Abstract

The activity budgets of seven captive tigers (*Panthera tigris*) housed in four zoological gardens (A, B, C, D) were analysed to assess their welfare and to relate it to several variables, including enclosure type, management, and animal history. Behaviours were recorded by instantaneous focal animal sampling at 2-minute intervals. Data were collected by five observers using an ethogram listing 26 behaviours adapted from the literature. To process the data, the activity budgets of each tiger and the overall activity budget were constructed. On the basis of previous literature, some of the behaviours, listed in the ethogram, were labelled as indicators of diminished welfare and some were labelled as indicators of enhanced welfare. Statistical analysis was carried out to determine in which zoo the tigers were more prone to exhibit indicators of enhanced welfare and which feature(s) had a major effect on their welfare. Over 195 hours of data were collected and 5867 observations were recorded. The tigers in zoo A (OR = 4.11, 95% confidence interval [CI] 3.2-5.3) and zoo C (OR = 1.83, 95% CI 1.4-2.4) were more prone to express indicators of enhanced welfare with respect to Zoo D as the reference. Among the variables describing animal peculiarity, daily routine management, and enclosure features, the presence of a water pool with clean water was significantly associated with enhanced welfare (OR = 2.04, 95% CI 1.4-3.04). The data suggested that none of the tigers displayed consistent signs of stress and that all experienced a basic welfare status. An essential feature that helped to enhance good animal welfare was a water pool in the enclosure containing clean water.

Key words

Panthera tigris, zoo, enhanced welfare, activity budget, behavioural analysis.

1. Introduction

The tiger (*Panthera tigris*) is currently listed as endangered by the International Union for Conservation of Nature, due to poaching and a decline in its home range by over 50% during the last three generations (21-27 years) (http://www.iucnredlist.org/details/15955/0, last accessed on 13/10/2015). At present, the wild population count is approximately 3000 individuals, of which fewer than 2500 are mature and potentially of reproductive age (http://www.iucnredlist.org/details/15955/0, last accessed on 13/10/2015). Paradoxically, tigers are one of the most commonly exhibited species worldwide: they reproduce well in captivity (Brown, 2011), are tolerant to heat and cold (Shoemaker et al., 1997), and figure among the charismatic megafauna thanks to their great potential to attract zoo visitors (Brown, 2011; Skibins and Powell, 2013). Four out of six zoological gardens located in Piedmont (area 25,400 km^2 in northwest Italy) host tigers, although providing adequate welfare to these animals is extremely complicated because the captive environment is dramatically different from what the animals experience in the wild (Clubb and Mason, 2007). A good example is the home range: wild tigers tend to occupy extensive territories (ranging from 7 to 1000 km^2, with a reported median home range area of 48.40 km^2), which cannot reasonably be provided in captivity (Breton and Barrot, 2014; Clubb and Mason, 2007).

Pacing is the main and most frequent form of stereotypy that big cats develop when kept in zoos (Clubb and Mason, 2007). Because animals that typically occupy large home ranges in the wild tend to fare worse in captivity and are much more vulnerable to welfare problems (Clubb and Mason, 2007; Szokalski et al., 2012), research has been dedicated to finding the causes (Chosy et al., 2014; Lyons et al., 1997; Mohapatra et al., 2014) and how to prevent or reduce such behaviour (Bashaw et al., 2007; Breton and Barrot, 2014; Jenny and Schmid, 2002; Miller et al., 2008; Skibiel et al., 2007). During the last decade, many zoos have undertaken efforts to reduce abnormal behaviours by restructuring enclosure architecture and improving animal management.

Nonetheless, ensuring adequate welfare entails not only fulfilling essential needs and preventing the onset of stereotypies, but also encouraging animals to express their most complete behavioural repertoire, providing resources towards which animals are motivated only when more immediate deficiencies have been met (Hemsworth et al., 2015; Maple and Perdue, 2013; Yeates and Main, 2008). Promoting positive experiences is one way to give captive wild animals a better quality of life, safeguard and possibly improve their health status (Boissy et al., 2007; Maple and Perdue, 2013).

3

77 Such experiences may also benefit zoo visitors. As visitors become increasingly attuned to animal welfare,

78 they expect to see animals engaged in natural behaviours and can recognize the main stereotypies when

79 displayed. For example, people who watched a video of a tiger pacing perceived the animal as receiving

80 lower levels of care than visitors who viewed a tiger resting (Miller, 2012). In addition, the study participants

81 were less interested in supporting zoological facilities after seeing the video of a tiger pacing. In contrast,

82 visitor interest was closely related to activity in cat exhibits: it was found to be greater when the cats were

83 active (Margulis et al., 2003). Watching animals displaying positive behaviours may increase a visitor's

84 connection to wildlife and knowledge about a certain species, turning it into an educative experience that

85 fosters an interest in conservation. Education and conservation are among the main purposes of modern zoos,

86 as required by law in the European Union (EU Council Directive 1999/22/EC).

87 The aim of the present multi-zoo study was to assess the welfare of tigers housed in four different zoological

88 gardens located in Piedmont. Specific attention was paid to identify in which zoo tigers were more prone to

89 perform behaviours considered as indicators of enhanced welfare. Another goal was to detect features

90 (regarding enclosure type, management and animal history) statistically linked to the expression of indicators

91 of enhanced welfare. The main challenge was to identify features that could be easily implemented in zoo

92 settings, to be recommended to facilities already hosting or willing to host big cats.

93

94 **2. Material and methods**

95 *2.1 Animals, enclosures, management*

96 Four zoological gardens (A, B, C, D) were involved in the study. Zoos C and D are safari parks, where it is

97 possible to drive through the enclosure where tigers are displayed. All zoos are privately owned. The study

98 population was seven captive tigers (SIL, TOA, TOB, MPO, FPO, MMU, FMU), three males and four

99 females. All animals were captive born. Tiger signalment, host zoo, history, and medical history are reported

100 in Table 1. All were adult individuals (age range 4-17 years, mean 7.86 years, SD = 4.49) and all, but one

101 (SIL), were housed in pairs. Both members of the pairs were included in the study.

102 The tigers were on exhibit in their outdoor enclosures every day, from morning to late afternoon, with on-

103 exhibition time varying between zoos and seasons. All enclosures can be considered naturalistic. The areas

104 ranged from 700 to 10,000 m^2. A glass separated the tiger enclosure from the public point of view in Zoos A

105 and B partly or entirely, respectively. Trees, logs, elevated platforms, and water pools were the main

4

106 furniture. Though all enclosures had a water pool, the water level was low, dirty or muddy in some. Data on

107 the quality of shade, presence of areas visually inaccessible to visitors' sight, and presence/quality of

108 enclosure furniture were recorded (Table 2).

109 Table 3 presents the main characteristics of animal management: time that the animals can spend in the on-

110 exhibition area, diet and feeding routine, and presence/absence of enrichment plans. None of the zoos

111 participating the study had a routine enrichment plan (i.e., planned provision of different types of enrichment

112 to animals) in place.

113

114 *2.2 Ethological study*

115 An ethogram composed of 26 behaviour items (Table 4) was adapted from the literature (Bashaw et al.,

116 2007; De Rouck et al., 2005; Lyons et al., 1997; Miller and Kuhar, 2008). Five observers performed the

117 ethological study. To standardize recording of the behavioural patterns and to refine the ethogram, an

118 informal period of preliminary observation was conducted. It consisted of an, 8-hour session of *ad libitum*

119 sampling method (Martin and Bateson, 2007) carried out on each animal in the study, by all observers.

120 Behaviours were verbally described in the form of long-hand written notes. Moreover, different

121 measurement techniques, points of view and sampling intervals were tried out. Data obtained during the pilot

122 were discarded and not used for further analysis.

123 All five observers were involved in the main data collection. Before beginning the study, between-observer

124 reliability was assessed by having the observers simultaneously watching a 60-minute video recorded during

125 the pilot observation. Within-observer reliability was assessed by having them watching the same video (the

126 one utilized for the between-observer reliability evaluation) during two separate sessions carried out on two

127 different days. Behaviours were recorded by instantaneous focal animal sampling at 2-minute intervals

128 (Martin and Bateson, 2007), using a gridded checklist with the columns denoting the different behaviour

129 categories and the rows denoting successive time sample intervals. At the end of each sample interval, at the

130 signal of a stopwatch, the observer recorded the behaviour on the relative row of the checklist. The data were

131 then progressively transferred onto a computerized spreadsheet (Microsoft Excel 2003. Microsoft. Redmond,

132 WA, USA). The reliability of the observation method was assessed using Cohen's Kappa (Stata 13.0 SE®;

133 StataCorp, College Station, TX, USA).

134 Each zoo was visited five times from April 2012 to October 2012, and observations were taken from public-

135 viewing areas when the animals were on exhibition. In zoos C and D observations were taken from a car

136 inside the enclosures. Three visits were made on work days and two on holidays, with a maximum of six

137 hours of observation. Each cat was observed for eight/twelve 30-minute sessions a day. The sessions began

138 between 9.30 AM and 11.00 AM.

139 Behaviours were recorded as described for the assessment of within and between-reliabilities and were

140 collected by all the five observers.

141

142 *2.3 Data analysis*

143 To process the data, the activity budgets of each tiger and the overall activity budget were constructed by

144 calculating the percentage of time each behaviour was observed over the whole observation period. In some

145 circumstances at the moment of the sampling, the observer was not able to see the animals because of a

146 visual barrier (e.g. cars or a large group of people staying between the tiger and the observer, animal staying

147 in spots that were blind for the observer only). These records were excluded form further analysis. On the

148 other hand, the clear choice of the animals to hide in shelters or behind vegetation was recorded as

149 "intentional out of sight" and considered for analysis.

150 On the basis of peer reviewed papers, published in the last 15 years, some of the behaviours, listed in the

151 ethogram, were labelled as indicators of diminished welfare (pacing, aggression, flee, avoid) and some were

152 labelled as indicators of enhanced welfare (self-grooming, immersion, affiliative behaviours, intentional out

153 of sight, interaction with environment). Table 5 describes the rationale of our choice and the literature

154 references. A behaviour that we could not consider for the further statistical analysis was "vocalize" (making

155 a sound with the voice). Even though it has been suggested that vocalizations could be markers of both

156 diminished and enhanced welfare (Boissy et al., 2007) and Miller and colleagues (2013) used some sounds

157 as indicators of welfare, the observers involved in the present study could not be sure of every vocalization,

158 since the used view points did not give the chance to hear all the sounds that tigers might have emitted.

159 Any behaviour expressed for less than 20 minutes of total time was excluded from further statistical analysis,

160 because the inclusion in the model of those sparce data would have added rumors and casuality to the output.

161 A multinomial logistic regression model was then fitted in order to determine in which zoo the tigers were

162 more prone to exhibit behaviours labelled as indicators of enhanced welfare. In order to identify which

163   aspects had a major effect on tiger welfare, animal peculiarity, daily routine management, and enclosure

164   features potentially influencing the welfare status of captive tigers were listed, categorised, and analysed

165   using a mixed-effects models for binary responses (Stata 13.0 SE®; StataCorp, College Station, TX, USA).

166   The variables used in the models and their categories are listed in Table 6. To assess which of the enclosure

167   features were associated with indicators of enhanced welfare, a multilevel mixed-effect logistic regression

168   was fitted using the single individual as the grouping variable (Stata 13.0 SE®; StataCorp, College Station,

169   TX, USA). All the outcomes of the dependent variables, given the random effect, have been treated as

170   dummy variables, according to a Bernoulli distribution (Rabe-Hesketh and Skrondal, 2012). Zoo D was

171   taken as the reference zoo, because it was the institution where the maximum number of observations was

172   taken. This choice allowed the best precision of the estimates and the narrowest confidential interval.

173

174   **3. Results**

175   Before beginning the study, the observers reached a within-observer reliability in the range of 0.72 (95 % CI

176   0.54–0.9) to 1 (95 % CI 0.82-1) and a between-observer reliability of 0.95 (95 % CI 0.9-1). Over 195 hours

177   of data were collected. Of the total of 5867 observations recorded, 809 were excluded from further analysis

178   because the animal was not visible due to a visual barrier between observers and animals (i.e., cars, people)

179   as described previously.

180   Overall and single tiger activity budgets are reported in Table 7. The main item on the activity budget was

181   the time spent sleeping (32.64%, range 24.18 to 41.84%), followed by resting (27.5 %, range 9.47 to

182   47.51%), and walking (17.3 %, range 6.18 to 28.09%).

183   All the tigers displayed indicators of diminished welfare for 0.69% (range 0.13 to 1.99%) of the total

184   observation, with pacing accounting for 0.43% (range 0.00 to 1.36%) of time. No episodes of aggression

185   with physical contact between the tigers were observed. Indicators of enhanced welfare were observed in

186   11.74% (range 6.67 to 21.70%) of recordings. The percentage of time that the tigers spent in displaying

187   behaviours considered as indicators of either diminished or enhanced welfare is reported in Table 7.

188   The behaviours excluded from further analysis because performed less than 20 minutes of total observation

189   time were: avoid, run, body shake, flee, jump, stretch, aggression and scratch.

190 Table 8 presents the results of the multinomial logistic regression model. Behaviours labelled as indicators of

191 enhanced welfare were more often expressed by the tigers hosted in zoo A (OR=4.11, 95% CI 3.2-5.3) and

192 zoo C (OR=1.83, 95% CI 1.4-2.4) than those in zoos B and D.

193 Among the variables describing animal peculiarity, daily routine management and enclosure features, the

194 presence of a water pool with clean water was significantly associated with the expression of indicators of

195 enhanced welfare (OR=2.04, 95% CI 1.4-3.04).

196

197 **4. Discussion**

198 To assess welfare of captive tigers an observational study was carried out, being the least invasive and

199 intrusive form of welfare assessment and because behaviours, as recognised indicators of the presence of

200 pleasant and/or unpleasant feelings, can be employed as a means to assess both diminished and positive well-

201 being (Dawkins, 2004; Szokalski et al., 2012). Behaviours can be considered as powerful welfare indicators

202 because they reflect an animal's first attempts to cope with a stressor and so may indicate a situation where

203 welfare is at risk at an early stage (Dawkins, 2004).

204 The multi-zoo approach was chosen in order to enlarge the sample size and properly weigh the variables

205 analysed. As a matter of fact it is suggested to perform multi-zoo studies to tease out the effects of a number

206 of variables and to find out about the prevalence of phenomena in which researchers are interested (Hosey et

207 al., 2009). Few studies have been published on tigers' welfare so far (Breton and Barrot, 2014; De Rouck et

208 al., 2005; Pitsko, 2003).

209 The present multi-zoo study may have some limitations: the study sample was small and some variable could

210 not be inserted in the analysis either because records were not available (i.e. hand rearing/parental rearing) or

211 because they were not present in the studied zoos (enrichment plans).

212 These limitations notwithstanding, the high number of observations (totalling more than 195 hours) provided

213 a good basis for constructing the activity budgets, and a firm starting point for deriving a meaningful

214 outcome from statistical analysis. Indeed, the analysis of the variables by means of a model adjusted for all

215 parameters, so as to avoid introducing any confounding variables, allowed to obtain statistically significant

216 results.

217 The obtained activity budgets showed that the observed tigers spent most of their time sleeping (32.64%) and

218 resting (27.50%), as expected given that felids are often inactive (Karanth and Sunquist, 2000). The third

most frequently observed behaviour was walking (17.30%). Wild tigers, being wide-ranging species, travel a

minimum of 4.86 km every day looking for food and controlling their territory (Clubb and Mason, 2007). In

such territorial animals kept in captivity, walking different routes across an enclosure may mirror the

animal's need to perform locomotory behaviours and to patrol their home range (De Rouck et al., 2005).

In all the studied zoos none of the tigers displayed consistent signs of poor welfare. Pace was observed for

only 0.43% of the total observations. This datum is shared by only two previous studies. Observers of a

group of six female tigers recorded percentages of pacing of 0.47% of all scans when housed at night in a

group and of 0.61% when housed at night alone (Miller et al., 2013), and the three tigers involved in the

study by Lyons and colleagues (1997) did not pace at all. Conversely, the majority of studies in this field

reported higher values: between 4.67 and 23.91% in 15 animals hosted in nine European zoos (De Rouck et

al., 2005), 16.43% in a review by Clubb and Mason (2007), nearly 60% in two tigers observed before a

feeding enrichment experiment (Bashaw et al., 2003), and an average of $23.02 \pm 14.27\%$ recorded in 19

captive tigers in Nandakanan Zoological Park (India) (Mohapatra et al., 2014). The tigers we observed thus

appeared to enjoy a basic welfare status, which may be the result of the efforts that the zoos made to reduce

abnormal behaviours by adopting adequate enclosure architecture and animal management. Furthermore, the

multinomial logistic regression model revealed that zoo A and zoo C were those facilities where animals

were more prone to express behaviours considered as indicators of enhanced welfare. Accordingly, the

statistical analysis focused mainly on identifying the variables that potentially enhance tiger welfare.

The results of the model showed that the presence of a water pool with clean water was the only variable

significantly associated with indicators of enhanced welfare. Water pools are structural features that

international guidelines recommend to be present in tiger enclosures (Backer, 2006; Shoemaker et al., 1997,

Tilson et al., 1994). The presence of a water body has been already observed to increase exploratory

behaviours and reduce stereotypic pacing (Pitsko, 2003). Moreover entering in a pool can elicit a natural

behaviour, since wild tigers like water and can swim for kilometres (Bracke and Hopster, 2006; Mazak,

1981). In the present study, the presence of a water pool was classified as "present, with a low water level or

dirty water" and "present, with clean water", because this difference in the management of the pools was

noticed during the informal pilot observation session. It should be highlighted that it is not only the presence

of a pool but the quality of the water that makes the difference in playing a key role in tiger welfare. As a

matter of fact the tiger SIL, housed in zoo A, performed the behaviour "immersion" more consistently than

248   all the other animals (6.60% rather than less than 2%). The subjects MPO and FPO, housed in zoo C (a

249   facility where tigers statistically performed more indicators of enhanced welfare and where the enclosure is

250   provided with a pool with clean water) did not seem to make remarkable use of this feature, thus it can be

251   inferred that the only presence of a water pool with clean water encourages tigers to perform behaviours

252   considered as indicators of enhanced welfare. The statistical association, stated by the present study, is

253   reliable because the multilevel mixed-effect logistic regression carried out has taken into account all the

254   possible confounders and the results are not fortuitous. Furthermore, it is accurate, given the point and

255   interval estimate.

256   Another result of the mixed-effect model was that enclosure size was not correlated with tigers' display of

257   indicators of enhanced welfare. In their recent study, Breton and Barrot (2014) observed tigers in 14

258   enclosures ranging from 21.25 m^2 to 35,865 m^2, eight of them around or less than 1000 m^2, and quantified

259   the influence of enclosure size on the distances covered and paced. One of their main results was that

260   enclosure size was negatively linked with pacing. This finding is in agreement with those of Clubb and

261   Mason (2007), but is in contrast with the results of Lyons and colleagues (1997) who observed that total size

262   of enclosures was not a major factor in pacing activity. Breton and Barrot (2014) recommended to build or to

263   modify existing enclosures to provide tigers with more than 1000 m^2. In the present study, the size of two out

264   of four enclosures was smaller than 1000 m^2 (Zoo A: 850 m^2, Zoo B: 700 m^2) but the animals were observed

265   to perform pacing in less than 0.5% of the total scans. On the other hand enclosure size resulted not linked

266   with indicators of enhanced welfare. Prefacing that all the outdoor exhibits in the present study were

267   naturalistic ones, it can be concluded that, with regard to enclosures that are not barren, quality, also in terms

268   of complexity, of space is more important than its quantity, as supposed by Lyon and colleagues (1997) and

269   stated by Maple and Perdue (2013).

270

271   **5. Conclusion**

272   The tigers observed in this study appeared to experience a basic welfare status. However, access to a water

273   pool with abundant clean water substantially enhances their overall welfare. The costs and staff commitment

274   for the installation and maintenance of this essential feature in already existing or newly planned zoos

275   hosting tigers are surely outweighed by the benefits.

Tables

Table 1: Animal signalment, known history, and hosting zoo. ♂: male; ♀: female.

Animal	Zoo	Subspecies	Sex	Age (years)	Origin	Medical history
SIL	A	Siberian x Bengal	♂	17	Circus	Exocrine pancreatic insufficiency, chronic arthritis
TOA	B	Siberian	♀	9	Born in place	Chronic lameness right forelimb
TOB	B	Siberian	♀	9	Born in place	
MPO	C	Siberian	♂	5	Born in place	
FPO	C	Siberian	♀	5	Born in place	
MMU	D	Siberian	♂	6	Born in place	
FMU	D	Siberian	♀	4	Born in place	

364

365

366   Table 2: Enclosure features: quality of shade, presence of areas visually inaccessible to visitors, and

367   presence/quality of enclosure furniture.

Zoo	On-exhibit area (m^2)	Quality of shadow	Elevated platform	Water pool	Log	Visually inaccessible area
A	850	Half shade	No	Present: clean water.	Yes	Yes
B	700	Full shade	No	Present: low water level or dirty water or filled with mud	Yes	Yes
C	10000	Half shade	Yes	Present: clean water.	No	No
D	6000	Half shade	Yes	Present: low water level or dirty water or filled with mud	Yes	Yes

368

369

370   Table 3: Tiger management: time that animals are allowed to spend in the on-exhibition area, diet and

371   feeding routine, presence/absence of enrichment plans.

Zoo	Time of on-exhibit stay	Diet and feeding days	Enrichment plans
A	From 10:00 AM to 6:00-7:00 PM	Beef meat (every evening)	No
B	Spring - Summer: from 6:30 AM to 7:00 PM Autumn - Winter: from 8:00 AM to 5:00 PM	Beef, chicken, rabbit meat (six days per week)	No
C	Spring - Summer: from 11:00 AM to 6:00 PM Autumn - Winter: from 11:00 AM to 5:00 PM	Beef meat (Wednesday, Saturday, Sunday)	Rare
D	Access to the on-exhibition area always possible	Beef and chicken meat (Wednesday, Thursday, Saturday, Sunday)	No

372

373

Table 4: Ethogram: observed behaviours, in alphabetical order, and their description.

Observed behaviours	Description
Affiliative behaviours	Any non-aggressive social interactions with other animals, including allogrooming and play one another
Aggression	Striking with paws, biting, pouncing, charging, threatening other tiger or animal keeper
Avoid	Changing direction when moving towards to or being approached by another cat or person
Body shake	Moving the body in short, quick movements
Drink	Consumption of water
Eat	Eating, licking, or chewing food
Flee	Running away from a tiger, human or something else
Grass	Consumption of grass
Immersion	Entering a water pool with any part of the body other than the mouth
Interaction with environment	**Spray**: horizontal ejection of urine against vertical surface **Mark**: claws being drawn or cheeks being rubbed over any non-animal surface **Sniff**: taking air through the nose in repeated small sniffs **Flehemen**: grimacing facial expression with the tongue out of the mouth while drawing scent over the facial glands **Listen**: lifting up and turning ears in direction of a noise **Play**: any playful behaviour directed towards an object
Jump	Leaping with all four legs off the substrate from one point to another
Intentional out of sight	Animal, on purpose, is in an area which is visually inaccessible to observer (mainly staying in a shelter or behind vegetation).
Pacing	Walking on a distance back and forth, immediately after this distance has been paced once in both directions
Rest	Lying down or sitting with eyes opened, focused on object, animals or humans
Roll over	Animal on one side and completely rotates to the other side while lying down
Run	High speed forward locomotion
Scratch	Rubbing own skin with claws
Self-grooming	Licking and/or biting any part of own body (no physical indicators of overgrooming)
Sleep	Lying down with eyes closed
Stand	Animal is upright, supported on all four extended legs, but not in motion
Stalk	Slow walking movement, with all legs slightly bent, and eyes focused on a specific item
Stretch	Extended forelegs, depressed body from standing position
Urinate / Defecate	Send urine or faeces out of the body

Vocalize	Making a sound with the voice
Walk	A symmetrical gait in which each foot is on the ground more than half the time in a specific direction
Yawn	Fully extending then closing the jaw, with eyes closed

Table 5: rationale of the choice to suggest particular behaviours as indicators of diminished or enhanced welfare and the literature references.

Category	Behaviour	Rationale	References
Indicators of diminished welfare	Pacing	Pacing is the main stereotypy reported in tigers. It likely reflects present or past inadequate environment and is one of the most commonly used measures of compromised animal welfare, for tigers in particular. As any other stereotypy, pacing should always be taken seriously as a warning sign of potential suffering, but never used as the sole index of welfare.	Bashaw et al., 2003; Bashaw et al., 2007; Clubb and Mason, 2007; Maple and Perdue, 2013; Mason et al, 2007; Mason and Latham, 2004; Mellor, 2015a; Miller et al., 2013.
	Aggression	Aggression, not related to hunting behaviours, is expressed when animals appear frustrated, threatened or otherwise irritated and, probably, feeling anger. It is deemed as a long-term symptom of stress. We suggest it as an indicator of a social issue between members of the group or between animals and humans. Aggression, in all its meanings, has already been used to monitor interactions between female tigers forced to be housed together.	Bashaw et al., 2003; DEFRA, 2012; Hemsworth et al., 2015; Hosey et a., 2009; Mellor, 2012; Mellor, 2015b; Miller and Kuhar, 2008.
	Flee and Avoid	Both behaviours reflect a state of fear in response to aggressive threats or intimidating situations, especially if both intense and prolonged. Also aversive handling can elicit these behaviours. Moreover the freedom from fear is one of the "five freedoms".	DEFRA, 2012; Hemsworth et al., 2015; Hosey et al., 2009; Mellor, 2012.
Indicator of enhanced welfare	Self-grooming	Miller and colleagues (2013) suggested self-grooming as a potential enhanced welfare indicator in tigers. It has been proposed that it may be performed when social grooming is not possible, to reduce arousal. On the other hand, self-grooming may also occur as a displacement activity, i.e. with a relaxation effect, and overgrooming has been recognised as an abnormal form of behaviour in felids because it appears to be repetitive, non functional, and may lead to self-inflicted physical harm. The ethogram we used specified the behaviour item groom as "licking and/or biting any part of own body (no physical indicators of overgrooming)" so as to discriminate a normal action from a stereotypy.	Boissy et al., 2007; Miller et al., 2013.
	Immersion	In nature, wild tigers like to enter in water ponds. If in zoo settings they enter a water pool, they are expressing a natural behaviour. The combination of natural conditions and animal preferences are the reasons that lead some authors to address positive natural behaviours (pleasurable and promoting biological functioning) as a good indicator of enhanced welfare.	Bashaw et al., 2003; Bracke and Hopster, 2006; Maple and Perdue, 2013; Mazak, 1981.

	Affiliative behaviours	Affiliative behaviours represent positive interactions that initiate or strengthen the bonds between animals. Allo-grooming is though to play a major role in reinforcing social bonds and reducing tension in a group of animals. Moreover, the play behaviour is a sign that animals feel relatively safe or unstressed.	Boissy et al., 2007; DEFRA, 2012; Hemsworth et al., 2015; Mellor, 2012; Mellor, 2015a; Mellor, 2015b.
	Intentionally out of sight	Providing conditions that allow animals to hide or escape from potential dangers has been associated with lowered stereotypy. Indian leopard have been seen to occupy the central and back areas of their enclosure in high visitors-presence days. If animals have the opportunity to be out of sight intentionally and get this chance, it may be inferred that they exert control on their environment and make the choice to reduce the level of their own stress.	Clubb and Mason, 2007; Clubb and Vickery, 2006; Mallapur and Chellam, 2002.
	Interaction with environment	This group of behaviours comprises actions that tigers engage in order to obtain information from the environment (sniff, flehemen, listen) and leave their own signature on (spray and mark), other than playing with it. Exploring the territory provides animals with information on their home range that is vital both in wild and captive environment. It is a behaviour that most species of animals are motivated to perform, fulfilling a behavioural need. Moreover it helps animals to gradually approach to new objects and situations: explore the environment may give back information about ongoing changes, so it may be easy for animals to cope. Playing with objects available in the environment may have the same rationale than playing with another animal, thus being a sign that animals feel relatively safe or unstressed.	Boissy et al., 2007; DEFRA, 2012; Hemsworth et al., 2015; Mellor, 2012; Mellor, 2015a; Mellor, 2015b.

382   Table 6: List and categories of variables that describe animal peculiarity, daily routine management, and

383   enclosure features analysed using a mixed-effects models for binary and binomial responses.

Variable	Category
Is there the possibility for the visitor to drive through the enclosure where animals are displayed?	No. Yes.
Day of observation	Weekday. Weekend/holiday (high visitor turnout)..
Weather conditions	Sunny. Cloudy. Drizzle. Heavy rain. Fog.
Temperature	$5 – 9$ °C. $10 - 14$ °C. $15 – 19$ °C. $20 – 24$ °C. $25 – 29$ °C. $30 – 34$ °C. $35 – 39$ °C.
Enclosure area	Less than 1000 m^2. More than 1000 m^2.
Amount of time the animal spend on exhibition	$6 – 9$ hours. $10 – 13$ hours. Access to the on-exhibition area always possible.
Group	Single or couple. More than two tigers.
Shadow	Absent. Half shade. Full shade.
Water pool	Absent. Present: low water level or dirty water or filled with mud. Present: clean water.
Elevated platform	Absent. Present.
Log	Absent. Present.
Interaction with keepers	No interaction. Antagonistic interaction. Positive interaction.
Medical history	Absent. Chronic. Acute.
Observation time slots	10:00 AM – 11:59 AM. 12:00 AM – 1:59 PM. 2:00 PM – 3:59 PM. 4:00 PM – 6:30 PM.

384

385

Table 7: Tiger's activity budget (%) and total observations made per animal, overall activity budget (%), and percentage of behaviours labelled as indicators of diminished or enhanced welfare.
