.05$ ). In 57% of the cases differences were higher than 15%. 71% of the girls presented a probability to valgus moment during landing higher than 85%. Discussion The main finding of this study was that more than 70% of subjects showed a probability above 85% to risky knee valgus moment during landing, highly related to prediction of ACL non-contact injuries (Hewett, 2005). Additionally bibliography defines strength deficit between limbs as a risk factor to future ACL injury (Hewett, 2005). In this pilot study more than 50% of the players had an impulse deficit above 15%. This results agreed with others studies where the lack of neuromuscular control in similar aged female was demonstrated (Zazulak, 2007). We would recommend to apply this test to other groups for an early prediction of possible ACL knee injuries because of the extremely high risk injury factor found in our sample. In the same direction, prevention protocols for the improvement of neuromuscular control should be included in training plans to reduce the probability of ACL injury (Myklebust, 2007). ## INDIVIDUALLY SHAPED FORCE-VELOCITY RELATIONS EFFECT MUSCLE STRESS DURING ISOKINETIC LEG PRESS MOVEMENTS WITH MVC

Penasso, H., Binder, I., Thaller, S.

University of Graz

Introduction Various studies use isokinetic movements to evoke fatigue (e.g. Babault et al., 2006; De Ruyter et al., 1999; James et al., 1995). Based on simulated maximal concentric isokinetic leg press movements we demonstrate how individual differences in the force-velocity relation of muscles affect the amount of stress the muscle is exposed to. Methods According to Siebert et al. (2007) we determined individual neuromuscular properties (INP) for the knee extensors of nine healthy male subjects ( $m = 79.1 \pm 6.9$  kg,  $age = 23.0 \pm 1.86$  yrs,  $h = 1.83 \pm 0.09$  m). For simulations two datasets (subject A and B) with equal maximal isometric muscle force  $f_{iso}$  ( $\pm 2.3\%$ ) but different curvature  $a/f_{iso}$  ( $\pm 67.0\%$ ) of the force-velocity relation were selected. The model was parameterized with INP as well as with individual or equal anthropometric lengths. After vertically accelerating a point-like 15 kg mass, a maximal isokinetic leg press movement at 0.4 m/s constant external velocity (EV) was simulated. The motion lasted 0.8 s and ranged from 70 to  $126 \pm 1$  deg. The calculated force-, velocity- and power-time relations of the model muscles were compared inbetween the two subjects. Results The nine subjects' mean values were  $f_{iso} = 21190 \pm 5264$  N,  $a/f_{iso} = 0.3 \pm 0.14$ , and optimal contraction velocity  $v_{opt} = 0.4 \pm 0.1$  m/s. During constant EV the contraction velocity (CV) varied by  $32.8 \pm 1.0\%$ , the muscle force in subject A varied from 118.7 to 258.6% of  $f_{opt}$  and in B from 91.1 to 218.6%. The integrated power- and force-time relations showed a 9.4% greater value for force and a 16.7% greater value for power in B. The effects of individual anthropometry were  $<1.0\%$  in force and  $<5.5\%$  in power, those of acceleration period and muscle activation were overall  $<1.7\%$ , and  $<0.14\%$ , resp., and thereby play a minor role. Discussion We show that during a constant EV the CV changes and that the muscles power- and force-output is influenced by the individual shape of the force-velocity relation. Related to their individual optimal values, muscles operate in different sections of the force-velocity relation and thus are differently stressed. Throughout the movement the muscle B produces more force and power than A. We demonstrate that for submaximal dynamic tasks (cf. training loads) a normalization condition given in %  $f_{iso}$  is not sufficient if equal muscle stress is intended. ## BIOMECHANICS OF RUGBY SCRUMMAGING: KINEMATIC AND KINETIC ANALYSIS ACROSS ENGAGEMENT CONDITIONS

Cazzola, D., Preatoni, E., Stokes, K.A., England, M., Trewartha, G.

*University of Bath*

**Introduction** Biomechanical studies of the rugby union scrum have typically been conducted using scrum machines (Milburn, 1990; Preatoni et al., 2013), but a biomechanical analysis of rugby union scrummaging (team A against team B) is still lacking. The aim of this study was to analyse kinematic and kinetic variables during contested scrummaging in three different engagement conditions designed in part to modify the loading conditions on players: Crouch-Touch-Pause-Engage (CTPE, in use prior to 2012/13 season), Crouch-Touch-Set (CTS, current) and Touch-Held (TH, test). **Methods** Sixteen forward packs (n=128 players) from two playing categories (International and Professional Club) performed repeated scrum trials, outdoors on natural turf, following instruction in each of the experimental conditions. Two scrums per condition per team (8 teams, 48 scrums in total) were analysed. Exerted forces between teams' front rows were estimated by using pre-calibrated pressure sensors positioned on the right and left shoulders of front row players in team A. Inertial Measurement Units (IMU) were placed on the forehead and C7 of each team's front row players, and both the overall and single axes accelerations were computed. Multiple camera views allowed the recording and subsequent analysis of player movements, in the primary transverse and sagittal planes of motion. A control system (Preatoni et al., 2012) executed pre-recorded audio commands to players with consistent timings and synchronised data streams. **Results** Biomechanical variables across the conditions were divided by scrum phases. In general the TH technique reduced the biomechanical loading on players, while there was no difference between conditions in terms of body motions relating to stability. Prior to engagement the TH condition showed a lower set-up distance between front rows versus both CTPE (29%) and CTS (30%). During Engagement, closing speed was reduced in TH compared with CTPE (22%) and CTS (19%). During Initial-Engagement, peak force was lower in TH as opposed to CTPE (24%) and CTS (24%) and overall acceleration peak on C7 was lower ( $p<0.05$ ) in TH compared with CTPE (20%) and CTS (16%). The average force did not differ between conditions during the Sustained scrummaging phase. **Discussion** In this study the biomechanical demands of contested rugby scrummaging were measured for the first time. The findings are stimulating in terms of injury prevention and performance analysis, proposing biomechanical solutions to minimise potential injury risk and a novel method to evaluate different scrum techniques. **References** Milburn PD. ## VALIDITY OF A TWO-DIMENSIONAL MOTION ANALYSIS TECHNIQUE FOR QUANTIFYING DYNAMIC KNEE VALGUS DURING SINGLE LEG DROP LANDING

Kagaya, Y., Itoh, W., Fujii, Y., Nishizono, H.

*Showa University*

**Introduction** Landing with dynamic knee valgus is considered a risk factor of non-contact anterior cruciate ligament (ACL) injury. To identify athletes at a higher risk, we developed a two-dimensional (2D) video-based screening test to determine hip abductor function as well as dynamic rearfoot and knee valgus (Kagaya et al. 2009). However, validity of our analysis technique for quantifying dynamic knee valgus remains unclear. The purpose of this study was to validate the accuracy of the indices for dynamic knee valgus derived from knee-in distance (KID) and hip-out distance (HOD) using the 2D-video images. **Methods** Twenty healthy university students (10 female, 10 male) agreed to participate in this study. Their mean age was  $21.1\pm 1.7$  years, height and weight were  $166.8\pm 10.2$  cm and  $58.7\pm 9.0$  kg, respectively. Subjects were asked to step off a 30-cm box and land on one leg. This procedure was recorded simultaneously using a 2D video camera in the frontal plane and the Vicon motion capture system. KID was measured as the distance from hallux to the point where the line connecting the center of the patella and the anterior superior iliac spine (ASIS) intersects the floor. HOD measured as the distance from hallux to the projection of ASIS on the floor. Pearson's correlations examined associations between KID normalized by height (KID/H) as well as HOD normalized by height (HOD/H) and three-dimensional knee valgus (3D-valgus) or 3D tibial internal rotation (3D-IR). Statistical significance was established at a level of  $p<0.05$ . Informed written consent was obtained from all subjects and approved by the Research Ethics Committee of School of Nursing and Rehabilitation Sciences at Showa University. **Results** Significant correlation was found between the KID/H and 3D-valgus ( $r=0.73$ ,  $p<0.01$ ). However, association was not significant between KID/H and 3D-IR ( $r=0.03$ ). A positive moderate correlation between HOD/H and 3D-valgus ( $r=0.50$ ,  $p<0.05$ ), as well as a negative moderate correlation between HOD/H and 3D-IR ( $r=-0.51$ ,  $P<0.05$ ) was also observed. **Discussion** McLean et al.(2005) reported that an excellent regression relationship was obtained to make a comparison between 2D analysis and 3D analysis of the knee valgus during side jump. Nagano et al.(2008) also reported that there was a significant regression relationship between 2D analysis and 3D analysis among the knee valgus in continuous jump landing task. They measured the knee valgus by the angle on the frontal plane. However, we analyzed it by the distance of KID and HOD. As a result, KID was a reliable alternative for the 3D-valgus and the HOD was for the 3D-valgus and tibial external rotation. The 2D video-based screening test is expected to have practical application in the field of sports. **References** Kagaya, Y., et al. (2009). *Jpn J Phys Fitness Med*, 58, 55-62(In Japanese). ## THE NUMERICAL ANALYSIS OF NASAL PROTECTOR FOR SPORTS ACTIVITIES

Granero, R.1, Driemeier, L.2, Dias, R.1, Noritomi, P.3, Coto, N.1

*1.University of São Paulo, Faculty of Dentistry(São Paulo, Brazil); 2.University of São Paulo, Polytechnic School(São Paulo, Brazil); 3. ITC- Renato Archer (Campinas, Brazil)*

**Introduction** In recent years a significant increase in the number of facial fractures in sports activities is noticed, being the nasal bone one of the most affected (Antoun, 2008). The use of nasal protector is recommended by researchers; however, there is no standardization about its material or geometry. Particularly about the material, clinical experience has shown that the combination of both flexible and rigid blades of copolymer of ethylene and vinyl acetate (EVA) offers comfort and safety for the athlete. **Methods** The numerical study of generated by the impact of a ball on the nasal bone in models with and without EVA protector. A cranial facial model was built with images obtained from computerized tomography (Deuffhard, 2006). The nose protection was modelled with two layers of EVA with a total thickness of 3 mm, following the soft tissue geometry. For the inner layer, 2 mm of flexible EVA was assigned; while the outside layer was made with 1 mm of rigid EVA. The finite element analysis was performed using the commercial software LS Dyna (Coto et al, 2012). The bone and rigid EVA were represented as linear elastic materials, the soft tissue and flexible EVA as hyperelastic materials. The impact of

a rigid sphere on the frontal region was simulated, with constant speed of 20 m/s. The impact event was analysed within the time interval of 9.1 ms. The model with no protector was used as control. The distributions of maximum principal stresses in the face bones were analysed. Discussion In the model without the protector the maximum principal stress in the nasal bone has exceeded its limit of rupture of 0.13 MPa (Hodgson,1967). In the model with the protector, stresses remained below this critical value. Based in these numerical results, the nasal protector made of a combination of flexible and rigid EVA proved to be effective in the face protection. ### **ANALYSIS OF SPINE MOVEMENT IN TRIATHLON WITH RESPECT TO BACK PAIN**

Felker, K., Babel, S., Platen, P.

*Ruhr-University Bochum*

**Introduction** Back pain is reported by approximately 30% of athletes. The lifetime incidence of low-back pain in triathlon has been reported to be 68%. The two main mechanisms of long-term pain include sports-related injuries and overuse. In order to better understand underlying mechanism the purpose of the present investigation was to evaluate triathlon specific motion patterns regarding the range of motion of different parts of the spine and to quantify the occurrence and the duration of exposure during training and competition. **Methods** We analyzed range of motion of different parts of the spine during the sub-disciplines cycling and running in 4 competitive triathletes (n=2 male, n=2 female), and during swimming in 1 athlete. 8 high-frequency cameras captured the trajectories of 18 light reflecting markers which had been fixed on the skin at different points on the subject's spine and front side. Using the software Simi Motion 13 angles were used to describe the ranges of motion of the cervical, thoracic and lumbar spine with respect to flexion, extension, and lateral flexion. The data was evaluated by assorting certain angles of risk according to the classification of DIN EN 1005-4. **Results** The most important findings include the following: nearly during the whole time of cycling, extension of the cervical spine statically remained in the red range (< 0°, range: -21° - -28°). Furthermore, flexion of the total spine was in the yellow range (20° - 60°) in 3 subjects during the whole time of cycling, while lateral flexion of all parts of the spine remained in the green range. During nearly all runs, flexion of total spine was in the red range (< 0°). Flexion of the cervical spine inter-individually varied broadly, while lateral flexion of all parts of the spine remained in the green range. During the whole time of swimming the crawl, cervical flexion was in the red range (< 0°), and during 50% of the time, cervical lateral flexion also was in the red range (> 10° or < -10°). **Discussion** The analysis of spine movements indicate, that triathlon specific body positions during training and competition imply an increased risk for back pain mainly in the area of the cervical spine. This is in line with clinical findings of a nearly 50% lifetime incidence of neck pain in triathletes. The total stress of the spine is composed of the type of discipline, duration, intensity, and individual style of all training units and competition. Further factors, like vibration forces while cycling and the impact while running are of importance as well and should be considered in further research to evaluate back-specific risk areas in triathlon. The results of this investigation underline the necessity of specific spine stabilizing training programs in addition to the discipline specific training units. **Acknowledgement** The study was supported by the Federal Institute for Sport Science, Germany (IIA1-080102B/11-14).

### **INVESTIGATE THE ELBOW JOINT LOADING DURING WII BOXING SPORTS GAME**

Hung, S.P., Tsai, Y.P., Hsu, H.M., Kuo, L.C., Lin, H.T.

*Kaohsiung Medical University*

**Introduction** The Wii sports• has becoming popular in the world. Not only it is fascinated by adolescents but people of all ages. However, few previous studies were discussed the possible side-effect of this exercise. From the previous reports, there were some symptoms, such as delayed onset muscle soreness and acute muscle and tendon injury, coming out after playing Wii games. The purpose of this study is to investigate the elbow joint loading during playing Wii boxing game in the practice and game modes. **Methods** Five subjects aged from 18 to 25 yrs without any upper extremity injuries or diseases in the last six months were recruited in this study. The subjects played the WiiTM boxing game in both practice and game modes. Fourteen reflective markers were attached on the subject's anatomical positions and using Qualisys• motion capture system to record the boxing motion. The Euler parameter and inverse dynamic analysis were applied for calculating angular velocity, joint reaction force and moment, and joint power. **Results** From the analysis results, the joint force in elbow is about 60-80 N, the maximum loading is along the longitudinal axis. The joint torque is about 15-20 N-m, the peak value is occurred in longitudinal axial rotation. The joint torque, joint acceleration and joint power of the elbow in game mode were higher than in practice mode. Especially the joint power of elbow in the game mode is almost two times higher than in the practice mode. **Discussion** Due to the keen competition in the game mode, the subjects punched more quickly and powerfully. From the previous study, the punch force and the joint acceleration are positive correlation (Wu, 2008). Therefore, in order to have better boxing performance, the subject shoulder accelerate the joints as fast as possible in upper extremity, that results higher joint loading both in shoulder and elbow. In this study, we also found that the subject afforded higher elbow joint loading during playing Wii Box in the game mode than in the practice mode. This study also found that the peak loading of the elbow joint was not very high. However, the repetitions and action frequency during the game were much higher than normal exercises. Subjects do the intensive activities, and it may cause higher risk of damage (Sparks D et al., 2009). The improper use of force and suddenly changed motion (joint acceleration) might cause the injury in the musculoskeletal system easily. Therefore, before playing Wii game especially like Boxing, the player need warm-up, and doing the stretch after the game. Moreover, know the biomechanical loading could help us to prevent injury during playing Wii game. **References** Nett MP, Collins MS, Sperling JW. (2008). *Skeletal Radiol*, 37, 481-483. ### **RISK FACTORS OF KNEE INJURY DURING CROSSOVER AND CUTTING MANEUVER IN FEMALE BASKETBALL ATHLETES**

Lee, H., Tseng, T., Lee, Y.

*National Taiwan Normal University*

**Introduction** Female basketball players suffer ACL injuries at a 4 to 6 fold greater rate than male players. Most ACL injuries in female athletes were noncontact injuries, typically during deceleration, lateral pivoting, or landing tasks that are often associated with high external knee joint loads and high anterior knee shear forces. The purpose of this study was to determine ACL injury risk factors between cutting and cross over step maneuvers in female basketball athletes. **Methods** 12 healthy female basketball players participated in this

study (age: 20.3yrs). Subjects were instructed to land with both feet on separated force plates, then immediately performed cutting or cross over step to the dominant side and kept running for 3 meters. Subjects performed 5 successful trials in each step maneuver with 30 s of rest between trials to minimize the potential effects of fatigue. The motion capture system consisted of 10 digital cameras (200Hz) were used to collect 3D trajectories from 28 reflective markers. The 2 force platforms collected GRF data at 1000 Hz and were time synchronized with the motion capture data. One-way ANOVA with significance level of 0.05 was used to compare biomechanical measures of the supporting leg between two different step maneuvers. Results The peak anterior tibial shear force of the cutting step supporting leg was significantly greater ( $p=.006$ ) than the cross over step supporting leg. The peak knee valgus moment of cutting step supporting leg was significantly greater ( $p=.003$ ) than cutting step stepping leg. Discussion Knee anterior tibial shear forces and valgus moments are the primary predictors of ACL injury risk. Physiologic valgus moments on the knee can increase anterior tibial translation and loads on the ACL by several-fold (Pollard et al., 2010). Quadriceps force could generate anterior tibial shear force and apply stress and strain to the ACL when the knee is near fully extension (Li et al., 1999). If anterior tibial shear force generated by the eccentric quadriceps contraction was excessive, the hamstring may not provide adequate force to counter anterior tibial shear force. The risk of ACL injury will be high at this moment (Brazen et al., 2010). The current findings indicate that female basketball players might have higher risk of knee injury during cutting step than cross over step maneuver. Future studies should focus on investigating the best jump landing and stepping strategy, and on analyzing better ways to coordinate lower extremity joints to reduce non-contact ACL injury risks. This work is particularly supported by NSC (100-2628-H-003-013-MY2) and 'Aim for the Top University Plan' of the National Taiwan Normal University and the Ministry of Education, Taiwan, R.O.C References Li G, Rudy T, Sakane M, Kanamori A, Ma C & Woo S. ### IMITATION IN ADULTS WITH AUTISM SPECTRUM CONDITIONS: THE EFFECTS OF SOCIAL MODULATION AND MOTOR ABILITY

Andrew, M., Bennett, S.J., Elliott, D., Gowen, E., Hayes, S.J.

*Liverpool John Moores University*

Introduction Individuals with autism spectrum conditions (ASC) struggle to engage in social interactions. One difficulty is voluntary imitation, which affects learning new motor behaviours and is related to copying how (kinematics) a movement is performed. This difficulty is hypothesised to be based on brain structures associated with social modulation and/or motor ability (Hamilton, 2013). To this end, in Experiment 1 we investigated the social modulation hypothesis by examining imitation of unnatural and natural movement kinematics by using a non-human agent that removes social context. In Experiment 2, we investigated the motor ability hypothesis by examining the acquisition of a related, but novel spatial-temporal movement sequence through motor training. Methods Nine adults with ASC and nine age and IQ matched typical adults volunteered for the study. All provided informed consent which was approved by host University ethics committee. In Experiment 1, all volunteers imitated a non-human agent (white dot) where the movement trajectory was manipulated to display novel kinematic profiles (unnatural; natural; constant velocity). Imitation accuracy was examined using separate ANOVAs. In Experiment 2, all volunteers practised a novel spatial-temporal sequence through motor training. Following practice all participants performed a retention test. Motor performance accuracy and variability were examined using separate repeated measures ANOVAs. Results The performance data in Experiment 1 indicated the ASC group were 262 ms more accurate ( $F(1, 16) = 4.387, P = 0.05$ ) at imitating the model's movement time than the typical control group. The kinematic data indicated that both groups ( $F(2, 32) = 22.929, P < 0.01$ ) imitated the natural and unnatural movement kinematic profiles. In Experiment 2 the performance data showed both groups became more accurate ( $F(6, 96) = 21.342, P < 0.01$ ) and less variable ( $F(6, 96) = 22.322, P < 0.01$ ) at executing the novel spatial-temporal sequence task across practice and retention. Discussion Individuals with ASC imitated unnatural movement kinematics to the same extent as a typical group, yet were more accurate at imitating movement time. Therefore, they showed adaptive and functional motor behaviour. These data suggest a previously well established broken mirror neuron hypothesis cannot account for imitation deficits observed in ASC. Having controlled for motor ability and modulating social contiguity with a non-human agent, the findings support suggestions that a deficit in imitation in those with ASC is associated with top-down control (Hamilton, 2013). References Hamilton, A. F. d. C. (2013). Dev. Cog. Neuro. 3(0), 91-105.

##### ANALYSIS ON THE MATCH PHYSICAL DEMAND CHARACTERISTICS OF CHINESE ELITE MALE FIELD HOCKEY PLAYERS

Hongyou, L.1, Gang, Z.2, Hui, K.2, Javier, S.1

*1: Polytechnic University of Madrid (Madrid, Spain), 2: Shenzhen University (Shenzhen, China)*

Introduction The motional patterns of field hockey matches are complicated, the intensity and property of players' physical load keep varying at different match time. Carrying experimental equipments by the players is forbidden by the rules, so it is impossible to track players' physiological indices during matches. What is more, various aerobic and anaerobic loads coming out at different intensities and time, accompanying with irregular body contacts and intermissions, make it much more difficult to assess the players' match physical load. In purpose to evaluate players' physical demand statistically; this paper analyzed the players' running distance, technique using, and intermissions in matches. Methods All matches played in the 11th Chinese National Games which was held in Shandong 2009 were filmed. The software of SIMI Scout was undertaken to analyze the recorded match films to draw out related statistics. Running distance, technique using and match intermissions of 38 players from different positions (defender, midfield and forward) were analyzed. ANOVA analysis was undertaken to compare the positional differences. Results (1) During the matches of the 11th Chinese National Games, the players' average running distance is  $7334 \pm 877$  (mean  $\pm$  s) meters,  $3693 \pm 441$  meters in the first half and  $3640 \pm 437$  meters in the second, both the total distance covered and running distance at various speed differ from players of distinct positions ( $P < 0.05$ ); (2) The undertaken techniques of ball passing and touching, marking and defense-assistance also differ from the players of different positions ( $P < 0.05$ ); (3)

The average intermittent time per match is  $1838.1 \pm 247.8$  seconds, the average number of intermissions is  $155.6 \pm 13.5$  times, the average intermittent time is  $11.8 \pm 7.4$  seconds. Discussion It has been verified that "performance in (field) games can be analyzed by notating players' actions" (Thomas Reilly, 2001) and it is "a consensus in sport science that the most effective training for preparing athletes for competition is that which most closely replicates competitive performance conditions" (V. Di Salvo et al., 2007). This study verified the differences of performance and demands of Chinese male field hockey players in different individual positions during match play; therefore it could provide some guidance on evaluating players and formulating training prescriptions. ### EFFECTS OF LOW-VOLUME HIGH-INTENSITY INTERVAL TRAINING ON CARDIORESPIRATORY FITNESS IN ADULTS: A META-ANALYSIS OF CONTROLLED AND NON-CONTROLLED TRIALS.

Taylor, K.1, Batterham, A.M.1, Weston, M.1, Hopkins, W.G.2

1 Teesside University (Middlesbrough, UK) 2 AUT University (Auckland, New Zealand)

**Background** Low cardiorespiratory fitness is a risk factor for cardiovascular and total mortality. Improving fitness in the general population with efficient training programmes is therefore worthwhile. Here we present the first meta-analytical review of the effects of low-volume high-intensity interval training on fitness represented by peak oxygen uptake ( $VO_{2peak}$ ). **Methods** A search of five literature databases yielded 24 interval-training studies meeting the following eligibility criteria: adult subjects;  $VO_{2peak}$  assessed pre and post training; training period of at least 2 weeks; repetition duration 30-60 s; work/rest ratio <1; and exercise intensity maximal or near maximal. The total of 44 mean effects on  $VO_{2peak}$  in training and control groups were converted to percent changes for a novel mixed-model meta-analysis that included the usual between-study random effect and a within-study random effect to account for studies with control groups. The fixed effects in the model included type of study (controlled, uncontrolled), subject characteristics (sex, training status, pre  $VO_{2peak}$ ) and training parameters (number of training sessions, work/rest ratio). Effects were weighted using percent standard errors from exact p-values or from estimated errors of measurement. Probabilistic inferences were based on standardized thresholds for small, moderate and large changes (3.2, 9.6 and 19% for sedentary subjects; 1.2, 3.6, and 7.2% for active non-athletes) derived from between-subject SDs for pre  $VO_{2peak}$ . **Results** The meta-analysed effect on  $VO_{2peak}$  of an average interval-training protocol (13 sessions, 0.14 work/rest ratio) in a controlled study was a possibly large increase of 6.4% (90% confidence limits  $\pm 3.8\%$ ) in male non-athletes with a pre  $VO_{2peak}$  of 45 ml/min/kg and a possibly moderate increase of 11.5% ( $\pm 6.6\%$ ) in sedentary males with a pre  $VO_{2peak}$  of 30 ml/min/kg. Study and subject characteristics had the following modifying effects, ranging from moderate to trivial and unclear: -3.9% ( $\pm 3.5\%$ ) for subjects with  $VO_{2peak}$  higher by 10 ml/min/kg; 3.0% ( $\pm 3.1\%$ ) for each 3-fold increase in number of sessions; -1.5% ( $\pm 3.1\%$ ) for each 3-fold increase in work:rest ratio; and -1.7% ( $\pm 6.3\%$ ) for females. Unexplained variation in effects between research settings was typically  $\pm 3.0\%$ . **Discussion** Low-volume high-intensity interval training produces clear substantial improvements in cardiorespiratory fitness of sedentary and active males, with greater benefit for the less fit. More studies are needed to confirm the benefit of such time-efficient training in females.

### QUALITATIVE ANALYSIS ON FOOTBALLERS' BEHAVIOURS LEADING TO AN HANDLING THE BALL INFRINGEMENT

Moreira, M.1, Pina, J.2, Pereira, V.2

1 Univ Tecn Lisboa, Fac Motricidade Humana, 2 Portuguese Football Association, Referee Committee

**Introduction** Referees and assistant referees still have difficulties analysing and applying the rules when it comes to call an handling the ball foul because of the subjective feature called "deliberate act" (in Law XII, FIFA booklet Laws of the Game). The aim of this study is to identify the player's behaviours that lead to an infringement and to find performance indicators that help to produce new training programmes to a better refereeing. **Methods** Data was crossed through out: experts' opinions (to identify and classify the most problematic situations); motor behaviours' structure and functional analysis (to acquit infringements' indicators); bibliographic support of reference studies. Experts were experienced Portuguese top-standard referees (n=22, 1st and 2nd inquiry) and assistant referees (n=34, 1st inquiry; n=46, 2nd inquiry). Referees (n=7, 1st inquiry; n=10, 2nd inquiry) and assistant referees (n=6, 1st and 2nd inquiry) were on the FIFA list. Through percentages, a descriptive data analysis was done. Structural analysis was based on the Law 12 "Handling the ball". The distance between the opponent and the ball was calculated using the SIMI Motion Twin software. Both last analyses were videos analysis from Portuguese professional leagues. **Results** Experts mention that the difficulty to identify the infringement is related with lack of visibility (22%), deliberate act (21%) and the distance between the opponent and the ball (18%). 62.5% mentioned the crossover as one of the most difficult actions to identify and other 20% identified the rebound. 28.6% were when the distance between the opponent and the ball was 1- 2m and 21.4% when it was 2- 3m; these were identified when the action was done in the penalty area (28,6%) or near the touch line (19%). Due to shoulder structure (humerus, clavicle and scapula) and the ball size, when the arm is raised and there is a ball contact with the shoulder, there is always a contact with the arm and therefore it is an infringement. Having as a reference the running, the vertical jump and the arm rise to reach a ball motor patterns, present in other sports, we perceive that in football the over head action has the aim of reaching for the ball. Considering a 200ms visuo-motor delay, a 25m/s ball speed, after the kick, and a 100ms between the toe-off and the ball-contact, at least 2.5m of distance is necessary for the opponent to achieve movement reprogramming and intercept the ball deliberately. **Discussion** In order to improve refereeing it is important to know how to read body movements in the usual circumstances where handling the ball occurs. Training programs should provide drills to improve visibility and decision-making experiences required on apply the handling the ball law.

### LESSONS FROM THE LONDON OLYMPICS: ATHLETICS, SWIMMING AND HOME NATION MEDAL ADVANTAGE

Stefani, R.

California State University, Long Beach

**Introduction** A mention of London 2012 brings to mind images of the charismatic Usain Bolt in athletics, Michael Phelps with his record haul of swimming medals and Jessica Ennis striking gold in the women's heptathlon, with all of Great Britain's weight on her shoulders. There is much more to learn about athletics, swimming and home nation medal advantage. **Athletics** The fraction of 1988 winners who would still win dropped from 68% in 2000 to 50% in 2008 only to rise to 57% in 2012. Athletics winners at London were worse than those in 1988, after which a crackdown began on performance enhancing drugs. By 2008, Olympic champions had caught up with their coun-

terparts from 1988, only to lose ground in 2012, coincident with post 2008 proactive anti-doping surveillance such as introduction of the chemical passport by WADA. Swim Suits Following the 2008 Olympics, when men's swimming times improved 1.69% over one Olympiad, FINA concluded that high tech suits were contributing to that improvement (even though times had improved 1.63% per Olympiad from 1956-1988). Effective January 1, 2010, lower tech suits had to be used. If FINA was correct, times should have especially deteriorated for men. That did not happen. There had been a 0.82% average four-year improvement for the last World Short Course, World Long Course and Olympic competition using the high tech suits. In fact, there was a higher average four-year improvement of 0.99% for those same three competitions when the lower tech suits were first worn. Home Nation Medal Advantage Over the last 13 fully attended Games, the home nation won an average of 13 more medals at home than it had won four years before and the home nation then won an average of seven fewer medals, four years after being host. For London, Great Britain was projected to win 47+13=60 medals (65 were won). China was projected to win 100-7=93 medals (88 were won). The average prediction error was zero. For Rio in 2016, Brazil is projected to win 17+13=30 medals while Great Britain should win 65-7=58 medals.

## ANALYSIS OF SET FOR UNDER-19, UNDER-21 AND ELITE MALE BEACH VOLLEYBALL ACCORDING TO PLAYER ROLE

Medeiros, A.1, Marcelino, R.1, Mesquita, I.1, Palao, J.2

1: *University of Porto (Portugal)*, 2: *University of Murcia (Spain)*

**Introduction** In beach volleyball, the set is the action that has the purpose to provide the best conditions for the attacker to finalize the rally [1]. In indoor volleyball, the set is executed primarily using the overhand. However in beach volleyball the rules only allow clean overhand pass. Therefore, players use the overhand pass and forearm pass to perform the set. In beach volleyball, there are two player role, according to their action in defense, defender and blocker, what affect their physical characteristics [2]. It has not found information in the literature review related to the way of execution the set in relation to role player and age group. Therefore, the purpose of this study was to determine the types of settings used in a game in the categories under-19, under-21 and elite, according to player role (blocker and defender). **Methods** A total of 810 side out setting's (30 sets) from Under-19, 713 side out setting's (24 sets) from Under-21, and 1271 side out setting's (42 sets) from Elite. Actions were collected from their respective World Championships (season 2010 and 2011). Sets analyzed were selected randomly according their level of the teams and their confrontation. Only two-set matches were observed. The variables studied were: overhand pass (OP), forearm pass (FP), player role (defenders = DF, & blockers = BO), and age groups (U-19, U-21 and Elite). Chi-square test was used to test differences between analyzed variables. Statistic significance was set at  $p < 0.05$ . **Results** Results show that in the U-19 category, there are no differences between the types of setting ( $p = 0.940$ ) according to player role, i.e. OP (DF = 20.5% vs. BO = 20.2%) and FP (DF = 79.5% vs. BO = 79.8%). Therefore, results showed that there are significant differences between the types of setting in the category U-21 ( $p = 0.001$ ) according to player role, i.e. OP (DF = 44.5% vs. BO = 24.5%) and FP (DF = 55.5% vs. BO = 75.5%) and elite ( $p = 0.001$ ) according to player role, i.e. OP (DF = 41.8% vs. BO = 32.5%) and FP (DF = 58.2% vs. BO = 67.5%). **Conclusions** The present study showed the forearm pass was the most type of set more used by blockers and defenders in the different age groups studied. In U-21 and elite, defenders used with more frequency the overhand pass that blockers. **Acknowledgments** This research was supported by grants from Capes Foundation, Brazilian Ministry of Education (068812-6/2012). **References** [1] Homberg, S., & Papageorgiou, A. (1995). Handbook for beach volleyball: Meyer & Meyer Verlag. [2] Palao, J. M., Gutiérrez, D., & Frideres, J. E. (2008). ## RELIABILITY AND VALIDITY OF JUDGING ARTISTRY ON BALANCE BEAM AT WORLD CHAMPIONSHIP IN TOKIO 2011

Bucar Pajek, M., Cuk, I., Pajek, J., Kovac, M., Leskosek, B.

*University of Ljubljana, Faculty of sport and University Medical Centre Ljubljana*

**INTRODUCTION** The judging in artistic gymnastics crucially determines outcome. Currently, final score is a sum of difficulty score and execution (E) score by the panel of 6 judges. E score is calculated by subtracting deductions for various mistakes from 10 points, including the deductions for flaws in artistry. Evaluation of artistry could be associated with serious insufficiencies of reliability and validity. We have analyzed the reliability and validity of deductions in artistry at one of the top gymnastics competitions. **METHODS** The evaluated categories of artistry are: inappropriate gesture or mimic, insufficient variation in rhythm, sureness of performance and lack of creative choreography. We have used the data from judge evaluation sheets to examine the deductions for artistry for each individual contestant. We have calculated the correlation coefficients (Kendall's tau-b) for association between the total artistry deduction and final E score. Same method was used to calculate the correlations in separate categories of artistry between all possible judge-pairs. Finally, the special aspect of judging validity was examined by calculating the Kendall's W statistic - this method gives high and statistically significant values of W, when individual judges systematically give relatively high or low deductions (systematic bias). **RESULTS** The number of contestants penalized for other components of artistry was highly variable between the judges: no deduction for insufficient variation in rhythm was given to either 10 contestants (judge 5), 46-88 contestants (judges 1,3 and 4), but even up to 138 contestants (judge 2). High variability was found in the magnitude of deductions: for the sureness of performance judge 1 used the 0,3 deduction in 158 contestants and judge 3 in only 9 contestants. The range of mean total deductions for artistry was 0,18-0,39. The average Kendall's tau-b correlation coefficient between the total artistry deduction and final E score for the 5 judges was -0,61 (range -0,49 to -0,71,  $p$  for all  $< 0,001$ ). The average correlation between judge pairs in same artistry categories was 0,45 (range 0,01-0,83). When the total artistry deductions were examined for validity, the Kendall's W statistic was high: 0,53 ( $p < 0,001$ ). The highest problems in validity were found in sureness of performance: Kendall's W 0,53 ( $p < 0,001$ ). **DISCUSSION** Our results have shown that reliability of judging artistry is low: there was a high variability between the judges in the number of penalized contestants in separate categories of artistry and a very low average correlation between judge-pairs for the same categories of artistry. Of highest concern is our finding of significant systematic bias between judges implicating a lack of validity. It is clear that we have to monitor the judging of artistry in future and if such findings are repetitively found, the justification for including artistry deductions should be reassessed by the regulating body (FIG).

## ESTIMATION OF PHYSICAL ACTIVITY ENERGY EXPENDITURE IN CHILDREN DURING SIMULATED FREE-LIVING ACTIVITIES: PRECISION OF THE ACTIHEART SENSOR

Innerd, A.L., Avezedo, L.B., Batterham, A.M.

*Teesside University*

**Introduction** The validity of the Actiheart – a combined heart rate and movement sensor – for assessing physical activity energy expenditure has been demonstrated in older children during treadmill walking and running and in a limited range of ‘lifestyle’ physical activities (Corder et al., 2005, 2007). Our aim was to evaluate the precision of the Actiheart in younger children performing a wider range of child-relevant simulated free-living activities. **Methods** Thirty-two children (13 girls and 19 boys) aged 9–11 years volunteered to participate. Using regional data on the most commonly performed physical activities in this age group, we devised two routines of six activities ranging from sedentary (e.g. card playing) to vigorous intensity (e.g. soccer). Participants were randomly assigned to one routine, performing each activity for 5 min, with 5 min rest. Indirect calorimetry (Cosmed, K4 b2) was used to estimate resting energy expenditure (short protocol) and criterion physical activity energy expenditure above rest in J/min/kg (Weir, 1949). We derived Actiheart-based estimates from the built-in child ‘group’ equation, and from individual heart rate: energy expenditure relationships observed in a modified 8-min ramped step test. Valid data were available for 21 children (9 girls, 12 boys). Accounting for the hierarchical structure of the data (repeated measures within subjects) we applied a linear mixed model (random slopes and intercepts, unstructured covariance) to derive the within-subjects standard error of the estimate. This statistic provides the typical error in predicting criterion physical activity energy expenditure from either of the Actiheart estimates, at the level of the individual participant. **Results** There was no substantial difference between methods in the mean physical activity energy expenditure. The within-subjects standard error of the estimate from the Actiheart group equation was 53 J/kg/min (90% confidence interval 44 to 63 J/min/kg), versus 49 J/min/kg (42 to 58 J/kg/min) from the Actiheart individual calibration equation. **Discussion** The increase in precision afforded by the simple individual calibration was trivial. The typical within-subject prediction error from both Actiheart equations was around 15% of the mean across all activities (336 J/kg/min). We conclude that this level of precision is adequate for the assessment of free-living physical activity energy expenditure in children. **References** Corder, K., Brage, S., Wareham, N.J., et al (2005). *Med. Sci. Sports Exerc.*, 37 (10), 1761–1767. Corder, K., Brage, S., Mattocks, et al (2007). Comparison of Two Methods to Assess PAEE during Six Activities in Children. *Med. Sci. Sports Exerc.*, 39 (12), 2180–2188. Weir (1949). *J Physiol.*, 109 (1-2), 1-9.

## RELATIONSHIP BETWEEN REGIONAL AND WHOLE-BODY COMPOSITION TO ONE MAXIMAL WEIGHT-LIFT PERFORMANCE <1RM>

Pessôa Filho, D.1, Neiva, C.M.1, Verardi, C.E.L.1, Peinado, A.B.2, Benito, P.J.2

*(1) São Paulo State University and (2) Technical University of Madrid*

**Introduction** The assessment of 1RM from modeling approaches had observed that lift repetition performance with submaximal weight is suitable to ensure a valid reference of 1RM (statistically confidence) and soft protocol (avoiding heavier loads) (Abadie; Wentworth, 2000). Although, the reliance of anthropometrics data to predict 1RM has not same goodness of the estimative, despite force ability has been related to parameters of body shape and size (Mayhew et al., 1993). However, the concerning that general anthropometric data input would constrain the power of the estimative equation of 1RM has not been appropriately investigated. This study aimed to compare the power of regional and whole-body composition to estimate 1RM in weight-lift systems. **Methods** Fifteen well-trained males (23.7 (5.3) years, 180.4 (5.6) cm, 83.6 (10.6) kg, and 18.9 (4.9)% body fat) were undergone to three standardized 1RM test protocol, repeated at the same time of the day with 24h of rest, in Bench-press (BP), Seated row (R), Arm-curl (AC), French triceps press (FTP), Leg-press 45° (LP45), Knee-extension (KE), and Leg-curl (LC). Anthropometric measurements were: girths (arm, shoulder, waist, and thigh), bone breadth (humerus, wrist, femur, and biacromial), and skinfolds thickness (biceps, triceps, chest, subscapular, suprailiac, and thigh). Whole and regional body compositions were evaluated from DXA (Hologic Discovery QDR, plus software APEX). Multiple linear regression analysis was applied to adjust the data from stepwise method. Significance level was set at 0.05. **Results** The mean values of force for the best score were: BP (96.8•21.9kg), AC (50.9 (10.1) kg), FTP (48.9 (8.9) kg), R (114.1 (22.0) kg), KE (147.1 (36.0) kg), LC (100.9 (21.5) kg), and e LP45 (366.8 (59.3) kg). The lean mass of upper limbs (9.1 (1.5) kg) was the best predictor of 1RM in BP (R<sup>2</sup> = 0.812, SEE = 9.7kg) and AC (R<sup>2</sup> = 0.747, SEE = 5.2kg), whereas arm girth (33.5 (3.4) cm) did influence FTP (R<sup>2</sup> = 0.630, SEE = 5.4kg), and lean body mass (66.3 (6.7) kg) predicted 1RM in R (R<sup>2</sup> = 0.837, SEE = 9.2kg), KE (R<sup>2</sup> = 0.720, SEE = 19.6kg), LC (R<sup>2</sup> = 0.645, SEE = 14.4kg), and LP45 (R<sup>2</sup> = 0.407, SEE = 44.3kg). **Discussion** Regression analysis did support the high reliance of maximal dynamics force on body composition parameters, rather than girth and breath data. Thus, regional composition has not better power than whole-body composition to predict 1RM weight-lift performance. Furthermore, despite the goodness of the adjustments between force and anthropometric data, the statistical indexes are not in the same order than those for submaximal force score (Mayhew et al., 1993). **References** Abadie BR, Wentworth MC. (2000). *J Exerc Physiol.* 3,1-7. Mayhew JL, Piper FC, Ware JS. (1993). *J Sports Med Phys Fitness.* 33, 159-65.

## THE RELATIONSHIP BETWEEN THE DIRECT AND INDIRECT MEASUREMENT OF VO<sub>2</sub>MAX IN THE 20-M SHUTTLE RUN TEST AMONG A GROUP OF ADOLESCENT BOYS LIVING IN THE NORTH WEST PROVINCE OF SOUTH AFRICA – PAHL STUDY

Pienaar, C.1, Coetzee, B.1, Twisk, J.W.R.2

*1: NWU (Potchefstroom, South Africa), 2: VU (Amsterdam)*

**Introduction** The methods that have thus far been used to test the validity of the 20-m SRT have not been empirical sound (Chatterjee et al., 2009; Mahar et al., 2006). Therefore, the purpose, of this investigation was to determine the relationship between the indirect (predicted) and direct measurements of oxygen uptake (VO<sub>2</sub>max) in the 20-m SRT. **Methods** A total of 52 boys in grade 8 of high schools in the Tlokwe District (Potchefstroom area) of the North West Province of South Africa were randomly selected out of a total of 247 learners to be fitted with a portable gas analyser while they ran the 20-m SRT. The gas analyser was used to sample expired air continuously and the rate of oxygen consumption (VO<sub>2</sub>), carbon dioxide production (CO<sub>2</sub>), minute ventilation (VE), the respiratory exchanges ratio (RER) and record the heart rate for each 5 second period. The Bland and Altman plot method was used to compare the two measurement techniques (Bland and Altman, 1986). **Results** The results of the Bland and Altman plot showed that almost all of the participants’ VO<sub>2</sub>max-values were under predicted by the 20-m SRT. Also, all of the participants’ VO<sub>2</sub>max-differences, except for three participants, fell in between the 95% limits of agreement range that was set. **Discussion** To our knowledge, this is the first study to investigate the relationship between the indirect and direct VO<sub>2</sub>max values obtained from the 20-m SRT, among adolescent boys in the North West Province of South

Africa. Almost all of the participants' VO<sub>2</sub>max results were under predicted by the 20-m SRT indirect measurement when compared to the direct portable gas analysis obtained values. The underestimation of the 20-m SRT VO<sub>2</sub>max derived values are probably related to age, gender and racial differences between the population of our study and that of the European adults from which the original Légar and Lambert 20m-SRT VO<sub>2</sub>max prediction equation was developed (Légar and Lambert, 1982). In conclusion these results show that the 20-m SRT is not a valid test for the accurate prediction of VO<sub>2</sub> and VO<sub>2</sub>max in a group of adolescents and that new prediction equations need to be developed for practitioners who want to use the 20m-SRT to predict the VO<sub>2</sub>max values of especially children. ### THE CIRCUS IN PHYSICAL EDUCATION: A PORTRAIT OF PRODUCTION AVAILABLE IN THE MAGAZINE PHYSIQUE ET ÉDUCATION SPORT / FRANCE

Duprat, R.1, Ontanon, T.1, Bortoleto, M.1, Mateu, M.2, Martinez, A.2

1. UNICAMP (CAMPINAS, BRAZIL) 2. INEFC (BARCELONA, SPAIN) Unicamp Brazil / INEF Barcelona

**Introduction** The academic production about the circus and its relationship with physical education has significantly increased in recent decades (ONTAÑÓN, DUPRAT, BORTOLETO, 2012). Much of this production has been published by the French magazine 'Éducation Physique et Sport' (EP&S) placing it as an important vehicle for the dissemination of the progress made on the issue. Thus, the present study is an analysis of all EP&S's articles published between 1969 and 2012. **Methods** It was a literature review in all editions of the Journals EP&S and EP&S1 (available at the library of the 'Institut Nacional d'Educació Física de Catalunya' (INEFC Barcelona -Spain-). The articles selected were analyzed based on the content analysis method (BARDIN, 2002). **Results** A whole of 31 papers were analyzed, which 3 were published in the 1980s, 7 in 1990s, 13 between 2000 and 2010 and 8 articles between 2011 and 2012, showing a continued and regular growth. The content of articles focuses on three broad categories: - Pedagogy of circus techniques: 15 articles dedicated to juggling, balance ball, slack-line, stilts, rola-bola and cigarbox; - Professional circus schools or circus companies: 3 articles explaining experiences in the field of education / training. - Educational experiences reports in physical education classes: 13 articles that the circus stands out as physical education content. **Discussion** We analyzed only items directly related to the circus. However, many others were not considered, although there was possibility for transfer, like the acrosport or oscillating ropes. The first papers date from 80s, when the 'new circus' (WALLON, 2010) takes shape as a growing art and when the French government began to invest in training, production and research of aesthetics circus. Remarkably steady growth of the production, although after 2000 a significant growth is perceived, showing increased attention of physical education professionals with the pedagogical, historical and social circus aspects (FOUCHET, 2003). Most articles concern how to teach some of different circus modalities (juggling, for example), or the school experiences reports. We didn't identify comparative and longitudinal studies that show effectively the circus educational potential and what the most appropriate ways to teach. **References** BARDIN, L. ### THE USE OF THE ADIDAS MICOACH TO QUANTIFY THE PHYSIOLOGICAL LOAD OF HIGH-LEVEL BASKETBALL GAMES

Moreno, D.1, Peña, J.2

Club Joventut de Badalona 1, Universitat de Vic 2

**Introduction** The Adidas miCoach Speed\_CellTM is a triaxial accelerometer developed as a personal training system. However, its design and accuracy (Porta et al., 2012) suggested its further use to quantify the load imposed during professional sports practice. Regarding to basketball, some research has been done to determine the physiological demands (McInnes et al., 1995; Narazaki et al., 2009) and their differences according to playing positions (Ben Abdelkrim et al., 2007) but none of these studies used accelerometers in their methods. The present provides additional data to the field of study. **Methods** The study sample consisted of 24 matches played during the pre-season and first leg of the 2012-2013 regular season of the Spanish professional basketball league (Liga Endesa). We selected randomly two players from the same team, who wore a Speed\_CellTM sensor attached to the right shoelaces throughout the game. The Speed\_CellTM sensor registered the active time (AT), total load in meters covered (LOAD), maximum speed in meters per second (MS). We could obtain also the amount of high-intensity efforts ratio per minute (HIER, those which exceed de speed of 1.6 m/s), short duration high-intensity efforts to active time ratio (SDHIER, consisting in efforts lasting up to three seconds), and long duration high-intensity efforts to active time ratio (LDHIER, over three seconds) and the distance to active time ratio (DATR). **Results** The averages and standard deviations per player were: 67.28±13.63 min for AT, 6004±963 m for LOAD, 1.78±0.26 for HIER (divided between the value of 1.00±0.18 for SDHIER and the 0.78±0.23 for LDHIER), 90.1±8.3 m for DATR and 5.49±0.48 m/s for MS. Some differences have been found between groups. HIER is higher for forwards than for guards while centers showed lower MS. **Discussion** The Speed\_CellTM sensor is a useful tool to assess physiological demands in professional basketball. The device allows the assessment of high-intensity efforts that seem to be a better predictor of the playing level than other physiological indicators (Ben Abdelkrim et al., 2007). Our findings differ from previous studies in which guards were pointed out as the players with a greater game load and intensity. **References** Ben Abdelkrim N, El Fazaia S, El Ati J. ## EFFECT OF APPLICATION OF PREPARATORY MOVEMENTS AND ACTIONS BEFORE SHOOTING ON THE ACCURACY OF FREE THROWS

Kreivyte, R.

*Lithuanian Sports University*

**Introduction** Many scientists claim that movement accuracy is much determined by the preparation to perform the movement – the preparation phase. Before a free throw basketball players perform preparatory movements and actions which are defined as a set of motor, affective and cognitive behaviors before the performance of the main action. It has been established that preparatory actions and movements of skilled basketball players influence beginners. **Methods** The research methods applied: experiment; testing free throws before the experiment and after experiment. Before the experiment the experimental group was provided with all information and preparatory movements were demonstrated as well as their sequence according to the methodology of Amberry (1996). The subjects (young aged 14-15 female basketball players) performed 30 free throws (10 sets of three free throws) according to new methods. The control group performed free throws under usual conditions, as they had learnt before. The teaching lasted for one month, and practice sessions took place four times a week. **Results** After a month of learning, when the experimental group learnt free shots applying a sequence of preparatory movements and actions before them, the second testing was carried out, and the results of it were as follows: for players in the experimental group 70.3% ( $21.1 \pm 3.1$  accurate free throws), for players in the control group 63.3% ( $19.0 \pm 2.1$ ). The indices of the second testing showed that the average number of successful free throws in the experimental group statistically significantly increased ( $p < 0.05$ ) compared to the results of the first testing. **Discussion** Preparatory movements as well as their sequence, efficiently affect the accuracy of free throws for young female basketball players (Czech et al., 2004). We found that the accuracy of free throws of young basketball players who had learnt the sequence of preparatory movements and actions according to the methodology of Amberry (1996) improved by 9%, when the accuracy of free throws in the control group remained unchanged. While using preparatory movements, athletes carry out their individual plans of actions before starting the performance of their task (Lidor, 2007). Our research revealed that one month of learning preparatory movements, actions and their sequence appeared to be efficient for the accuracy of free throws for young (aged 14-15) female basketball players. **References** Amberry T. ## UNDERSTANDING THE FEINT IN FOOTBALL – QUANTIFYING FOR TRAINING

Lopes, H., Fernando, C., Vicente, A.

*University of Madeira, University of Beira Interior, CIDESD*

**Introduction** The feint in football is, in a very simplified form, a situation where a stimulus that is given by one player and one time the opponent will react. This is a situation where players often try to deceive their opponents so that they can have an advantage over them and be successful (Vicente et al., 2010). The objective of this study is to characterize some of the times involved in the feint in football in order to improve efficiency in training, quantifying the execution times of possible trajectories of the foot over the ball by the attacking player. **Methods** We've filmed 30 subjects (sports science college students, being 15 of them football players) that had to move one foot (outer edge facing the ball) as fast as possible over the ball touching the ground on the other side and returning to the starting position. Each individual held the position three times (with three preliminary attempts) and decided when to start the movement. The footage was taken with a camera to capture speed of 50 frames per second, having been digitized and analyzed using Pinnacle Studio 12. **Results** The average times obtained by the students footballers was of 987 milliseconds and the average time obtained by the not footballers was 1003 milliseconds. There were no significant differences between the obtained times from footballers and not footballers. **Discussion** The obtained times (approximately 1000 milliseconds) allow the opponent to realize that, if we consider acceptable reaction times (400 to 500 milliseconds), it's possible to intercept the ball during this movement. If players don't do it's probably because they are looking to react to the movement as a way to counter a possible movement of the ball. However, this movement can lead to situations that may allow the players who perform it a chance of passing. The fact that the time it takes to move your foot over the ball is not significantly different between those who play football and those who do not play reinforces the idea that what is essential is not the feint technical execution speed but the dialogue established between the players what should be taken into account when training players in this situation. **References** Vicente, A., Fernando, C., Lopes, H. & Almada, F. ## COMMUNICATION AND MOTIVATION IN THE COACH-ATHLETE RELATIONSHIP

Imrik, L.

*Norwegian University of Science and Technology*

**Introduction** Several sports scientists share the common opinion that the coach is the one person who can influence an athlete motivation the most (Mageau, Vallerand, 2003; Amaro, Anderson-Butcher, 2007; Guzmán, Calpe-Gómez, 2011). For better or for worse, the coach can have an impact on how the athletes perform. Research within the framework of Self-Determination Theory (SDT), have reached the conclusion that it's easier to have motivated athletes if the coach adapts an autonomy-supportive coaching style (Mouratidis et al, 2010; Gillett et al. 2009). The aim of this study is to investigate the role of communication in the coach-athlete relationship, and how it affects athlete motivation. It's interesting to investigate **Methods** The method used to investigate this is topic was focusgroup interviews (Postholm, 2010). The sample in this study consisted of boys and girls (aged 16-19 years) from three different Norwegian basketball clubs. From each team it was conducted one interview with the boys team and one with the girls team, adding to a total of six interviews. Group sizes varied from 4 to 8 participants. The duration of the interviews varied from 45 to 55 minutes. **Results** The preliminary results of this study show that both the boys and girls would like to have a coach that cares for them, seems interested and have enough experience. They also highlight that autonomy-supportive communication from the coach has the biggest influence on their own motivation towards playing basketball. These findings are similar to what Mouratidis et al. (2010) and Gillett et al. (2009) found in their studies. However, the athletes also highlight the importance of having a coach that is disciplined towards them, and that the autonomy-supportive aspects isn't always necessary in order for the coach to motivate them. **References** Amaro, Anthony J., Anderson-Butcher, Dawn. ### ESTIMATING THE BASKETBALL WINNING FACTORS FROM PLAYERS RECORDS AND GAME STRATEGIES

Choi, D.

*Sogang University, Seoul Korea*

**Introduction** The purpose of this study was to figure it out the basketball winning factors through analyzing players game records and their position for scores via video records. **Methods** We have collected the data from 2012-2013 Korea Basketball League(KBL) which 10 games for each team. We have collected the six offence factors(2p%, 3p%, FT%, Offense Rebound, Assist, Turn Over) and four defense factors(Defense Rebound, Steal, Good Defence, Block Shoot). We also have recorded game which was analyzed the players score position and running time. The data were analyzed that which factors was most contribute for the winning the game using Pearson correlation and logistic multiple step regression. All significance levels were set at  $p < .05$ . **Results** We have estimate the determinants of winning and lost game and three offense factors(2p%, 3p%, FT%) were significantly affecting game winning. Also, Two defence factors(DB, ST) were significantly affecting game winning percent. In addition we calculated the players scoring position via watching video tape, and court elbow area and free throw area were most scoring position. **Discussion** This study is still on going study and we have not analyzed all data for video records and players scoring position. However, we have tried to estimate the game winning factors which is not shown in offence and defence data. We tried to estimated the data according players role and position that which position is more critical for scoring situation and winning the game. **Reference** Park D.,(2012). ### ATTACKING IN FOOTBALL: POSSIBLE STRATEGIES TO STOP WASTING OPPORTUNITIES

Vicente, A., Lopes, H., Fernando, C.

*University of Beira Interior, University of Madeira, CIDESD*

**Introduction** In the FIFA World Cup 2010 there were 1810 shots on the 64 matches (an average of 28.28 shots per game) but only 683 on target. However, from these shots only 145 resulted in goal (8%) meaning that, in average, a team needed to shot more that 12 times (12,48) to score. It wasn't much different in the UEFA Euro 2012 where teams shot 822 times in 31 matches to get 76 goals (9,23% success), shooting more that 10 times (10,82) to score one goal. The top scorer (Fernando Torres) achieved 3 goals in a total of 189 minutes played (5 matches) from 10 shots (7 on target). There are few opportunities to shoot in a game. And when opportunities appear players tend to waste the vast majority of them. However, there are few studies on this situation (mainly empirical) and there is not enough knowledge to understand it functionally so that it can be improved and players can become more efficient. The aim of this study was to analyse a set of attacking situations from a major football competition (Euro2012) in order to understand them functionally in the continuation of previous studies (e.g. Vicente et al., 2012). **Methods** Using a team sports model (Almada et al., 2008) we've analyzed twenty attacking situations that resulted in finishing attempts from the Euro2012 Final (Spain vs. Italy), focusing specifically in the last attacking player actions and his relation with the opponent(s). We've defined an analysis grid to understand the player's actions and also to quantify their action times (t - strikers time, t' - defenders time) to determine other possible solutions for the play. **Results** From our analysis the attacking players mostly started their movement before the defenders and, in average, 200 milliseconds (ms) before the ball being passed by their team-mates. Attackers tended to had enough time (320 ms in average) to choose another action or to prepare better the chosen one. But in 68% of the situations strikers had opportunity shot lines to the goal but missed them and in the other 32% they had no opportunity shot line but still decided for shooting. **Discussion** Understanding the relations between attacking and defending players according to their actions times, and by knowing the inherent variables, it's possible to identify how to improve player's performance. Players do not need to be faster but they can look for other options to get advantage over the opponents to succeed taking advantage of most opportunities that the team creates to score. For this to happen, beyond training the skill players need to face situations in order to train decision-making. **References** Almada F., Fernando C., Lopes H., Vicente A., Vitoria M. (2008). ### RUNNING A TEAM IS LIKE LAYING A PUZZLE – COACHES' EXPERIENCES OF WOMEN'S ICE HOCKEY

Henriksson, T., Fjellman-Wiklund, A., Gilenstam, K.

*Institution of Surgical and Perioperative Science*

**Introduction:** Women's ice hockey (WIH) is dominated by two countries, Canada and the U.S.. The large difference in quality between North America and the other countries has been used as an argument for exclusion of the sport from the Winter Olympic program. The reason for the large differences in ice hockey performance has not been investigated. Thus, the aim of this study was to investigate socio-cultural influences and demands important to performance in elite WIH in North America and Sweden. **Methods:** Thematized interviews were conducted and analyzed according to Qualitative content analysis (1). Eight ice hockey coaches, two women and six men, from the top ten teams in Sweden and North America, were purposely sampled as informants. **Results:** The results show one theme, "Running a team is like laying a puzzle". It reveals the complex structure of running and organizing a top-level team while at the same time fighting for necessary resources, since WIH is a low priority in comparison to male professional sports. Further results reveal seven categories involving gendered approach on coaching, access and use of resources, perspectives of performance, view of WIH and its development. The coaches perceive that performance is context bound but also dependent on the individual's skills and resources, and development of individual skills requires resources. The North American teams are associated to universities, which provide resources for individual development through expertise and personnel available through sport-related courses. This ensures a high quality of coaching and knowledge in accordance with current research. In Sweden teams belong to general sports clubs, which do not have the same natural access to knowledge. Very few players in the countries concerned are professionals in the sense that they can live on their sport. However, the North American players' access to athletic scholarships enable them to play ice hockey full time even at senior level. In Sweden, there are sports schools for young girls, but after the age of 19 they are forced to work part-time to make a living, which affects time available to spend on ice hockey. **Conclusion:** Running a team requires access to money, time, knowledge and personnel. WIH needs greater support from their federations in terms of gender equity, economy and marketing, which coaches experience significant for

increasing the value of WIH and make it more competitive. Reference: Graneheim U, Lundman, B. (2004). Qualitative content analysis in nursing research: concepts, procedures and measures to achieve trustworthiness. *Nurse Education Today*, 24(2), 105-112.

### **FACTORS INFLUENCING DECISION MAKING DURING THE FAST-BREAK IN BASKETBALL GAMES**

Yaita, A., Aoyagi, O.

*Kyushukyokyo University*

**Purpose:** This study aimed to investigate factors influencing decision-making in the fast-break of basketball games while considering the team's athletic abilities. **Method:** Participants included 177 university basketball players (98 males and 79 females) who took a decision-making ability test in which they were asked to estimate or choose the next situation or optimal play just after stopping a projection of a videotaped basketball game scene. The test battery consisted of 81 test items based on 29 play scenes. Each test item measured 4 decision-making processes. We defined the "correct" play/situation as that which  $\geq 4$  of 8 basketball authorities chose as the correct answer. The total score for correct answers was analyzed using Quantification Theory Type 1, in which various factors such as athletic level evaluated by the coach, gender, and position were independent variables. **Results:** Results of deviance analysis indicated that this model was significantly fitted at the .1% level (chi-square=255.8, degree of freedom=5). Ranges of category weights in each item were 3.01, 1.18, and 0.57 for position, athletic level evaluated by the coach, and gender, respectively, indicating that the most influential factor was position, followed by athletic level evaluated by the coach, and gender. However, as the influence of gender was small and this analysis did not consider the athletic level of teams, we reanalyzed it using position, athletic level evaluated by the coach, and team as independent variables. Results of deviance analysis indicated that this model was also significantly fitted at the .1% level (chi-square=409.5, degree of freedom=11). Ranges of category weights in each item were 3.21, 2.97, and 1.57 for team, position, and athletic level evaluated by the coach, respectively. In short, the most influential factor on decision-making ability in fast-break was the team, followed by position played, and athletic level evaluated by the coach. Category weights were 1.24, -0.46, and -1.74 for guards, forwards, and centers, respectively, indicating that guards had excellent decision-making abilities but centers did not. The order of the category weights for teams was almost equivalent to that of their game performance. In terms of athletic level evaluated by the coach, the category weights were 0.851 in starting players, -0.168 in not-attending-games players, and -0.720 in second-string players. Starting players who had extensive game experience had the highest category weight, but players who did not play in games and could objectively watch the games had a higher weight than second-string players who were considered to be better in skills and tactics. **Conclusion:** Team factors, characterized by main tactics, coaching philosophy, training methods, and so on, have a greater influence on decision-making ability than athletic level evaluated by the coach, which characterizes the game-playing experience.

### **THE ASSOCIATION BETWEEN BASEBALL ATHLETES' PERFORMANCE EVALUATION AND PSYCHOLOGICAL ADAPTATION TO UNIVERSITY BASEBALL TEAMS**

Shimizu, Y., Miyazaki, M.

*International Christian University, J.F. Oberlin University*

**Introduction** Baseball is one of the most popular club sports from elementary school to university level in Japan. One of the prevalent problems in baseball clubs is athletes' maladjustment to teams and dropout from clubs. The purpose of this study was to develop Psychological Adaptation Scale for Baseball Club Activities (PASBCA) and Subjective Performance Evaluation Scale for Baseball Athletes (SPESBA) and to examine the relationship between the subscales of PASBCA and SPESBA. **Methods** The subjects of 264 baseball athletes (mean age=19.45, SD=0.89, mean baseball experience=11.30, SD=2.24) in high competitive four official university baseball teams were asked to answer a questionnaire composed of question items on socio-demographic background as well as 30 baseball athletes' psychological adaptation evaluation question items and 12 baseball athletes' subjective performance evaluation question items, both of which were developed from our preliminary survey in 2010. Exploratory factor analyses and reliability analyses were conducted to develop PASBCA and SPESBA. Multiple regression analysis with stepwise method was employed to examine the relationship between PASBCA and SPESBA. **Results** The results of exploratory factor analyses yielded for PASBCA a 4-factor model ("Avoidance," "Weariness," "Negative Human Relationships," "Satisfaction") with 24 items and for SPESBA a 1-factor model with 12 items. Reliability analyses confirmed that each scale had acceptable satisfactory Cronbach's alpha reliability from 0.916 to 0.964. The results of multiple regression analyses showed that the subscales of "Avoidance" and "Satisfaction" in PASBCA had significantly positive association with SPESBA. **Discussion** The findings above suggests that baseball athletes with high satisfaction of club activities tend to have high evaluation on their own performance, and this implies that psychological intervention programs which aim to enhance athletes' adaptation to their team can lead to improvement of their performance evaluation. However, contrary to our expectation, reluctant athletes also have high evaluation of their performance. This may be because they place little value on team practice as they think that their performance is good enough or better than their teammates. Future research with a larger sample size and longitudinal design will be needed in order to explore effective psychological coaching intervention methods. **References** Saki MURAIISHI, Yasuo SHIMIZU (2011) Development of Psychological Adaptation Scale for Junior High School Sport Club Activities. *Kyusyu Journal of Sport Psychology*. 23:50-51.

**15:00 - 16:00****Mini-Orals****PP-SH25 Misc. topics 2****THE EFFECT OF AERODYNAMIC DRAG IN THE SERVICE SPEED OF HIGH-LEVEL MEN'S VOLLEYBALL.**

Peña, J.1, Buscà, B.2, Moreno-Galcerán, D.3, Bauzá, J.3

*1: University of Vic (Barcelona, Spain), 2: FPCEE Blanquerna Ramon Llull University (Barcelona, Spain), 3: INEFC-Barcelona (Barcelona, Spain)*

**Introduction** The serve speed is an important factor for the game performance in volleyball (Moras et al., 2008; Quiroga et al., 2010). However, even more relevant seems to be the ball speed at the reception contact. The aim of the present study was to analyse if due to drag effect, the speed at which the ball reaches the receiver has significant differences with the peak velocities registered during service execution and to determine if this parameter is relevant to assess the serve outcome in high-level men's volleyball. **Methods** The present study was carried out in January 2012. 774 services from the Spanish Volleyball Cup held in Teruel were analysed. Service velocities were recorded and assessed using a Stalker ATS II radar-gun and the Stalker ATS software (Stalker Pro, Radar Sales Inc., Minneapolis, USA). The services included in the sample were the jump topspin (JT) and the jump float (JF) serves because of their preferential use in high-level men's volleyball (Ageloniadis, 2004; Häyrynen et al., 2011). Two expert observers executed the recording and the encoding of the data in every game. The first observer started speed recording with the authorization of the service and stopped it when the ball contacted with the receiver. The second observer introduced additional data referred to the analysed serve in a worksheet (player, type and effect of the serve). An intraclass correlation analysis and descriptive statistical tests were performed to all records. **Results:** The average peak speed recorded for the JT was  $25.69 \pm 3.58$  m/s and for the JF was  $14.97 \pm 1.61$  m/s. The average speed at which the ball reached the receiver was  $20.79 \pm 3.46$  m/s and  $13.14 \pm 1.49$  m/s respectively; the average loss rate due to aerodynamic drag effect was  $4.89 \pm 1.39$  m/s for the JT and  $1.90 \pm 0.78$  m/s for the JF. An intraclass correlation coefficient of 0.964 indicates agreement between peak and reception velocities. **Discussion:** Significant differences can be found between the peak velocities and the speed at which the ball reaches the receiver in a volleyball service due to the effect of aerodynamic drag. Reception contact speed records provide a better value to assess the effect of the different services in game-like situations, with a higher adjustment to the conditions in which the reception is performed. **References:** Ageloniadis Y. (2004). *J Hum Movement Stud*, 47, 205-213. Häyrynen M, Mikkola T, Honkanen P, Lahtinen P, Paananen A, Blomqvist M. (2011). *J Sport Med*, 45, 543. **COMPUTER-BASED MUSCLE DYSMORPHIA ASSESSMENT**

González-Martí, I., Sokolova, M., Contreras, O., Fernández, J.

*University of Castilla-La Mancha*

**Introduction** Muscle Dysmorphia (MD) is a mental disorder which a person who suffer it self-perceive lean and weak, but he/she is big and strong indeed. This disorder is more prevalent in weightlifters and bodybuilders. The first study on MD was in 1993 (Pope, Katz y Hudson, 1993), it is a relative new discovery. Actually this is the reason for there are not much instruments to detect it. The aim of this study is describe the process like a prospective to develop a program computer for assessment MD, based on data mining. **Methods** A total of 734 participants (562 male and 172 female) with an average of seven hour per week lifting weights took part in this study. We administered Escala de Satisfacción Muscular (ESM; González-Martí, Fernández, Contreras, & Mayville, 2012), Somatomorphic Matrix (Gruber, Pope, Borowiecki, & Cohane, 1998) to know MD symptoms, and we measured the weight, height, and skinfolds. In other hand we applied a Demographic and Physical Self-concept (Goni, Ruiz de Azúa, & Liberal, 2004) questionnaires too. **Results** After having revised a number of available data mining solutions, it was decided to use regression analysis, and decision trees and rule learners. Finally, regression models and decision tree and rule classifiers were calculated for the target variable, "Bodybuilding Dependence", an ESM factor. As a result, a set of indicators which describe a psychological profile of a person was obtained with good correlation coefficient ( $R = .77-.78$ ). Moreover, low, medium and high levels of the disease were analyzed, and the most influential factors for every degree were stated. **Discussion** Modelling and simulation have demonstrated that several models can be used for the diagnosis and prevention of the MD (Hildebrandt, Alfano & Laungenbucher, 2010). The models obtained with regression analysis enable evaluation of each explanatory variable in relation to the target variable "Bodybuilding Dependence". Application of decision tree models and rule learners permits to identify the most influential factors which can be used with diagnostic purpose. The results of this case study can facilitate important references during evaluation of bodybuilders and weightlifters in order to organize early prevention and treatment. **References** Hildebrandt T, Alfano L, Laungenbucher JW. **PRACTICALITY OF A TENNIS SIMULATOR FOR PLAYER IMPROVEMENT**

Viney, M., Bedford, A., Kondo, E.

*RMIT UNIVERSITY*

**Introduction** When a tennis match is in-play, the viewer has knowledge on in-play serving statistics such as first and second percentage of serves in and won. There has been various works involved in applying serving statistics to increase serving performance and to find the optimal serving strategy. Barnett et al. (2008) suggest separating serving statistics in relations to the surface of the court, Gale (1971) applied a simple mathematical model, whilst George (1973) applied a probabilistic model. Although various research has been performed, limited research has involved in applying in-play serving statistics to increase serving and player performance. The aim of this

study was to apply in-play serving statistics into a set simulator to determine whether this application is an effective coaching tool for player improvement. Methods The set simulator allows the inclusion of faults to increase the accuracy of the probability of winning a set in tennis. This simulator has the ability to adjust the server's probability of winning a point on first and second serve at any phase of the set in order to calculate the likelihood of each player winning the set. To test the effectiveness of the set simulated, it was compared against the Markov Chain model that was applied to a case study. The Markov Chain model is generally used in the tennis literature to calculate the probability of winning a game, set and match before and during a match. To increase the accuracy of the results, serving statistics are collected from the first set and applied to calculate the probability of winning the second set. Results Results showed that the simulator was superior in estimating the outcome of the set. In comparing the two methods, the Markov model gave an extra 0.13 probability to the underdog to win the set, where the favourite won the set 6-1. Thus the simulator was more effective in this case study. By increasing the underdog's serving statistics by two percent, resulted in increasing the simulated probability of winning the set by six percent. If the underdog decides to change serving strategy by increasing the percentage of first serves in by five percent, the simulated increased the likelihood of winning the set by three percent. Discussion The results suggest that the simulator that incorporates the faults and in-play match statistics is a more effective approach than using the Markov Chain model. From the results showed, this simulator can be an effective coaching tool to improve player's performance such as altering serving strategy to improve the outcome of the match. ### TACTICAL ANALYSIS IN FOOTBALL. T-PATTERNS RELATED TO COUNTER-ATTACK

Barbosa, A.1, Sarmiento, H.2, Anzano, A.1, Campaniço, J.3

*Institut Nacional d'Educació Física de Catalunya*

Introduction The detection and analysis of regular structures of behavior in Football has received increasing attention from researchers and trainers. The main purpose of this study was to detect temporal regular structures (t-pattern) of behavior in International Milan (IM 2009/2010) Real Madrid (RM 2010/2011) counter- attack. Methods 24 games (12 of each team) were analyzed. To collect data we used the observational instrument developed and validated by Sarmiento et al. (2010). Software THÈME 5.0, was used in order to detect the existence of t-patterns. This is a professional system for detecting and analyzing hidden patterns in behavior, by performing intensive structural analysis of behavioral data. The study of the reliability shows high levels (above 0.90 for all criteria) for the intra and observer agreement. For pattern detection, we only considered completed patterns, that were repeated 3 times, and the significance level was set at 0.005. Relatively to the results, there are not completed T-patterns related to IM counterattack, and only tree patterns related to RM counterattack . The t-pattern refers to the whole process, from recovering possession of the ball until completing the offensive process (OP) successfully. The analysis of the completed t-pattern allows us to understand that the recovery of possession is due to an interception of the ball in the left corridor of the offensive midfield. The second action happens in the central corridor of the offensive midfield, and it is a ball reception. The process ended when the ball entered the zone eleven (offensive third). Conclusion As noted in previous studies the results demonstrate the potential of THEME 5.0 software for detecting structures of regular behavior in football, but the unpredictability of the game is an obstacle in order to determine the existence of completed patterns. ### THE SCORING SKILLS THAT DETERMINE THE FINAL OUTCOME OF VOLLEYBALL HIGH LEVEL IN SENIOR MEN'S WORLD LEAGUE 2011

João, P.V.1,2, Mota, M.P.1,2, Paulo, T.N.2

*1) University of Trás-os-Montes and Alto Douro (UTAD)*

Introduction The game analysis assumes a leading role so that coaches play a more fruitful part in the direction and conduct of training and competition (João, et al., 2010; Zetou et al., 2007). It is thus intended with this study to determine which of these actions, terminals or non terminals are more influential in the final outcome of the volleyball games in high level teams. Methods This study sample was drawn from two groups of the World League of 2011 Senior Men teams, Group C, Portugal, Finland, Argentina and Serbia and Group B, Russia, Bulgaria, Germany and Japan, composed by  $n = 24$  games. The recording and analysis of the data was performed by the software Data Volley. The discriminating function analysis was used in order to identify indicators that contribute most to establish the maximum difference between wins and losses. We considered as relevant to the interpretation of the linear composites  $|SC| \geq .30$  (Tabachnick & Fidell, 1996). The significance level was set at 5%. The results calculation was performed by the SPSS software version 17.0. Results Regarding the results, only the variable excellent reception differ significantly. The variables that contributed most to the discrimination between defeat and victory were: attack error (SC= -.66), the service error (SC= -.45), excellent service (SC= -.42), opponent error (SC= -.38) and also excellent reception (SC= .36). Discussion The excellent service, excellent reception and opponent's errors variables seem to be associated to victory. The variables, attack error and service error, may be associated with defeat. Since the high level Volleyball teams are very and balanced and with the results obtained in this study, it was concluded to be more important not to miss than to score. (2007). *Journal of Quantitative Analysis in Sports*, 3 (4), 1-9.

### A CASE STUDY OF A TOTAL SUPPORT SYSTEM FOR THE ACTIVATION OF YOUTH SPORTS IN MEDIUM-SIZED CITIES

Kim, S.H., Jun, H.M.

*Mokpo National University*

Introduction In South Korea today, school physical education policies have shifted the focus from school athletic clubs to school sports clubs for general students. Despite those policy efforts, however, youth sports activities still remain in a poor situation in small local cities. This study thus set out to propose a university-based support system case as a youth sports support system and explore its meanings for the activation of youth sports in small- and medium-sized cities. Methodology As a case study, the study collected cases of networking among university, community, and schooleducational agency) in M, a medium-sized city, and analyzed a series of implementation processes. Results M University held an 'open-Gym (oG)' and 'Youth Sports Festival' to help activate local youth sports. In September, 2012, the university set up the Youth Sports Education Center for the activation of youth sports in the community and took on a project leading the networking efforts between the community and school (educational agency) with initiative. The first step of such efforts was the 'oG'

program. The program was designed to open the gym to adolescents, who would usually devote the evening after school to going to a private educational institute and playing games on the Internet, for free and be run in an autonomous manner by emphasizing autonomy, initiative, and responsibility to adolescents, the participants. Today only the gym is open to them to play basketball and futsal. In addition, a basketball and futsal competition took place as part of 'Youth Sports Festival' in December last year. There was no participation fee in the competition, whose budget was supported by the Athletics Department of M University and a community sports club. The competition was run by the Basketball Team of M University and Youth Sports Education Center and promoted by the local educational agency. A good number of students have shown their interest in the 'oG' program and have started to visit the gym since the Youth Sports Festival. Discussion 'oG' and 'Youth Sports Festival' have become after-school play and exercise places for adolescents in M in the evening and examples of community youth sports education based on the network among university, community, and educational agency. School sports clubs and Sports Day on Saturdays, which are actively facilitated by the government these days, can be actively applied to students and schools in the heart of a city, but they can face many issues due to lack of human resources and facilities and no accessibility in local areas beyond the urban perimeter. A university-community-educational agency support system can be an alternative to solve the problem of policy alienation and promote the activation of youth sports. The case of M University is an important case of a university-based community-educational agency support system.

### THE RUGBY ATTACK ASSESSMENT INSTRUMENT : RESULTS IN A LEARNING SEQUENCE

Llobet, B., López-Ros, V., Barrera-Gómez, J., Comino, J.

*University of Girona, CREAL and UAB*

**Introduction** The assessment of game performance in team sports made a turn after the emergence of teaching models based on tactics such as TGfU (Bunker & Thorpe, 1982). The GPAI (Osolin et al., 1998) and the TSAP (Gréhaigne et al., 1997) are the most used tests to assess performance in this context (Arias & Castejón, 2012; Memmert & Harvey, 2008). The purpose of this paper is to present the results obtained applying the RAAI, an instrument used to assess the actions of the ball carrier in a learning sequence of rugby. **Methods** The RAAI is based on the video analysis of a 5 vs. 5 situation of simplified rugby. The units of analysis are the actions of the players with the ball. These actions are codified as favourable actions (F) or unfavourable actions (D) in relation to the principles of the game. Actions are also identified as simple actions (S) or combined actions (C). To obtain the Index of Performance (IP) all actions are weighted with magnitude and sign (positive/negative) according to its tactical relevance. Four trials were performed during a learning sequence of 11 sessions with 10 novice players. **Results** The IP values for the four trials were 58.4, 54.1, 51.0 and 55.4 for team A, and 55.6, 55.9, 50.8 and 58.6 for team B. Other specific data emerge from the use of RAAI, for example, the total number of weighted F actions of both teams: 159, 136, 120 and 176, or the total number of weighted D actions: 19, 29, 34, 30. **Discussion** With the present results, the RAAI can be a useful instrument to assess ball carrier's actions (Llobet et al., 2012). However, there are some issues that need revision: (a) the value of some partial actions weights on the IP, (b) some actions outside the IP, like the number of passes or the amount of defence breaks, and (c) the absolute number of observed actions. Further research should contemplate these considerations. **References** Arias, JL & Castejón, FJ (2012). ### EFFECT OF RESISTANCE TRAINING ON BDNF EXPRESSION AND MUSCLE QUALITY IN TYPE 2 DIABETIC SKELETAL MUSCLE

Song, W., Kim, H., Oh, S., Kim, Y.

*Seoul National University*

**Introduction** Recent evidence demonstrates that brain-derived neurotrophic factor (BDNF) plays a role not only in central metabolism, but also in regulating energy metabolism in peripheral organs. However, the changes of BDNF expression following resistance training in diabetic skeletal muscle with severe glucose tolerance have not fully established. The purpose of this study was to investigate the effect of progressive resistance training on BDNF expression and its relation to muscle quality in ZDF (Zucker diabetic fatty) rat skeletal muscle. **Methods** Six week-old male ZDF and ZLC (Zucker lean control) rats were randomly divided into 3 groups: sedentary ZLC (ZLC-Con), sedentary ZDF (ZDF-Con), and exercised ZDF (ZDF-Ex). ZDF-Ex rats were trained (once every 3 days for 8 weeks) to climb a 1.1-m vertical (80° incline) ladder with weight secured to their tail for progressive resistance exercise. Body weight, grip strength, and glucose tolerance were evaluated at every weekend. The volume of skeletal muscle was analyzed by PET-CT (positron emission tomography-computed tomography) and expression of BDNF was measured using ELISA in extracted skeletal muscles. **Results** After 8 weeks of resistance training, substantial reduction of body weight was observed in ZDF-Ex compared to ZDF-Con. Grip strength and muscle quality was significantly increased ( $p < 0.05$ ) in ZDF-Ex compared to ZDF-Con without change of the skeletal muscle volume (hypertrophy). The area under the curve (AUC) values of plasma glucose during glucose tolerance test in ZDF-Ex was significantly reduced ( $p < 0.05$ ) compared to ZDF-Con. In solves, expression of BDNF was increased in ZDF-Con, but significantly decreased ( $p < 0.05$ ) in ZDF-Ex showing training effect. Moreover, we found that there was a negative correlation ( $r = -0.657$ ;  $p = 0.004$ ) between grip strength and BDNF expression whereas there was a positive correlation ( $r = 0.612$ ;  $p = 0.008$ ) between plasma glucose level and BDNF expression in skeletal muscle. **Discussion** Progressive resistance training significantly improved grip strength and glucose tolerance in type 2 diabetic rats. Although the volume of total skeletal muscle was not changed following 8 weeks of resistance training, significant improvement of muscle quality (weight/volume) was found in ZDF-Ex compared to ZDF-Con suggesting substantial muscle function seems to be increased. Regarding BDNF expression in skeletal muscle, resistance training is likely to decrease BDNF levels in type 2 diabetic skeletal muscle including soleus, tibialis anterior and EDL muscles. Based upon our results, muscle-derived BDNF might be a potential mediator for the preventive effect of resistance training on progress of type 2 diabetes, however, further research is needed to elucidate the regulatory role of muscle-derived BDNF in type 2 diabetic skeletal muscle.

**WORKING MEMORY CAPACITY AS CONTROLLED ATTENTION IN SPORTS**

Furley, P., Memmert, D.

*German Sport University Cologne*

**Introduction** The controlled attention theory (CAT, Engle, 2002) of working memory suggests that working memory capacity (WMC) represents a domain free limitation in the ability to control attention and is predictive of an individual's capability of staying focused, avoiding distraction, and impulsive errors. In two experiments (Furley & Memmert, 2012) we tested the predictive power of WMC in computer-based sport tasks. **Method** In our general methodological approach we sampled the WMC of athletes (69 basketball players; 55 ice-hockey players) using complex span measures (e.g. Engle, 2002) and subsequently invited the upper and lower quartiles of the distribution to take computer based sport tasks. In Experiment 1 basketball players had to perform a speeded forced-choice basketball decision making task under auditory distraction conditions (di- and monosyllabic nouns) using stereo head-phones. After a certain time the first name of the participant appeared (once) in the distracting auditory stream and participants were asked at the end of the task whether they had noticed their name. In Experiment 2 ice-hockey players performed a speeded forced-choice ice-hockey decision making task. Some decision making trials were preceded by a simulated team time-out in which participants received tactical information from a virtual coach. The experimental manipulation involved whether the tactical information received from the coach "fits" a subsequent game situation—valid information—or does not fit the game situation—invalid information. **Results** Experiment 1: In line with CAT we found that low WMC athletes performed worse on the decision making task ( $p = .0001$ ) and were more prone to distraction (noticed name more often;  $p = .002$ ) which was further supported by a significant correlation of WMC and a questionnaire measuring distractibility in everyday life ( $r = -.37$ ,  $p = .001$ ). Experiment 2: Again, in line with CAT low span ice-hockey players were more likely to follow the tactical information given in a time-out, if it did not fit the subsequent game situation (invalid trial,  $p = .004$ ) and failed to adapt their decision according to the game situation. **Discussion** Based on these findings WMC measures are promising in identifying people who have a superior ability to control their attention: i.e. staying focused on performance and blocking out irrelevant distraction and resolving response competition in interference situations. **References** Furley, P., & Memmert, D. (2012). Working Memory Capacity as controlled attention in tactical decision making. *Journal of Sport and Exercise Psychology*, 34, 322–344. Engle, R.W. (2002). **THE PARADOX OF TRAUMA AND PSYCHOLOGICAL GROWTH: EXAMINING THE EXPERIENCES OF PARALYMPIC ATHLETES**

Day, M.C.

*University of Chichester*

**Introduction** It is clear that the occurrence of a traumatic and disabling injury can present the individual with a multitude of life changes. Yet while research has predominantly concentrated on the negative impacts of trauma, an emerging body of research has supported the notion of posttraumatic growth. This study aimed to examine the positive experiences of athletes with an acquired disability caused by physical trauma, prior to competing in the London 2012 Paralympic Games. **Methods** Participants were 7 Paralympic athletes representing a wide range of sports, including both team or partnered sports, and individual sports. Participants took part in either 2 or 3 life history interviews. These interviews lasted between 2.5 and 4 hours. A holistic content analysis was used to focus on the content presented in each participant's story. This method allows for the patterns and themes within the narratives to be revealed. **Results** A number of themes emerged which demonstrate how being a Paralympic athlete allowed participants to experience psychological growth following trauma. All participants outlined initial difficulties accepting and adjusting to disability, reported feeling socially isolated, and struggled to find purpose and meaning in their lives. Yet despite these experiences, participation in Paralympic sport allowed participants to reconstruct their self and identity, to gain social support and understanding through shared experiences, re-enforced coping ability, and enhanced determination. While latter themes were inherently positive, results highlight that psychological growth is gradual, often emerging alongside negative experiences of trauma. **Discussion** Results highlight the complexities associated with posttraumatic growth. While post-traumatic growth and posttraumatic stress have often been viewed as separate entities, this research supports the emerging perspective that these should be considered together in order to understand the experience of the individual. This study highlights the importance for research and practice to consider that growth can not only occur alongside trauma symptoms, but further, that the experience and acceptance of negative symptoms may even form part of the process of achieving positive growth. Consequently, the 'supercrip' stereotype, often associated with those who achieve after disability, may conceal the difficulties and complexities associated with achieving posttraumatic growth.

**COGNITIVE FUNCTION IN OBESITY: INTERVAL VERSUS CONTINUOUS EXERCISE INTERVENTION**

Weeks, A., Khalil, A., Harris, E., Dye, L., Birch, K.M., Lawton, C.L.

*University of Leeds*

**Introduction** Cognitive deficits in executive function, verbal memory and attention have been observed in obese subjects when compared to healthy weight controls (1), with cardiovascular risk factors suggested as mechanisms. The domains vulnerable to impairment in obesity are responsive to change via aerobic exercise in non-obese samples (2). However, aerobic exercise has not been investigated as a tool for improving cognitive function in obese subjects. The aim of the study was to investigate the effect of interval (INT) or continuous (CON) aerobic exercise training on cognitive function and cardiometabolic risk factors in middle-aged women. **Methods** 20 women (42±1 yrs, BMI 31.9±3.6 km/m<sup>2</sup>) completed tests of executive function, verbal memory and attention. Subjects were assessed for body composition and cardiovascular fitness and randomised to CON (n=10) or INT (n=10) cycle ergometer training groups. Groups exercised twice/week for 12 weeks in the heavy intensity domain, matched for work (KJ). The work/recovery ratio for INT was 40s:80s. Baseline tests

were repeated at week 6 and 13. Results Following CON, delayed verbal recall significantly increased (pre  $9.78 \pm 1.99$ , mid  $13.44 \pm 2.60$  words) whereas INT did not change (pre  $10.67 \pm 3.04$ , mid  $10.88 \pm 3.01$ ; gp x time interaction  $p < 0.05$ ). A trend for significance was observed following INT for a reduction in time to solve an executive function task (pre  $265.84 \pm 60.94$ s, post  $219.55 \pm 57.21$ s), whereas CON showed less improvement (pre  $242.53 \pm 60.94$ s, post  $235.32 \pm 76.48$ s; gp x time interaction  $p = 0.09$ ). Although not significant, absolute  $VO_2\max$  increased in INT (pre  $2081.36 \pm 430.45$ , post  $2131.14 \pm 367.04$  ml/min) and CON (pre  $2118.68 \pm 287.18$ , post  $2193.41 \pm 270.78$  ml/min  $p > 0.05$ ). Systolic blood pressure (SBP), although non-significant decreased following INT (pre  $124.3 \pm 11.37$ , post  $118.70 \pm 7.31$  mm/Hg) and did not change following CON (pre  $124.8 \pm 15.27$ , post  $124.1 \pm 14.75$  mm/Hg,  $p > 0.05$ ). Discussion Superior improvements were observed in delayed verbal memory for CON, whereas INT demonstrated greater improvements in executive function,  $VO_2\max$  and SBP. Verbal memory is supported by the hippocampus and linked with glucoregulation and insulin sensitivity (3), suggesting the work/recovery ratio for INT was not appropriate for such metabolic changes. The enhanced alteration in SBP and oxygen uptake in INT may serve to drive executive function in the dorsolateral and medial frontal cortices (2, 4). References 1. Selbom & Gunstad, (2012) Journal of Alzheimer's Disease 30, 1–7 2. Erickson et al., (2012), Aging Research 3(1), 34–47 3. Awad et al, (2002), Behavioral Neuroscience, 116, No. 4, 691–702 4. ### THE EFFECTS OF AN EXERCISE INTERVENTION ON SYMPTOMS OF PREMENSTRUAL SYNDROME AND QUALITY OF LIFE

Hillier, S.E.1, Craven, R.P.1, Wheeler, S.J.1, Venables, M.C.1,2

*Oxford Brookes University*

Introduction Premenstrual syndrome (PMS) is a diverse collection of symptoms affecting 75–85% of women of reproductive age during the luteal phase of the menstrual cycle. Previous observations have suggested that physically-active women report fewer PMS symptoms compared to sedentary individuals (Choi and Salmon, 1995). However, few studies have confirmed any effect of an exercise intervention in previously sedentary individuals, nor have they been able to identify potential mechanisms. The current study investigated whether a moderate intensity exercise intervention had any effect on PMS symptoms and Quality of Life (QoL) and whether any such effect is mediated by changes in plasma sex hormone concentrations. Methods Twenty-five sedentary women, identified as suffering moderate PMS symptoms, were recruited to a randomised control trial spanning four menstrual cycles, the first served as a baseline followed by three cycles of intervention. Participants were randomised into either an exercise (EX) group ( $n=13$ ), which involved three supervised 30-minute moderate-intensity (70–80% HR max) exercise sessions per week, or to a control (CON) group ( $n=12$ ) which included a 90-minute, one-to-one meeting once per week with the investigator. Venous blood samples were collected three times per week during cycle 1 and cycle 4 to determine plasma estradiol and progesterone concentrations. PMS symptoms were evaluated every other day by a prospective symptom questionnaire throughout the study (Moos, 1968). Results Participants assigned to the EX group showed a reduction in PMS symptoms between cycles 1 and 4 (pain, water retention, autonomic reaction & impaired concentration,  $P < 0.05$ ), whereas no difference was observed in the CON group. Neither group showed any differences in arousal, although the EX group demonstrated a marginal reduction in negative affect ( $P = 0.07$ ) and behaviour change ( $P = 0.08$ ) that was not observed in the CON group. A 15% decrease in total symptom scores was reported between cycle 1 and cycle 4 in the EX group. The EX group also reported a 13% reduction in the number of 'unhealthy' QoL days during cycle 4 compared with cycle 1 ( $P < 0.05$ ). There were no differences in QoL indices in the CON group. No differences were observed in peak plasma estradiol or progesterone concentrations between cycle 1 and cycle 4, in either the EX group or CON group. Discussion Moderate-intensity exercise over three months may reduce the symptoms of PMS and improve QoL; however this effect is not mediated by changes in plasma estradiol or progesterone concentrations References Choi PYL, Salmon P (1995). Br J Clin Psychol, 34, 447–460. Moos RH (1968). Psycho Med, 30(6), 853–867.

### PSYCHOLOGICAL STATE ASSOCIATED WITH MENSTRUAL CYCLE PHASES IN WELL TRAINED AND RECREATIONAL ATHLETES.

Tengah, R.1, Mohd Rasyid, N.1, Mokhtar, A.B.2, Yusof, A.2

*1: Sultan Idris Education University, (Malaysia), 2: University of Malaya, (Malaysia).*

Introduction The aim of this study was to determine attitudes towards menstrual cycles in well trained and recreational athletes. Methods Attitudes toward menstruation were assessed by Menstrual Attitude Questionnaire (MAQ). Subjects were asked to fill the questionnaires before menses. Participants were 16 elite athletes and 17 recreational athletes, respectively 19 - 26 years old. Results Well trained athletes (WTA) gave the highest mean agreement on attitude towards menstrual cycle rating from subscale "menstruation is natural event" ( $5.11 \pm 0.55$ ), followed by "anticipation and prediction of onset of menstruation" ( $4.95 \pm 0.59$ ), "menstruation is a debilitating event" ( $4.42 \pm 0.46$ ), "menstruation is bothersome event" ( $4.33 \pm 0.55$ ) and "denial of any effect of menstruation" ( $3.96 \pm 0.62$ ). Recreational athletes (RA) attitude towards menstrual cycle ranked from "menstruation is natural event" ( $5.26 \pm 0.36$ ), followed by "anticipation and prediction of onset of menstruation" ( $5.26 \pm 0.65$ ), "menstruation is bothersome event" ( $4.63 \pm 0.69$ ), then "menstruation is a debilitating event" ( $4.52 \pm 0.62$ ), and finally "denial of any effect of menstruation" ( $3.32 \pm 0.83$ ). Even though attitude toward menstrual cycle in WTA and RA are about the same but there is significant different in subscale denial of any effect of menstruation. Independent samples t-test showed there was a significant difference on the subscale denial of any effect of menstruation between groups,  $t(31) = 2.517$ ,  $p < 0.05$ . Well trained athletes ( $3.96 \pm 0.62$ ) strongly denied that they were affected by the menstrual cycle compared to recreational athletes ( $3.32 \pm 0.83$ ). Discussion The findings of this study suggested that both well trained and recreational athletes believed menstrual cycle is a natural event and they can predict and anticipate of onset of menstruation very well. However they claimed that menstruation is a bothersome and debilitating event. One of the most significant findings of the attitude towards menstruation was on dimension of 'denial of any effect of menstruation'. This observation suggests that well trained athlete deny of any effect of menstruation in their daily life although they need to be involved in strenuous exercises or activities. Therefore a strong need for denial will help these athletes to accept changes in their body, and not turning their symptoms into uncontrolled behaviours. It is known that the need for denial is related to the desire or tendency to submit passively to external force, to admit inferiority, error or failure (Gaion, et al., 2011). Thus, as the way to reject failure in performance female athletes shall be provided with the menstruation knowledge campaign and coping strategies intervention. References Chang, Y.T., & Chen, Y.C., (2009). Study of Menstrual Attitudes and Distress Among Postmenarcheal Female Students in Hualien County. Journal of Nursing Research. 17 (1), 20–29. ## DIABETES ASSOCIATED COGNITIVE DECLINE IN PATIENTS WITH TYPE 1 DIABETES, AN EPIDEMIOLOGICAL CROSS SECTIONAL STUDY.

Tonoli, C.1,2, Heyman, E.2, Roelands, B.1,3, Buyse, L.1, Berthoin, S.2, Meeusen, R.1

1:VUB (Brussels, Belgium), 2: UL (Lille, France), 3: FWO (Belgium).

**Introduction** Type 1 Diabetes (T1D) can have a significant impact on brain function, better known as a Diabetes Associated Cognitive Decline (DACD) (1). In the last decennia there is a growing interest in the relationship between physical activity (PA) and cognitive function (CF) (2-4). In patients with T1D, surprisingly few studies have been conducted regarding the effects of PA on CF. Therefore, the purpose of this study is to evaluate possible predictors of a DACD, and to investigate the relation between the level of PA, diabetes associated factors and CF in T1D. **Methods** A cross-sectional study was performed using 2 questionnaires (Barriers of Physical Activity in Type 1 Diabetes, International Physical Activity Questionnaire) and 5 cognitive tests (TMTA & B, the STROOP test, the OSPAN test and the SMT) in T1D adults. Blood samples were collected to determine markers of neuroplasticity (e.g. IGF-1), and glycaeted haemoglobin (HbA1c), an indicator of chronic glycaemic control. Statistical analysis was performed using single and multiple regression analysis. Differences were considered significant when  $p < 0.05$  was achieved. **Results** A total of 98 T1D subjects (51 males, 47 females; mean age 36.87 ( $\pm 14.39$ ) yrs) participated in this study. Episodes of severe hypoglycaemia ( $p = 0.027$ ), poor chronic glycaemic control ( $p = 0.027$ ), poor performance in the memory ( $p = 0.44$ ) and executive function ( $p = 0.021$ ) domain predict a negative influence on attention ( $R^2 = 0.99$ ). The strongest predictors of a DACD in the executive function were a combination of age ( $p = 0.00$ ), poor memory performance ( $p = 0.00$ ) and having a long diabetes duration ( $R^2 = 0.996$ ). In men, level of PA was also a predictor of a DACD ( $R^2 = 0.22$ ;  $p = 0.020$ ). Education ( $p = 0.005$ ), poor performance on the executive function ( $p = 0.00$ ,  $R^2 = 0.98$ ). Diabetes duration ( $p = 0.029$ ,  $R^2 = 0.97$ ) significantly predicted a DACD in the spatial memory function in female T1D patients. Preliminary data of IGF-1 did not show significant results. **Discussion** A combination of personal (e.g. age, level of PA, education, level of PA) and diabetes associated factors (e.g. episodes of severe hypoglycaemia, diabetes duration and poor glycaemic control) can induce a DACD. This suggests that aggressive glucose management (e.g. glycaemic control, preventing hypoglycaemic episodes and the prevention of other diabetes associated complications) with the combination of PA could be a preventive tool for the control of a DACD. **References** (1) Mijnhout GS, et al. *Diabetologia*. 2006 Jun;49(6):1447-8 (2) Hillman CH, et al. *Nat Rev Neurosci*. 2008;9(1):58-65 (3) Erickson KI, et al. *Proc Natl Acad Sci USA*. 2011;108(7):3017-22. ## THE USE OF MINDFULNESS IN SPORT PSYCHOLOGY: A SYSTEMATIC REVIEW

Sole, S., Palmi, J.

INEFC Lleida

**Introduction** A psycho-social approach in the different aspects of Sport Psychology is very important to face the challenges that the sportists find in their careers. To look for a higher performance with a minimum injuries' risk will allow them a sustainable practice, maintaining the sportist's quality of life and well-being. The objective of this study is to make a systematic review about the use of mindfulness concept in the world of Sport Psychology. Mindfulness is an ancient concept that comes from "sattī", a Sanskrit word and has not a clear translation. It is a way of paying attention that originated in Eastern meditation practices. It has been described as "paying attention in a particular way: on purpose, in the present moment, and nonjudgmentally" (Kabat-Zinn, 1990). Mindfulness is situated in the called third generation in Behavioural Therapy model, (Hayes, 2002). **Methods** A literature research was taken using Medline, Psychinfo, Web of Science, Cochrane, Ebscohost, Isi Web of Knowledge databases and references of retrieved articles. The search included original articles, books and dissertation published since 1985 to 2012. For the final selection the books and dissertations were excluded. The main search terms were mindfulness, sports and sport psychology. All articles were coded for their design, type of control, study population and outcome measures. Nine studies were considered eligible for the present review and are presented in a table. **Results** In this present review we can observe that there are a few number of studies, with little samples and methodological limitations, such as nonrandomization. Despite of this, the preliminary results indicate that the use of mindfulness-based interventions can increase the sport performance (Bernier et al, 2009, Gardner & Moore, 2004, Lutkenhouse, 2007, Shwanhausser, 2009, Shaji John et al, 2011, Thompson et al, 2011). In addition to this, mindfulness levels increased significantly (Aherne et al, 2011, Kauffman et al, 2009, Schwanhausser, 2009, Thompson et al, 2011) and a significant reduction of pre-competition stress and anxiety was found (Gardner & Moore, 2004, Schwanhausser, 2009, Shaji John et al, 2011, Thompson et al, 2011). **Discussion and Conclusions** Although the use of mindfulness in sport psychology is very new, it seems that it can be a promising research line. Two mindfulness-based interventions are already being used: the Mindfulness-Acceptance-Commitment Approach (MAC) and Mindfulness Sport Performance Enhancement (MSPE). To confirm their efficacy, it would be also necessary to understand better the physio-neurological mechanisms, to adapt it to different sports or evaluate physiological variables as well. New mindfulness-based interventions with a better research methodology are suggested and will be the objective of future studies.

## OPINIONS AND PERCEPTIONS OF POLICY MAKERS TOWARDS PROMOTION OF PHYSICAL ACTIVITY

Pietrantonio, L., Prati, G.

UNIVERSITY OF BOLOGNA

Because most adults in industrialized countries do not meet physical activity guidelines, population-wide interventions are needed. Environmental and policy interventions are based on ecological models of behavior and have the potential to influence entire populations. Policy refers to legislative, regulatory, or policy-making actions that have the potential to affect physical activity. Policies are organizational statements or rules that are meant to influence behavior. They may be explicit or implicit and their effects can be intentional or unintentional. Policies are considered sociocultural influences because people often make policies to respond to the perceived needs or desires of their constituents. On this regard, it is important to take into consideration policymakers' opinions and perceptions. An e-mail survey of 175 mayors of the Emilia Romagna and Piemonte regions (Italy) was conducted. This survey investigated mayors' attitudes toward physical activity promotion and their perceptions. Most of the participants rated as very important the promotion of physical activity. However, they think it is not so easy to motivate citizens. Among the most feasible ways to promote physical activity, participants reported promotion of walking groups and low-threshold interventions. Most of the participants reported that lack of resources is one of the most important barriers to promote physical activity.

## THE PHENOMENON OF DOPING FROM THE PERSPECTIVE OF THE SPANISH OLYMPIC CYCLING NATIONAL TEAMS

Morente-Sánchez, J., Freire, C., Zabala, M.

*Faculty of Sport Sciences, University of Granada (Spain)*

THE PHENOMENON OF DOPING FROM THE PERSPECTIVE OF THE SPANISH OLYMPIC CYCLING NATIONAL TEAMS Morente-Sánchez, J.I, Freire, C.I, & Zabala, M.I. 1 Faculty of Sport Sciences, University of Granada (Spain) 2 Spanish Cycling Federation, Madrid (Spain) Introduction Recent events such as "Operation Puerto" in 2006 or the dispossessions of the 7 Tours of France to Lance Armstrong in 2012 have made cycling lose much of its credibility from a social point of view [1]. The aim of this study was to know and compare the opinion of the Spanish cyclists about doping discriminating according to Olympic disciplines. Methods A sample of 72 Spanish national team cyclists, (19.7±4.7 years, 51 males, 21 females) was divided into four groups according to the 4 different Olympic cycling disciplines: Mountain bike -MTB- (n = 18), Bicycle Moto Cross -BMX- (n = 12), Track -TRA- (n=9) and Road -ROA-(n=33). A descriptive design was carried out using a bespoke questionnaire consisting in 7 free-response questions whose answers were analyzed and categorized. Results Data were expressed in terms of percentage of participants who mentioned some (one, two or three) of the three most mentioned statements (% n), and were shown in the following order: "Total sample"; MTB, BMX, Track and Road. 1- Words associated with doping: Cheating ("44.6"; 50.0%, 33.3%, 66.7%, 42.4%), Lie ("28.4"; 55.6%, 0, 22.2%, 27.3%). 2- Responsible agents of Doping: Doctor ("51.3"; 50.0%, 8.3%, 11.1%, 84.8%), Cyclists ("48.6"; 55.6%, 41.7%, 33.3%, 45.5%), and Coach/Manager ("40.5"; 22.2%, 16.7%, 11.1%, 63.6%). 3- Differences Cycling vs Other sports: Different treatment ("47.3"; 27.7%, 16.7%, 55.6%, 66.7%), Numbers of controls ("20.3"; 27.8%, 8.3%, 22.2%, 30.3%). 4- Reasons for initiation in doping: Sport achievements ("44.6"; 44.4%, 25.0%, 88.9%, 100%), External pressures ("28.4"; 38.9%, 8.3%, 11.1%, 39.4%), Contract/money ("25.7"; 22.2%, 25.0%, 55.6%, 27.3%) 5 - Have you ever been suggested to dope? "Yes" ("5/72"; 1/33, 0, 1/12, 3/9) 6 - Have you ever seen another person inciting/being incited? "Yes" ("7/72"; 2/33, 0, 1/12, 4/9). 7- Proposed solutions: the three most mentioned suggestion to eradicate doping in sport were "More controls" ("41.9"; 72.2, 41.7, 44.4, 36.3), Prevention early ages ("21.62"; 27.8%, 8.3%, 22.2%, 24.2%), No solution ("20.3%; 0, 33.3%, 22.2%, 27.3%). Discussion Low percentage of cyclists saw a was suggested to dope (<10%). "Doctor" was the main responsible agent o doping only for ROA, others groups focused on "cyclists". "Sport achievement" was the main reason while "More controls" the main proposed solution. It is claimed prevention in early ages as it was suggested in previous studies [1, 2]. It would be interesting to propose similar studies in other type of sports to make comparisons. References 1. Morente-Sánchez J, Zabala M. Sports Medicine 2013 May; 43(2): ahead of print. 2. ## PSYCHOLOGICAL FACTORS TOWARD TO DOPING AND SUBSTANCE ABUSE IN IRANIAN ELITE ATHLETES

Same-Siahkalroodi, L.I, Poor-kazemi, L.2

*Sport Medicine Federation of Iran (SMFI)*

Introduction: Doping is regularly studied in sports, but we have found no such data for elite athletes. We have studied doping in athletes at 2011-2012. The researcher-made questionnaire for studying doping and psychological factors was used. This study aimed to determine the relations between cognitive variables (self-efficacy, locus of Control, and dysfunctional attitudes) and psychological factors with using doping agents in elite athletes. Methods: We conducted a case-control study in Iran among elite athletes using 100 athletic drug users with reported use as a case group and 100 athletic nonusers and 100 nonathletic nonusers as controls that were matched on salient demographics (aged 18 years or older). Controls selected by a simple random sampling. They were then studied by self-efficacy questionnaire, locus of control scale, dysfunctional attitude scale, and general health questionnaire. Hypotheses tested by variance analysis and Tukey's test. In addition, outcome measures included sport orientation (win and goal orientation and competitiveness), doping attitude, beliefs and self-reported past or current use of doping. A structural equation model was developed based on the strength of relationships between these outcome measures. Results: Our findings showed that athletic drug users had a lower self-efficacy, more dysfunctional attitudes, and exhibited external locus of control rather than control groups. They were also more sensitive to psychological morbidity. Most of relations were statistically significant. Discussion: In general, the possible reasons toward doping including: 1) the athlete is given the chance of becoming a member of a famous team, of financial gain, social recognition, and national fame. 2) The coach and the medical team may play an important role in strengthening the pressure to train and assisting in the attempts to fulfill the training schedule irrespective of any signs and indications of fatigue or over training. 3) The athlete who is most at risk of taking forbidden substances is the one who tries to conform to the picture of a 'super person' that the sport system wants him or her to represent, and this may mean that he/she feels the need to cheat. 4) The athlete may develop a psychological imbalance and a loss of self-confidence to cope with the pressure to excel by his or her own means. In this situation, doping may offer to the athlete a quick solution for coping with the extant pressure. Our findings were in accordance with the theoretical basis of cognitive psychology. More than 85% of all the athletes included in our study do rely on coaches. In other words, the pressure for the first by coach, Join and stable in national team, fear of failure in competition and winning at any cost are important factors for players that they are toward doping and substance abuse. In conclusion, we strongly suggest permanent educational anti-doping programs and sport psychology for elite athletes as well as for their coaches and physicians.

## SEARCHING FOR THE PERFECT EXPERIENCE: THROUGH THE COMPARATIVE EXAMINATION OF THE HIP – HOP DANCE AND HANDBALL

Balogh, L., Domokos, E.

*University of Szeged, Faculty of Juhász Gyula Pedagogy*

Introduction In hip-hop dance it's evident that Flow-experience evolves in hip-hop dancers really soon, because it allows freer motions and happens to music which can cause stream experience if we seriously pay attention for it. On the other hand, in playing handball the number of collisions, violence and aggression is too much which can block that feeling. Csikszentmihályi in 1991 defined Flow first. Susan A. and Csikszentmihályi studied the contact of the sport and Flow in 2001. Karageorghis (1999) made more previous researches about Flow and the music. Looking through the pre-Flow researches I didn't find an answer for in the dance what kind of level is Flow? In playing handball is Flow present or not, what kind of level on and do the two values show significance? My hypothesis 'that in hip-hop dancing the value of Flow is much higher. Methods The method of the research happened with the distribution of a three-page questionnaire which in I used Oláh's questionnaire (Oláh, 2005, page 141-143) and 26 attributes for the expression of Flow-state (Jackson and Csikszentmihályi, 2001, page 22). The experimental group consists of 18 and 23-years old handball players (70 people), the control group consists of 18 and 23-years old competition hip-hop dancers (70 people). Results The results supported my hypothesis that at hip-hop

dancers the value of Flow is much higher than at handball players, but this isn't excluded to be fulfilled. It's shocking I got high Flow value in the handball. The feeling of weariness and discomfort is higher in the handball. All results were significant maximally, so the results don't due to accidental. Discussion We have already known that the dance is very strong in the feeling of FLOW. But that was the very first examination that show us the FLOW level of team handball: You play hard and tough however you enjoy it and be in the Zone! References Jackson, S., Csíkszentmihályi, M. ### PSYCHOLOGICAL DEVELOPMENT ACROSS AN INTENSIVE WRESTLING CAMP: A MIXED METHOD CASE STUDY

Cowburn, I., Pierce, S., Driska, A., Gould, D.

*Michigan State University*

**Introduction** There has been an increased interest in studying how sport can influence psychological growth and development in recent years (Gould et al., 2012; Larson et al., 2006). Despite this interest, little attention has been paid to the process of development, especially at the individual level. An intensive wrestling camp in the United States, following an Army Ranger approach to training, promised improvements in psychological development. The purpose of this study was to provide an idiographic examination of psychological development across the camp and evaluate the effectiveness on development of one of the athletes enrolled. **Methods** An in-depth case study was conducted on one male wrestler, age 16, who attended an intensive 14 day wrestling camp. He was selected because he reported psychological gains that allowed the researchers to understand the specifics of development. In-depth interviews were conducted prior to and immediately after the camp and 8 months later after a full season of competition. A parent and a coach will be interviewed at follow-up to triangulate information from athlete interviews. Two researchers were embedded at the camp, making observations and field notes. The athlete completed a pre, post and follow-up camp questionnaire, which employed psychometrically valid instruments. An idiographic profile was created for the athlete using questionnaire data, hierarchical content-analysis, field notes and observations. The resulting profile provided a narrative of psychological development from the beginning to the end of camp (8 month follow-up underway). **Results** The athlete made gains in psychological and life-skills across camp, including imagery, goal-setting, responsibility, and accountability, as well as wrestling skills. Additionally, the athlete consciously identified the significance of psychological skills, such as personal responsibility, to help him deal life events off the mat. Presence of a reflective style and good work ethic entering camp, and readiness to reflect on and learn from camp experiences were important contributors to development. Additionally, interactions with camp counselors, other wrestlers, and the camp structure influenced development. Results from 8-month follow up will also be presented. **Discussion** Camp participation enhanced psychological and life skills development. Results are consistent with research in non-sport settings that suggests youth learn from the surrounding culture and environment to enhance understanding of emotional episodes (Larson & Brown, 2007). The intense Army Ranger nature of the camp will be discussed as it differs from typical youth sport programs and links to achievement goal theory will be made. The 8 month follow-up will be used to examine lasting influence of the camp. **References** Gould, D., Flett, M.R., & Lauer, L. (2012). *Psych of Sport & Exer*, 13(1), 80-87 Larson, R., & Brown, J.R. ### THE INFLUENCE OF ACUTE BOUT OF MODERATE-INTENSITY WALKING ON EXECUTIVE FUNCTION IN ADOLESCENTS

Soga, K.1, Shishido, T.2, Nagatomi, R.1

*1: Tohoku University (Miyagi, Japan), 2: Osaka Kyoiku University (Osaka, Japan)*

**Introduction** During moderate-intensity aerobic exercise, it was reported that executive function (EF) transiently declines in young adults aged 18-24 yr (Pontifex & Hillman., 2007). In preadolescents aged 9-11 yr, however, EF was demonstrated to be maintained during and after moderate-intensity walking (Drollette et al., 2012). It was, therefore suggested that exercise influence on EF may change depending on the age group probably due to the development or maturation of the brain and its function. The purpose of this study was to demonstrate the effect of moderate intensity exercise on EF in adolescence when brain tissue becomes structurally stable. **Methods** EF was assessed using a modified flanker task and a modified spatial n (0, 1, 2) - back task to assess inhibitory control and working memory (WM), respectively. In a randomized within-subjects counterbalance design, twenty eight Japanese adolescents aged 15-16 yr (mean age = 15.7 ± 0.5 yr) completed cognitive tasks under following conditions: 1) walking on treadmill at 60 to 70 % of estimated maximum heart rate for approximately 15 minutes, and 2) seated on a chair for approximately 15 minutes. Tasks were performed in a randomized order with an interval of at least one day. **Results** Response accuracy in Flanker task did not change during-exercise as compared to baseline before the exercise (95.0% ± 4.4% vs. 96.0% ± 3.6%,  $p > 0.05$ ), but increased after-exercise as compared to during-exercise (96.9% ± 3.0% vs. 95.0% ± 4.4%,  $p < 0.01$ ). Reaction time (RT) in n-back task was shortened after-exercise compared to during-exercise (418.2ms ± 87.6ms vs. 449.1ms ± 62.6ms,  $p < 0.01$ ), and elongated during-exercise compared to resting state (449.1 ms ± 72.2 ms vs. 406.8 ms ± 62.6 ms,  $p < 0.01$ ). **Discussion** There was a discrepancy in the effect of moderate exercise on 2 EF tasks in adolescents. There was substantially no effect of exercise on inhibition control, whereas a transient decline in WM function was observed during moderate intensity exercise. These findings may represent a transitional stage of maturation of brain function in the adolescence. **References** Pontifex M. B. Hillman C. H. (2007). *Clinl Neurophysiol*, 118(3), 570-80. #### MUSLIM MAGHRIBIAN WOMEN WAYS OF PARTICIPATION IN SPORT AND PHYSICAL ACTIVITY IN CATALONIA: ATTITUDES AND EXPERIENCES

Nasri, K., Soler, S.

*Inefc - Barcelona*

Muslim Maghribian Women (MMW) are characterized for a low participation in the Catalan society (Nash, 2001). In relation with sport participation, several experiences include MMW doing activities as football, gymnastics or aerobic in Immigrant Associations or Immigrants Support Organizations (IAISO) (Soler, Gaztelu, & Serra, 2010; Balibrea, 2005). Nevertheless, this practise is still "invisible" and the way in which they do sport is still unknown. According to various studies, this situation is due to a combination of social, economic, political and also cultural and religious factors (Nasri & Soler, 2012; Nasri, 2011; Jawad, 2011). Giving this "invisibility" and influencing factors, we have analysed how MMW participate (or not) in sports and why. By 30 interviews, we have found MMW that did not practice sport and now they practice in Catalonia reaching several forms to combine religion and sport. Most of them try to pass unnoticed even some don't venture to do outdoor activities for modesty. The IAISO have an important role to promote MMW sport practice, but sometimes it can reinforce their "invisibility". Finally, some women say that they don't do sport because of the lack of female spaces or because they don't know them. In conclusion, we have observed that MMW have diverse attitudes towards sport and they practise it in different ways or not, depending on the personal and social circumstances.

#### GENDER DIFFERENCES IN SPANISH ONLINE SPORTS NEWSPAPERS

Schiefer, M.1,2, Gómez Ruano, M.A.1, Fernandez Aguila, J.1, García-Quismondo, J.1, Marín Marín, G.1, Liu, H.1, Frangeul, G.1, Grams, L.1,3

*1: Technical University of Madrid, 2: German Sport University Cologne, 3: Hannover Medical School*

Introduction The available research over the last decades showed tremendous differences in sports media coverage between male and female athletes (Pratt et al., 2008; Stone & Horne, 2008). This includes the number of articles, words per article, pictures in print media, but especially differences in attributes and characteristics (Kane & Maxwell 2011). Since "Marca" and "AS" are the most important online sports newspapers in Spain, the aim of this study was to evaluate both of them concerning their coverage of female athletes. The hypothesis predicted that these online Spanish newspapers publish more news about male than female athletes. Methods All articles were gathered from the open access web domains (www.marca.es and www.as.com) during one week, randomly selected in the year 2010 and searched for gender specific variables, photos and words per article. They were distinguished between male, female and neutral (both genders). To evaluate the hypothesis, descriptive statistics (means and frequencies), Pearson's chi-square test, and one-way ANOVA with post hoc test (DMS) using the statistical software program SPSS 20.0 were applied. Significance level was set to  $p < 0.05$ . Results There was no significant difference between both online newspapers, "AS" and "Marca" concerning number of articles and pictures ( $\chi^2 = 0.61$ ;  $p = 0.74$ ;  $\chi^2 = 5.39$ ;  $p = 0.05$ ). The newspaper "AS" contained 86.7% male, 5.6% women and 7.7% neutral articles. In the other reviewed newspaper ("Marca") 84.2% male, 1.8% female and 14.0 % neutral items were detected. Regarding pictures, "AS" published 89.2% male, 5.4% female specific and 5.4% neutral. Likewise "Marca" printed more male than female athletes' pictures (94.7% vs. 1.1%; 4.3% neutral). The one-way ANOVA test was significant ( $p < 0.001$ ) in words per article between groups, and post hoc test of DMS displayed greater values in men compared to women and neutral ( $p < 0.01$ ). Discussion Results support the hypothesis that male athletes are more frequently represented in the two examined Spanish online newspapers than female athletes. Frideres et al. (2008) recommend campaigns against female athletes' discrimination in order to equalize them to male athletes. Furthermore there is still an essential need to change the way of how women are displayed in several sport media coverage to promote women's sport in society (Kane & Maxwell, 2011). #### MEDIATED GENDER RELATIONS IN A GENDER MIXED SPORT – REPRESENTATIONS OF GENDER IN EQUESTRIAN SPORTS DURING THE OLYMPIC GAMES IN 2012

Hellborg, A., Hedenborg, S.

*Malmö University*

Introduction In contemporary Sweden equestrian sport is one of the most popular sports and horse riding is number two when it comes to girls' sport activities. On a "sports for all" level horse riding is associated with women and femininity but on elite level, however, the number of men is higher than on the "sports for all" level (Hedenborg, 2012). Method In this study articles from two different Swedish morning papers have been analysed. The study is based on articles, notifications and columns published between 27th of July and 13th of August 2012. Butler's framework is used together with insights from Connell and Ridgway in order to understand mediated gender constructions in a gender mixed sport. Results Four mediated gender stories appear as the most dominant stories in the papers. One is focused on a Swedish female competitor who won a silver medal in eventing. Her performance is in different ways devalued in the mediated story. Another depict two male riders, where a dressage rider is associated with rock music and a jumping rider is described as gentlemanlike when he withdraws from competition due to his horse's injury. A third story deals with a female rider who crashed badly in the first round of the jumping competition and then continued to compete the day after. There is more pity than admiration in the mediated story about her. Several stories concern the excuses for failures. In the media narrative it seems like the failures of the male riders were caused by external factors while the female riders seem to cause their own failures. Discussion The gender mixing evoked questions in this article on whether equestrian sports could be an arena where gender constructions are less visible or different in comparison to other sports and in what way women and men were described in media. But it seems as the media narratives are confirming the binary gender system Butler states is the basis of our understanding of society (Butler, 2006). Many of the stories about the male and

female riders refer to gender appropriate attributes and behaviours. Ridgeway (1997) means that there are expectations that men are more competent than women, and this study shows how this becomes a complicating factor in the equestrian event. At the same time there are many contradictions that are found when narratives on femininity and masculinity are to be analysed. Yet, the mediated stories are consistent when it comes to gender separation. In this analysis of the morning papers it is clearly a gender difference evident in the depiction of the riders. ### **GENDER INEQUALITY AND DEMAND FOR WOMEN'S SPORT: UNIFIED GERMANY AS A NATURAL EXPERIMENT**

Meier, H.E., Konjer, M., Leinwather, M.

*Institute for Sport and Exercise Sciences, University of Münster*

Sport is a highly gendered social sphere. Accordingly, gender inequality within societies is correlated with women's opportunities to participate in high-performance sport and national performance levels. Since sex-discriminatory socialisation appears to play a decisive role for sport consumption, the main question addressed here is whether socialisation by more gender equal policies serves to increase demand for women's high performance sport. In order to test this idea TV ratings for the German women's national football team are analysed because re-unification has created a unique natural experiment on socialisation effects of gender policies. Results provide no support for the idea that a stronger social acceptance for non-familiar roles of women increases audience demand for women's sport. Rather, it seems that gender divisions specific to sport matter, which has important implications for future research and policies aimed at popularising women's sport.

### **EQUALITY AT STAKE: THE PRESENCE OF WOMEN AND GENDER PERSPECTIVE IN STUDIES OF PHYSICAL ACTIVITY AND SPORT**

Serra Payeras, P., Vilanova Soler, A., Soler Prat, S.

*Institut Nacional d'Educació Física de Catalunya - Barcelona (INEFC Barcelona)*

Introduction For more than a decade, the number of female students in Spanish universities has been slightly higher than male students. However, percentages of both sexes in some areas of knowledge differ considerably. As in engineering, Physical Activity Sciences and Sport also have a low percentage of female students (CEIFCAFyD, 2011). The aim of this presentation is to describe the research design and preliminary results of this research, financed by the Ministerio de Economía y Competitividad with "ayudas para la realización de proyectos de investigación fundamental no orientada (DEP2012-31275, de la Convocatoria I+D 2012) whose main objectives are the following: 1)To diagnose women interest and final presence in PAS studies: Professional education, "CAFE" degree, MEF degree, Master, PhD, and as university lecturers. 2)To analyze perception and attitudes of students in the last year of compulsory secondary education (ESO, 16 years) and in the 2ndof Preuniversity course (18 years) related to PAS and possible causes of the lack of interest of young girls. 3)To describe how gender perspective is included in the curricula of degrees and masters of PAS Education. 4)To develop some proposals for promotion and recruitment of women students and teachers at different levels of PAS Education, as models of good practice adding gender perspective in these studies. Methods For each objective, different methods will be used. We are combining quantitative and qualitative approaches depending on the objective. For the first one, a secondary analysis based on the enrollment data in different kind of studies related to sports. These data is available in the education institutions. For the second aim two tools are use: a survey on PAS Education perception to 16 years girls and a focus group to discuss different perceptions on PAS. For the third objective a content analysis of public "syllabus" is done together with in-depth interviews to secondary education teachers. Finally, for the last objective, a content analysis of other good practice proposals to increase women presence in university studies is done in order to relate it to our own findings. Results The preliminary results of this research, based on INEF Catalonia, shows that the number of girls who have interest for this kind of studies are decreasing vertiginously. In 2006 a decrease process starts in the number of PASS enrollment, and thus in the interests' girls too. The percentage of female enrollment had been of 32 % until 2006; nowadays, percentage is of 21%, and it keeps going down. Discussion Through this research we want to create an intervention program to increase the number of women in these studies and improve the image of PAS studies to make them more attractive and most appealing to girls.

### **SOCIETAL EFFECTS OF PHYSICAL ACTIVITY INTERVENTIONS, A SYSTEMATIC REVIEW**

Barte, J., Mikolajczak, J., Hermens, N., Wendel-Vos, G.

*National Institute for Public Health and the Environment*

Introduction: Physical activity has many positive health, personal, and economical effects. Besides these consequences, physical activity also has a potential societal effect. Physical activity policy is often (partly) based on this conviction that physical activity has positive social consequences. However, conclusive evidence for such a statement is lacking. Therefore, the aim of our study is to systematically review the societal effects of physical activity interventions in order to give insight in the available evidence for such an effect. Methods: A systematic search in the databases Medline, Embase, SciSearch, Social SciSearch, and PsycInfo was performed. Articles were selected when describing interventions including physical activity or aiming for an increase in physical activity and measuring the social effects on the society. These societal effects were divided into five categories: 'social capital and social cohesion', 'social participation and integration', 'anti-social behavior', and 'other possible effects on social behavior or relations between (groups of) people'. Results: 1260 potentially eligible records were identified and after the selection procedures 5 studies were included in the review, of which two were randomized controlled trials. The included studies show a great variety in type of physical activity, study population, and social outcome. Intervention programs consisted of sport training, fitness, water exercise, walking, and playing Wii. Study populations include inactive women, children with autism or Asperger syndrome, youth with intellectual disability, and elderly. Social outcomes embrace social capital, children's social behaviour, social participation and loneliness. In general, the studies indicate a positive societal effect of the interventions. Conclusion: Notwithstanding a possible positive effect of physical activity on social outcomes, the scarcity of and diversity in studies addressing this relationship prohibits a conclusive statement. Therefore, more research is needed to investigate this causal relationship and to establish the magnitude of this possible effect. For policy decisions the other effects of physical activity, which are not discussed in this review, should also be taken into account. Therefore, despite the lack of convincing evidence for the societal effects of physical activity promotion enhancing physical activity levels will remain an important focus for policy makers.

## TIME EFFECT ON MOTIVATIONAL ACHIEVEMENT AND SPORT ATTITUDES IN CONTRASTING FOOTBALL CLUBS

Domingues, M., Gonçalves, C.E.

*Faculty of Sports Science. University of Coimbra*

**Aim:** The study's purpose is to understand how contrasting contexts of practice influence the athletes' perceptions of motivational climate and attitudes towards sport, acting the perceived climate as a predictor of moral attitudes. **Design:** To analyze the effect of context on bivariate statistics the researchers employed one way ANOVA. Factor analysis was conducted considering four sub-scales for SAQ (cheating, gamesmanship, convention and commitment) and three factors for PMCSQ-2 (Important role, Effort/Improvement, Punishment for Mistakes and Unequal Recognition). Correlation matrix was also used to determine possible statistical relationships between variables. **Method:** Participants were young male football players (n= 74) from two contrasting football clubs in the north and center region of Portugal. A professional oriented club (POC, n=53 Mage=14.43 yrs, age range: 13-17 years, SD=1.076) and a social oriented club (SOC, n=21 Mage=14.26yrs, 13-17 years, SD=1.129). **Results:** Furthermore, correlation matrix revealed moderate statistically significant relations between perceived motivational climate sub scales and attitudes toward sport. There is a context effect that determines the way young athletes perceive sport. Findings from the cross sectional analysis contradicts the initial assumption regarding SOC, results show no difference in terms of performance oriented climate between the two clubs with significant differences in mastery involving climate. These higher values from the POC demonstrate a better internal organization and sport motivational climate. **Conclusion:** The findings highlight the importance of distinguishing between competitive contexts when examining ecological variables. It is also important to study the impact motivational climate has on moral functioning in youth football.

## ABLED RIDERS AND EQUESTRIAN SPORTS

Larneby, M., Hedenborg, S.

*Malmö University*

In Sweden, equestrianism is the most popular disability sport, and horse riding for disabled people is integrated in the Swedish Equestrian Federation (SEF 2012). The SEF provides and organizes horse riding as sport and recreation, not as therapy. This study focus on perceptions of the body as expressed in contemporary discourses on ability and disability in equestrian sports, on an organisational level in Sweden. **Method** Empirical data for the analysis consists of semi-structured interviews with persons linked to organised riding for the disabled, and various texts from the SEF. A discursive approach and a theoretical framework based on insights from crip theory is used to uncover ideas about able and disabled bodies. McRuer (2006) presents the theory of compulsory able-bodiedness, arguing that the able-bodied norm in a sense produces disability. **Results** Three major recurring themes have been identified in the organisational discourses on horse riding for disabled people. First, equality and inclusion is an important issue for the SEF, to give everybody unregarding ability the opportunity to ride horses. Second, concealed exclusion and segregation is challenging the rhetoric of inclusion. All riding schools don't offer riding for disabled, which is explained partly due to negative attitudes of disability. When offered, it is often in segregated groups with ability as a determinant. Third, acceptance and differentiation through focus on impairment is visible in various texts. Disabled riders are generally portrayed as objects of therapy rather than athletic subjects, implying that impairment differentiates riders but simultaneously accepts ability differences among equestrian riders. **Discussion** Contemporary discourses on horse riding for disabled people in Sweden poses questions whether equestrian sports, as a sporting institutional site, is an arena for the production, securement and containment of disability. A solid inclusivity discourse surrounds horse riding for disabled people and the idea that equestrian sports are empowering rather than rehabilitating can be seen as a way of including all horse riders in the same sport. However, this discourse is contradicted by attitudes to disability that can be interpreted as ideas of segregation, which in practice may actually lead to exclusion of organised riding for disabled people. The riders want to focus on the ability, yet disability is focused because it contrasts the able-bodied riders. Compulsory able-bodiedness (McRuer 2006) is prevalent in the discourses examined, producing both a flexible body in the inclusivity discourse and a disabled body in the exclusion discourse. As this study shows, a true permissiveness and inclusivity could be based on an understanding of how compulsory able-bodiedness is imposed through discourses that produce and reproduce wider societal attitudes. **References** McRuer, R. ## THE IMPACT OF OLD-AGE RETIREMENT ON LEISURE-TIME PHYSICAL ACTIVITY

Lahti, J., Laaksonen, M., Lahelma, E., Rahkonen, O.

*University of Helsinki*

The impact of old-age retirement on leisure-time physical activity Lahti Jouni, Laaksonen Mikko, Lahelma Eero, Rahkonen Ossi Department of Public Health, University of Helsinki, Helsinki, Finland **Introduction** Physical activity is an important part of healthy ageing (1). Physical inactivity is associated with increased risk of chronic diseases and loss of functioning (2). However, many older adults do not engage in physical activity as recommended for maintaining good health (3). Retirement is a major life change with possible consequences for lifestyles. Thus the aim of this study was to examine whether transition to old-age retirement impacts moderate and vigorous intensity leisure-time physical activity and whether the proportion of those physically inactive changes. **Methods** The baseline data were collected in 2000, 2001 and 2002 among 40–60-year-old employees of the City of Helsinki. A follow-up survey data were collected among the baseline respondents in 2007 (n=7332, response rate 83%). Employment status, type of retirement pension and date of retirement was asked at the follow-up. Respondents with missing information in any of the study variables (n=432) and respondents who were on disability retirement (n=231) or non-employed (n=194) were excluded. This study included 5453 female and 1253 male employees of which 1057 retired due to old-age during the follow-up. Leisure-time physical activity was asked with similar questions in both surveys. **Results** Old-age retirees increased significantly their time used in moderately intensive leisure-time physical activity: mean increase among women was 31 (95% CI=18–44) minutes per week and among men 42 (95% CI=18–67) minutes per week. Such changes were not found among those remaining employed. There were no changes in vigorous activity. Physical inactivity at follow-up was lower among old-age retirees compared with employees of nearly the same age (OR 0.78, 95% CI 0.63–0.95) when gender and baseline inactivity were adjusted for. Adjusting for potential baseline confounders had no effects on these findings. **Discussion** The mean increase found among the old-age retirees was relatively small considering that about 40 hours per week can be used in leisure pursuits after retirement. From a public health perspective it is encouraging that those inactive employees increased their physical activity after transition to retirement. Nonetheless, physical activity among those about to retire should be encouraged. **References** 1. Peel NM, McClure RJ, Bartlett HP. ### **NORWEGIAN POLICE STUDENTS TRAINING AND PHYSICAL PERFORMANCE DURING THE THREE-YEARS OF POLICE EDUCATION.**

Lagestad, P.

*Norwegian Police University College*

**INTRODUCTION** Physical skills is important in police work (Lagestad, 2012; Shephard & Bonneau, 2003), and police students had to conduct and pass four physical tests (bench press, pull in the boom, standing long jump and a 3000-metre run) at the Norwegian Police University College. This study will compare male and female police students training forms at the start and the end of their three-year of police studies. Furthermore, the study will examine the physical performances in the four physical tests among male and female police students in the same period. **METHODS** 235 police students answered a survey upon training forms (maximal strength, body building, strength endurance, endurance, power and sprint) at the start and the end of their three-years of police studies, while 85 police students participated in the four physical tests at the same period. **RESULTS** The results showed that maximal strength training became significantly more important for both men and women during the police studies, while strength endurance, endurance and sprint training significantly decreased for both gender. No significant differences were found in training body building and power training. The change in training forms was also shown in the results in the performance tests, where the bench press and pull-up performance increased considerably for both gender. **DISCUSSION** The results was surprising since exactly the same selection of police students reported that endurance was the most required physical skill in relation to police work, while maximum strength was the second least important physical skill (Lagestad, 2011). This is also suggested by other studies (Birzer & Craig, 1996; Lönn, Lönn & Hansen, 2006; Waddington, 1999). According to this finding, the police student don't exercise in relation to their own beliefs. It is argued that maximum strength seems to be a highly valued training form among the police students, probably because maximum strength is important if they have to use physical force. **REFERENCES** Birzer, M.L., & Craig, D.E. ### **SEGMENTING THE SPECTATORS OF THE 23RD MEN'S HANDBALL WORLD CHAMPIONSHIP SPAIN 2013**

García, P.

*Universitat de Girona*

**Introduction** The 23rd Men's Handball World Championship was held in Spain from which some preliminary matches and the final were carried out in Barcelona. Spectators from different countries with different backgrounds came to the city searching different experiences at the same sport contest. Therefore, the aim of this study was to analyse the public's characteristics of this event in order to classify them into segments. **Methods** Based on the existent literature, we conducted a survey analysing the demographic characteristics, the cultural and economic level, the sport habits and the motivations and experiences (Hunt, Bristol, and Barshaw, 1999, Funk, Mahony, Nakazawa and Hirakawa, 2001, Huang, Lee, and Hou 2011). We also used the Sporting Event Experience Search (SEES) scale developed by Bouchet, Bodet, Bernache-Assollant and Kada (2011) in order to categorize the fans into four dimensions corresponding to their consumptions patterns. The data were in the Palau Sant Jordi on game day 5 in the Group D and during the final match. **Results** The total number of spectators was 23.060 (9.760 Day 5, 13.300 final). Our sample consisted of 204 spectators from which approximately 70% were male and their average age was 32 years (SD = 10.60). Half of them were Spanish (51%), followed by French (19%) and German (14%). A 47% practiced sport between 1h and 5h per week, being handball (36%) the most common sport. Following the SESS scale the 54% were identified as aesthete, 8% as interactive, 19% as supporters and 8% as opportunist. The analysis of the qualitative data reinforces the description given by Bouchet et al. (2011) for these four dimensions. **Discussion** The results revealed different motivations that made the spectators attend to the championship. The most frequent dimension was the aesthetic one, which is mainly related to the beauty of the game. Our research was limited to a concrete sport event and it would be recommendable to compare these results in other contexts. The information obtained in this study can be useful for future organizers of similar tournaments, for the cities that are balancing the possibility of hosting this event as well as for the managers of the general sport events sector. **References** Bouchet P, Bodet G, Bernache-Assollant I, Kada F. ### **THE COVERAGE OF HANDBALL NEWS IN TURKISH PRINT MEDIA: A CASE STUDY IN ESKISEHIR**

Celiksoy, S.1, Çeliksoy, M.A.2, Argan, M.3, Çeliksoy, Ç.

*Anadolu University*

**Introduction** Local papers are not only part of the cities but also they are integrated. The succes in any sport branch has been anticipated as the succes of the city itself (Kaya, 2001). Especially coverage of handball in local print media was quite popular during the year of 1980-1995. For this reason, the frequency of print media coverage of handball started to decrease after 1995. Some factors such as media,

institutionalization, advertisements, and organizations are very important. For this reason the study advises that several projects should be carried out immediately. There might be some ways to enlarge print media coverage of handball (Çeliksoy et al., 2008). The aim of the research is to analyze contents of 2011 coverage of handball news in Eskişehir print media such as Sakarya, İstikbal, Milli İrade, İki Eylül, Son Haber. Methods A content analyze form, which has 20 subjects, has been used in the analyze and evaluation process. Before the content analyzes process, the newspapers have been scrutinized, subjects have been identified. SPSS 21 program has been used. Frequency and percentage analyzes have been used in evaluation process. Results These newspapers are outstanding in respect to their selling and editions. The range of the coverage of handball in the newspapers is as follows: İstikbal %44.3. On weekdays it is 61.5% but at weekends it is 38.5%. The most coverage is on the back cover of the newspapers, 73.2%. Middle page has taken the first place with a percentage of 41.1%. In the topics distribution, "The most emphasized topics" are team % 40.0, score %21.2. The majority size of the coverage was 10.1-20.0 cm<sup>2</sup> with %31.5, 21.0-30.0 cm<sup>2</sup> with %23.4. Constructive critics of the coverage is 47.8%, neutral is 43.3%, negative is 8.9%. Discussion The most coverage of handball is in İstikbal (%44.3). 61.5 % of the coverage of handball is on weekdays. Football has more coverage than other sports at weekends. The percentage of the back coverage of the newspapers, is 73.2%. Because teams weren't successful enough in 2008 championships, so coverage of handball didn't appear on other pages. The majority size of the coverage is 0-30.0 cm<sup>2</sup> with 69 %, generally team and score (%61.2) were reported in the news and they were objective and constructive critics (%91.1). ## GALES OF LAUGHTER FROM SCHOOL SPORTS MANAGEMENT PERSPECTIVE

Cheung, S.T.J.

*The Chinese University of Hong Kong*

The government, public, schools and Physical Education (PE) Teachers of Hong Kong aware the importance of health and physical activity level in students' development. Not only physical fitness, wellness is also highly concerned as a whole-person development. The prime goal of PE is to cultivate students to be active generation for developing active lifestyle and life-long exercise habits. // In this action research, a co-educational secondary school in Hong Kong is examined to see the circumstance of students' participation in physical activity during lunch time. This school promotes sporting experiences, habits and culture, and provides wide range of physical activity for students during and out of PE lessons. For lunch time, the school opens sports venues for students taking part in physical activity. Those activities are not structured and organized one, and the participants are regular. Therefore, this research aims to study how the change on managerial roles and skills of teachers affects students' participation in physical activity during lunch time and how the GALES framework established. // In normal practice, PE teachers of this school act as observers at different school sports venues during lunch time to ensure students' safety. To effectively manage and organize physical activity during lunch time, the roles of PE Teachers are changed from being observers to trainers and managers. As a trainer, PE panel head organizes sports leadership training workshop to a group of Students Sports Ambassadors, named "Lunch Sports Buddies". These sports ambassadors execute their duties during lunch time to organize sports programs/activities, do exercises with other students and monitor students' safety. At the venues, PE teachers also act as managers to mainly provide instant advices on safety measures or emergency cases to sports ambassadors. // Two cycles of interventions are implemented in this action research. In Cycle 1, PE teachers/panel head arrange a sports leadership workshop to sports ambassadors. Sports ambassadors carry out a three-day sports program/activity during lunch time. PE Teachers record the numbers of participants per session and jot down the points on a reflection sheet for evaluation with the researcher and then with sports ambassadors. Based on the evaluations made in Cycle 1, Cycle 2 begins and the second leadership training workshop is held for modifications and improvements on managing and organizing the three-day sports programs/activities. Similar to Cycle 1, sports ambassadors carry out a three-day sports program/activity during lunch time. Number of participants will be reported. The researcher records the changes of managerial roles and skills of PE Teachers and sports ambassadors and other related aspects and outcomes. Interviews with PE Teachers, sports ambassadors and participants of the sports programs are arranged to evaluate the effectiveness of the managerial roles and skills of PE teachers on organizing sports programs/activities for cultivating active generation.

## COMPETENCIES DEVELOPMENT IMPLICATIONS TOWARDS THE PREPARATION OF SPORT MANAGERS

Valantiniene, I., Krikstaponyte, I.

*Lithuanian Sports University*

Introduction In the process of the development of persons career it is very important to help student to make the decision and to choose the right education, professional training and work so that the needs of person and work world would be satisfied (Jarvis, 2003). The competence of the employees is one of the main features, which could influence the competitiveness of organizations and their activity efficiency. In the practice of sport management in most of the European countries there are no requirements for the sports managers for the professional qualification and in this context there are no general competencies as the main, settling of comprehensive person development, professional flexibility and mobility. Scientific research shows the growing significance of general competencies, the importance of their development in the organization (Boyatzis, 2002). Less research are made in which competencies of sports managers and their development are discussed. The activity of sport organizations, the competencies of their managers are more emphasized in them (Chelladurai, 2006). Methods One (accidental) questionnaire was aimed to evaluate future sports managers attitude to the development of general competencies and their personal features and values. Other one was constructed to evaluate the opinion of sports managers specialists on the general competencies. Results Sports managers mostly lack main knowledge skills and their use in practice, such as, activity organization and control, the implementation of organizations consumers demand research, conflicts solving at work, to determine and analyze problems of sport organization activity, to analyze, generalize the results of organizations activity, to use holistic attitude to the organizations activity and to the influencing environment, by using innovations in technologies and organizations internal and external environment valuation, by paying attention to the countries economy and conditions of European economical and social stability. In the analysis of theoretical knowledge, mostly lack basic knowledge: finance and calculation; marketing research organization and implementation; advertising and promotion, human resource management, strategic planning, orientated to the consumer marketing. By generalizing such competencies, which working sports management specialists think to be very important in the work of sports manager, can be excluded: main professional knowledge, ability to plan and organize, to make decisions, to work in command and independently. References Jarvis, P. S. (2003). Career Management Paradigm Shift: Prosperity for Citizens, Windfalls for Governments.

### **BRAZILIAN SPORT CLUBS: MANAGEMENT PERSPECTIVES FROM A CASE STUDY IN A SPANISH BASKETBALL CLUB**

Galatti, L.R., Morato, M.P., Montero, A.S., Paes, R.R.

*CDS-UFSC; UDC; GEPESP-FEF-UNICAMP; EEFERP-USP*

**Introduction** As in the eighteenth century in England, nowadays the sport clubs are one of the leading organizations promoting sport, especially in the western world, like Brazil. However, in recent decades sport changed and is adapting to the globalized world, to the consumer society and to the speed of the media, manifesting itself in multiple ways and contributing to different segments of society. The sport clubs, in contrast, are divided between traditional aspects of its management and operation and the current demands of diversification and professionalization (GALATTI, 2010). From this perspective, the study addresses the interface between sport and sport clubs in order to understand the current moment in the Brazilian context, intending to signal new opportunities of development. **Methods** The investigation started with a literature review about sport and club in Brazil and in Spain; then, the study advances to a case study in a Spanish Basketball club. It was made with document research at club documents and from semi-structured interviews with directors of the club in order to identify management actions that have made possible the sportive and institutional club growth. **Results** The management actions has shown success in providing basketball, with an increase of 374.5% federated athletes linked to the club in the last five years and also results for their basketball adult team that led them to ascend in three professional leagues in Spain. The specific actions founded in this club were: strengthening interdependence between base teams and professional team; athletes of the base teams as fans and consumers of the products of the club; diversification of the club products and people involved; professionalization of services - internal and external audiences; Respect with the social group that motivates and keeps the club (fans and consumers). **Discussion** Brazilians sport clubs, with representative teams at sport leagues, are not enough professional as the contemporary sport. As seen in the Spanish models of sport clubs management, it's necessary to improve sport as a cultural heritage, with more practices. From that, it's necessary to professionalize managers, with the perception of sport as a possibility of promoting the club in the contemporary, as much as the club like a place of improving sport in Brazil, especially with the big sport events coming to the country. **References** GALATTI, L.R. (2010) *Esporte e clube sócio-esportivo: percurso, contextos e perspectivas a partir de estudo de caso em clube esportivo espanhol*. Tese (Doutorado em Educação Física)-Faculdade de Educação Física. ### **STATISTICAL DATA ANALYSIS OF ANTI-DOPING AGENCY OF SERBIA IN LAST 7 YEARS**

Dikic, N., Vukasinovic, V.M., Andjelkovic, M., Antic, T., Vajagic, B.

*Anti-doping Agency of Serbia*

**Introduction** Anti-doping Agency of Serbia (ADAS) was founded in 2005. After ratification of the UNESCO International convention against doping in sport, complete anti-doping regulations in Republic of Serbia are in line with World Anti-Doping Code and ADAS is "Code Compliant" with 2009 World Anti-Doping Code. The results of ADAS work showed importance of continuing the fight against doping in sport. **Methods** In this cross sectional study, we analyzed official statistical data from ADAS for last 7 years, from 2006 to 2012. We evaluated the number of conducted doping controls (in and out of competition), total number of adverse analytical findings (AAF), prohibited substances used as doping and, in the end, in which sports doping was present the most. **Results** Basic statistic showed that for the last 7 years, from 2006 to 2012, we performed in total 3,982 doping controls. Total number of AAFs in this period was 48, while in the same period there had been 3 other Anti-doping rule violations. During this period there was 4.03% of AAFs which is two times more compared to world statistics for the same period of time. In 2011 and 2012 that percentage was 1.75% which is in line with world statistics for these years. We tested athletes in 50 different sports and there were AAFs in 21 of them. First 5 sports by AAF are: wrestling (13%), body building (13%), boxing (11%), handball (11%) and athletics (6%). For the last 7 years 67 different prohibited substances were used as doping by athletes and in 13 cases athletes used more than 1 of prohibited substances. In addition, six different groups of prohibited substances were used: S1.anabolic agents (50%), S8. cannabinoids (16.67%), S5. diuretics and other masking agents (16.67%), S6. stimulants (13.64%), S3. beta 2 agonists (1.52%) and P2. beta blockers (1.52%). **Conclusion** Despite increase in number of doping controls, Serbia still performs two times less doping controls comparing with countries with similar number of inhabitants, economic and sports potential. In 2006 most of sport workers in Serbia thought of doping as something which is not significant problem in this country. During this period ADAS showed that doping is significant problem in Serbian sport which has been presented by number of AAFs. Thanks to systematic approach to this problem and continues education we finished 2012 with 7 times less numbers of AAFs. The challenge of developing a rigorous global Anti-doping program, as well as Athlete Outreach program, requires acceptance of doping as a problem by sport organizations, athletes, and public authorities. Individual stakeholders must be prepared to preserve the values of sport, which means free from doping. This will require vigilance by all interested parties for the benefit of elite athletes and society overall. **References** 1. Fraser AD. Doping control from a global and national perspective, *The Drug Monit.* 2004 Apr.

### **SUPPORTING THE STUDENT ATHLETES IN THE UK: THE CASE OF THE TALENTED ATHLETE SCHOLARSHIP SCHEME**

Lee, P., Jiang, R.

*National Taichung University of Education, Taiwan; Loughborough University, UK*

**Introduction** It is increasingly recognized that helping talented elite athletes to cope with their academic studies and sport is one of the most commonly encountered issues in different countries. In the UK, the Talented Athlete Scholarship Scheme (TASS), which is a government backed partnership between talented young athletes, educational institutes and national governing bodies of sport, was launched in 2004. **Objectives** This discussion is about elite, or high performance, sport and primarily about how the UK provides life support for talented [student] elite athletes. The concern is of the major contributions of implementing the TASS since 2004. **Materials & Methods** The documentary-based element takes the form of qualitative content analysis, which applied to the form of analysis of a number of British sport official reports, academic articles, and media commentaries and so on. In total, 65 references were reviewed and 33 commentaries were identified to conduct this research. The data was subject to analysis and coding employing the NVivo 9 software package. **Results & Discussion** In 2004, the Department for Culture, Media and Sport (DCMS) administered a TASS programme which serves athletes below the World Class Performance Programme (WCPP) as an initiative to reduce the drop-out rate from athletes unable to maintain the balance between sports and education and other life pressures (Henry, Amara, Aquilina, & PMP Consultants, 2004). Two major services were provided through the TASS program, namely, "Core Services" (strength and conditioning, physiotherapy and medical sup-

port, lifestyle support/mentoring and education and career support) and "Sport Specific Services" (coaching, competition and training expenses, equipment and sport science) (DCMS, 2011). The TASS service has made a significant contribution to supporting the UK's elite sport performance, with 66% TASS athletes and alumni in the last Olympic and Paralympic cycle. At the recent London Olympic Games, over 200 current or former TASS athletes competed for the UK and 44 of these athletes won the medals (57), 10 of whom won multiple medals (TASS, 2012). Conclusions To some extent, delivery of the TASS has met those 'needs' of government, educational institutes, NGBs, and student athletes in some elements. This implies that such a scheme is able to assist student athletes balance other aspects of their academic life with their sport training and competing. And, the major contributions of the TASS are concluded as the followings: contributions to medals, athlete welfare, and athlete focus. References DCMS. (2011). ### **THE PUBLIC-PRIVATE PARTNERSHIPS OF CONSTRUCTING SPORTS FACILITY IN THE UNITED STATES: A CASE STUDY OF DALLAS COWBOYS STADIUM**

Lee, K.W., Lee, P.C., Yang, C.W., Lin, C.R., Huang, J.H.

*National Taichung University of Education (NTCU)*

**Introduction** Over the past four decades, state and city governments in the United States have invested billions of public dollars in professional sports facilities (Long, 2012). However, taxpayers were not always called upon to pay for the venues where privately-owned sports franchises played (Siegfried & Zimbalist, 2000). Therefore, the aim of this research seeks to understand the interactions between the U.S. government and private cooperation on the construction of sports facilities. **Methods** The research analyzed the success case of Dallas Cowboys Stadium using the view point of public-private partnership. The document analysis and in-depth interviews were used to collect research data from public and private sectors involved in the construction of the Dallas Cowboys Stadium. **Results** The construction cost of Cowboys Stadium was \$1.15 billion. The City of Arlington provided over \$325 million in bonds as funding. Also, the NFL provided the Cowboys with an additional \$150 million loan, as per their policy for facilitating financing for the construction of new stadiums. And Cowboys owner covered the other construction costs of the stadium. Participants in the Cowboys Stadium deal included city government, team and other private entities. The findings show that the project was benefited by sustained advocacy from public officials together with numerous government incentives and other forms of economic assistance. The land acquisition costs for this sports facility were almost entirely borne by taxpayers. In addition to Cowboys owner, the projects received other private-sector financial support, provided as a business investment. **Discussion** The results found in the present study coincides with previous findings that cities provide the owners of professional sports franchises with hundreds of millions of dollars of subsidies for the construction of new stadiums and arenas and expect these facilities to generate economic benefits exceeding these subsidies (Coates & Humphreys, 2003). Also, the public-private partnerships for major league sports facilities have become complex. The public cost and public share of deal could be broke down into two categories of development costs (building, land, and infrastructure) and ongoing annual costs (lease expenses net of lease revenues, foregone property taxes). The financing packages for sports facilities required years to negotiate, and involve varying combinations of public and private partners, debt and equity financing, and facility and non-facility revenues. These findings reiterated information found in the literature on this subject (Long, 2012). **References** Coates, D., & Humphreys, B. R. (2003). ### **SWIMMING POOLS AND CHEMICAL TREATMENTS OF WATER: A QUALITATIVE VISION FOR MAINTENANCE MANAGERS**

Fernández-Luna, A.1, Burillo, P.2, Felipe, J.L.1, Sánchez-Sánchez, J.3, García-Unanue, J.3, Plaza-Carmona, M.3, Ubago, E.3, Hernández, E.3, Gallardo, L.3

*1: Universidad Europea de Madrid (Spain), 2: UCJC (Madrid, Spain), 3: UCLM (Toledo, Spain)*

**Introduction** Attendance at indoor swimming pools involves exposure to chlorine gas and disinfection byproducts (DBPs) generated through chlorine and bromine. The exposure to these products is associated to numerous health problems. There are alternative water treatments such as ozone, UV lamps and salt chlorination that could reduce the presence of DBPs in pool water and environment, and they can also improve the management of the facility. Thus, the aim of this research was to evaluate the characteristics of the chemical treatments used in indoor swimming pools **Methods** A semi-structured interview was designed. The sample consists of pool maintenance managers who use different chemical treatments (n = 15). **Results** Most of the maintenance managers have specific training for their workstation and have received training during their working life. Although they ask for most useful content for daily routine in the installation in seminars. Chlorine is considered the cheaper chemical treatment and UV lamps and ozone are considered the greenest. The most popular chemical treatments are ozone and salt chlorination because of the safety of users, the viability of the facility, saving water and disinfectant power. Working with chemical treatments has adversely effects to the health of maintenance managers that use chlorine or bromine, while managers who use other treatments feel more comfortable in their jobs. **Discussion** An adequate training in the maintenance of indoor swimming pools is needed in Spain because there is not a specific qualification, as shown in a qualitative study where maintenance managers have identified the need for a better training (Mapfre. Prevention Service, 2007). Ozone and UV treatments generate fewer DBPs (Cassan et al., 2006, Lee et al., 2009), resulting in lower water consumption and a lower risk to the health of users and swimming pool workers. Moreover, both treatments are better disinfectants than chlorine or bromine. Working with a combined chemical treatment reduces direct contact with corrosive substances by maintenance workers, thereby decreasing the risk of health problems and increasing their satisfaction. **References** Cassan D., Mercier B., Castex F., Rambaud A. ## WHAT IS THE ROLE OF THE STAKEHOLDERS IN DECISION MAKING? EVIDENCE FROM A FOOTBALL CLUB

Miragaia, D., Ferreira, J., Carreira, A.

*University of Beira Interior*

**Introduction** We know little about the relationships between sport management organizations and stakeholders (Russo & Vito, 2011). For that reason, organizations must identify and prioritize stakeholders in order to improve the efficiency and outcomes of their decision-making processes (Anagnostopoulos, 2011). This study aims to identify and prioritize the perceptions of internal and external decision-makers as regards sports organization stakeholders, based on Mitchell, Agle and Wood (1997) approach. **Methods** The study focuses on a Portuguese football club. A questionnaire was applied to the internal and external decision-makers (Agle, Mitchell, & Sonnenfeld, 1999). A multiple linear regression analysis was done to assess the influence of the attributes of power, legitimacy and urgency to the stakeholder's respective salience. To identify and prioritize the perceptions of internal and external decision-makers a correlations analysis between the three attributes was done. **Results** In validating the hypotheses corresponding to external decision-makers the attribute of power has a positive relationship only with salience of operational management ( $\beta = .58$ ); regulatory bodies ( $\beta = .55$ ); and suppliers ( $\beta = .65$ ) presenting adjusted  $R^2$  coefficient values of .25; .3 and .37, respectively. To internal decision-makers the power attribute correlates only with the salience of the local community ( $\beta = .64$ ;  $R^2$  adjusted = .79), with power being the factor best explaining the salience of this stakeholder group. The results show convergence between external and internal decision-maker perceptions regarding the three main stakeholder groups: top management, sponsors, and association members. Furthermore, four types of stakeholders were identified: definitive, dangerous, demanding and non-stakeholders. **Discussion** The study suggests that organizational success will depend on both identifying and assessing the relevance of stakeholders, and highlighting just who should get priority in strategic decision-making and why. We suggest there should be a pro-active approach to organizational management able to anticipate and coordinate the responses and requests of the various stakeholders. This attitude ensures the maximization and maintenance of a favourable position in relation to all organizational interests in strategic decision-making. **References** Agle, B., Mitchell, R., & Sonnenfeld, J. ## EVALUATION OF INTERNATIONAL YOUTH VOLLEYBALL PERFORMANCE CENTRES

Rath, G., Tilp, M.

*Karl-Franzens University Graz*

**Introduction** For the majority of European volleyball federations, youth high performance centres are an essential part of athlete development. These centres should primarily prepare its athletes for a future professional career (Rodríguez-Ruiz et al., 2010; Emrich et al., 2009). The aim of the present study is to evaluate European high performance centres for volleyball and identify structural characteristics which are responsible for the development of top athletes. **Methods** Fourteen high performance volleyball centres situated in eight countries participated in this study. Data of the centres' structural characteristics were obtained through interviews and questionnaires during research stays. Basis for the assessment of the centres' outcome was the percentage of athletes participating in the highest national league and/or senior national team, normalized to CEV (European volleyball federation) and FIVB (world volleyball federation) rankings. Based on this procedure all surveyed centres were ranked and subsequently correlations (Spearman,  $\alpha=0.05$ ) were performed to relate data of the questionnaire with the ranking. **Results** Significant correlations to high performance outcome were inter alia found regarding the existing years of the centre ( $r_s -0.928/\alpha -0.00$ ), the existing years of the talent development program ( $r_s -0.761/\alpha -0.03$ ), the annual average budget ( $r_s -0.787/\alpha -0.02$ ), the percentage of membership fee ( $r_s 0.854/\alpha -0.01$ ), the percentage of athletes living in boarding schools ( $r_s -0.749/\alpha -0.03$ ), and the number of sport medical tests/year ( $r_s -0.831/\alpha -0.01$ ). A negative Spearman's rho is based on a correlation between a low (=better) ranking number and a high value of the respective questionnaire item. **Discussion** Data revealed that successful centres are equipped with an appropriate financial funding and their athletes are subjected to medical sports tests on a regular basis. Regarding the obligatory membership fees at high ranked centres, the results show that these centres and development programs should be open to everybody and financially affordable. Furthermore, it appears to be favourable to provide a boarding school to combine training and education. The results might provide valuable information of how to organise a high performance centre, for reassessing and restructuring already established centres, and for a design of young athletes' development programs. **References** Rodríguez-Ruiz, D., García-Manso, J.M., Muchaga, F.L.F., Fernández, D.C., & Dantas E. ## HOW SPAIN IS ADAPTING THE SPORTS TRAINING TECHNICIAN EUROPEAN MODEL

Seguí, J., Nebot, R., Camps, A., Papous, S.

*INEFC-Lleida*

**Introduction** Spanish Sports Act (10/1990) introduced the need to adapt the Spanish sports training technician model to the characteristics of the education system, to the needs of the market and the European standards. Spanish sports federations were reluctant due to loss of their monopoly (management and income). Accounted for the strong Spanish sports federations opposition have taken more than 20 years to reach a standardized process in accordance with the European Union demands of training and access to work model. We present in this communication how the Spanish technical sports training model has been adapted to those European standards and which instruments were used. How the model was implemented? The Law 5/2002 of professional qualifications and vocational training laid the foundation for defining, by INCUAL, professional qualifications in the sports sector and more specifically to the "physical and sporting activities" family. The National Catalogue of Professional Qualifications recognizes 25 different qualifications into 3 levels. It is from the professional qualifications and its skills which are defined what academic training is necessary and what titles can be derived by them. The system allows people, without academic qualification or formal training, to enter into the market or into qualifications programs by accrediting competences to the public bodies. This accreditation is based on professional experience and knowledge acquired throughout life. How the formation is structured? The technical sport training has two different models: a- Training included in the special regime of vocational training. Managed by the education system. - Adapted to Bologna Titles: Caving, Diving, Horse Riding, Sailing, judo / self-defence and Lifesaving and rescue. - Titles not adapted to Bologna: Mountaineering, Skiing, Soccer, Basketball, Athletics and Handball. b- Formation in the transitional period. Managed by the sports system. The strong reluctance of sports federations has made a

significant number of disciplines and modalities have not been integrated into the education system. From 2007 these configurations must necessarily conform to the qualifications and skills of the European model. In that way the training structures and the appropriations for each subject have been unified. When these trainings will be integrated into the education system, diplomas will be recognized as Bologna effects. In either of the two models is fixed an intermediate qualification, with two levels of training (Level I and Level II), and an advanced qualification (Level III). References Law 10/1990. Law 5/2002. ### WHAT MAKES THE EXCELLENCE OF SPAIN'S TEAM SPORTS?

Hongyou, L., Javier, S.M.

*Faculty of Physical Activity and Sport Science (INEF), Polytechnic University of Madrid (UPM)*

With the latest success in the Men's Handball World Championship, Spain's sport teams, including football, basketball, volleyball, field hockey, handball, baseball, water polo, roller hockey and futsal, have won 173 medals in the Olympic Games, World Championships and European Championships, 65 gold, 66 silver and 42 bronze. Most of the trophies were obtained in the recent 25 years, especially the women's who won their first medal in 1992. A question comes that: what makes the current excellence of the Spain's team sports? In order to answer it, a comprehensive analysis was conducted to the sport policies, coach and technician teams, tactic and technique systems and competition systems of the team sports in Spain. Results show that: (1) the founding of "Association of Olympic Sports" (ADO) after 1988 Korea Olympic Games is the initiation of a series of reforms in sport policies who set up lots of centers, councils, laws and regulations which created a favorable atmosphere for the development of the team sports; (2) the well-trained and experienced head coaches, officially certificated assistant and technique coaches, physiotherapists, IT and video specialized technicians, directors and managers consist a cooperative multidisciplinary technical team; (3) the insistence of its own style, the emphasis on match process instead of results and the stress on team spirits lead to a perfect tactic and technique system in all kinds of team sports in Spain; (4) all the 9 kinds of team sports are professionalized in Spain and various league and cup games are running throughout all the years.

#### CAFFEINE AND PERFORMANCE OVER TWO DAYS OF SIMULATED CROSS-COUNTRY SKIING COMPETITION

Stadheim, H.K., Spencer, M., Jensen, J.

*Norwegian School of Sport Sciences*

Introduction Performance improvements on exercise tasks lasting 10-90 min after caffeine (CAF) ingestion is well documented (1-2). In most competitions e.g.: Tour de France, Tour de Ski, or World Championships athletes compete several days in a row. Indeed, it is possible an improved performance after CAF ingestion may cause augmented fatigue and impair performance the following day. However to the author's knowledge studies testing effects of CAF so far have used a one day protocol. The aim of the study was therefore to test effects of placebo (PLA) and two different CAF dosages (3 and 4.5 mg•kg<sup>-1</sup> bodyweight) on performance in a cross-country double poling ergometer test (C-PT) two days in a row. Methods 8 highly trained male cross-country skiers (VO<sub>2</sub>max-run 78.5±1.6 ml•kg<sup>-1</sup>•min<sup>-1</sup>) participated in the study which had a randomized double-blinded, placebo-controlled, cross-over-design. Performance was assessed as mean speed during a 10 min all out C-PT. Prior to the all out C-PT two standardized workloads equivalent of 75% (10 min) and 80% (5 min) of VO<sub>2</sub>max-poling was performed. A standardized warm-up protocol consisting of four workloads from 50-65% of VO<sub>2</sub>max-poling was performed on each testing day before the 15 min+10 min all out C-PT. Oral ingestion of CAF or PLA was done 75 min before the all-out C-PT. Similar treatment was done both days in a row. Results Increased poling speed after CAF ingestions compared to PLA was observed both days. The improvement was 4.2% for both CAF dosages (P<0.05), on day one while improvements on day two were 5.0 and 5.1% for CAF3 and CAF4.5 respectively compared to PLA. Mean speed on the 10 min C-PT were 15.5 ±0.2 and 15.4±0.4 km • h<sup>-1</sup> for PLA day one and two, while it increased day one to 16.2 ±0.4 km • h<sup>-1</sup> for both CAF3 and CAF4.5. Day two, same mean speed was observed for CAF4.5, while a small decrease was observed to 16.1±0.4 km • h<sup>-1</sup> for CAF3 compared to PLA (n.s). Of all subjects participating 87.5% improved performance on both days after CAF ingestions. Discussion The novel heading in this study is that CAF ingestion improved performance both competing days. Higher speed was associated with increased heart rate (HR), blood lactate (LA-) and VO<sub>2</sub> consumption after CAF ingestions. No difference in HR, LA- or VO<sub>2</sub> was observed during the warm-up or during the first 15 min of the C-PT were workloads were similar between treatments. In conclusion ingestion of both CAF dosages increases subjects physiological capacity, also when competing two days in a row. The higher physiological stress on day one did not impair performance the following day when CAF was ingested. #### EFFICACY OF FLYWHEEL RESISTANCE EXERCISE TO MAINTAIN MYOSTATIN AND OXIDATIVE AND GLYCOLYTIC POTENTIAL OF MUSCLE DURING 90 D BED REST

Rodriguez-Miguel, P.1, Fernandez-Gonzalo, R.2, Tesch, P.A.2,3

*1: Institute of Biomedicine (IBIOMED) (León, Spain); 2: Karolinska Institutet (Stockholm, Sweden) 3: Mid Sweden University (Östersund, Sweden)*

EFFICACY OF FLYWHEEL RESISTANCE EXERCISE TO MAINTAIN MYOSTATIN AND OXIDATIVE AND GLYCOLYTIC POTENTIAL OF MUSCLE DURING 90 D BED REST Introduction Skeletal muscle atrophy and metabolic perturbations may jeopardize health and fitness of astronauts during long-term spaceflight. Although alterations in muscle function and morphology after spaceflight simulation have been well described, there is lack of knowledge in regards to related skeletal muscle metabolic adaptations. While resistance exercise (RE) training is shown to

maintain muscle size and function during 90 d bed rest (Alkner & Tesch 2004), this study determined muscle oxidative and glycolytic potential along with myostatin before and after 90 d bed rest with or without RE. Methods Twenty-one healthy males (26-41 yrs) were randomly assigned to either 6° head-down tilt bed rest with (BRE; n=9) or without (BR; n=12) concurrent resistance exercise (RE) for 90 d. RE was performed every third d using iso-inertial flywheel technology (4 x 7 maximal concentric-eccentric supine squats). Before (PRE) and after (POST) the intervention, muscle biopsies were obtained from m. vastus lateralis, and mRNA expression of regulators of muscle mass (myostatin), oxidative capacity (peroxisome proliferator-activated receptor gamma coactivator-1alpha; PGC-1alpha, and vascular endothelial growth factor; VEGF) and glycolytic potential (phosphofructokinase; PFK), were subsequently analyzed. Results PGC-1alpha and VEGF mRNA expression decreased ( $P < 0.002$ ) in both BR (PGC-1alpha; 1.3-fold, VEGF; 1.3-fold) and BRE (PGC-1alpha; 1.5-fold, VEGF; 1.8-fold). PFK mRNA content increased from PRE to POST in BR ( $P < 0.001$ ; 1.5-fold) but not in BRE. Thus, PFK expression was greater in BR than BRE at POST ( $P < 0.03$ ; 1.4-fold). Myostatin mRNA levels increased from PRE to POST in BR only ( $P < 0.001$ ; 2.4-fold). BR showed greater myostatin expression than BRE at POST ( $P < 0.001$ ; 3.7-fold). Discussion A single bout of the RE paradigm employed here increased PGC-1alpha and VEGF in ambulatory subjects (Fernandez-Gonzalo et al 2013). However, this stimulus, when offered every third day, was insufficient to counteract unloading-induced alterations in these markers of oxidative capacity. Nevertheless, the RE carried out by BRE ameliorated the increase in PFK and myostatin induced by spaceflight simulation. This suggests both muscle glycolytic potential and muscle size are maintained with use of the current RE regimen. Hence, additional exercise countermeasures are needed to preserve muscle oxidative potential during long-haul space missions. References Alkner BA, Tesch PA (2004). *Eur J Appl Physiol* 93: 294-305. ### CREATINE SUPPLEMENTATION ASSOCIATED OR NOT WITH STRENGTH TRAINING UPON DEPRESSION AND COGNITION IN OLDER WOMEN

Gualano, B., Alves, C.R.R., Merege Filho, C.A.A., Benatti, F.B., Brucki, S., Pereira, R.M.R., de Sá Pinto, A.L., Lima, F.R., Roschel, H.

*University of Sao Paulo*

**Introduction** In spite of the potential therapeutic role of isolated strength training or creatine supplementation on cognition and depression in older individuals, no studies have investigated the possible additive effects of these strategies combined. Therefore, the aim of this study was to assess the effects of creatine supplementation, associated or not with strength training, upon depression and cognition in old individuals. **Methods** This is a 24-week, parallel-group, double-blind, randomized, placebo-controlled trial. The individuals were randomly allocated into one of the following groups (n=14 each): 1) placebo, 2) creatine supplementation, 3) placebo associated with strength training or 4) creatine supplementation associated with strength training. According to their allocation, the participants were given creatine (4 x 5 g/d for 5 days followed by 5 g/d) or placebo (dextrose at the same dosage) and were strength trained or not. Cognitive function, assessed by a comprehensive battery of tests involving memory, selective attention, and inhibitory control, and depressive symptoms, assessed by the Geriatric Depression Scale, were evaluated at baseline, after 12 and 24 weeks of the intervention. Muscle strength and food intake were evaluated at baseline and after 24 weeks. **Results** After the 24-week intervention, both training groups (ingesting creatine supplementation and placebo) had significant reductions on the Geriatric Depression Scale scores when compared with the non-trained placebo group ( $p=0.004$  and  $p=0.029$ , respectively) and the non-trained creatine group ( $p<0.001$  and  $p=0.002$ , respectively). However, no significant differences were observed between the non-trained placebo and creatine ( $p=0.77$ ) groups, or between the trained placebo and creatine groups ( $p=0.83$ ). Both trained groups, irrespective of creatine supplementation, had better muscle strength performance than the non-trained groups. Neither strength training nor creatine supplementation altered any parameter of cognitive performance. Food intake remained unchanged. **Conclusion** Creatine supplementation did not promote any significant change in cognitive function and depression parameters in apparently healthy older individuals. In addition, strength training per se improved depression and muscle strength, but not cognition, with no additive effects of creatine supplementation. Registered at Clinicaltrials.gov as NCT01164020.

### VITAMIN D DEFICIENCY AND EVALUATION OF APPLIED SUPPLEMENTATION IN POLISH ATHLETES

Krzywanski, J.1, Krysztofiak, H.2,1, Misiorowska, J.1, Ziemia, A.2, Mikulski, T.2

*1 National Centre of Sports Medicine, Warsaw, Poland. 2 Mossakowski Medical Research Centre, PAS, Warsaw, Poland.*

**Introduction** Recently Vitamin D is considered as an important factor not only in calcium homeostasis but in muscle metabolism involved in sports activity as well. Poland has a moderate climate, thus sun dependent activation of provitamin D is limited resulting in increased risk of hypovitaminosis (below 30 ng/ml) in general population and in athletes (desired at least 40 ng/ml). The aim of this study was to evaluate the concentration of vitamin D in Polish athletes and effectiveness of recommended supplementation. **Methods** Professional athletes of track and field, fencing, handball and volleyball were monitored regularly for three years for blood total vitamin 25(OH)D concentration (number of samples: 2010 – 190; 2011 – 209; 2012 – 250). In 2011 according to blood monitoring results supplementation program was introduced with dose of 1000 units daily. In subjects who showed no improvement doses of 2000-4000 units daily were applied in 2012. Influence of training camp abroad with high sunshine exposure during winter was evaluated in 2012. **Results** Annual average vitamin 25(OH)D concentration in 2010 was  $27.6 \pm 0.6$  ng/ml, with clear seasonal rhythm (winter Dec-Feb  $25.0 \pm 1.3$  ng/ml; summer Jun-Aug  $29.1 \pm 0.7$  ng/ml,  $p<0.01$ ). Athletes who had trained during winter abroad with high sunshine exposure showed significantly enhanced vitamin 25(OH)D concentrations of  $53.1 \pm 1.8$  ng/ml, compared to  $34.0 \pm 1.3$  ng/ml,  $p<0.001$  in subjects who stayed in Poland. Supplementation with 1000 units daily showed significant improvement in 2011 ( $37.5 \pm 1.0$  ng/ml,  $p<0.001$ ), higher doses of 2000-4000 units daily produced further improvement in 2012 ( $40.9 \pm 1.3$  ng/ml,  $p<0.05$ ). **Discussion** Vitamin D deficiency was confirmed in population of Polish athletes, especially in winter. Monitoring of vitamin D is necessary, as primary recommendations for supplementation of 1000 units daily have proved to be effective, but in some athletes higher doses of max 4000 units daily are required in order to produce desired results. The other, natural but more difficult, way to prevent hypovitaminosis is to spend some part of winter in warm and sunny climate.

### MITOCHONDRIAL BIOGENESIS AND ENDURANCE PERFORMANCE IN RESPONSE TO HIGH INTENSITY INTERVAL TRAINING AND ENDURANCE TRAINING IN GAELIC FOOTBALL PLAYERS
