(BESIII Collaboration)
We report a study of the process $e^+e^- \rightarrow (D^*\bar{D}^*)^0\pi^0$ using $e^+e^-$ collision data samples with integrated luminosities of 1092 pb$^{-1}$ at $\sqrt{s} = 4.23$ GeV and 826 pb$^{-1}$ at $\sqrt{s} = 4.26$ GeV collected with the BESIII detector at the BEPCII storage ring. We observe a new neutral structure near the $(D^*\bar{D}^*)^0$ mass threshold in the $\pi^0$ recoil mass spectrum, which we denote as $Z_c(4025)^0$. Assuming a Breit-Wigner line shape, its pole mass and pole width are determined to be $(4025.5^{+2.0}_{-4.7} \pm 3.1)$ MeV/$c^2$ and $(23.0 \pm 6.0 \pm 1.0)$ MeV, respectively. The Born cross sections of $e^+e^- \rightarrow Z_c(4025)^0\pi^0 \rightarrow (D^*\bar{D}^*)^0\pi^0$ are measured to be $(61.6 \pm 8.2 \pm 9.0)$ pb at $\sqrt{s} = 4.23$ GeV and $(43.4 \pm 8.0 \pm 5.4)$ pb at $\sqrt{s} = 4.26$ GeV. The first uncertainties are statistical and the second are systematic.

Recent discoveries of new charmoniumlike states that do not fit naturally with the predictions of the quark model have generated great experimental and theoretical interest [1]. Among these so-called XYZ particles are charged states with decay modes that clearly demonstrate a structure consisting of at least four quarks, including a $c\bar{c}$ pair. The first charged charmoniumlike state $Z(4430)^+$ was discovered by Belle [2]. LHCb confirmed the existence of this state. Belle determined its spin-parity to be $1^+$ [3], which is supported by a new result from LHCb [4]. Recently, the BESIII Collaboration observed four charged $Z_c$ states, $Z_c(3885)^\pm$ [5], $Z_c(3900)^\pm$ [6], $Z_c(4020)^\mp$ [7], and $Z_c(4025)^\pm$ [8], produced in $e^+e^- \rightarrow \pi^+\pi^-$ events [9]. The observed decay channels are $Z_c(3900)^0 \rightarrow \pi^+J/\psi$, $Z_c(3885)^\pm \rightarrow (D\bar{D}^*)^\pm$, $Z_c(4020)^0 \rightarrow \pi^+h_{c\bar{c}}$, and $Z_c(4025)^0 \rightarrow (D^*\bar{D})^0$. These states are close to the $D\bar{D}^*$ or $D^*\bar{D}$ threshold. The $Z_c(3900)^0$ was also observed by [9] and with CLEO-c data [10].

Thus far, the nature of these new states has been elusive. Interpretations in terms of tetraquarks, molecules, hadro-charmonium, and cusp effects have been proposed [11–19]. Searching for their neutral partners in experiments of importance in understanding their properties, especially for identifying their isospin properties. Previously, based on CLEO-c data, evidence of a neutral state $Z_c(3900)^0$ decaying to $\pi^0J/\psi$ [20] was reported. Recently, two neutral states, $Z_c(3900)^0$ and $Z_c(4020)^0$, were discovered in their decays, $Z_c(3900)^0 \rightarrow \pi^0J/\psi$ and $Z_c(4020)^0 \rightarrow \pi^+h_{c\bar{c}}$, by BESIII [21,22]. These can be interpreted as the isospin partners of the $Z_c(3900)^\pm$ and $Z_c(4020)^\mp$. Analogously, it is natural to search for the neutral partner of the $Z_c(4025)^\pm$ [8] in its decay to $(D^*\bar{D})^0$.

In this Letter, we report a search for the neutral partner of the $Z_c(4025)^\pm$ through the reactions $e^+e^- \rightarrow D^0\bar{D}^0(D^+\bar{D}^-)^\pm$, as the charged $Z_c(4025)^\pm$ [8] couples to $(D^*\bar{D})^\pm$ and has a mass close to the $(D^*\bar{D})^0$ mass threshold. We denote the investigated final state products as $(D^*\bar{D})^0\pi^0$, where $D^*$ refers to $D^{*0}$ or $D^{*+}$ and $\bar{D}$ stands for their antiparticles. A partial reconstruction method is applied to identify the $(D^*\bar{D})^0\pi^0$ final states. This method requires detection of a $D$ and a $\bar{D}$ originating from $D^*$ and $\bar{D}$ decays of $D^* \rightarrow D\pi$ and $D\gamma$, and the $\pi^0$ from the primary production (denoted as the "bachelor $\pi^0$"). The data sample analyzed corresponds to $e^+e^-$ collisions with integrated luminosities of 1092 pb$^{-1}$ at $\sqrt{s} = 4.23$ GeV and 826 pb$^{-1}$ at $\sqrt{s} = 4.26$ GeV [23] collected with the BESIII detector [24] at the BEPCII storage ring [25].

BESIII is a cylindrically symmetric detector which, from inner to outer parts, consists of the following components: a helium-gas based multilayer drift chamber (MDC), a time-of-flight counter (TOF), a CsI(Tl) crystal electromagnetic calorimeter (EMC), a 1-T superconducting solenoid magnet and a nine-layer resistive-plate-chamber-based muon chamber system. The momentum resolution for charged tracks in the MDC is 0.5% at a momentum of 1 GeV/$c$. The energy resolution for photons in EMC with an energy of 1 GeV is 2.5% for the center region (the barrel) and 5% for the rest of the detector (the end caps). For charged particle identification (PID), probabilities $\mathcal{L}(h)$ for particle hypotheses $h = \pi$ or $K$ are evaluated based on the normalized energy loss $dE/dx$ in the MDC and the time of flight in the TOF. More details on the BESIII spectrometer can be found in Ref. [24].

To optimize data-selection criteria, understanding backgrounds, and estimate the detection efficiency, we simulate the $e^+e^-$ annihilation processes with the KKMC algorithm [26], which takes into account continuum processes, initial state radiation (ISR) return to $\psi$ and $Y$ states, and inclusive $D(s)$ production. The known decay rates are taken from the Particle Data Group (PDG) [27] and the decays are modeled with EVTGEN [28]. The remaining decays are simulated with the LUNDCHARM package [29]. The nonresonant, three-body phase space (PHSP) processes $e^+e^- \rightarrow D^*\bar{D}\pi^0$ are simulated according to uniform distributions in momentum phase space. We assume that $Z_c(4025)^0$ has a spin-parity of $1^+$ by considering the measurements of other $Z$ resonances [3,4] and the signal process $e^+e^- \rightarrow Z_c(4025)^0\pi^0$ followed by $Z_c(4025)^0 \rightarrow (D^*\bar{D})^0$ proceeds in $S$ waves. The $D^*$ is required to decay inclusively according to its decay branching ratios from PDG [27]. The $D^*$ is required to decay into $K^-\pi^+\pi^+$, while $D^{*0}$ is required to decay into $K^-\pi^+\pi^+$, $K^-\pi^0\pi^-$, and $K^-\pi^0\pi^0$. These decay modes are the ones used to reconstruct $D$ mesons [30]. All simulated MC events are fed into a GEANT4-based [31] software package, taking into account detector geometry and response.
The charged tracks of $K^-$ and $\pi^+$ are reconstructed in the MDC. For each charged track, the polar angle $\theta$ defined with respect to the $e^+e^-$ beam is required to satisfy $|\cos \theta| < 0.93$. The closest approach to the $e^+e^-$ interaction point is required to be within $\pm 10$ cm along the beam direction and within $1$ cm in the plane perpendicular to the beam direction. A track is identified to be a $K$ when the PID probabilities satisfy $L(K) > L(\pi)$ [$L(K) < L(\pi)$], according to the information from $dE/dx$ and the TOF.

The $\pi^0$ candidates are reconstructed by combining pairs of photons reconstructed in the EMC that are not associated with charged tracks. For each photon, the energy deposition in the EMC barrel region is required to be greater than 25 MeV, while in the end-cap region, it must be greater than 50 MeV due to the differing detector resolution and the probability of reconstructing a fake photon. To suppress electronics noise and energy deposits unrelated to the event, the EMC cluster time is restricted to be within a 700 ns window near the event start time. The invariant mass of any pair of photons $M(\gamma\gamma)$ is required to be within $(0.120, 0.145)$ GeV/$c^2$ and is constrained to the nominal $\pi^0$ mass. The kinematics of the two photons is updated according to the constraint fit.

We consider all possible combinations of selected charged tracks and $\pi^0$ to form $D$ candidates. The charged tracks from a $D$ decay candidate are required to originate from a common vertex. The $\chi^2_{VF}$ of the vertex fit is required to satisfy $\chi^2_{VF} < 100$. We constrain the reconstructed masses of the final state particles to the corresponding $D$ nominal masses and require $\chi^2_{KF}(D)$ for the kinematic fit to be less than 15 for the final states of $D$ decays including charged tracks only, and less than 20 for the final state including $\pi^0$. We select signal event candidates which consist of at least one pair of $D\bar{D}$ candidates that do not share particles in the final state. If there is more than one pair of $D\bar{D}$ candidates in an event, only the one with the minimum $\chi^2_{KF}(D) + \chi^2_{KF}(\bar{D})$ is kept for further analysis.

We reconstruct the bachelor $\pi^0$ from the remaining photon showers that are not assigned to the $D\bar{D}$ pair. To further reject backgrounds, each photon candidate originating from the bachelor $\pi^0$ is required not to form a $\pi^0$ candidate with any other photon in the event. A mass constraint of the two photons to the $\pi^0$ nominal mass is implemented and the corresponding fit quality is required to satisfy $\chi^2_{KF}(\pi^0) < 20$. To reject the background for the bachelor $\pi^0$ from $D^* \to D\pi^0$ decays, we require the $D\pi^0$ invariant mass to be greater than 2.02 GeV/$c^2$.

To identify the decay products of the signal process $e^+e^- \to D^*D^\pi^0$, we plot the recoil mass spectra of $D\pi^0$ [RM($D\pi^0$)], as shown in Fig. 1. The peaks around 2 GeV/$c^2$ correspond to the process $e^+e^- \to D^*D^\pi^0$ with a missing $D^*$. Besides these peaks, we see clear bumps around 2.15 GeV/$c^2$ in the data. These bumps are consistent with the MC simulations of the $D^*D^*\pi^0$ final state. The peak position roughly corresponds to the sum of the mass of $D^*$ and the mass of a $\pi$, since the $\pi$ originating from $D^*$ is soft and is not used in the computation of the recoil mass. The backgrounds beneath the bumps is soft and is not used in the computation of the recoil mass. The backgrounds beneath the bumps are mostly from ISR production of the $D^*D^*$ process. Other processes, such as $e^+e^- \to D^*D^* \to D^*D^* \pi^0$, are expected to be absent, according to simulation studies. This is understandable because the process $D^*_1(2400) \to D^* \pi^0$ is forbidden due to the conservation of spin-parity. $D^*_1(2420)^0$ [$D^*_2(2460)^0$] is narrow, and the sum of the mass of $D^*_1(2420)^0$ [$D^*_2(2460)^0$] and $D^*$ is much larger than 4.26 GeV. To extract the signals, we keep events within the two-dimensional oval regions in the distributions of RM($D\pi^0$) and RM($D\pi^0$) shown in Figs. 1(c) and 1(d). We choose the specific dimensions due to different resolutions at different momentum phase spaces at two energy points. They are determined according to MC simulation.

The selected events are used to produce the recoil mass distribution of the bachelor $\pi^0$ [RM($\pi^0$)], shown in Fig. 2. We observe enhancements in the RM($\pi^0$) distribution over the inclusive backgrounds for both data samples, which can not be explained by three-body nonresonant processes. We assume the presence of an S-wave Breit-Wigner resonance structure [denoted as $Z_c(4025)^0$] with a mass-dependent width, using the form given in Ref. [32]:

\[ \text{Signal region} \]

![Figure 1](color online). Distributions of RM($D\pi^0$) at $\sqrt{s} = 4.23$ GeV (a) and $\sqrt{s} = 4.26$ GeV (b). Points with error bars are data and the shaded histograms represent the inclusive backgrounds in MC simulations. The solid line and the dashed line are the $Z_c(4025)^0$ signal shape and the PHSP shape with arbitrary normalization, respectively. The third row gives the scatter plot of RM($D\pi^0$) vs RM($D\pi^0$) at $\sqrt{s} = 4.23$ GeV (c) and $\sqrt{s} = 4.26$ GeV (d), where the solid ovals indicate the signal regions.
FIG. 2 (color online). Fits to RM($\pi^0$). (a) A fit to the background, PHSP, and Z(4025)$^0$ signal process for the combination of all data (main panel), and the two collision energies separately (insets). (b) Fits using only the inclusive background and PHSP. The points with error bars are the data, the solid line is the sum of all data (main panel), and the two collision energies separately (insets). The shape of the filled area represents the inclusive backgrounds, and the dashed-dotted line is the PHSP process.

Here, $k = 1$ and 2 denote the neutral channel $Z_c(4025)^0 \rightarrow D^{0}\bar{D}^{0}$ and the charged channel $Z_c(4025)^0 \rightarrow D^{*+}\bar{D}^{-}$, respectively. $f_k$ is the ratio of the partial decay width for channel $k$. $M$ is the reconstructed mass, $m$ is the resonance mass, and $\Gamma$ is the resonance width. $p_k(q_k)$ is the $D^*$ momentum in the rest frame of the $D^*\bar{D}$ system (the initial $e^+e^-$ system) and $p_t^D$ is the momentum of $D^*$ in the $Z_c(4025)^0$ rest frame at $M = m$. We assume that the $Z_c(4025)^0$ decay rates to the neutral channel and the charged channel are equal, i.e., $f_k = 0.5$, based on isospin symmetry.

We perform a simultaneous unbinned maximum likelihood fit to the spectra of RM($\pi^0$) at $\sqrt{s} = 4.23$ and 4.26 GeV. The signal shapes are taken as convolutions of the efficiency-weighted Breit-Wigner functions with resolution functions obtained from MC simulations. The detector resolutions are 4 MeV at $\sqrt{s} = 4.23$ GeV and 4.5 MeV at $\sqrt{s} = 4.26$ GeV. Backgrounds are modeled with kernel-estimated nonparametric shapes [33] based on the inclusive MC simulations, and their magnitudes are fixed according to the simulations since the inclusive MC samples well describe the background. The shape of the PHSP process is adopted from MC simulations. We combine the data at $\sqrt{s} = 4.23$ GeV and $\sqrt{s} = 4.26$ GeV together, as shown in Fig. 2. The fit determines $m$ and $\Gamma$ to be $(4031.7 \pm 2.1)$ MeV/$c^2$ and $(25.9 \pm 8.8)$ MeV, respectively. The corresponding pole position $m_{\text{pole}}(Z_c(4025)^0) - i[\Gamma_{\text{pole}}(Z_c(4025)^0)]/2$ is calculated to be

$$m_{\text{pole}}(Z_c(4025)^0) = (4025.5^{+2.0}_{-1.4}) \text{ MeV}/c^2,$$

$$\Gamma_{\text{pole}}(Z_c(4025)^0) = (23.0 \pm 6.0) \text{ MeV}.$$

The significance with systematic errors is estimated by comparing the likelihoods of the fits with and without the $Z_c(4025)^0$ signal component included. The likelihood difference is $2\Delta\ln L = 45.3$ and the difference of the number of free parameters is 4. When the systematic uncertainties are taken into account with the assumption of Gaussian distribution, the significance is estimated to be $5.9\sigma$.

The Born cross section $\sigma(e^+e^- \rightarrow Z_c(4025)^0\pi^0 \rightarrow (D^0\bar{D}^0 + D^{*+}\bar{D}^{-})\pi^0)$ is calculated from the equation

$$\sigma = \frac{n_{\text{sig}}}{L(f_1B_1\epsilon_1 + f_2B_2\epsilon_2)(1 + \delta)(1 + \delta_{\text{vac}})},$$

where $L$ is the integrated luminosity, $\epsilon_1$ ($\epsilon_2$) is the detection efficiency of the neutral (charged) channel, $f_1$ ($f_2$) is the ratio of the cross section of the neutral (charged) channel to the sum of both channels, $B_1$ ($B_2$) is the product branching fraction of the neutral (charged) $D^*$ decays to the final states we detected, $(1 + \delta)$ is the radiative correction factor and $(1 + \delta_{\text{vac}})$ is the vacuum polarization factor. From the simultaneous fit, we obtain 69.5 $\pm$ 9.2 signal events at $\sqrt{s} = 4.23$ GeV and 46.1 $\pm$ 8.5 signal events at $\sqrt{s} = 4.26$ GeV. $(1 + \delta)$ is calculated to be 0.744 at $\sqrt{s} = 4.23$ GeV and 0.793 at $\sqrt{s} = 4.26$ GeV to the second order in QED [34], where the input line shape of the cross section is assumed to be the same as for $e^+e^- \rightarrow (D^*\bar{D})^+\pi^-$, as extracted directly from BESIII data. $(1 + \delta_{\text{vac}})$ is given as 1.054 following the formula in Ref. [35]. The efficiency $\epsilon_1$ ($\epsilon_2$) is determined to be 1.49% (3.87%) at $\sqrt{s} = 4.23$ GeV and 1.84% (4.37%) at $\sqrt{s} = 4.26$ GeV. Thus, the cross sections are measured to be (61.6 $\pm$ 8.2) pb and (43.4 $\pm$ 8.0) pb at $\sqrt{s} = 4.23$ and 4.26 GeV, respectively. The contribution of the PHSP process is found to be negligible according to the fit.

Sources of systematic uncertainties in the measurement of the $Z_c(4025)^0$ resonance parameters and cross sections are listed in Table I. Uncertainties of tracking and PID are each 1% per track [36]. The uncertainty of the $\pi^0$ reconstruction efficiency is 4% [37]. We study the photon veto by fitting the recoil mass of $D\bar{D}^0$ with and without this veto in selecting the control sample of $e^+e^- \rightarrow (D^*\bar{D})^0\pi^0$ in the data. The efficiency-corrected signal yields are used...
TABLE I. Summary of systematic uncertainties on the \( Z_c(4025)^0 \) resonance parameters and cross sections \( \sigma_{4230} \) at \( \sqrt{s} = 4.23 \) GeV and \( \sigma_{4260} \) at 4.26 GeV. "..." means that the uncertainty is negligible. The total systematic uncertainty is taken as the root of the quadratic sum of the individual uncertainties.

Bhabha events [7]. We vary the ratio \( f_k \) from 0.4 to 0.6 to take into account potential isospin violation between the neutral and charged processes. The corresponding changes are assigned as systematic uncertainties. The systematic uncertainty of the vacuum polarization factor is 0.5\% [35].

In summary, using \( e^+ e^- \) annihilation data at \( \sqrt{s} = 4.23 \) and 4.26 GeV, we observe enhancements in the \( \rho^0 \) recoil mass spectrum in the process \( e^+ e^- \rightarrow D^0 \bar{D}^0(D^+D^-)\rho^0 \). Assuming that the enhancement is due to a neutral charmoniumlike state decaying to \( D^+ \bar{D}^- \) and that it has a spin-parity of \( 1^+ \), the mass and the width of its pole position are determined to be \( m_{\text{pole}}(Z_c(4025)^0) = (4025.5^{+2.0}_{-1.7} \pm 3.1) \text{ MeV}/c^2 \) and \( \Gamma_{\text{pole}}(Z_c(4025)^0) = (23.0\pm6.0 \pm 1.0) \text{ MeV} \), respectively. The Born cross section \( \sigma(e^+ e^- \rightarrow Z_c(4025)^0\rho^0 \rightarrow (D^0 \bar{D}^0 + D^+ D^\pi^-)\rho^0) \) is measured to be \( (61.6\pm8.2\pm9.0) \text{ pb} \) at \( \sqrt{s} = 4.23 \) GeV and \( (43.4\pm8.0 \pm 5.4) \text{ pb} \) at \( \sqrt{s} = 4.26 \) GeV. Hence, we estimate the ratio \( \sigma(e^+ e^- \rightarrow Z_c(4025)^0\rho^0 \rightarrow (D^0 \bar{D}^0 + D^+ D^\pi^-)\rho^0) / \sigma(e^+ e^- \rightarrow Z_c(4025)^+ \pi^- \rightarrow (D^+ \bar{D}^-)\pi^-) \) to be compatible with unity at \( \sqrt{s} = 4.26 \) GeV, which is expected from isospin symmetry. In addition, the \( Z_c(4025)^0 \) has mass and width very close to those of the \( Z_c(4025)^\pm \), which couples to \( (D^* \bar{D}^*)^\pm \) [8]. Therefore, the observed \( Z_c(4025)^0 \) state in this Letter is a good candidate to be the isospin partner of \( Z_c(4025)^\pm \).
