Abstract. We define a notion of rational closure for the logic SHIQ, which does not enjoys the finite model property, building on the notion of rational closure introduced by Lehmann and Magidor in [24]. We provide a semantic characterization of rational closure in SHIQ in terms of a preferential semantics, based on a finite rank characterization of minimal models. We show that the rational closure of a TBox can be computed in ExpTime using entailment in SHIQ.

1 Introduction

Recently, a large amount of work has been done in order to extend the basic formalism of Description Logics (for short, DLs) with nonmonotonic reasoning features [27, 1, 10, 11, 13, 17, 21, 4, 2, 6, 26, 23]; the purpose of these extensions is that of allowing reasoning about prototypical properties of individuals or classes of individuals. In these extensions one can represent, for instance, knowledge expressing the fact that the hematocrit level is usually under 50%, with the exceptions of newborns and of males residing at high altitudes, that have usually much higher levels (even over 65%). Furthermore, one can infer that an individual enjoys all the typical properties of the classes it belongs to. As an example, in the absence of information that Carlos and the son of Fernando are either newborns or adult males living at a high altitude, one would assume that the hematocrit levels of Carlos and Fernando’s son are under 50%. This kind of inferences apply to individual explicitly named in the knowledge base as well as to individuals implicitly introduced by relations among individuals (the son of Fernando).

In spite of the number of works in this direction, finding a solution to the problem of extending DLs for reasoning about prototypical properties seems far from being solved. The most well known semantics for nonmonotonic reasoning have been used to the purpose, from default logic [1], to circumscription [2], to Lifschitz’s nonmonotonic logic MKNF [10, 26], to preferential reasoning [13, 4, 17], to rational closure [6, 9].

In this work, we focus on rational closure and, specifically, on the rational closure for SHIQ. The interest of rational closure in DLs is that it provides a significant and reasonable nonmonotonic inference mechanism, still remaining computationally inexpensive. As shown for ALC in [6], its complexity can be expected not to exceed the one of the underlying monotonic DL. This is a striking difference with most of the other approaches to nonmonotonic reasoning in DLs mentioned above, with some exception such as [26, 23]. More specifically, we define a rational closure for the logic SHIQ, building on the notion of rational closure in [24] for propositional logic. This is a difference with respect to the rational closure construction introduced in [6] for ALC, which is more similar to the one by Freund [12] for propositional logic (for propositional logic, the two definitions of rational closure are shown to be equivalent [12]). We provide
a semantic characterization of rational closure in $SHI\mathcal{Q}$ in terms of a preferential semantics, by generalizing to $SHI\mathcal{Q}$ the results for rational closure in $ALC$ presented in [18]. This generalization is not trivial, since $SHI\mathcal{Q}$ lacks a crucial property of $ALC$, the finite model property [20]. Our construction exploits an extension of $SHI\mathcal{Q}$ with a typicality operator $T$, that selects the most typical instances of a concept $C$, $T(C)$. We define a minimal model semantics and a notion of minimal entailment for the resulting logic, $SHI\mathcal{Q}^R T$, and we show that the inclusions belonging to the rational closure of a TBox are those minimally entailed by the TBox, when restricting to canonical models. This result exploits a characterization of minimal models, showing that we can restrict to models with finite ranks. We also show that the rational closure construction of a TBox can be done exploiting entailment in $SHI\mathcal{Q}$, without requiring to reason in $SHI\mathcal{Q}^R T$, and that the problem of deciding whether an inclusion belongs to the rational closure of a TBox is in ExpTime.

Concerning ABox reasoning, because of the interaction between individuals (due to roles) it is not possible to separately assign a unique minimal rank to each individual and alternative minimal ranks must be considered. We end up with a kind of skeptical inference with respect to the ABox, whose complexity in ExpTime as well.

For an extended version of this paper with the proofs of the results see [19].

2 A nonmonotonic extension of $SHI\mathcal{Q}$

Following the approach in [14, 17], we introduce an extension of $SHI\mathcal{Q}$ [20] with a typicality operator $T$ in order to express typical inclusions, obtaining the logic $SHI\mathcal{Q}^R T$. The intuitive idea is to allow concepts of the form $T(C)$, whose intuitive meaning is that $T(C)$ selects the typical instances of a concept $C$. We can therefore distinguish between the properties that hold for all instances of $C$ ($C \subseteq D$), and those that only hold for the typical such instances ($T(C) \subseteq D$). Since we are dealing here with rational closure, we attribute to $T$ properties of rational consequence relation [24]. We consider an alphabet of concept names $C$, role names $R$, transitive roles $R^+ \subseteq R$, and individual constants $O$. Given $A \in C$, $S \in R$, and $n \in \mathbb{N}$ we define:

$$
C_R := A \mid T \mid \bot \mid \neg C_R \mid C_R \cap C_R \mid C_R \cup C_R \mid \forall S.C_R \mid \exists S.C_R \mid (\geq nS.C_R) \mid (\leq nS.C_R)
$$

$$
C_L := C_R \mid T(C_R) \quad S := R \mid R^-
$$

As usual, we assume that transitive roles cannot be used in number restrictions [20]. A KB is a pair $(TBox, ABox)$. TBox contains a finite set of concept inclusions $C_L \subseteq C_R$ and role inclusions $R \subseteq S$. ABox contains assertions of the form $C_L(a)$ and $S(a,b)$, where $a, b \in O$.

The semantics of $SHI\mathcal{Q}^R T$ is formulated in terms of rational models: ordinary models of $SHI\mathcal{Q}$ are equipped with a preference relation $<$ on the domain, whose intuitive meaning is to compare the “typicality” of domain elements, that is to say, $x < y$ means that $x$ is more typical than $y$. Typical instances of a concept $C$ (the instances of $T(C)$) are the instances $x$ of $C$ that are minimal with respect to the preference relation $<$ (so that there is no other instance of $C$ preferred to $x$).

---

4 As for the logic $ALC^R T$ in [15], an alternative semantic characterization of $T$ can be given by means of a set of postulates that are essentially a reformulation of the properties of rational consequence relation [24].
Definition 1 (Semantics of $SHIQ^R T$). A $SHIQ^R T$ model $M$ is any structure $(\Delta, <, I)$ where: $\Delta$ is the domain; $<$ is an irreflexive, transitive, well-founded, and modular (for all $x, y, z \in \Delta$, if $x < y$ then $x < z$ or $z < y$) relation over $\Delta$; $I$ is the extension function that maps each concept $C$ to $C^I \subseteq \Delta$, and each role $R$ to $R^I \subseteq \Delta^I \times \Delta^I$. For concepts of $SHIQ$, $C^I$ is defined as usual. For the $T$ operator, we have $(T(C))^I = Min_<(C^I)$, where $Min_<(S) = \{ u : u \in S$ and $\not\exists z \in S$ s.t. $z < u \}$.

As for rational models in [24] (see Lemma 14), $SHIQ^R T$ models can be equivalently defined by postulating the existence of a function $k_M : \Delta \mapsto \text{Ord}$ assigning an ordinal to each domain element, and then letting $x < y$ if and only if $k_M(x) < k_M(y)$. We call $k_M(x)$ the rank of element $x$ in $M$. When finite, $k_M(x)$ can be understood as the length of a chain $x_0 < \cdots < x$ from $x$ to a minimal $x_0$ (an $x_0$ s.t. for no $x'$, $x' < x_0$).

Definition 2 (Model satisfying a knowledge base). Given a $SHIQ^R T$ model $M = (\Delta, <, I)$, we say that: - a model $M$ satisfies an inclusion $C \subseteq D$ if $C^I \subseteq D^I$; similarly for role inclusions; - $M$ satisfies an assertion $C(a)$ if $a^I \in C^I$; and $M$ satisfies an assertion $R(a, b)$ if $(a^I,b^I) \in R^I$. Given a KB=$(TBox,ABox)$, we say that: $M$ satisfies $TBox$ if $M$ satisfies all inclusions in $TBox$; $M$ satisfies $ABox$ if $M$ satisfies all assertions in $ABox$; $M$ is a model of $KB$ if it satisfies both its $TBox$ and its $ABox$.

The logic $SHIQ^R T$, as well as the underlying $SHIQ$, does not enjoy the finite model property [20].

Given a KB, let $F$ be an inclusion or an assertion. We say that $F$ is entailed by KB, written $KB \models_{SHIQ^R T} F$, if for all models $M = (\Delta, <, I)$ of KB, $M$ satisfies $F$.

Let us now introduce the notions of rank of a $SHIQ$ concept.

Definition 3 (Rank of a concept $k_M(C_R)$). Given a model $M = (\Delta, <, I)$, we define the rank $k_M(C_R)$ of a concept $C_R$ in the model $M$ as $k_M(C_R) = \min\{ k_M(x) \mid x \in C_R^I \}$. If $C_R^I = \emptyset$, then $C_R$ has no rank and we write $k_M(C_R) = \infty$.

Proposition 1. For any $M = (\Delta, <, I)$, we have that $M$ satisfies $T(C) \subseteq D$ if and only if $k_M(C \cap D) < k_M(C \cap \neg D)$.

It is immediate to verify that the typicality operator $T$ itself is nonmonotonic: $T(C) \subseteq D$ does not imply $T(C \cap E) \subseteq D$. This nonmonotonicity of $T$ allows to express the properties that hold for the typical instances of a class (not only the properties that hold for all the members of the class). However, the logic $SHIQ^R T$ is monotonic: what is inferred from KB can still be inferred from any KB’ with KB $\subseteq$ KB’. This is a clear limitation in DLs. As a consequence of the monotonicity of $SHIQ^R T$, one cannot deal with irrelevance. For instance, KB = \{VIP $\subseteq$ Person, T(Person) $\subseteq$ $\leq$ 1 HasMarried.Person, T(VIP) $\subseteq$ $\geq$ 2 HasMarried.Person\} does not entail KB $\models_{SHIQ^R T}$ T(VIP $\cap$ Tall) $\subseteq$ $\geq$ 2 HasMarried.Person, even if the property of being tall is irrelevant with respect to the number of marriages. Observe that we do not want to draw this conclusion in a monotonic way from $SHIQ^R T$, since otherwise we would not be able to retract it when knowing, for instance, that typical tall VIPs have just one marriage (see also Example 1). Rather, we would like to obtain this conclusion in a nonmonotonic way. In order to obtain this nonmonotonic behavior, we strengthen the semantics of $SHIQ^R T$ by defining a minimal models mechanism which is similar, in
spirit, to circumscription. Given a KB, the idea is to: 1. define a preference relation among SHIQRT models, giving preference to the model in which domain elements have a lower rank; 2. restrict entailment to minimal SHIQRT models (w.r.t. the above preference relation) of KB.

Definition 4 (Minimal models). Given \( M = \langle \Delta, <, I \rangle \) and \( M' = \langle \Delta', <', I' \rangle \) we say that \( M \) is preferred to \( M' \) (\( M <_{FIMS} M' \)) if (i) \( \Delta = \Delta' \), (ii) \( C^I = C'^I \) for all concepts \( C \), and (iii) for all \( x \in \Delta \), \( k_M(x) \leq k_M'(x) \) whereas there exists \( y \in \Delta \) such that \( k_M(y) < k_M'(y) \). Given a KB, we say that \( M \) is a minimal model of KB with respect to \( <_{FIMS} \) if it is a model satisfying KB and there is no \( M' \) model satisfying KB such that \( M' <_{FIMS} M \).

Proposition 2 (Existence of minimal models). Let KB be a finite knowledge base, if KB is satisfiable then it has a minimal model.

The minimal model semantics introduced is similar to the one introduced in [17] for ALC. However, it is worth noticing that the notion of minimality here is based on the minimization of the ranks of the worlds, rather than on the minimization of formulas of a specific kind.

The following theorem says that reasoning in SHIQRT has the same complexity as reasoning in SHIQ, i.e. it is in ExpTime. Its proof is given by providing an encoding of satisfiability in SHIQRT into satisfiability SHIQ, which is known to be an ExpTime-complete problem. The proof is omitted due to space limitations.

Theorem 1. Satisfiability in SHIQRT is an ExpTime-complete problem.

3 Rational Closure for SHIQ

In this section, we extend to SHIQ the notion of rational closure proposed by Lehmann and Magidor [24] for the propositional case. Given the typicality operator, the typicality inclusions \( T(C) \subseteq D \) (all the typical \( C \)'s are \( D \)'s) play the role of conditional assertions \( C \models D \) in [24]. Here we define the rational closure of the TBox. In Section 6 we will discuss an extension of rational closure that also takes into account the ABox.

Definition 5 (Exceptionality of concepts and inclusions). Let \( T_B \) be a TBox and \( C \) a concept. \( C \) is said to be exceptional for \( T_B \) if and only if \( T_B \models_{SHIQ^R\text{T}} T(\top) \subseteq \neg C \). A T-inclusion \( T(C) \subseteq D \) is exceptional for \( T_B \) if \( C \) is exceptional for \( T_B \). The set of T-inclusions of \( T_B \) which are exceptional in \( T_B \) will be denoted as \( E(T_B) \).

Given a DL KB=(TBox,ABox), it is possible to define a sequence of non increasing subsets of TBox \( E_0 \supseteq E_1 \supseteq E_2 \ldots \) by letting \( E_0 = \text{TBox} \) and, for \( i > 0 \), \( E_i = E(i-1) \cup \{ C \subseteq D \in \text{TBox} \text{ s.t. T does not occur in } C \} \). Observe that, being KB finite, there is an \( n \geq 0 \) such that, for all \( m > n, E_m = E_n \) or \( E_m = \emptyset \). Observe also that the definition of the \( E_i \)'s is the same as the definition of the \( C_i \)'s in Lehmann and Magidor’s rational closure [22], except for that here, at each step, we also add all the “strict” inclusions \( C \subseteq D \) (where T does not occur in C).
Definition 6 (Rank of a concept). A concept $C$ has rank $i$ (denoted by $\text{rank}(C) = i$) for $\text{KB}= (\text{TBox}, \text{ABox})$, if $i$ is the least natural number for which $C$ is not exceptional for $E_i$. If $C$ is exceptional for all $E_i$, then $\text{rank}(C) = \infty$, and we say that $C$ has no rank.

The notion of rank of a formula allows to define the rational closure of the TBox of a KB. Let $\models_{\text{SHIQ}}$ be the entailment in $\text{SHIQ}$. In the following definition, by $\text{KB} \models_{\text{SHIQ}} F$ we mean $K_F \models_{\text{SHIQ}} F$, where $K_F$ does not include the defeasible inclusions in $\text{KB}$.

Definition 7 (Rational closure of TBox). Let $\text{KB}= (\text{TBox}, \text{ABox})$ be a DL knowledge base. We define, $\overline{\text{TBox}}$, the rational closure of TBox, as $\overline{\text{TBox}} = \{ \text{T}(C) \subseteq D \mid \text{either} \; \text{rank}(C) < \text{rank}(C \cap \neg D) \; \text{or} \; \text{rank}(C) = \infty \} \cup \{ C \subseteq D \mid \text{KB} \models_{\text{SHIQ}} C \subseteq D \}$, where $C$ and $D$ are arbitrary $\text{SHIQ}$ concepts.

Observe that, apart from the addition of strict inclusions, the above definition of rational closure is the same as the one by Lehmann and Magidor in [24]. The rational closure of TBox is a nonmonotonic strengthening of $\text{SHIQ}^\text{PT}$. For instance, it allows to deal with irrelevance, as the following example shows.

Example 1. Let $\text{TBox} = \{ \text{T}(\text{Actor}) \subseteq \text{Charming} \}$. It can be verified that $\text{T}(\text{Actor} \cap \text{Comic}) \subseteq \text{Charming} \in \overline{\text{TBox}}$. This is a nonmonotonic inference that does no longer follow if we discover that indeed comic actors are not charming (and in this respect are untypical actors): indeed given $\text{TBox}' = \text{TBox} \cup \{ \text{T}(\text{Actor} \cap \text{Comic}) \subseteq \neg \text{Charming} \}$, we have that $\text{T}(\text{Actor} \cap \text{Comic}) \subseteq \text{Charming} \notin \overline{\text{TBox}'}$. Furthermore, as for the propositional case, rational closure is closed under rational monotonicity [22]: from $\text{T}(\text{Actor}) \subseteq \text{Charming} \in \overline{\text{TBox}}$ and $\text{T}(\text{Actor}) \subseteq \text{Bold} \notin \overline{\text{TBox}}$ it follows that $\text{T}(\neg \text{Bold}) \subseteq \text{Charming} \in \overline{\text{TBox}}$.

Although the rational closure $\overline{\text{TBox}}$ is an infinite set, its definition is based on the construction of a finite sequence $E_0, E_1, \ldots, E_n$ of subsets of TBox, and the problem of verifying that an inclusion $\text{T}(C) \subseteq D \in \overline{\text{TBox}}$ is in EXPTime. Let us first prove the following proposition:

Proposition 3. Let $\text{KB}= (\text{TBox}, \emptyset)$ be a knowledge base with empty ABox. $\text{KB} \models_{\text{SHIQ}^\text{PT}} \text{C}_L \subseteq \text{C}_R$ iff $\text{KB}' \models_{\text{SHIQ}^\text{PT}} \text{C}'_L \subseteq \text{C}'_R$, where $\text{KB}'$, $\text{C}'_L$, and $\text{C}'_R$ are polynomial encodings in $\text{SHIQ}$ of $\text{KB}$, $\text{C}_L$, and $\text{C}_R$, respectively.

Proof. (Sketch) First of all, let us remember that rational entailment is equivalent to preferential entailment for a knowledge base only containing positive non-monotonic implications $A \bowtie B$ (see [24]). The same holds in preferential description logics with typicality. Let $\text{SHIQ}^\text{PT}$ be the logic that we obtain when we remove the requirement of modularity in the definition of $\text{SHIQ}^\text{PT}$. In this logic the typicality operator has a preferential semantics [22], based on the preferential models of $\text{P}$ rather then on the ranked models of $\text{R}$ [22]. It is possible to prove that entailment in $\text{SHIQ}^\text{PT}$ and entailment in $\text{SHIQ}^\text{PT}$ are equivalent if we restrict to KBs with empty ABox, as TBox contains inclusions (positive non-monotonic implications). Hence, to prove the thesis it suffices to show that for all inclusions $\text{C}_L \subseteq \text{C}_R$ in $\text{SHIQ}^\text{PT}$: $\text{KB} \models_{\text{SHIQ}^\text{PT}} \text{C}_L \subseteq \text{C}_R$ iff $\text{KB}' \models_{\text{SHIQ}^\text{PT}} \text{C}'_L \subseteq \text{C}'_R$, for some polynomial encoding $\text{KB}'$, $\text{C}'_L$, $\text{C}'_R$ in $\text{SHIQ}$. 
The idea of the encoding exploits the definition of the typicality operator $T$ introduced in [14] (for $\mathcal{ALC}$), in terms of a Gödel -Löb modality $\Box$ as follows: $T(C)$ is defined as $C \sqcap \Box \neg C$ where the accessibility relation of the modality $\Box$ is the preference relation $<$ in preferential models.

We define the encoding $KB’=\langle TBox’, ABox’ \rangle$ of $KB$ in $\mathcal{SHIQ}$ as follows. First, $ABox’=\emptyset$. For each $A \sqsubseteq B \in TBox$, not containing $T$, we introduce $A \sqsubseteq B$ in $TBox’$. For each $T(A)$ occurring in the $TBox$, we introduce a new atomic concept $\Box \neg A$ and, for each inclusion $T(A) \sqsubseteq B \in TBox$, we add to $TBox’$ the inclusion: $A \sqcap \Box \neg A \sqsubseteq B$.

Furthermore, to capture the properties of the $\Box$ modality, a new role $R$ is introduced to represent the relation $<$ in preferential models, and the following inclusions are introduced in $TBox’$: $\Box \neg A \sqsubseteq \forall R. (\neg A \sqcap \Box \neg A)$ and $\Box \neg A \sqsubseteq \exists R. (A \sqcap \Box \neg A)$.

For the inclusion $C_L \sqsubseteq C_R$, we let $C_R’ = C_R$. For a strict inclusion ($C_L \neq T(A)$), we let $C_L’ = C_L$, while for a defeasible inclusion ($C_L = T(A)$), we let $C_L’ = A \sqcap \Box \neg A$. It is clear that the size of $KB’$ is polynomial in the size of the $KB$. Given the above encoding, it can be proved that: $KB \models_{\mathcal{SHIQ}}^p T C_L \sqsubseteq C_R \iff KB’ \models_{\mathcal{SHIQ}} C_L’ \sqsubseteq C_R’$.

**Theorem 2 (Complexity of rational closure over $TBox$).** Given a $TBox$, the problem of deciding whether $T(C) \sqsubseteq D \in TBox$ is in $\text{ExpTime}$.

**Proof.** Checking if $T(C) \sqsubseteq D \in TBox$ can be done by computing the finite sequence $E_0, E_1, \ldots, E_n$ of non increasing subsets of $TBox$ inclusions in the construction of the rational closure. Note that the number $n$ of the $E_i$ is $O(|KB|)$, where $|KB|$ is the size of the knowledge base $KB$. Computing each $E_i = \mathcal{E}(E_{i-1})$, requires to check, for all concepts $A$ occurring on the left hand side of an inclusion in the $TBox$, whether $E_{i-1} \models_{\mathcal{SHIQ}} T(\top) \sqsubseteq \neg A$. Regarding $E_{i-1}$ as a knowledge base with empty $ABox$, by Proposition 3 it is enough to check that $E_{i-1}’ \models_{\mathcal{SHIQ}} T(\top) \sqcup \Box \neg T \sqsubseteq \neg A$, which requires an exponential time in the size of $E_{i-1}’$ (and hence in the size of $KB$). If not already checked, the exceptionality of $C$ and of $C \sqcap \neg D$ have to be checked for each $E_i$, to determine the ranks of $C$ and of $C \sqcap \neg D$ (which can be computed in $\mathcal{SHIQ}$ as well). Hence, verifying if $T(C) \sqsubseteq D \in TBox$ is in $\text{ExpTime}$.

The above proof also shows that the rational closure of a $TBox$ can be computed simply using the entailment in $\mathcal{SHIQ}$.

### 4 Infinite Minimal Models with finite ranks

In the following we provide a characterization of minimal models of a $KB$ in terms of their rank: intuitively minimal models are exactly those where each domain element has rank $0$ if it satisfies all defeasible inclusions, and otherwise has the smallest rank greater than the rank of any concept $C$ occurring in a defeasible inclusion $T(C) \sqsubseteq D$ of the $KB$ falsified by the element. Exploiting this intuitive characterization of minimal models, we are able to show that, for a finite $KB$, minimal models have always a finite ranking function, no matter whether they have a finite domain or not. This result allows us to provide a semantic characterization of rational closure of the previous section to logics, like $\mathcal{SHIQ}$, that do not have the finite model property.

Given a model $M = \langle \Delta, <, I \rangle$, let us define the set $S^M_x$ of defeasible inclusions falsified by a domain element $x \in \Delta$, as $S^M_x = \{ T(C) \sqsubseteq D \in K_D \mid x \in (C \sqcap \neg D)^I \}$. 

Proposition 4. Let $M = \langle \Delta, <, I \rangle$ be a model of $KB$ and $x \in \Delta$, then: (a) if $k_M(x) = 0$ then $S^M_x = \emptyset$; (b) if $S^M_x \neq \emptyset$ then $k_M(x) > k_M(C)$ for every $C$ such that, for some $D$, $T(C) \subseteq D \in S^M_x$.

Let us define $K_F = \{ C \subseteq D \in TBox : T$ does not occur in $C \} \cup ABox$ and $K_D = \{ T(C) \subseteq D \in TBox \}$, so that $KB = K_F \cup K_D$.

Proposition 5. Let $KB = K_F \cup K_D$ and $M = \langle \Delta, <, I \rangle$ be a model of $K_F$; suppose that for any $x \in \Delta$ it holds that: - if $k_M(x) = 0$ then $S^M_x = \emptyset$; - if $S^M_x \neq \emptyset$ then $k_M(x) > k_M(C)$ for every $C$ s.t., for some $D$, $T(C) \subseteq D \in S^M_x$. Then $M \models KB$.

From Propositions 4 and 5, we obtain the following characterization of minimal models.

Theorem 3. Let $KB = K_F \cup K_D$, and let $M = \langle \Delta, <, I \rangle$ be a model of $K_F$. The following are equivalent:

- $M$ is a minimal model of $KB$
- For every $x \in \Delta$ it holds: (a) $S^M_x = \emptyset$ iff $k_M(x) = 0$ (b) if $S^M_x \neq \emptyset$ then $k_M(x) = 1 + \max\{k_M(C) \mid T(C) \subseteq D \in S^M_x\}$.

The following proposition shows that in any minimal model the rank of each domain element is finite.

Proposition 6. Let $KB = K_F \cup K_D$ and $M = \langle \Delta, <, I \rangle$ a minimal model of $KB$, for every $x \in \Delta$ $k_M(x)$ is a finite ordinal ($k_M(x) < \omega$).

The previous proposition is essential for establishing a correspondence between the minimal model semantics of a KB and its rational closure. From now on, we can assume that the ranking function assigns to each domain element in $\Delta$ a natural number, i.e. that $k_M : \Delta \rightarrow \mathbb{N}$.

5 A Minimal Model Semantics for Rational Closure in $SHIQ$

In previous sections we have extended to $SHIQ$ the syntactic notion of rational closure introduced in [24] for propositional logic. To provide a semantic characterization of this notion, we define a special class of minimal models, exploiting the fact that, by Proposition 6, in all minimal $SHIQ^R T$ models the rank of each domain element is always finite. First of all, we can observe that the minimal model semantics in Definition 4 as it cannot capture the rational closure of a TBox.

Consider the following $KB = (TBox, \emptyset)$, where $TBox$ contains: $VIP \subseteq Person$, $T(Person) \subseteq \leq 1 Has Married. Person$, $T(VIP) \subseteq \geq 2 Has Married. Person$. We observe that $T(VIP \cap Tall) \subseteq \geq 2 Has Married. Person$ does not hold in all minimal $SHIQ^R T$ models of $KB$ w.r.t. Definition 4. Indeed there can be a model $\mathcal{M} = \langle \Delta, <, I \rangle$ in which $\Delta = \{ x, y, z \}$, $VIP^I = \{ x, y \}$, $Person^I = \{ x, y, z \}$, $\leq 1 Has Married. Person^I = \{ x, y \}$, $Tall^I = \{ x \}$, and $z < y < x$. $\mathcal{M}$ is a model of $KB$, and it is minimal. Also, $x$ is a typical tallVIP in $\mathcal{M}$ (since there is no other tall VIP preferred to him) and has no more than one spouse, therefore $T(VIP \cap Tall) \subseteq \geq 2 Has Married. Person$ does not hold in $\mathcal{M}$. On the contrary, it can be verified that $T(VIP \cap Tall) \subseteq \geq 2 Has Married. Person \in TBox$. 

Things change if we consider the minimal models semantics applied to models that contain a domain element for each combination of concepts consistent with KB. We call these models canonical models. Therefore, in order to semantically characterize the rational closure of a SHIQR KB, we restrict our attention to minimal canonical models. First, we define $S$ as the set of all the concepts (and subconcepts) occurring in KB or in the query $F$ together with their complements.

In order to define canonical models, we consider all the sets of concepts $\{C_1, C_2, \ldots, C_n\} \subseteq S$ that are consistent with KB, i.e., s.t. $KB \not\models_{SHIQR} C_1 \cap C_2 \cap \cdots \cap C_n \sqsubseteq \bot$.

**Definition 8 (Canonical model with respect to $S$).** Given $KB=(TBox,ABox)$ and a query $F$, a model $M = (\Delta, <, I)$ satisfying $KB$ is canonical with respect to $S$ if it contains at least a domain element $x \in \Delta$ s.t $x \in (C_1 \cap C_2 \cap \cdots \cap C_n)$, for each set of concepts $\{C_1, C_2, \ldots, C_n\} \subseteq S$ that is consistent with KB.

Next we define the notion of minimal canonical model.

**Definition 9 (Minimal canonical models (w.r.t. $S$)).** $M$ is a minimal canonical model of $KB$ if it satisfies $KB$, it is minimal (with respect to Definition 4) and it is canonical (as defined in Definition 8).

**Proposition 7 (Existence of minimal canonical models).** Let $KB$ be a finite knowledge base, if $KB$ is satisfiable then it has a minimal canonical model.

To prove the correspondence between minimal canonical models and the rational closure of a TBox, we need to introduce some propositions. The next one concerns all SHIQR TBox models. Given a SHIQR TBox model $M = (\Delta, <, I)$, we define a sequence $M_0, M_1, M_2, \ldots$ of models as follows: We let $M_0 = M$ and, for all $i$, we let $M_i = (\Delta, <, I)$ be the SHIQR TBox model obtained from $M$ by assigning a rank 0 to all the domain elements $x$ with $k_M(x) < i$, i.e., $k_{M_i}(x) = k_M(x) - i$ if $k_M(x) > i$, and $k_M(x) = 0$ otherwise. We can prove the following:

**Proposition 8.** Let $KB= (TBox, ABox)$ and let $M = (\Delta, <, I)$ be any SHIQR TBox model of TBox. For any concept $C$, if $\text{rank}(C) \geq i$, then 1) $\text{rank}(C) \geq i$, and 2) if $T(C) \sqsubseteq D$ is entailed by $E_i$, then $M_i$ satisfies $T(C) \sqsubseteq D$.

Let us now focus our attention on minimal canonical models by proving the correspondence between rank of a formula (as in Definition 6) and rank of a formula in a model (as in Definition 3). The following proposition is proved by induction on the rank $i$:

**Proposition 9.** Given $KB$ and $S$, for all $C \in S$, if $\text{rank}(C) = i$, then: 1. there is a $\{C_1 \ldots C_n\} \subseteq S$ maximal and consistent with $KB$ such that $C \in \{C_1 \ldots C_n\}$ and $\text{rank}(C_1 \cap \cdots \cap C_n) = i$; 2. for any $M$ minimal canonical model of $KB$, $k_M(C) = i$.

The following theorem follows from the propositions above:

**Theorem 4.** Let $KB= (TBox, ABox)$ be a knowledge base and $C \subseteq D$ a query. We have that $C \subseteq D$ in TBox if and only if $C \subseteq D$ holds in all minimal canonical models of $KB$ with respect to $S$. 

6 Rational Closure over the ABox

The definition of rational closure in Section 3 takes only into account the TBox. We address the issue of ABox reasoning first by the semantical side: as for any domain element, we would like to attribute to each individual constant named in the ABox the lowest possible rank. Therefore we further refine Definition 9 of minimal canonical models with respect to TBox by taking into account the interpretation of individual constants of the ABox.

**Definition 10 (Minimal canonical model w.r.t. ABox).** Given $\text{KB}=\text{TBox, ABox}$, let $\mathcal{M} = (\Delta, \leq, I)$ and $\mathcal{M}' = (\Delta', <', I')$ be two canonical models of $\text{KB}$ which are minimal w.r.t. Definition 9. We say that $\mathcal{M}$ is preferred to $\mathcal{M}'$ w.r.t. $\text{ABox}$ ($\mathcal{M} <_{\text{ABox}} \mathcal{M}'$) if, for all individual constants $a$ occurring in $\text{ABox}$, $k_\mathcal{M}(a^l) \leq k_{\mathcal{M}'}(a'^l)$ and there is at least one individual constant $b$ occurring in $\text{ABox}$ such that $k_\mathcal{M}(b^l) < k_{\mathcal{M}'}(b'^l)$.

As a consequence of Proposition 7 we can prove that:

**Theorem 5.** For any $\text{KB} = (\text{TBox}, \text{ABox})$ there exists a minimal canonical model of $\text{KB}$ with respect to $\text{ABox}$.

In order to see the strength of the above semantics, consider our example about marriages and VIPs.

**Example 2.** Suppose we have a $\text{KB}=(\text{TBox, ABox})$ where: $\text{TBox}=\{\text{HasMarried(Person), T(VIP)} \subseteq \geq 1 \text{HasMarried(Person), VIP} \subseteq \text{Person}\}$, and $\text{ABox} = \{\text{VIP(demi)}, \text{Person(marco)}\}$. Knowing that Marco is a person and Demi is a VIP, we would like to be able to assume, in the absence of other information, that Marco is a typical person, whereas Demi is a typical VIP, and therefore Marco has at most one spouse, whereas Demi has at least two. Consider any minimal canonical model $\mathcal{M}$ of $\text{KB}$. Being canonical, $\mathcal{M}$ will contain, among other elements, the following:

- $x \in (\text{Person})^l$, $x \in (\leq 1 \text{HasMarried(Person)})^l$, $x \in (\neg \text{VIP})^l$, $k_\mathcal{M}(x) = 0$;
- $y \in (\text{Person})^l$, $y \in (\geq 2 \text{HasMarried(Person)})^l$, $y \in (\neg \text{VIP})^l$, $k_\mathcal{M}(y) = 1$;
- $z \in (\text{VIP})^l$, $z \in (\text{Person})^l$, $z \in (\geq 2 \text{HasMarried(Person)})^l$, $k_\mathcal{M}(z) = 1$;
- $w \in (\text{VIP})^l$, $w \in (\text{Person})^l$, $w \in (\leq 1 \text{HasMarried(Person)})^l$, $k_\mathcal{M}(w) = 2$.

so that $x$ is a typical person and $z$ is a typical VIP. According to Definition 10, there is a unique minimal canonical model w.r.t. $\text{ABox}$ in which $(\text{marco})^l = x$ and $(\text{demi})^l = z$.

We next provide an algorithmic construction for the rational closure of ABox. The idea is that of considering all the possible minimal consistent assignments of ranks to the individuals explicitly named in the ABox. We adopt a skeptical view by considering only those conclusions which hold for all assignments. In order to calculate the rational closure of ABox, written $\overline{\text{ABox}}$, for all individual constants of the ABox we find out which is the lowest possible rank they can have in minimal canonical models with respect to Definition 9: the idea is that an individual constant $a_i$ can have a given rank $k_j(a_i)$ just in case it is compatible with all the inclusions $\text{T}(A) \subseteq D$ of the TBox whose antecedent $A$’s rank is $\geq k_j(a_i)$ (the inclusions whose antecedent $A$’s rank is $< k_j(a_i)$ do not matter since, in the canonical model, there will be an instance of $A$ with rank $< k_j(a_i)$ and therefore $a_i$ is not a typical instance of $A$). The algorithm below computes all minimal rank assignments $k_j$s to all individual constants: $\mu_i^l$ contains all the concepts that $a_i$
would need to satisfy in case it had the rank attributed by \( k_j \). The algorithm verifies whether \( \mu^j \) is compatible with \((TBox, ABox)\) and whether it is minimal. Notice that, in this phase, all constants are considered simultaneously (indeed, the possible ranks of different individual constants depend on each other).

**Definition 11** \((ABox; \text{rational closure of ABox})\). Let \( a_1, \ldots, a_m \) be the individuals explicitly named in the ABox. Let \( k_1, k_2, \ldots, k_h \) be all the possible rank assignments (ranging from 1 to \( n \)) to the individuals occurring in ABox.

- Given a rank assignment \( k_j \) we define:
  - for each \( a_i \) \( \mu^i_j = \{(-C \cup D)(a_i) \text{ s.t. } C, D \in S, T(C) \subseteq D \text{ in } TBox, \text{ and } k_j(a_i) \leq \text{rank}(C) \} \cup \{(-C \cup D)(a_i) \text{ s.t. } C \subseteq D \text{ in } TBox \}; \)
  - let \( \mu_j = \mu^1_j \cup \cdots \cup \mu^m_j \) for all \( \mu^1_j, \ldots, \mu^m_j \) just calculated for all \( a_1, \ldots, a_m \) in ABox

- \( k_j \) is minimal and consistent with \((TBox, ABox)\), i.e.: (i) \( TBox \cup ABox \cup \mu_j \) is consistent in \( SHIQ^R T \); (ii) there is no \( k_i \) consistent with \((TBox, ABox)\) s.t. for all \( a_i, k_i(a_i) \leq k_j(a_i) \) and for some \( b, k_i(b) < k_j(b) \).

- The rational closure of ABox \((ABox)\) is the set of all assertions derivable in \( SHIQ^R T \) from \( TBox \cup ABox \cup \mu_j \) for all minimal consistent rank assignments \( k_j \), i.e:

\[
\overline{ABox} = \bigcap \{C(a) : TBox \cup ABox \cup \mu_j \models SHIQ^R T C(a)\}
\]

The example below is the syntactic counterpart of the semantic Example 2 above.

**Example 3.** Consider the KB in Example 2. Computing the ranking of concepts we get that \( \text{rank}(Person) = 0 \), \( \text{rank}(VIP) = 1 \), \( \text{rank}(Person \cap \geq 2 \text{ HasMarried}.Person) = 1 \), \( \text{rank}(VIP \cap \leq 1 \text{ HasMarried}.Person) = 2 \). The set \( \mu^1 \) contains, among the others, \((-VIP \cup \geq 2 \text{ HasMarried}.Person)(demi) \cdot (\neg Person \cap \leq 1 \text{ HasMarried}.Person)(marco)\). It is tedious but easy to check that \( KB \cup \mu^1 \) is consistent and that \( k_1 \) is the only minimal consistent assignment, thus both \((\geq 2 \text{ HasMarried}.Person)(demi)\) and \((\leq 1 \text{ HasMarried}.Person)(marco)\) belong to \( \overline{ABox} \).

**Theorem 6** (Soundness and completeness of \( \overline{ABox} \)). Given \( KB=(TBox, ABox) \), for each individual constant \( a \) in ABox, \( C(a) \in \overline{ABox} \) if and only if \( C(a) \) holds in all minimal canonical models with respect to ABox of KB.

**Theorem 7** (Complexity of rational closure over the ABox). Given a knowledge base \( KB=(TBox, ABox) \) in \( SHIQ^R T \), an individual constant \( a \) and a concept \( C \), the problem of deciding whether \( C(a) \in \overline{ABox} \) is \( \text{ExpTime} \)-complete.

The proof is similar to the one for rational closure over ABox in \( ALC \) (Theorem 5 [18]).

### 7 Related Works

There are a number of works which are closely related to our proposal.

In [14, 17] nonmonotonic extensions of DLs based on the \( T \) operator have been proposed. In these extensions, focused on the basic DL \( ALC \), the semantics of \( T \) is based on preferential logic \( P[22] \). Moreover and more importantly, the notion of minimal model adopted here is completely independent from the language and is determined only by the relational structure of models.

In [7], a semantic characterization of a variant of the notion of rational closure in [6] is presented, based on a generalization to $ALC$ of our semantics in [16].

An approach related to ours can be found in [3]. The basic idea of their semantics is similar to ours, but it is restricted to the propositional case. Furthermore, their construction relies on a specific representation of models and it provides a recipe to build a model of the rational closure, rather than a characterization of its properties. Our semantics, defined in terms of standard Kripke models, can be more easily generalized to richer languages, as we have done here for $SHIQ$.

In [5] the semantics of the logic of defeasible subsumptions is strengthened by a preferential semantics. Furthermore, the authors describe an $EXPTIME$ algorithm in order to compute the rational closure of a given TBox in $ALC$. In [25] a plug-in for the Protégé ontology editor implementing the mentioned algorithm for computing the rational closure for a TBox for OWL ontologies is described.

Recent works discuss the combination of open and closed world reasoning in DLs. In particular, formalisms have been defined for combining DLs with logic programming rules (see, for instance, [11] and [26]). A grounded circumscription approach for DLs with local closed world capabilities has been defined in [23].

8 Conclusions

In this work we have proposed an extension of the rational closure defined by Lehmann and Magidor to the Description Logic $SHIQ$, taking into account both TBox and ABox reasoning. One of the contributions is that of extending the semantic characterization of rational closure proposed in [16] for propositional logic, to $SHIQ$, which does not enjoy the finite model property. We have shown that in all minimal models of a finite KB in $SHIQ$ the rank of domain elements is always finite, although the domain might be infinite. We have proved an $EXPTIME$ upper bound for both TBox and ABox reasoning with the rational closure shown that the rational closure of a TBox can be computed using entailment in $SHIQ$.

The rational closure construction in itself can be applied to any description logic. We would like to extend its semantic characterization to stronger logics, such as $SHOIQ$, for which the notion of canonical model as defined in this paper is too strong due to the interaction of nominals with number restrictions.

It is well known that rational closure has some weaknesses that accompany its well-known qualities. Among the weaknesses is the fact that one cannot separately reason property by property, so that, if a subclass of $C$ is exceptional for a given aspect, it is exceptional “tout court” and does not inherit any of the typical properties of $C$. Among the strengths there is its computational lightness, which is crucial in Description Logics. Both the qualities and the weaknesses seems to be inherited by its extension to Description Logics. To address the mentioned weakness of rational closure, we may think of attacking the problem from a semantic point of view by considering a finer semantics where models are equipped with several preference relations; in such a semantics it might be possible to relativize the notion of typicality, whence to reason about typical properties independently from each other.
