### 55th IFLA World Congress Organising Committee

**Organising Chair**: Mr Damian Tang  
**SILA President**: Mr Ronnie Tan  
**Acting SILA President**: Ms Sri Gopal  
**Advisor**: Ms Tay Bee Choo  
**Secretary General & Exhibition Co-chair**: Mr Terence Tan  
**Exhibition Chair**: Ms Maurene Tan  
**Conference Chair**: Ms Audrey Xu Jing Yi  
**Conference Co-Chair**: Ms Yvonne Tan  
**Scientific Chair**: Dr Russell Arthur Smith  
**Publicity Chair**: Mr Derek Loei  
**Publicity Co-Chair**: Dr Yazid Ninsalam  
**Technical Tour Chair**: Mr Jeverss Choo  
**Technical Tour Co-Chair**: Ms Maria Boey Yuet Mei  
**Student Competition Host Chair**: Mr Goh Weixiang  
**Student Charrette Host Chair**: Ms Anna Yap Lai Fong  
**Ms Heng Juit Lian**

The Vision of Biophilic Cities

Professor Timothy Beatley
Teresa Heinz Professor of Sustainable Communities, in the Department of Urban and Environmental Planning
University of Virginia: School of Architecture
United States of America

Synopsis:
Evidence continues to build that the benefits provided by contact with nature are profound and deep. Biophilia holds that we are innately drawn to nature and living systems, that preferences for and benefits derived from nature are hard-wired, the result of a long evolutionary process. As the planet continues its rapid pace towards urbanization (new projections are that almost 70% of the world’s population will live in cities by 2050), contact with the natural world becomes ever more important, and the need for biophilic design and planning is ever more critical. Daily contact with nature is not optional but absolutely essential flourishing life. We need more biophilic buildings, but we need as well to design the spaces between and beyond buildings with abundant nature. Beatley argues that we will need to reimagine cities as places of biophilic contact and flourishing, and as places that sustain and support biodiversity. We need to advance a new model of urbanization and city-building that puts nature at the center of design and planning.

This vision of future cities is one where citizens are able to live and work surrounded by and immersed in nature. The kinds of nature will depend on the city and its location and setting. Much of this urban nature is in the form of native flora, fauna, fungi, and wildlands, but much of it, especially in dense vertical cities, will take the form of human-designed and constructed nature (for instance, green rooftops and vertical living walls). Increasingly urban nature will take blended or hybrid forms (for instance the Supertrees of Singapore). There are other important metrics for judging the extent to which a city is biophilic, including the kinds and extent of engagement the public has with the nature around them (how much time is spend outdoors enjoying nature, how much time engaged in ecological restoration work or citizen science, how much do citizens care about plants and animals?)

Beatley will explain this new model of urbanism, its key elements and will describe some of the early efforts of cities to put this vision into practice. He will also progress made in developing and growing the new global Biophilic Cities Network and provide examples of innovative design and planning underway in these cities. Examples are provided a variety of emerging Biophilic Cities, including San Francisco, Washington, Wellington, Edmonton and (of course) Singapore, among others. Each is doing remarkable work in protecting, celebrating and integrating its unique nature(s).

Beatley will argue that becoming a more biophilic city will also make a city more sustainable and resilient. Finally, Beatley will explore some of the key challenges faced globally in implementing the Biophilic Cities vision, including the need for a more socially just distribution of urban nature and the need to more effectively confront the unintended consequences of investing in urban nature (the issue of eco-gentrification). Other challenges include how biophilic design and planning can be applied to the growing informal housing sector in many cities of the Global South, and the ways in which cities must also support conservation of more distant nature.

For additional information about Biophilic Cities please visit BiohilicCities.org
“Greening our Red Dot” – Creating Liveable Density

Dr Cheong Koon Hean
Chief Executive Officer
Housing & Development Board
Singapore

Synopsis:
Today, many cities face rapid urbanisation, insufficient infrastructure and housing and environmental degradation. Many strive to green their cities as a means of improving the living environment, but implementation is difficult, often hampered by a lack of resources and weak institutional and legislative processes.

Urbanisation challenges are even more stark for Singapore, a city state sometimes referred to as the red dot, which has to deal with severe land constraints, a high density environment and climate change. Yet, Singapore has worked hard over the decades to become a City in a Garden. In her presentation, Dr Cheong will illustrate how greenery and water elements are intrinsically woven into its planning processes and institutionally embedded to ensure successful execution so as to create liveable density and a resilient Singapore.

She will also share how the Housing & Development Board (HDB), Singapore’s public housing authority, plays a key role in shaping the living environment, through town planning, urban design and greening. With more than 80% of Singapore’s population housed in some 26 high density HDB towns and estates, it is critical that HDB deploys innovative strategies to achieve a good quality living environment. These include deploying the enduring planning principle of creating a hierarchy of greenery. In addition, Dr Cheong will share HDB’s latest Biophilic Town Framework which was recently launched, arising from its R&D efforts in partnership with other agencies. The new generation of HDB towns will be guided by biophilic design strategies which incorporate multiple uses for green and blue spaces to enhance social and ecological connectivity and functions, assisted by urban environmental modelling to address environmental, ecological, economic and socio-cultural needs.
Ecosystem Services in the Urban Landscape

Professor Peter Edwards
Principal Investigator
Future Cities Laboratory
Switzerland

Synopsis:
Until rather recently, the main motivations for greening urban areas were aesthetic and recreational. However, we now recognise that plants and vegetation do much more than look beautiful, but provide a wide range of other benefits that are known as ecosystem services. In this talk, I consider some of these ecosystem services, and their contribution in mitigating environmental problems in urban areas. I focus especially upon cities of the humid tropics, notably Singapore, and the role of vegetation in cooling the city and preventing flooding. I argue that vegetation and other ecosystems are the 'natural capital' of a city. To realise the full value of this capital, we need much more information about the capacity of different types of urban vegetation to deliver ecosystem services.

I make four points about how ecosystem services can be incorporated into planning. Firstly, I argue that a systems approach is important in planning for these services. A good example is Singapore’s Active, Beautiful, Clean Waters (ABC Waters) Programme, which is based upon a detailed understanding of how water flows through an urban catchment. The ABC programme incorporates a variety of measures for retaining water at the source, thereby ensuring that less water is lost in storm runoff and reducing the need for large storm drains.

Secondly, urban landscapes need to fulfill many functions, especially in a land-scarce city such as Singapore. In particular, all green areas should contribute to regulating environmental conditions, rather as in the rainforest that existed before the city was built. A good example of how this can be achieved, is the Kallang River segment in Bishan Park, Singapore.

Thirdly, the ecological links between green areas need to be strengthened. In this respect, I welcome the emerging trend in Singapore and elsewhere for hard boundaries between buildings and green spaces to disappear. Buildings are increasingly clothed with greenery, which merge – sometimes imperceptibly – with the vegetation of the surrounding land.

Finally, to obtain the greatest value from ecosystem services, new tools and approaches are needed. Interactive computer tools can allow designers to access ecological information, in much the same way as they can access information about the properties of building materials, and use this information to assess the environmental benefits of particular designs. An exciting new source of information is point-cloud data obtained from Lidar scanners. I describe some recent research aimed at developing such tools.

I conclude with a vision of a sustainable tropical city that uses ecological processes to keep cool, to avoid flooding, and to purify air and water. Such a city is less dependent upon expensive infrastructure, such as storm drains and large, centralised water-purification facilities. And the buildings are closely integrated with the surrounding ecosystems, and are themselves a source of ecosystem services.
Naturalising a High Density City. The Reality and Logistics

Henry Steed,
Director
ICN Design International Pte Ltd
Singapore

Synopsis:
The concept is to convert the man-made, high-density City into a liveable green place for us and our wildlife neighbours. To be more than a concept, we have to build it, pay for it, plant it, nurture it, and maintain it in perpetuity. Let’s look ahead for the next thirty years.

Given the current state of many cities, the scale of transformation will be big. For the concept to be feasible, relevant policies and resources in manpower, machinery, materials and money are needed. For all those, including practising Landscape Architects, whose job is to physically turn the hard city to a soft city, balancing concrete and steel with gardens, parks, shaded streets, and sky-rise greenery these are concerns. This has been my work here for 35 years, but I am the past generation. Now younger and better educated generations will have to step up to see these ideas designed and built.

So how do we make sure these Biophilic concepts can be built and sustained? Many urban districts in most cities need to be upgraded. The prime tools for stimulating necessary change are workable policies, and the means for implementation. In Singapore, the Urban Redevelopment Authority and NParks have introduced many policies aimed at stimulating mass urban landscape at a nation-wide scale. The 100% Landscape Replacement Area policy is a dramatic response to the stripping away of real land in the City confines. With City land in such short supply, we can’t keep on going out sideways, making vast cities. The sky is empty, so up we go.

Nevertheless, high buildings present environmental difficulties for ‘sky-rise greenery’ that are not adequately understood. There is a need for all parties to share communal know-how, about the complex integration processes needed for simulating nature in City conditions. Nature colonises easily, but for us it will be much harder to truly achieve the benefits that this enhanced status will bring. Are we geared up for the challenge?

The Biophilic Vision demands increased resources: large numbers of quality trees, and mountains of high grade soil-media are just two items. Every part of the new landscape must be transformed to an industrial scale, with well-crafted and agreed industry standards, properly paid for.

City-wide landscape maintenance will also escalate to an industrial scale. Though in desperately short supply, large numbers of skilled people are needed, but young people are not attracted. Automation will not be the answer for many years, so it will still be people who do the work.

Where do we go from here? I will explain, through some recent examples of projects we have worked on in Singapore, which begin to touch on the Biophilic subject.

Long term landscape resilience will come from a combination of intelligent design, good contractors, qualified and educated workforce, planned logistics and programming, effective technology, fair and appropriate pricing, and enlightened authorities and building owners.

Creating and sustaining of Biophilic Green Cities as our habitat is a truly worthy task, though it will be difficult and endless.
Biophilic City in a Garden: Restoring Nature, Nurturing Communities

Kenneth Er
Chief Executive Officer
National Parks Board
Singapore

Synopsis:
Singapore is widely recognised as one of the greenest cities in the world. This greening movement took roots from the country’s early years in the 1960s, when its former Prime Minister Lee Kuan Yew directed that a tree planting campaign be launched across the island. Today, a well-established matrix of lush greenery, park spaces and natural habitats form the foundation of what we know to be the City in a Garden. Yet, reality presents growing land constraints and urbanisation in the coming years for the island, making the future for greenery in Singapore inevitably hard to articulate.

This presentation will share how Singapore has leveraged on the existing green infrastructure in a systematic manner, strengthening urban ecosystems and building community stewardship, to augment the current City in a Garden vision to an even more biophilic one. Real-life projects undertaken in recent years by the National Parks Board Singapore illustrate key initiatives that lend to this aspiration.

It is essentially a two pronged strategy; one, to add legibility to the current network of green spaces so that the overall ecosystem is a more resilient one where enhanced ecological benefits can be gleaned. Second, to help communities become active stewards of nature, recognising how a virtuous cycle can be established between the flourishing of our green spaces, and the enhancement of civic ownership.

Strategy 1: Restoring nature through the defragmentation of ecological connection

Each one of Singapore’s nature reserves represents a distinct natural habitats ranging from primary to secondary lowland rainforests, freshwater swamp forest, mangroves and mudflats. It is therefore vital to strengthen the resilience of these habitats which forms the main sources of biodiversity for the nation. Taking reference from Richard Foreman’s landscape ecology concepts, the presentation will share how efforts have been taken to achieve resilience — not only through the safeguarding of nature parks as buffer spaces, nature ways and park connectors as ecological corridors between the remaining tracts of habitats that are available in Singapore, but also enhancing and restoring of natural habitats within parks so that they become important ecological ‘stepping stones’ for native biodiversity.

Strategy 2: Nurturing communities to delight and steward nature

Being a biophilic city goes beyond just having nature in the built environment. Nature and urban parks are increasingly curated to allow visitors to engage more closely with nature and to glean a better understanding of them through interpretive elements.

There is also an intentional shift in programming from participation to active stewardship, recognising that this is a more effective way in nurturing a biophilic community. When various stakeholders, ranging from researchers, conservation and heritage enthusiasts, as well as regular park goers, have a say in how spaces should be activated for all, more community ownership can be built and green spaces sustainably stewarded.
Christchurch New Zealand: Re-building a Resilient Post-earthquake City

*Resilience: an ability to recover from or adjust easily to misfortune or change.*

Rachel De Lambert  
Landscape Architect & Director  
Boffa Miskel  
New Zealand

**Synopsis:**

*Before dawn on September 4th 2010 Christchurch experienced a massive 7.1 magnitude earthquake -- a force on par with the devastating January 2010 earthquake in Haiti. Although infrastructure was disrupted, the city was back up and working within days.*

*Tremors -- numbering into their thousands -- continued; and on February 22nd 2011, a shallow magnitude 6.3 aftershock rocked the city.*

*This devastated Christchurch's commercial city centre and eastern residential suburbs. 185 people were killed. If Christchurch was to remain it would need to be re-built.*

*Christchurch City Council began a process of engaging with the city's residents, asking people to 'share their ideas' for a re-imagined city. Public forums were initiated with local, national and international speakers invited to identify opportunities that the re-build presented.*

*The New Zealand Government established the Canterbury Earthquake Recovery Authority (CERA) to progress the city’s recovery, informed by the ideas and aspirations captured during community consultation.*

*CERA put forth a competitive tender calling for the development of a spatial masterplan within 100 days. This plan -- called “The Blueprint” -- would provide a framework for the re-build of central Christchurch.*

*The successful Blueprint 100 Consortium comprised Boffa Miskell (landscape architects, urban planners and designers); Warren + Mahoney (architects); Sheppard + Rout (Christchurch-based architects); Woods Bagot (architects); Populous (architects) and RCP (project managers).*

*Rachel de Lambert, landscape architect and partner at Boffa Miskell, was the Spaces and Places Anchor Project lead.*

*Seven years later, completed Spaces and Places Anchor Projects include: Ōtākaro, the Avon River Precinct; Ruaora, a new 'East Frame' parkland; the Canterbury Earthquake Memorial; the Margaret Mahy playground; and a re-created Victoria Square. These landmarks have led the way in creating a reinvigorated central city.*
Alongside the official rebuild projects, a new creativity and proactive citizenship has emerged. The people of Christchurch initiated tactical projects involving memorials, temporary landscapes, installations, ‘Gap Filler’ activities and place making; and re-use of demolition materials.

The city’s interim “Re:Start” container mall gained worldwide recognition and provided a downtown destination whilst much of the traditional centre remained fenced-off or bulldozed flat.

Christchurch has shown its resilience. The city is re-emerging -- ecologically enhanced, culturally more diverse and fit for purpose in a post-quake world.
Landscapes for Our Heartlands: A Biophilic Landscape Design Approach

Leonard Cai
Deputy Director of Building & Research Institute
Housing & Development Board
Singapore

Synopsis:
Over the years, the Housing & Development Board (HDB) has been actively pursuing a better living environment through the provision of urban greenery to create vibrant and sustainable towns that support active and cohesive communities. As our heartlands develop into high-density townships, neighbourhood landscapes take on a critical role in mitigating the high densities and ensuring a quality living environment.

Being an integral part of the urban fabric, it is essential for urban landscapes to be carefully considered at all scales, from the master planning level, to the design of individual precincts and buildings. To achieve that, HDB developed a Biophilic Town Framework, which elaborates on the strategies and initiatives to achieve “Enhanced Greenery & Biodiversity”, one of the 10 desired outcomes under the broader HDB’s Sustainable Development Framework.

The HDB Biophilic Town Framework proposes a calibrated and holistic approach in the planning and design of urban landscapes to optimise the delivery of urban ecosystem services and to enable people to forge deep and meaningful connections with nature. Through the implementation of this framework, our towns and estates will promote greater sense of place, better well-being and an enhanced quality of life for our residents.
Escape from Sequestration Bondage: Soil Designs for Compact Neighbourhood Landscapes

Professor Jim Chi Yung
Education University of Hong Kong
Hong Kong, China

Synopsis:
In compact urban areas, the grey infrastructure prevails over the green infrastructure. The tight urban fabric imposes multiple challenges on tree growth to frustrate nature-based solutions. Fast urbanization and densification have increased pressure on trees. Most studies focused on subaerial parts and neglected the subterranean domain. From field and laboratory studies of urban soils in diverse landscape sites, field evaluations in different cities and literature review, key problems were analyzed and alternative solutions were proposed. Compact planting sites are beset by critical physical soil constraints, especially confined soil volume at narrow roadsides. They include internal (micro-scale) restrictions due to compaction and excessive coarse fractions such as gravels, and external (macro-scale) restrictions due to limited soil depth and width. Confined soil volume limits root spread, tree health and tree safety, inducing poor tree performance and premature decline. Poor soil quality is also traced to impermeable paving, organic-matter deficit, low nutrient and water holding capacity, and meagre nutrient stock. Soil volume expansion can be accompanied by a designed soil mix. Soil area provision (SAP) is assessed based on moisture need of trees. A creative soil design scheme is proposed to expand soil volume. Based on the principle of soil volume sharing, subsurface soil conduits and subsurface soil corridors supplemented the routine open soil corridor. SAP could extend from the narrow footpath to adjoining carriageway as soil peninsula and greenspace as offset soil volume. The surface of shared soil area can be co-used by pedestrians or vehicles. Soil compaction could be prevented by suitable suspended paving methods. Underground utility works can adopt mature trenchless technology to protect roots of important trees. Porous and pervious paving materials can enhance root growth. Modern subbase design of footpaths can prevent cracking and heaving of pavement by roots. Degraded soil of heritage trees can be rehabilitated. An urban soil specification for trees to forestall problems and ensure long-term maintenance of soil quality can be established. Urban tree managers can readily adopt out-of-the-box thinking to integrate soil design in landscape works. Interactions between science and practice can be cultivated to fulfill the goals of resilient cities.

Keywords: Urban soil; Soil volume restriction; Urban soil design; Subsurface soil conduit and corridor; Offset soil volume; Soil volume sharing
Landscapes of the Future

Daan Roosegaarde
Artist and Innovator
Studio Roosegaarde
Netherlands

Synopsis:
Dutch artist and innovator Daan Roosegaarde presents ‘Landscapes of the Future’, highlighting his innovative practice which merges people, technology and space to create a better world.

Virtual floods, smart highways and smog sucking towers; Roosegaarde pulls technology out of the screens to examine and activate solutions to improve daily life in urban environments. In his interactive talk, Roosegaarde explores the social role of design, the importance of “Schoonheid” (a Dutch word meaning both beauty and cleanliness) along with his vision for the future.

As the new ‘hippie with a business plan’ to quote the New York Times, Roosegaarde has been selected as a creative change maker by Forbes and Good 100 and is a young global leader of the World Economic Forum.
BIOPHILIC CITY
Intertwined Culture and Nature for the Urban Future
Cultural and Natural Heritage Assets as a Platform for Landscape Architect’s to Achieve the UN Sustainable Development Goals- 2030 Global Agenda

Patricia M. O’Donnell
Founder & Principal
Heritage Landscapes LLC
United States of America

Synopsis:
By responding to three important questions this paper explores the opportunities for the Landscape Architecture professions’ impact on culture/nature integration for healthful, livable, authentic cities.

How do the UN SDGs - 2030 Global Agenda relate to Biophilia, the urban future and Landscape Architects?
The United Nations Sustainable Development Goals (UN SDGs), 2030 Agenda, adopted by UN member nations in September 2015 lays out 17 goals and 169 targets that address human and planetary well-being through vectors of sustainable communities, life on land and in water, climate action, clean water and energy, reduced poverty and inequality, health, education and more (Figure 1 - UN SDGs 17 Goals). Many of these interrelated vectors can be achieved through our landscape stewardship, respecting inherited public landscapes and creatively innovating our practice on behalf of the living and the unborn, of all species.

Cities are vessels of biodiversity and cultural diversity. Landscape architects fill a critical role in an urban future that embraces Biophilic cities, local people and uniqueness. By applying the idea cities can harmonize nature and people, we function at a critical intersection in humanity’s global trajectory to achieve a sustainable planet or perish. As people weigh down a burdened globe, culture/nature integration in all we do offers a positive future. Action based on inseparable cultural diversity/biodiversity, rather than separated culture/nature, offers hope for our precious, embattled planet.

Why should culture and nature be integrated for a biophilic future?
Intensification of robust nature in cities is at the core of biophilic design. Landscape Architects can and should expand their work with allied professionals to enhance urban biodiversity that recognizes local cultural assets, traditions and practices. Working on this base, our interventions enhance authenticity of place, which is integrally linked to community pride, belonging, and true sustainability. Natural and cultural assets are shared uniqueness of human settlements, that foster authenticity and promote justice. The public commons provide the platform for inclusive urban revitalization that moves biophilia forward to aid in solving complex 21st century challenges. Implementing place-based landscape architectural works can be highly effective when based on a foundation of local peoples and valued places, toward achieving the UN SDGs.

How can every Landscape Architect aid the implementation of the UN SDGs yielding benefits to urban populations?
We see escalating human pressure causing rapid change, erratic weather, and resource scarcity that separates “haves and have nots”. The projection of 150 million climate change migrants by 2050 is shocking. Landscape Architects can take a significant role in addressing imbalances toward achieving the UN SDGs. We begin by embracing this global agenda, a first comprehensive worldwide vision. Potential benefits are environmental/social/economic, the three pillars of sustainability. Fully engaging culture and heritage assets is a core principle for actions that underpin urban vitality. Examples of how to integrate the UN SDGs for urban public landscapes, inherited from our past that support a biophilic future, include Washington’s National Mall, Chicago’s Jackson Park, and Pittsburgh’s Parks. Thank you for studying, integrating and championing the UNS SDGS in your professional works.

Figure 2. Human settlements all over the world are vessels of biological Diversity and Cultural Diversity working with this foundation of urban heritage. Landscape Architects can aid in achieving the UN Sustainable Development Goals, 2030 Agenda. Diagram courtesy Patricia M. O’Donnell, building on the IUCN-ICOMOS Connecting Practices Initiative, permission to use and distribute with O’Donnell credited.
Nature System in Chinese Cities- Past, Present and Future

Professor Wang Xiang-Rong  
Former Vice President of CHSLA, Dean of School of Architecture  
Beijing Forestry University  
People’s Republic of China

Synopsis:
China is a country with a vast territory. For thousands of years, this land has brought up huge population. Throughout the long history, people has been trying to control the flood, cultivate farmlands, develop agriculture, build settlements, and has gradually transformed this land into a granary.

Many Chinese artificial constructions in history, from buildings to hydraulic works, agriculture or cities, are all integrated with nature. Man and nature are in balance and in harmony, and lakes, ponds, fields, canal networks, villages and cities form a whole.

Most ancient Chinese cities are not large, but the site selection and the city construction were carried out with an integral vision and in big scale. The structure of cities was consistent with the landscape structure of the whole area, and cities and natural landscape have close relation and merge in a harmonious whole. Therefore, Chinese cities are full of natural spirit.

However, the landscapes have been rapidly changed during the last 40 years. The urbanization rate of China was 17.6% in 1977, while it surged up to 58.5% last year, and it is still increasing by 1% every year recently. In other words, there are more than 12 million people swarming into the city from countryside every year, and the urban built-up area has sprawled seven times since the past 20 years.

In some areas, the natural system outside and inside the city are gradually separated apart, and the nature began to become fragmented. The previous balance between natural and artificial systems have lost. These lead to the weakening of landscape diversity and its ecological function. The reasons might be concluded as: 1. The expanded city occupied the surrounding natural and semi-natural spaces. 2. Different from the historical cities, the cities today have no longer developed in related to the natural and agricultural systems in their surrounding areas. 3. Human’s attitude toward nature has converted from relying to modifying and intervening randomly. 4. More and more man-made systems have replaced the natural and semi-natural systems. The rapid urbanization will continue in the coming future, 170 million rural residents will move into newly constructed towns and cities successively over the next 10 years. Such scale and speed of urbanization has never occurred in the human history.

In the background of rapid urbanization, how to ensure the ecological security, and build the balance between city and natural system? With the premise that nature outside and inside the city are being continuous and integral as a whole, the approaches to construct this system are landscape preservation, restoration, transformation and integration.
Biophilic Railway Stations: Re-imagine the Nature of Transit Design

Dr Philip Roös
Senior Lecturer in Architect
Deakin University
Australia

Synopsis:
Across the world railway stations, transit centres and transport interchanges are rapidly evolving from purely functional transit spaces to new urban centres and destinations, resulting in activity hubs and gathering places. These stations generate high footfall creating life and vitality, and form the centre of daily routines for many urban dwellers. Train stations are places of connection, they are gateways to the city, and can be one of the most exciting places in an urban environment to experience. Some stations make great destinations with shops, restaurants, museums and exhibition spaces. New architecture for railway stations acknowledges the functions of transit; whilst the heritage of place, culture and the surrounding urban spaces can provide excellent public areas to celebrate our innate human connection to nature. Similar to the grandeur of old railway stations, new majestic spaces with biomorphic-inspired monumental elements can include the fundamental pattern language that underpins the principles of Biophilia.

Rail transport infrastructure, especially railway stations, significantly contributes to the quality of human life, sustainability and the economy of urban centres. Station buildings play a major role in efficient and vibrant places, and can be at the forefront of innovation and modernity. Due to the current unprecedented levels of global urbanization, cities and their governing entities are investing in more sustainable public transport systems. The rationale for this investment is to aid reduction in greenhouse gas emissions and, assist economic efficiencies in goods and people movements across and within cities providing better forms of transport, whilst assisting in the creation of improved sustainability and healthier urban environments. New major transit projects massively impact the city fabric, but also provide opportunities to reshape urban environments to include innovative biophilic design.

This paper investigates the opportunities that new transit hubs and railway stations and their associated infrastructure can provide for creating more sustainable and healthy urban environments, through the lens of Biophilic Design. In the foreword of a recent study Creating Healthy Places (2017, p9), Professor Tim Beatley raises the question, “might we re-imagine the very nature of a transit trip? Could it be not simply a trip to work or a travel to the high street, but perhaps a visit to the forest, a chance to hear and celebrate native birdsong, or a chance encounter with a butterfly. Perhaps food production becomes part of transit design, so that one picks a tomato or a desert plum on the way to catch the train. Why not a transit station in a forest?”

This paper explores the patterns of Biophilia and its application to railway stations. It further benchmarks old and new examples of railway stations across the world against Biophilic patterns, and reflects on the Creating Healthy Places (2017) study recently completed for the Metro Tunnel Project in Melbourne, Australia. It concludes with recommendations of key principles to be considered for Biophilia-inspired railway station design that can assist in advancing the larger vision and agenda of ecologically sustainable and Biophilic Cities.
Improving mental health in prisons through biophilic design

Jana Söderlund

Curtin University, Kent St. Bentley Perth WA 6102
Design by Nature, Keeling Way, Fremantle WA 6102

Abstract

Increasing nature and natural elements within a prison offers the potential to de-stress residents, improve mental health, cognitive functioning and learning, reduce recidivism and increase receptivity for behavioural change and restorative justice opportunities. Biophilic design is outlined as a set of principles and practices for cities to bring nature into urbanites’ daily life. The role of nature in restorative initiatives is traced back to the early work of innovative psychoanalyst Eric Fromm showing how his framework of human psychological pathways overlaps with biophilic design principles.

Fromm suggests that human awareness creates a division from nature, instilling anxiety and conflict. In seeking to overcome this anxiety there are choices in the pathways taken. A regressive pathway is where this anxiety is repressed, either by the collective culture through laws and religion or pathological behaviour such as necrophilia and narcissism. The opposite pathway follows a ‘syndrome of growth’ and here the anxiety is transcended and replaced. This is the progressive path, where love of life, biophilia, is the stronger force. Fromm saw cities as separating humans further from nature through their industrialised, commoditised and mechanistic designs, increasing anxiety and stress, as well lessening the impulse to pursue the progressive, biophilic pathway. He suggested that exposure to nature is needed to provide choice and strengthen the opportunity for biophilia, which is preferable in a prison environment.

Fromm was one of the pioneers in recognising the relationship between human psychology and environmental conditions yet it was the more recent conceptualising of the biophilic human being by socio-biologist, Edward Wilson, which more broadly launched the term biophilia. Together with fellow biologist, Stephen Kellert, the biophilia hypothesis emerged suggesting an innate human connection to nature. As with Fromm, Kellert and Wilson posited that humans have evolved to need nature for health, wellbeing and fulfilment. These two approaches of humanistic psychology and evolutionary biology overlapped and reached the same conclusion. As cities expanded, some theorists were suggesting cities were devoid of nature and thus human nourishment. Kellert and Wilson, along with a diverse group of colleagues, begun discussion of an approach to integrate nature in cities called biophilic design. Yet it is appreciating the origins of biophilic design through Fromm’s original usage of ‘biophilia’, meaning ‘love of life’, that can deepen the essential understanding of the principles of biophilic design.

Through biophilic design the opportunity exists to change the environment to nurture not the negative, but the positive responses, to enhance the physiological as well as the psychological. As much as the environment can cause negative reactions, environments can also enhance mental health and well-being, decreasing anxiety and stress. In the right environment our
innate love of life and connectedness can be nourished and sustained. We can journey on the progressive path of biophilia. Biophilic design focusses on strengthening the progressive pathway through provision of a greater exposure to nature and natural spaces and patterns, thus encouraging connection to, and love of, life and life processes.

Utilising appropriate biophilic design approaches and principles should provide new ways to improve the prison experience.

1. Introduction

Global studies of prisoner health suggest that they experience high levels of mental illness (Fazel & Baillargeon, 2011; Fazel & Danesh, 2002; Fraser, Gatherer, & Hayton, 2009; Gunn, Maden, & Swinton, 1991; Wright, Jordan, & Kane, 2014). Mental illness is well recognised as an increasing problem within the prison system, with some research suggesting that 89 percent of prisoners have depressive symptoms and 74 percent have stress-related symptoms, many of which are not diagnosed until incarceration (Fraser et al., 2009; Nurse, Woodcock, & Ormsby, 2003; Ogloff, 2002).

A study undertaken in five Australian prisons in 2004 revealed that nearly 50 percent of prisoners had a mental disorder, with post-traumatic stress disorder the most common (Butler, Allnutt, Cain, Owens, & Muller, 2005).

In a 2001 study of 23,000 prisoners in 12 countries, prisoners were found to have a two to four times higher rate of major depression and psychotic illnesses and a ten times higher rate of antisocial personality disorder than the general populace (Fazel & Danesh, 2002). Suicide rates in prisons are significant, often the most common cause of death (Fazel & Baillargeon, 2011; World Health Organisation & International Association for Suicide Prevention, 2007). The decrease of general societal mental health services is considered to play a large part in this phenomenon (Birmingham, 1999; Fazel & Baillargeon, 2011; Jordan, 2011; Ogloff, 2002; Butler et al., 2005).

Prisons tend to develop, or exacerbate, mental health problems in their residents, and many reoffend on their release, to once again re-enter the prison system (Birmingham, 1999; Butler et al., 2005; Fazel & Baillargeon, 2011; Ogloff, 2002). The psychological impact of institutionalisation, especially on admission, is under-acknowledged, with little done to address the effects or potential long term damage, for inmates or their families (Fazel & Danesh, 2002; Haney, 2003).

Although mental health in prisons is still considered an under-recognised issue, there are increasing attempts to address this spiralling problem. The primary suggestions within the literature focus on staffing and policy changes, level of assessment, placement and care changes and facility and activity changes (Fraser et al., 2009; Jordan, 2011; Picken, 2012; World Health Organisation & International Association for Suicide Prevention, 2007; Wright et al., 2014). There are isolated reports of prisons which have introduced gardening, animal husbandry and community based programmes that have been successful in aiding the less severe forms of mental illness, but there is little in the research literature on the physical form of prisons themselves. Yet there is little doubt a
prisoner’s physical environment plays a highly influential role on the prisoner’s health and well-being and thus the ability to ‘rehabilitate’ towards progressive life choices. The potential to utilise this physical design influence to address mental health problems such as stress and depression has not received much recognition and is the focus of this paper. The question that is addressed is, can Fromm’s perspective on biophilia be applied to the design of prisons and assist in improving mental health in prisons?

Biophilic design and biophilic urbanism has moved from academic and professional literature to being a new social movement in the design professions (Soderlund, 2016). The purpose of this paper is to discuss the potential of biophilic design to reduce stress and improve mental health in prisons. It is pertinent to delve into the origins of the term biophilia to begin the journey of understanding the potential of this approach as it was on this journey that the author discovered the pioneering work of Eric Fromm - a giant in the human psychology arena (See Fromm, The Heart of Man, 1964; The Art of Loving, 1956; To Have or to Be?, 1976; Escape from Freedom, 1941) - but little known by those in biophilic design.

2. The theory of biophilia: Fromm and beyond

Biophilia is often seen as being a term invented by Nobel Prize winning biologist E. O. Wilson (Wilson, 1984) and others since (e.g. Kellert & Heerwagen, 2008). This group developed the concept of human’s having an innate need for nature from their evolutionary biology perspective and thus created the concept that nature needs to be built into everyday life in our cities. However biophilia, meaning love of life, was a term first brought to life by the psychoanalyst Erich Fromm in his exploration of the “essence of man”, that which defines us (Fromm, 1964). He saw that awareness of our ‘beingness’, our mortality, separates us from nature, instilling a deep anxiety and conflict. This is a contradiction inherent in human existence, the belonging to two conflicting worlds. Fromm suggests it is this frightening contradiction and the quest to seek a solution that defines humankind. This search reveals choices, which are reflected in humans’ inherent ability for good or evil.

Early human societal existence tended to regress back to our unevolved roots – to our animalistic beginnings of nature and violence, our archaic selves, where the fear of the anxiety of separation can disappear. This regressive path is not just in primitive religions but also found in pathological behaviour involving necrophilia and narcissism. These are tendencies that may be repressed in a collective culture by laws and religions, but interestingly, if the tendencies are supported and shared by many, then consensus gives them credence, reason and reality. This pathway of regression Fromm calls ‘the syndrome of decay’ (p. 114). The opposite direction, following the ‘syndrome of growth’, is where the anxiety of separation is faced and transcended, and replaced by our love of life, where there is a “full development of human forces” (p. 114). This is the progressive path of life. Fromm suggests that in the majority of
people there is mostly a blend of the two orientations. Fromm saw our cities as becoming more mechanistic, industrialised and commoditised, separating us further from nature and increasing our anxiety and even hate for life (p. 10). In his 1964 book he was expressing concern that, even when there are known extreme consequences, such as in war, there is a stronger societal drive to go to war than to oppose it, which represents the regressive path being the stronger force. The potential for a triggered eruption of mass violence will always be present as long as there is any part of our archaic, regressive impulses within. Not until it is fully replaced by our love of life will this potential for regressive behaviour go. At the same time it is possible for our love of life to be fully replaced by the traits of regression. In either situation, the choice of which path to go down will be lost. It is of high importance therefore to retain the choice for prison inmates of which path to take and it is highly preferable to not foster regressive tendencies.

Fromm considers there are three orientations along the progressive path – freedom and independence, love for neighbour and love of life or biophilia (p. 110). Within the biophilic realm is the inherent motivation to live and survive that, as suggested by Fromm and other biologists and philosophers such as Spinoza (Fromm 1964, p. 41), all living substance possesses. Other biophilic qualities include the tendency to integrate and unite, to construct rather than just retain, to adventure to the new than stay with the certainty of the past, to use love and reason rather than force and control. “The biophilous conscience is motivated by its attraction to life and joy; the moral effort consists in strengthening the life-loving side in oneself” (Fromm 1964, p. 43).

Fromm is not alone in his recognition of the relationship between environmental conditions and human psychology but he was certainly a pioneer in its modern conception. However the more recent conceptualising of the biophilic human being came in 1984 from sociobiologist Edward Wilson in his book ‘Biophilia’ (Wilson, 1984). Wilson utilised the term biophilia to describe his deep feelings of connection to nature during a period of exploration and immersion in the natural world. Wilson was able to provide an evolutionary biologist’s view of the biophilic connection to nature as something that humans have evolved to need. Wilson, with fellow biologist Kellert, hypothesised that our connection with nature is innate and that we are genetically programmed to respond to nature physiologically as well as psychologically (Kellert & Wilson, 1993). Our potential to have a love of life, to follow the progressive pathway, as outlined by Fromm, appears to also offer the potential to nurture health and well-being and all of this requires exposure and connection to the natural world in some form.

As Kellert suggests the inherent need to affiliate with nature fulfills aesthetic, intellectual, cognitive and spiritual cravings (Kellert, 1993, p. 20). By positing that it was genetically innate Wilson and Kellert took the term biophilia from Fromm’s inner psychological journey to a term extending into the contemporary biological. The two approaches of humanistic psychology and evolutionary biology have therefore
This blending of psychology and biology was hugely significant as by introducing questioning about biological (physiological) responses to nature, a base for scientific testing of the biophilia hypothesis was established.

3. Testing the theory: physiological and psychological responses

Research on psychological responses to nature is increasing with supporting physiological evidence through more sophisticated investigative technology also mounting. Positive responses are evident not only with direct exposure to nature, but also where the patterns of nature, such as fractal patterns, and the spaces of nature, such as refuge and prospect, are found (Appleton, 1976; Biederman & Vessel, 2006; Ryan, Browning, Clancy, Andrews & Kallianpurkar, 2014; Heerwagen & Gregory, 2008; Salingaros & Masden, 2008; Taylor, 2006; Tenngart Ivarsson & Hagerhall, 2008). Physiological and psychological studies support both Kaplan’s (Kaplan, 1995) Attention Restoration theory and Ulrich’s Stress Recovery theory (Ulrich et al., 1991). The former theory proposes that prolonged directed attention and fatigue results in aggressive and irritable behaviour and that exposure to nature assists recovery from this (Kaplan, 1995). In Ulrich’s studies he found both physiological testing and verbal survey results indicated that recovery from stress was faster in a natural setting than an urban one. The physiological results also suggested an involvement of the parasympathetic nervous system in this recovery (Ulrich et al., 1991).

Studies since have shown that exposure to nature reduces heart rate variability and pulse rates, decreases blood pressure, lowers cortisol and increases parasympathetic nervous system activity whilst decreasing sympathetic nervous system activity (Li et al., 2011; Matsunaga, Park, Kobayashi, & Miyazaki, 2011; Park, Tsumetsugu, Kasetani, Kagawa, & Miyazaki, 2010; Tyrväinen et al., 2014). These responses contribute to improved cognitive functioning, working memory and learning rates and can also be triggered by indoor pot plants or even viewing pictures of nature (Berman, Jonides, & Kaplan, 2008; Berto, 2005; Raanaas, Evensen, Rich, Sjøstrøm, & Patil, 2011). In 2014, research by Ikei, Komatsu, Song, Himoro and Miyazaki demonstrated the use of both physiological and psychological markers. The studyrevealed that by simply viewing roses, parasympathetic nervous system activity increases, indicating lower stress and a greater sense of wellbeing (Ikei et al., 2014). Exposure to nature could be a valid supplement to treating depression and other disorders, with improvements to mood and memory span (Berman et al., 2012; Tyrväinen et al., 2014).

Reductions in pain and anxiety coupled with greater positive feelings have been exhibited in hospital patients with views of nature or potted plants in their rooms (S.H. Park & Mattson, 2008; Ulrich, 1984). A study in Michigan revealed a 24% less frequency of health care visits for prison residents with views of nature (Moore, 1981). Increasing greenery in housing estates resulted in less violence and aggression, less crime and better interpersonal relationships (Kuo &
Sullivan, 2001). Studies by Guègan and Stefan observed that short immersions in nature elicited a more positive mood and a greater desire to help others (Guéguen & Stefan, 2014).

It is not just direct exposure to the greenery of nature that has positive human responses. Researchers are discovering that there are different human responses to different natural forms and patterns. Prime amongst these are fractal patterns which studies reveal relax and de-stress people (Tenngart Ivarsson & Hagerhall, 2008; Beiderman and Vessel, 2006; Taylor, 2006; Ode, Hagerhall & Sang, 2010).

From the research already reviewed a list of socio-psychological benefits of exposure to nature and the patterns of nature can be compiled:

**Improved mental health:** (Ulrich, 1979; Ulrich et al., 1991; Berman et al., 2012; Tyrväinen et al., 2014).

**Reduced stress:** (Li et al., 2011; Berman et al., 2012; Matsunaga et al., 2011; Park et al., 2010; Tyrväinen et al., 2014; Berman et al., 2008; Ikei et al., 2014; Hagerhall et al., 2012; Taylor, 2006).

**Attention restoration:** (Kaplan, 1995; Berto, 2005; Tenngart Ivarsson & Hagerhall, 2008; Raanaas, 2011).

**Increased wellbeing:** (Li et al., 2011; Berman et al., 2012; Tyrväinen et al., 2014; Berman et al., 2008; Ikei et al., 2014; Hagerhall et al., 2012).

**Decreased violence and crime:** (Kuo & Sullivan, 2001).

**Faster healing rates in hospitals:** (Ulrich, 1984; Park & Mattson, 2008; Moore, 1981).

**Greater altruistic behaviour:** (Guèguen & Stefan, 2014).

The ability of architectural design to influence individuals’ physiological and psychological states is an extension of the biophilic connection to nature and the manifestation of Fromm’s theory of biophilia. Salingaros and Masden suggest that “environments devoid of neurologically nourishing information mimic signs of human pathology. Drab minimalist surfaces reproduce symptoms of strokes and macular degeneration, for example” (Salingaros & Masden, 2008, p. 69). Environments that are devoid of any representation of nature can not only make us psychologically unwell and regressive in our behaviour but we can also display physical symptoms and responses. A recent study which examined human responses to design stimuli, concluded that the primal flight or fight response is increased when individuals are exposed to hard edged architecture rather than curving contours (Nanda et al., 2013). They also suggested that this response is heightened when a person is already in a stressful environment such as a hospital (Nanda et al., 2013). This would also include the prison environment. Reductions in depression, stress and aggression, coupled with increased sociability, empathy and connection to living things, are characteristics and outcomes that prison administrators’ value and which aid reductions in recidivism (Nadkarni & Pacholke, 2013). They are qualities that
reflect a shift from regressive tendencies to a progressive pathway.

The reason it is important to now take the biophilic design approach into prisons is that the new professional approaches to biophilia are going beyond the individual psychological insights about prisoners and their plight, but take us into how the overall design and management of every aspect of prison life can be reviewed from the perspective of whether an innate connection to nature is being fostered or denied.

4. Principles of biophilic design

Expression of biophilia through biophilic design in architecture has occurred throughout history, not always consciously, or even acknowledged, conveying a subjectiveness which testifies to its inherent quality in humans. Nature can be mimicked by using the patterning, forms, materials, symbols and spaces which represent nature and evoke similar responses. Christopher Alexander recognised this in his seminal book “Pattern Language”, though not using the term biophilia, he expressed similar insights:

“Many of the patterns here are archetypal – so deep, so deeply rooted in the nature of things, that it seems likely that they will be a part of human nature, and human action, as much in 500 years as they are today “ (Alexander, 1977).

As with biophilic design theory, Alexander believed that the pattern language of the nature of things in the environment “can make people feel alive and human” (Alexander, 1977). When we cannot surround ourselves with nature, architecture and landscapes that contain some archetypal natural elements have found expression in our urban design.

Emerging in the literature on biophilic design is a growing list of these patterns and spaces considered to stimulate our innate biological responses. Although most designers are unaware of their linkage to Fromm’s theories the general acceptance of a psychological link to nature has its origins in Fromm’s work. Thus there are design practitioners who build detailed principles of what Fromm was attempting to explain in theory. In Table 1 the key design elements of biophilic architecture are summarized.
Table 1: Patterns of Biophilic Design

<td>one degree of separation away from true nature; patterns and materials that evoke nature.</td>
<td>the way humans respond psychologically and physiologically to different spatial configurations.</td>
</tr>
</tbody>
</table>

1. Visual connection with nature – plants inside and out, green roofs and living walls, water, nature artwork
2. Non-visual connection with nature – sun patches, textured materials, bird sounds, weather, nature scents
3. Non-rhythmic sensory stimuli – clouds, shadows, nature sounds, water reflections
4. Access to thermal and airflow variability – shade, radiant heat, seasonal vegetation
5. Presence of water – rivers, fountains, water walls, ponds, daylighted streams
6. Dynamic and diffuse light – light from different angles, ambient diffuse lighting, circadian lighting
7. Connection with natural systems – seasonal patterning, wildlife habitats, diurnal patterns
8. Biomorphic forms and patterns – organic building forms, structural systems (savannah effect),
9. Material connection with nature – wood, earth and stone construction, natural colours,
10. Complexity and order – fractal patterns, sky lines, plant selection and variety, material textures and colours
11. Prospect – views, balconies, 6 m and above focal lengths, open floor plans
12. Refuge – protected spaces, overhead canopies or lowered ceilings, places providing concealment
13. Mystery – winding paths, obscured features, flowing forms
14. Risk/Peril – floor to ceiling windows, water walks, high walk ways

(Adapted from Ryan et al., 2014)
Not all of these are possible or practical to be implemented within economic, safety and security constraints of prison design, but there is scope to incorporate biophilic design to improve prisoners’ sense of well-being, mental health and behaviour.

5. Biophilic design in prisons

Many of the conditions Fromm suggested for nourishment of biophilic tendencies are absent in our prisons and indeed would not be appropriate. It is probable that prison residents did not experience biophilic, or progressive, circumstances prior to incarceration. It is highly likely that environments that foster the necrophilic traits were the stronger influence. These could be childhood experiences and parental attitudes or general societal conditions. Fromm discusses the evolution of our industrialised, mechanically focussed societies and the psychological impact: “…intellectualisation, quantification, abstractification, bureaucratisation and reification….are not the principles of life but those of mechanics. People living in such a system become indifferent to life and even attracted to death” (Fromm 1964, p. 54). This mechanistic disconnect from nature has been portrayed in the design of our cities, architected by desire to overcome and separate from nature. The sterile blankness perpetuates a further disconnect, with abstract urban planning forgetting the intuitive more humanistic designs of our history. Our cities have become places where people are encouraged to consume and to commoditise, and where many of our urban spaces are constructed with design by modernist fashions and economics rather than design by health, well-being and a love of life. When the abstract, regressive human is nourished, anxiety and stress can be nurtured. Many urban prison designs are an extension of this kind of urban design with the potential to reinforce narcissitic, mechanistic and necrophilic tendencies that may already have been established within the prison residents’ psyche. Fromm suggests that prolonged imprisonment may break a person’s psychic system, allowing the archaic tendencies to surge up (Fromm 1964, p. 117). Salingaros and Masden propose that “we will instinctively react in a negative manner to a built environment that is neurologically non-nourishing or actually causes physical anxiety and distress” (Salingaros & Masden , 2008, p. 68). An individual’s surroundings are highly influential on their psychological and physiological being with the potential to reinforce either the progressive or regressive pathway (Burns, 2005; Nanda, Pati, Ghamari, & Bajema, 2013; Nesse & Williams, 1995).

The prison cellblock and associated buildings are built with security and function as the criteria, creating an environment that forces the disconnect from life processes and reinforces the regressive pathway of isolation and narcissism. Historically our prisons are designed to be effective in holding prisoners captive in a punishing manner, depriving them of comforts and reinforcing the fact that they have committed an offence. Prison designs tend to be bleak, sterile and barren, with incarceration within such a setting seen as the punishment (Lopez, 2014). Deprivation of freedom is extended by deprivation of sensory stimulus and connection to place. There is little opportunity to take Fromm’s progressive path, to nurture love, including the biophilic love of life. Ironically, with the majority of offenders likely to have stronger
regressive tendencies, they are more in need of opportunity to foster qualities from the progressive path of life, rather than strengthening of the regressive path.

Utilising biophilic design features such as fractal patterning, prospect and refuge and direct greenery to trigger biophilic responses gives support to the possibility of strengthening the innate qualities of individuals that can aid the progressive journey of life as outlined by Fromm. Forward thinkers are now beginning to examine prevailing prison design, which reflects punishment by incarceration, and to recognise the potential to change and work towards rehabilitation of prisoners through biophilic design.

6. Conclusions

From researching the current literature it appears that, while a small number of prison farms and gardening programmes have been successfully implemented globally, the incorporation of biophilic initiatives within prison design is a new and emerging field with few researched trials on the benefits of applying biophilic principles. Biophilic design has grown from a general need to link people in cities with nature in their everyday life. This approach that has been derived from evolutionary biology overlaps precisely with the insights of Erich Fromm in humanistic psychology. Fromm’s theories of the regressive and progressive pathways of life and the influences that support either pathway, suggest the importance of connecting individuals with biophilia through biophilic design. Fostering a biophilic love of life is an essential component of steering prison inmates from further regression into a ‘life of decay’ to a life where altruism and a sense of belonging are the greater forces. There is opportunity and potential to improve mental health and well-being for prison residents which can lead to a reduction in recidivism. Assisting prisoner rehabilitation and providing an opportunity to retain or increase their level of humanity would ultimately benefit all of society. The ability of nature and the architectural patterns of nature to trigger positive psychological and physiological forces are a valid and valuable tool. Research has provided the generic evidence and technology has provided the ability, to not only implement biophilic initiatives, but to also monitor outcomes. It is time to now show it in prisons. Detailed demonstration projects are needed that can establish biophilic designs in prisons and collect data on the physiological and psychological outcomes of people in highly stressed environments.

Abstract

Our senses is stimulated by amount of information received from daily environments, and psychological and physical health is influenced by these scenes. According to past research, we know that natural landscapes is more preferred than urban landscapes, furthermore, connecting to natural environments could reduce mental stress, improve our attention restoration ability, and release muscle tension. Today, with the technique of functional magnetic resonance imaging (fMRI), we are able to examine the impact of different environmental traits on human health focusing on the nerve system function specifically. We are interested in examining the brain reaction when doing the landscape design with fMRI technique as well.

In order to examine the characteristics of natural landscapes which have beneficial effects to human health, preference, attention restoration and brain activation, we categorized landscapes by four distinctive environmental traits. First is habitat types, for example urban areas, natural areas, forests, waterscapes; second is the configuration of the elements in landscapes, openness, cover ratio of green areas; third is the texture of the landscapes, spatial frequency; at last is the characteristics of attention restoration. Preliminary results of fMRI images indicated that brain activated differently when people see different landscape categories and restorative environmental characteristics. The result showed that there are more activated brain areas when viewing urban landscapes and less activated areas while viewing natural landscapes. Fascination environments is correlated to high cognition brain regions. Moreover, being away, extent and compatibility environments activated occipital visual area. Waterscape is the most preferred landscape type, followed by forest, mountain landscapes, and the least preferred type is urban landscapes.

The other critical gap in the current knowledge that we would like to fill is how the brain works in the process of landscape design, we try to clarify the details of the “black box” of the landscape designing process. On the one hand, we tried to examine the related brain area while doing design. On the other hand, we are trying to understand the activation pathway of brain areas.
Biophilic Cities

Keywords: functional magnetic resonance imaging; brain activity; landscape benefits; landscape design

1. Introduction

Living landscapes that people view and pass by daily have significant effects on human health. Research has shown that natural landscapes could restore voluntary attention (Berto, 2005; Berto et al., 2010) and positively influence one’s emotional experience (Van den Berg, Koole, & Van der Wulp, 2003). Other research proved that people had higher preference toward green environments, and when people viewed preferred scenes, they achieved better attention restorative ability (Kaplan, 2001; Van den Berg et al., 2003; Purcell, Peron, & Berto, 2001; Kaplan & Kaplan, 1989). Natural landscapes not only had an effect on psychological health but also physical health. Previous research has proven that one’s heart rate declined when watching videos of natural landscapes, while the heart rate remained steady when watching videos of urban landscapes (Ulrich et al., 1991). Another research suggested that when resting in a room with green views, the diastolic pressure reduced; however, when resting in a room without windows, the diastolic pressure increased (Hartig, Evans, Jamner, Davis, & Gärling, 2003). Therefore, previous studies have stated the positive influence of natural landscapes on humans in either subjective or objective manners.

In recent years, the technique of functional magnetic resonance imaging (fMRI) has matured, which has enabled scientists to examine the influence of natural environments from a psychophysiological perspective, and it is a relatively precise method to discover the interaction between environments and human health, particularly brain activity. The fMRI technique can distinguish the subtle differences in people’s reactions to different scenes of varying compositions and meanings by measuring brain activity (Blondin & Lepage, 2005). While viewing photographs of familiar and unfamiliar locations, people responded more strongly to images of familiar locations in scene-selective regions of the Parahippocampal Place Area, the Retrosplenial Cortex, and the Transverse Occipital Sulcus (Epstein, Higgins, Jablonski, & Feiler, 2007). Walther, Caddigan, Fei-Fei, and Beck (2009) found that the primary Visual Cortex, the Parahippocampal Place Area, the Retrosplenial Cortex, and the Lateral Occipital Complex all contain information that distinguishes among natural scene categories (forests vs. mountains vs. beaches).

Understanding brain activity while watching landscapes introduced the question of whether the brain areas for perceiving landscapes are the same as the brain areas for imagining the design of landscapes. In the landscape architecture field, there is no precedent measuring brain activity while performing landscape design. Landscape design is a problem-solving process containing a series of steps, including problem scoping, preliminary solutions, refinement, and detailing. In the step of generating the preliminary solutions, methods such as associating and recalling past experiences are used to propose the various attainable programs. These initial generated ideas are ambiguous; later, a more specific and concrete resolution is generated after the refinement process. The former process is called divergent thinking,
providing a variety of possibilities, while the refinement process is called convergent thinking (Guilford, 1956). Goel (2014) hypothesized the correlative brain area of the cognitive process, with the right Prefrontal Cortex involved in divergent thinking and the left Prefrontal Cortex involved in convergent thinking. Dietrich (2004) also proposed that the Frontal Lobe dominates the functions of working memory, sustained attention, and flexibility, which are essential for creativity; furthermore, the Prefrontal Cortex was thought to be critical when contemplating solutions and performing divergent thinking (Dietrich, 2004; Dietrich & Kanso, 2010).

The present paper includes a series of studies to comprehend how environments affect people from a neuroscience perspective and uses an fMRI instrument to examine how landscape scenes influence human health on a deeper level. This paper has two purposes: 1) to evaluate the beneficial health impacts of different landscape types and characteristics regarding brain activity and mental reaction; 2) to evaluate brain activity while performing landscape design. There are three studies supporting the first purpose, while one study supports the second purpose. Study 1 compared brain activities and the perceived restoration effect of viewing natural landscape types, including mountains, forests, and water, and urban landscape types (Tang et al., 2017). Study 2 compared the different brain activities and emotional reactions of viewing urban landscapes, natural green landscapes, and natural water landscapes, and it further examined the effects of these landscapes’ characteristics (Chang & Hsu, 2017). Study 3 compared brain activities, attention restoration, and preference of viewing coastal, forest, and urban landscapes, as well as the visual image characteristics of these landscape types (Chang & Lee, 2017). Study 4 interpreted the activated brain areas while performing landscape design in an fMRI experiment (Tsai & Chang, 2015).

2. Methods

This paper separated the research into two parts: the first part examines the activated brain areas of landscape perception, while the second part examines the activated brain areas of the landscape design process. The first part’s three studies collected photographs from free online photography galleries and categorized the photos into urban and natural landscapes; and examined the beneficial effects of landscapes on human health through psychological questionnaires and an fMRI instrument. The last study used design tasks to examine the brain activity when performing landscape design.

2.1 Participation restriction of fMRI experiments

Participants had to be over 20 years old, with normal mental condition, normal vision and hearing abilities, and no color blindness. Excluded participants included those with tattoos, permanent and temporary metal
devices inside their bodies, brain damage, cardiovascular disease, depression, post-traumatic stress disorder, and fears or phobias toward closed and narrow spaces. Pregnant women were also excluded.

2.2 fMRI experiment procedure

A Siemens Prisma 3T MRI Scanner in the Imaging Center for Integrated Body, Mind and Culture Research at the National Taiwan University was used. The fMRI experiments proceeded as follows. Before going into the fMRI room, participants were instructed about the experiment, signed a consent form, confirmed again that their health condition fit within the restrictions, and removed all metal materials, including watches, glasses, etc., and cosmetics as well. With assistance from the Imaging Center’s operators, participants entered the fMRI room and lay down on the fMRI instrument. The operators stabilized and adjusted the equipment to fit the participants’ head and to prevent movement. Participants wore goggles for showing the stimuli, and buttons were placed by their hands and a safety ball was placed on their body; whenever participants did not feel well during the scanning, they could squeeze the ball, and the operator would stop the fMRI machine immediately. The experiment started with an anatomical image scanning, which acquired 45 images of both the vertical and horizontal sections of the brain structure. Then, the functional image scanning started. During the scan, participants watched landscape images and accomplished tasks.

2.3 Data processing

To avoid errors due to head movement during the scanning period, collected data was processed through a realignment step. In this process, the translation and rotation of the x, y, and z axes would be adjusted, and those data that exceeded the threshold were excluded.

3. fMRI studies of perceiving landscapes

The research method and the results of the first three studies will be explained individually in this section.

3.1 Study 1: Landscape types and brain activities

The purpose of Tang et al (2017) was to compare brain activities and the perceived restoration effect of viewing different landscape types. For landscape variables in study 1, landscape types were categorized into mountain, forest, water, and urban landscapes.

3.1.1 Study 1: Research methods

There were three chosen photographs for each landscape type. The baseline images for all landscape types were created by shuffling the three photographs into one image using the Pixuffle software.

For its psychological variable, study 1 examined attention restoration with the short version of Berto’s (2005) Perceived Restorativeness Scale (PRS). Following Kaplan and Kaplan’s (1989) concept of attention restoration theory, the PRS included four aspects: being away, fascination, extent and compatibility.
For fMRI data collection, the experimental design was a block design. There were four total runs during the experiment, and each run showed one kind of landscape type. The experiment began with some descriptions showing the details of the experiment, and then a cross symbol appeared, upon which the participants were to focus their attention. Next, the four runs appeared one by one. The first run was the urban landscape, and then the three natural landscapes of mountains, forests, and water would appear randomly.

3.1.2 Study 1: Results

There were 142 total valid samples in the psychological experiment. The results showed that water and mountain landscapes had better perceived restorative quality than forest landscapes and that urban landscapes had the least perceived restorative quality.

There were 13 valid samples in the fMRI experiment. Regarding the brain areas that activated while viewing the photographs of the four landscapes, the right and left Cuneus were activated while viewing urban landscapes as opposed to mountain landscapes. The right and left Cuneus, right Cingulate Gyrus, and left Precuneus were activated while viewing urban landscapes as opposed to water landscapes.

3.2 Study 2: Landscape types, emotions, and brain activities

Chang and Hsu (2017) compared the different brain activities and emotional reactions to viewing urban landscapes, natural green landscapes, and natural water landscapes. To examine the detailed differences in the characteristics of these landscape types, the study depicted one characteristic for each landscape.

3.2.1 Study 2: Research methods

For the landscape stimuli, there were four types of landscapes. In the urban landscape group, the study examined street landscapes with and without trees; in the natural green landscape group, the study examined the openness of the landscape; in the natural water landscape group, the study examined dynamic and static waterscapes. There were six landscape stimuli categories total.

For the psychological variable, Chang and Hsu (2017) examined emotion with the scale proposed by Russell and Pratt (1980), a two-dimensional bipolar scale with separate spaces for arousal, sleepiness, pleasant, and unpleasant on each one of the poles, and the dimensions were measured with a nine-point Likert scale.

For fMRI data collection, there were five total runs in one experiment, containing six trials in each run, and three photographs of every landscape type were shown once randomly in each trial. In the end of each trial, the emotion scale displayed, and participants answered the scale by pressing buttons on the machine. There was a one-minute break between each run. In the entire experiment, participants needed to evaluate the emotion of one landscape stimulus category five times and viewed fifteen photographs of one landscape stimulus in total.

3.2.2 Study 2: Results
There were 34 valid samples in study 2. Participants’ emotions toward these three landscape types were statistically significantly different. For the pleasant and unpleasant emotions, participants felt natural water landscapes were the most pleasant landscape, natural green landscapes were second, and urban landscapes were the least pleasant. For the arousal and sleepiness emotions, participants felt more aroused while watching the urban landscape than the natural green landscape. Next, in comparing the results of emotion when examining the characteristics of landscapes, the results indicated that participants felt more aroused while viewing dynamic waterscapes than static waterscapes, felt more pleasant while viewing open green landscapes, and felt more aroused while viewing closed natural green landscapes.

Before analyzing the results of brain activation, data was excluded for those participants whose head movement exceeded the threshold, meaning the translation shifted over 3.5mm and the rotation rotated over ±1 degree.

There were 24 valid samples for the fMRI experiment. The results showed the participants’ brains were more activated while watching urban landscapes than natural green landscapes and natural water landscapes. Contrasted with natural green landscapes, the right Fusiform Gyrus, the left Middle Occipital Gyrus, the right Lingual Gyrus, the left Parahippocampal Gyrus, and the right and left Posterior Cingulate were activated while watching urban landscapes. Contrasted with natural water landscapes, the left Cuneus and the right Middle Occipital Gyrus were activated while watching urban landscapes. Regarding the influence of the landscapes’ more detailed characteristics on brain activity, only the left Lingual Gyrus activated while viewing closed natural green landscapes as opposed to open natural green landscapes.

3.3 Study 3: Landscape types, attention restoration, preference, and brain activities

Chang and Lee (2017) aimed to compare brain activities, attention restoration, and preference for viewing coastal, forest, and urban landscapes. Comparing the differences of the landscapes with different spatial frequencies was a relatively new manner of analyzing image characteristic.

3.3.1 Study 3: Research methods

Chang and Lee (2017) categorized natural landscapes into coastal and forest landscapes, and they separated the photographs of each landscape type into two groups, the high and the low groups, by analyzing the spatial frequency.

For the psychological variable, Chang and Lee (2017) examined preference with a five-point Likert scale and attention restoration using the Sustain Attention to Response Test (SART), which is a widely used attention test in the landscape research field. The SART results would provide accuracy rates and response times.

For fMRI data collection, there were six runs in the experiment. When the functional image scanning started, the experiment began with a pre-SART that lasted for 180
seconds, in which participants watched six photographs of one kind of landscape stimulus, and then the participants performed a post-SART that lasted for 180 seconds, and finally the photograph preferences were evaluated. This was the procedure for one run. Each run showed one kind of landscape stimulus, and the landscape stimulus order was random.

3.3.2 Study 3: Results

There were 34 total participants. After excluding participants whose SART accuracy rate was under 75%, there were 23 valid samples. The coastal landscape was the most preferred landscape, the forest landscape was second, and the urban landscape was the least preferred type; the spatial frequency had no significant influence on preference. Landscape types had no significant influence on the SART accuracy rate and response time, nor did the spatial frequency variable. In comparing the effect of spatial frequency on preference and attention restoration in the same landscape type, the findings proved that in the urban landscape, photographs with high frequency were more preferred than those with low spatial frequency; in the forest landscape type, participants who watched photographs with a high frequency had less response time in SART.

Comparing the fMRI results among landscape types found that subtracting the brain areas activated by urban landscapes from the brain areas activated by coastal landscapes determined the Parahippocampal Gyrus and the Frontal Lobe Sub-Gyrus were the contrasting brain areas. Contrasted with watching forest landscape images, the Middle Occipital Gyrus, the Occipital Lobe Sub-Gyrus, the Temporal Lobe Sub-Gyrus, and the Cerebellum Culmen were activated while watching urban landscapes. Lastly, contrasted with coastal landscape images, the Lingual Gyrus was activated while watching forest landscapes.

Comparing the brain activity differences between pre-SART and post-SART under the influence of spatial frequency, the results showed that the activated brain areas during post-SART after watching the low frequency landscape photographs were Lingual Gyrus and Cuneus. The activated brain area in the same situation after watching high-frequency landscape photographs was the Lingual Gyrus.

4. Discussion about brain activity while perceiving landscapes

Regarding the psychological response of different landscape types, study 2 indicated that natural water landscape photographs were the most pleasant landscape. Study 3 indicated that water landscapes were the most preferred landscape type, although the results did not support that natural landscapes can provide better attention restorative ability. Study 1’s results showed that water and mountain landscapes provided the best attention restorative quality among the four landscape types. Regarding preference and attention restoration, the results are in line with the previous research; White, Smith,
Humphries, Snelling, and Depledge (2010) suggested that water landscapes were the most preferred landscape type.

In terms of fMRI results, in general, when watching urban landscape photographs, participants needed to pay more attention, and the brain was processing and engaging in numerous matters. According to these three studies, brain areas such as the Middle Occipital Gyrus, the Lingual Gyrus, the Fusiform Gyrus, the Cuneus, the Precuneus, the Posterior Cingulate, the Parahippocampal Gyrus, the Occipital Lobe Sub-Gyrus, the Temporal Lobe Sub-Gyrus, and the Cerebellum Culmen were the activated brain areas when contrasting the results of urban landscapes with natural landscapes.

Some portion of these brain areas manage the function of visual image processing; for example, the Middle Occipital Gyrus, the Occipital Lobe Sub-Gyrus, and the Fusiform Gyrus process color information. The Cuneus processes the visual and spatial environment, while the Parahippocampal Gyrus processes complicated images. The Lingual Gyrus is where the brain processes vision.

Other brain areas are related to cognitive, attention, language, and memory, which refer to higher levels of information processing and cognitive activity. The Occipital Lobe Sub-Gyrus is related to emotion and attention. The Cuneus is the area in charge of attention, and the function of the Precuneus is cognitive activity, including episodic memory and consciousness. The Posterior Cingulate also functions for episodic memory and controls emotion and memory. The Parahippocampal Gyrus functions for coding and extracting memory. The Temporal Lobe Sub-Gyrus performs perception, memory extraction, and emotional reactions. Some areas, such as the Fusiform Gyrus and Lingual Gyrus, are associated with language, words, and character recognition.

According to the studies’ results, certain brain areas related to a higher level of cognitive activity were more activated when watching urban landscapes. This may be because information from natural landscapes is effortless to process; hence, there were more activated reactions in the brain while watching urban landscapes, and this consumed more cognitive functions and attention. Besides the composition and textures of the urban photographs, the studies also provided images with high variations, and the elements in the urban landscapes contained extensive visual information, which would lead to more activated brain areas related to a high level of cognition.

5. fMRI study of landscape design
5.1 Study 4: Brain activities during design process

The object of study 4 was to locate the brain areas related to the landscape design process and to separate the landscape design into two portions: the preliminary solutions and the process from refinement to detailing.

5.1.1 Study 4: Research methods
To measure the activated brain areas for performing landscape design, study 4 customized an acrylic table for participants to draw inside the fMRI machine. There were two tasks with two kinds of materials: landscape plans (Task A) and geometrical patterns (Task B). There were two parts in Tasks A and B. Task A1 was to read the landscape plans and imagine being inside the landscapes, the reading condition, and Task A2 was to copy those landscape plans, the copying condition. Task B1 was to think and develop a landscape diagram with some given geometrical patterns, the brainstorming condition, and Task B2 was the creative drawing condition of drawing the developed landscapes. The entire experiment was composed of two runs, with two A tasks and two B tasks in each run; to counterbalance, there were two kinds of texts with the order of ABAB BABA and BABA ABAB.

5.1.2 Study 4: Results

In the preliminary solutions, which was the brainstorming condition compared to the reading condition, the activated brain area was the Lateral Ventricle, and this area mainly functions as the buffer for strikes, the circulation of nutrition, and waste elimination. However, this brain area is not related to cognitive function. The outcome of examining the activated brain area for the refinement and detailing process, which was the creative drawing condition compared to the copying condition, showed the activated brain area was the left Middle Frontal Gyrus.

6. Discussion about brain activity when performing landscape design

The Middle Frontal Gyrus belonging to the Dorsolateral Prefrontal Cortex controls working memory and cognition. The process of drawing one of the imagined plans in the mind can be seen as refinement and detailing, and the result was in line with Goel’s (2014) hypothesis.

7. Conclusion

The first three studies showed the relationships between landscape types and brain areas, and the results showed the brain would be busier and more active while watching urban landscape photographs than natural landscape photographs; the results also explained that different landscape types might cause different brain areas to activate. Over half the population lives in urban areas with manifold landscape composition; thus, understanding the relationship between landscapes and brain activity may support residents in getting the exact desired function when in contact with urban landscapes.

Exploring the relationships between landscapes, landscape design, and brain activity is a relatively new perspective in the landscape architecture research field. The brain’s neuron network is complicated and interconnected; therefore, one experiment may not be able to examine all the brain areas related to the stimuli, and the results cannot assure other brain areas are not correlated to the stimuli. There are a variety...
Biophilic Cities

of characteristics inside landscapes, and even the same landscape type may activate different brain areas because of their subtle characteristics. Hence, future research should continue exploring the detailed and specific characteristics in landscapes. Furthermore, comparing the correlation between creative performance and brain activation would also be worth investigating.

Acknowledgements
The four studies were supported by Ministry of Science and Technology, and the experiments were done at the Imaging Center for Integrated Body, Mind and Culture Research, National Taiwan University.

Abstract

‘Learning landscape’ is an innovative approach incorporated in the current global education arena to facilitate optimal learning in students with the use of their need to affiliate with nature; biophilia. Being a concept which has not yet being introduced to Sri Lankan context, the present investigation focuses on the potential impacts of combining landscape in the design of preschools on the development of cognitive skills in local children. The factors which contribute in creating effective learning landscapes namely; flexibility, playfulness, safety, graduate challenges, and scale (Moore, 2013) were tested with reference to three preschools located in Kandy having incorporated the landscape in the learning environment in three levels; high (HLE), moderate (MLE) and low respectively (LLE). 20 students per each case were examined adopting a mixed method including behavioural mapping, interviews, close questioners and Marmara cognitive development scale.

The study established a direct association between the impact of landscape on learning and development of cognitive skills in pre-schoolers. The children exposed to HLE were found to have the highest ranking on Marmara cognitive scale while the children of LLE obtained the lowest ranking. As revealed via the behavioural maps, the highest involvement of the children was recorded in HLE which also witnessed the presence of the highest number of favourable responses regarding learning landscape characteristics; flexibility (95%), playfulness (95%), safety (90%), graduate challenges (90%), and scale (95%) and vice versa in terms of LLE; 15%, 10%, 5%, 15% and 5% respectively.

Based on the findings, introducing the concept of learning landscapes in designing future primary learning environments in Sri Lanka is highly recommend.

Key words: learning landscapes, Child’s Cognitive development, Preschool students
1. Introduction

‘Biophilia’ is explained as the inherent human need to affiliate with nature (Wilson 1984, Kellert and Wilson 1993). This need is found to be influential on the physical and mental well-being of a human being. Biophilic design strengthens and enforces ones affiliation with nature, which leads to a more contented and well balanced person. However, this need is not thoughtfully considered in most of the architectural and landscape architectural design interventions.

‘Learning landscape’ is an innovative and effective approach incorporated in the current global education arena which is to facilitate optimal learning in students with the use of their need to affiliate with nature. However this concept is yet to be introduced in the Sri Lankan context.

1.1. Problem statement

This investigation looks in to the potential impacts of combining landscape in the design of preschools on the development of cognitive skills in local pre-schoolers.

1.2. Objectives

- Exploring the potential of using ‘learning landscapes’ in improving learning environments.
- Identifying design strategies in introducing the concept of learning landscapes in designing future primary learning environments in Sri Lanka.

1.3. Methodology

Using a mixed method, several research tools were adopted for the investigation namely; behavioural mapping, interviews, close questioners and Marmara cognitive development scale. The observations were done to examine the level of involvement of children in the given learning environment with reference to time and activities with nature. (See appendix 1 for a flow chart showing the methodology)

1.4. Case study selection criteria

The selected area for the case study was Kandy, a city having a unique topographical character, located in the central province of Sri Lanka (7.2906° N, 80.6337° E). Three preschools located in Kandy were selected as cases namely; First Friends Preschool, Glenfall preschool and Sokanji Preschool based on the level to which landscape has been incorporated with the learning environment. Selected students belong to the same age category, social cultural, background, abilities, qualities, the learning methods, the climatic and topographical characteristics in each and every way. The parameter that vary from one pre-school to another was the level of involvement of the landscape.

1.5. Outcome

- Creating conducive spaces for the cognitive development of children though learning landscape characters; biophilic design
- Developing learning landscape designs which contribute in
maximizing the benefits from the spaces.

2. Learning landscape and preschool student’s cognitive skills.

2.1. Child and nature

Studies have proven that the natural environment supports to build children’s cognitive development physically and emotionally. Since nature functions as a restorative environment, studies on nature have proven its benefits on childhood mentality [2] (Gibson, 1979). As a holistic idea, a child’s interaction with the surrounding environment has found to help his/her growth. Connection, experience, and engagement with the nature have positive effects on the child’s cognitive, physical, social, emotional and spiritual development. Nature helps the child in instantly capturing diverse components in the society and learn new things quickly. Instead of indoor learning, the child gets the opportunity to learn a lot through outdoor environment. Thus, the nature of the surrounding, outdoor environment teaches the child to adapt himself depending on the context without much difficulty (Kellert, 1993).

2.2. Scope of learning landscape.

Learning landscapes is developed with the intention of supporting the child’s growth. They give much attention on physical, social, cognitive and emotional growth of the child. The concept of learning landscape defines the designing of an environment which supports the child’s growth by creating spaces, elements, visuals and links (Kellert, 1993).

2.3. Preschool student’s cognitive development

Children between three to five years of age are defined as preschool students. Children of this age are rapidly developing their physical, cognitive and psychological/social competence as they interact with their environment. [2] (Weave, 2000) Preschool student quickly grab what they experience from the surrounding nature. Thus, it is such and experience they come across or face freeing themselves from the fetters of the indoor areas. Therefore, the soul function of the concept of learning landscape is to support the growth of physical, social, cognitive and emotional skills through various factors in a way appealing to the child. (Kellert, 1993).

2.4. Theoretical framework of the study

There are many factors affecting human behavior in learning landscape designs. They help to develop children’s cognitive development by building up the foundation for children to interact with nature and society. The factors influencing the cognitive development of preschool students established by the previous studies are as below. (Kellert, 1993).

- Flexibility
- Playfulness
- Safety
- Graduated challenges
- Scale

2.4.1. Flexibility

Design space should be flexible for children without directing. If there is flexibility within
pre-school learning landscape, the child will engage in activities without any persuasion. It helps to develop preschool children’s cognitive skills. \( \text{(Kellert, 1993).} \)

2.4.2. Playfulness
Playfulness could be considered as a prominent factor within learning landscape. Colours, patterns and textures found in a learning landscape help him/her to gain a lot of new experiences. Therefore, it’s diversity will directly influence the cognitive development of the child. \( \text{(Kellert, 1993).} \)

2.4.3. Safety
Every human being has their own satisfaction through personal safety. Since a child is one who learns a lot through new experience, there should be a satisfaction within him/her that learning is not something troublesome. Child’s engagement in a task makes him/her involve in the problem-solving, memorizing or realizing. These will affect all cognitive factors. \( \text{(Kellert, 1993).} \)

2.4.4. Graduated challenges
This is one such important quality that could be found in a learning landscape. The mental development that takes place during the ear of pre-school will undoubtedly affect the child’s personality in future. Therefore, children will have their own self-esteem and confidence through ‘graduated challenges’.

2.4.5. Scale
Scale becomes an important and an effective factor of learning landscape as the child senses a lot through the scale. More often, preschool child shows a preference in gaining experiences symbolically. Therefore, the elements and their scales perceived by a child will directly have an effect on this symbolic experience of space. \( \text{(Kellert, 1993).} \)

2.5. Methodology of the study

As explained above, behavioral maps were produced defining the children’s activities and the places in which they were fond of spending time.

Children were randomly questioned in order to fill the questioner. When communicating with children, obtaining elaborate answers are not possible. As a remedy, ‘closed-ended questions’ were incorporated in the questionnaire design.

The Marmara Development Scale (Oktay and Bilgin-Aydin, 2002) was adopted to measure children’s cognitive skills in this investigation. For the purpose of the present study, only the Cognitive Development Subscale scores were used to measure children’s cognitive abilities. Teachers’ report was used to measure children’s cognitive skills.

3. Case studies and data presentation

3.1. Case studies

Three preschools located in Kandy area were selected based on the criteria mentioned above. A sample of normal, healthy 20 preschoolers (girls (n= 10) and boys (n=10), age; 4-5) were selected from each pre-school. These pre-schools were following the identical methods and techniques in teaching, learning and assessment. For instant all three was using AMI method and following their courses in English medium. The selected children were those who studied in the preschool for seven months.
3.2. Case study 01: First friend preschool

First Friends pre-school located in Niththawela, Kandy is special since children were involved in studies and activities mostly in the outdoor environment. Children were taken outside the classroom for engaging themselves in various outdoor activities. Further, they were given the chance to blend themselves with the nature by allowing them to play with sand, plants clay and water. They were given the opportunity to engage in a lot of activities not only in the classroom but also outside the classroom.

3.2.1. Photographic survey of first friend preschool.
See appendix 2 for a mood board showing photographic survey of first friend pre-school

3.2.2. Marmara scaling in first friend preschool
See appendix 3 for a polar graph showing Marmara scale in first friend pre-school.

3.2.3. Behavioral study on first friends preschool
See appendix 4 for a map shows behavioral study on first friend pre-school

3.2.4. Learning landscape Flexibility
See appendix 5 for a bar chart showing learning landscape flexibility in first friend pre-school.

3.2.5. Learning landscape playfulness
See appendix 6 for a bar chart showing learning landscape playfulness in first friend pre-school.

3.2.6. Learning landscape safety in first friend preschool
See appendix 7 for a bar chart showing learning landscape safety in first friend preschool.

3.2.7. Learning landscape graduated challenges in first friend preschool
See appendix 8 for a bar chart showing learning landscape graduated challenges in first friend pre-school.

3.2.8. Learning landscape scale in first friend preschool
See appendix 9 for a bar chart showing learning landscape scale in first friend pre-school.

3.3. Case study 2: Glenfal international preschool

This pre-school is located in Polgolla, Kandy, Sri Lanka. It has an outdoor landscape - apart from the classrooms - with sand pits and other play elements. However, children only get an opportunity to play during a specific time. There is a little space for children to run and play. Tranquillity and calmness of the environment cannot be seen in this location as it is located near the main road.

3.3.1. Photographic survey of Glenfal preschool.
See appendix 10 for a mood board showing photographic survey of Glenfal pre-school.

3.3.2. Marmara scaling in Glenfal preschool
See appendix 11 for a polar graph showing Marmara scale in Glenfal pre-school.
3.4. Case study 03: Sokanji pre-school

Sokanji pre-school is located in Kandy, near the main road. Children have a very limited space and therefore, there is no sufficient spacious area for them to mingle themselves with the outdoor landscape. Except for the classroom, there is no such space for children to play and do their activities. Therefore, they do their activities inside the classroom. At the same time, noises from vehicles is a major problem since it’s being located facing the main road. Although, there is a little space available, still there is a swing. Thus, the piece of land where the swing has been erected has no enough space to accommodate all children at one time.

3.4.1. Photographic survey of Sokanji preschool.

See appendix 12 for a mood board showing photographic survey of Sokanji pre-school.

3.4.2. Marmara scaling in Sokanji preschool

See appendix 13 for a polar graph showing Marmara scale in Sokanji pre-school.

4. Data analysis

4.1. Analysis according to the Marmara development scale

See appendix 14 for a polar graph showing comparison of Marmara development scale in each case study. According to the analysis, the highest growth of cognitive skills was shown by first friends pre-school whereas, Genfal International pre-school shows a medium growth whilst, growth of cognitive skill were depicted in a poor status or a low level in Sokanji pre-school. Thus, the reason for such result is the involvement of learning landscape being the independent variable of all cases studied. Therefore, the study provides evidence that the learning landscape has a direct impact on the growth and development of cognitive skills of pre-school children.

4.2. Analysis according to the behavioral map

(See appendix 15 for a graph showing comparison of pre-school child behavior in pre-school premises.) Children were allowed to be in the learning landscape from 9am – 10 am and 10 am – 11 am in First Friend pre-school. During the day, they engaged in different activities and learning activities whilst staying in the learning landscape. Thus, there are different spaces with in the learning landscape which help children gain experience through nature and develop cognitive skills. For instance, different types of spaces such as active spaces, gathering spaces, experimental spaces, individual spaces and ecological spaces could be seen. There is limited space in the learning landscape of Glenfal International pre-school. They were allowed to play in the learning landscape from 10.30 am – 11.30 am. Because of the space limitation, all the children do not play at one time, in the learning landscape. Some children do prefer to stay inside the classroom. This has only two types of spaces: gathering space and active play space. A child in Sokanji preschool rarely uses the outdoor landscape. They spend the entire day within the classroom and prefer playing and performing activities inside the classroom during the interval. This study of the behavioral map shows that children of First Friend pre-school spend a lot in leaning landscape. Further,
children of Glenfal International pre-school spend a limited time whilst children of Sokanji pre-school do not use the learning landscape at all.

4.3. Analysis according to cognitive skill development factors in learning landscapes

4.3.1. Flexibility
See appendix 16 for a bar chart showing comparison on flexibility factor in each pre-school.

4.3.2. Playfulness
See appendix 17 for a bar chart showing comparison on playfulness factor in each pre-school.

4.3.3. Safety
See appendix 18 for a bar chart showing comparison on safety factor in each pre-school.

4.3.4. Graduated challenges.
See appendix 19 for a bar chart showing comparison on graduated challenges factor in each pre-school.

4.3.5. Scale
See appendix 20 for a bar chart showing comparison on scale in each pre-school.

4.4. Summery
The behavioural maps analysis, enabled the study to identify that the level of the children’s involvement with the learning landscape at the respective pre-schools. Accordingly, the First Friends pre-school shows the highest number of learning landscape characteristics, followed respectively by Glenfal International pre-school and Sokanji pre-school.

According to the Marmara Development Scale, the highest cognitive skills was depicted by First Friend pre-school. Therefore, learning landscape factor has influenced the results taken through Marmara Development Scale.
The Behavioural map analysis shows that children’s involvement, learning landscape characters, and cognitive skills development is high at First Friends pre-school, while it is moderate at Glenfal International pre-school, and low at Sokanji pre-school. Hence, cognitive development is high in the pre-schools where there is an involvement of the learning landscape characters which supports biophilia. This shows that learning landscapes has a direct impact on the child’s cognitive skills development.
The literature review shows that factors affecting the cognitive development of the children are: flexibility, playfulness, safety, graduated challenges, and scale. These are high at First Friends pre-school and low at Sokanji pre-school. Glenfal International is relatively high in some areas while moderate and low in other areas.

5. Conclusion
This study investigated the factors of learning landscape and how the landscape impacts cognitive skills of preschool students. The five factors of; flexibility, playfulness, safety, graduated challenges and scale help in positively developing cognitive skills of a pre-schooler.
A learning landscape space has unique characteristics within it and the above factors facilitate the characters of its biophilic design. The study identifies these characters
as key spaces of a learning landscape. These key spaces are: active spaces, gathering spaces, individual spaces, ecological spaces, and experimental spaces. The research shows that these spaces help to develop the learning, perception, memory, thinking, and problem solving cognitive skills of the children. Importantly, this research proves that when learning landscapes are created, the above mentioned factors should be taken into consideration so as to create effective spaces for the children. This is because, children without an outdoor learning environment, develops at a relatively low level during their early childhood.

The limitations of this study needs to be considered in future research. Thereby, further research would need to be performed in a larger area and many more educational institutions, in order to examine associations among variables of the learning landscape. Also, the study can be improved by analysing cognitive development of a child through a periodical method.

Abstract

With China’s quick urbanization and modernization, big cities has attracted a large number of people to work in city leading to serious problems of left-behind children and empty-nesters in rural areas. In addition, the urban people have a fast-paced life, adults are usually in a state of high pressure with very tight schedules and it is rare for children to be close to nature. Over time, sub-health has taken place in both rural and urban areas, and everyone aspires to a "holy land" that can liberate the soul and the body. By introducing therapeutic landscapes to suburbs, we hope to achieve an effect on activating the vitality of city-suburban boundaries and promoting the physical and mental health of urban and rural residents. Taking the plant elements in horticultural therapy as the starting point, we will construct therapeutic landscapes by mobilizing the five senses of vision, hearing, smell, taste and touch. Colorful flowers and vast rice fields provide people with marvelous visual experience. By means of restoring water environment combined with the wetland design, water will be purified and biological diversity will be significantly increased in the restored ecosystems. The sounds of insects, diverse birds will bring a feast of hearing from nature. We plan to use a large number of local vegetables, featured fruits to create the edible landscape. The aroma of the plants and picking experience of fruits and vegetables will fully mobilize the sense of smell, touch, etc. We will try our best to protect the ancient and rare trees in the site, which will play a significant role in both public science education and economic value. “Four Southern Herbal Medicines” can provide convenience for the villagers' lives. Furthermore, we will do ecological design based on the low impact development. We will increase green infrastructure to improve suburban landscape service system. And we will also set up children's activity areas and outdoor science classrooms. There are two main categories of experience design, including static viewing based on leisure activities, and practical participation based on technical activities. These activities can enrich the leisure life of urban people. At the same time, they can bring considerable economic benefits to the villagers. This article takes Xianhe Village as the research object, exploring new ways that can activate the vitality of the city-suburban boundary and promote the coordinated development of the city-suburban areas. Introducing the new therapeutic landscapes in suburbs,
which can be edible, ornamental, and playable, can play an important role in alleviating the stress and restoring mental status of the urban people, rebuilding the connection between children and nature, and revitalizing the suburban economy.

**Keywords:** suburban landscape; therapeutic landscape; garden health; landscape architecture

### 1. Introduction

With the rapid development of China, a series of social problems have emerged in urban and rural areas. On the one hand, adequate job opportunities and high salary in cities have attracted a large number of rural young and middle-aged people to leave their hometowns and work in cities. This trend has led to a large number of left-behind children and empty-nesters in the countryside [1]. They are faced with both physical and mental problems and the quality of their life cannot be fully ensured. Insecure drinking water and backward medical conditions in rural areas affect their physical health. At the same time, they suffer from loneliness in the depth of their heart. On the other hand, the pace of life in the city is accelerating, and adults in the city are confronted with difficult problems from various aspects such as life and society. As a result, their physical and mental pressures are increasing, depressed emotions are getting worse, and immune system are declining. They have long been in a state of high tension and are vulnerable to diseases. Sub-health has become a common problem among urban residents. Health care has also become a hot topic in society. At the same time, children rarely have the opportunity to get close to nature, resulting in fractures between children and nature, such as stress, depression, loneliness, and attention disorders. It can be seen that people from all ages have different degrees of health problems wherever they are in city or in the countryside. The way to cure physical and mental diseases is not limited to drugs and instruments. The landscape approach has become a unique way of influencing people's health and gradually grabs people’s attention [2]. The suburbs, as the border between the city and the countryside, are the corridors to activate the vitality. The suburbs with convenient traffic have become the first choice for connecting cities and rural areas and narrowing the gap between cities and rural areas.

Based on this phenomenon, this paper takes the Xianhe Village project in Haikou City of Hainan Province as an example to carry out suburban landscape planning and designing. It is hoped that this study can provide reference for suburban landscape planning and designing with similar phenomena, so as to achieve the effective integration of production functions, ecological functions and recreational functions of suburban landscape, to achieve the social, economic and ecological benefits of suburban landscapes.

### 2. Site Condition and analysis of available resources

Xianhe Village is located in the northwest of Sanjiang Town, Meilan District, Haikou City, Hainan Province, 8 kilometers from Sanjiang Town center. With an excellent geographical location, abundant natural resources and a good ecological environment, Xianhe Village provides a good foundation for the later-period construction of therapeutic landscape.
2.1. Abundant natural resources

Xianhe Village boasts natural resources of lakes, forests, and farmlands, and has abundant plant resources. The site is mainly planted with economic trees like Hevea brasiliensis (Willd. ex A. Juss.) Muell. Arg, Musa nana Lour., Areca catechu L., native tree species like Roystonea regia (H.B.K) O.F.Cook, Casuarina equisetifolia Forst., Cocos nucifera L., etc, ancient and rare trees such as Dalbergia hainanensis Merr. & Chun, as well as fruit trees like Citrus maxima (Burm) Merr., Syzygium samarangense (Bl.) Merr. et Perry, Clausena lansium (Lour.) Skeels, Artocarpus heterophyllus Lam, etc. The rainfall is abundant throughout the year and it is adjacent to the Dingrong Reservoir, which has abundant hydrological resources.

2.2. Good ecological environment

Xianhe Village has a good natural ecological environment and has natural scenery such as lush mountains, lucid water, wheat fields, and wetlands.

2.3. Excellent geographical location and traffic advantages

Xianhe Village enjoys convenient traffic, with Haiwen Expressway and S201 Provincial Highway connecting Haikou in the north and Sanya, Wenchang to its south. The project is of great significance for the integration of rural tourism resources in Hainan Province.

2.4. Human resources

Xianhe Village is an old district with revolutionary history, with red cultural resources and primitive ecological villages. Su Xunsan County is an important part of the Qionghai-Wenchang Revolutionary Base. Hainan Doll Opera and Tiger Dance are listed as intangible cultural heritage by China and Hainan Province respectively.

2.5. Industrial resources

According to the township tourism plan in compliance to the overall plan of Sanjiang Town, Xianhe Village is located in the waterfront tourism area. In the industrial layout of the town, Xianhe Village is on the axis of the leisure agriculture industry and can rely on Xianhe Lake to develop the suburban tourism industry. In addition, Xianhe Village is also the base for cross-country auto racing and the base of Sanjiang HaofuJiang wax apple base.

3. Planning strategy

Taking the whole village into consideration, this landscape planning system has designed different areas corresponding to their respective resources and functions. The plan mainly contains five basic strategies.

3.1. Building a complete road network

We plan to upgrade the roads, build a complete road network, and take use of the
geographical advantages to promote urban-suburban inter-connectivity.

The roads in Xianhe Village cannot ensure free traffic flow yet. Thus, it is necessary to upgrade the traffic network to build a complete transportation system in order to facilitate the exchanges of urban and suburban residents. Furthermore, given that the elderly in the village may have difficulties in movement, the width of the road and the size of the ramp are designed in accordance with the principle of barrier-free [3]. The material of the road is appropriately chosen to ensure the smooth passage of the wheelchairs.

3.2. Constructing a suburban park

Taking good use of resources of lake, farmland and forest within the field, we plan to construct a suburban park and make it a center to serve residents of the surrounding cities and the rural areas. We plan to set up some diversified attractions including the Famous Wood Cognitive Park, teahouse, Jungle Experience Bridge, and Farmland Watch Tower, etc. By setting up children's activity area and outdoor science classroom, we want children to embrace nature and be closer to nature. A variety of activities are carried out to bring vitality to the venue.

3.3. Improving the infrastructure

We plan to improve the infrastructure, narrow the gap between the urban and the rural as to life quality. At the same time, a large number of local materials, such as wood, stone, fruit trees etc., will be reserved to preserve the suburban landscape. We will use low-impact development methods to carry out ecological design, increase the green infrastructures such as rainwater treatment devices, energy recycling systems, and garbage disposal, so as to improve the suburban landscape service system.

3.4. Establishing an ecological restoration mechanism

We plan to establish an ecological restoration mechanism to mobilize the human sensory system, in order to heal the body and mind. We plan to restore the water area in combination with the wetland design, and soften part of the water revetment. In the restored ecosystem, the water quality will be purified, the biodiversity will be significantly increased, and the sounds of various birds and insects will be added, along with the sound of water and wind blowing on the leaves, an auditory feast from nature is on the table.

3.5. Promoting multi-industry coordinated development

We plan to utilize the advantages of lakes, fields and forest resources in the site to promote multi-industry coordinated development, and establish a healthy cycle of urban-suburban collaborative development mechanism. This mechanism is driven by market. Taking an approach of therapeutic landscape, we plan to plant fruit trees and other economic crops, green fruits and vegetables, flowers and breed some fish in order to make the suburban land whose utilization rate was not high become a new opportunity for suburban development.
4. Planning and Designing

Based on the existing conditions, the site will be divided into eleven areas: entrance service area, outdoor classroom area, wetland reserve, forest conservation area, internal staff working area, aborigines’ living area, B&B accommodation area, land claiming area, picking area, forest exploration area, agricultural sightseeing area, according to the function and nature of the site.

4.1. Entrance Service Area

In the entrance service area, there are parking lots and visitor center. There are also other service facilities, such as coffee shop, convenience store and the medical station. This will facilitate people to play.

4.2. Outdoor Classroom Area

The outdoor classroom area is equipped with children's playground, interactive lawn, jungle experience viaduct, etc. This area can provide parent-child interaction landscapes. By setting up a jungle experience viaduct and planting fruit trees of different heights in this area, visitors can feel and touch the plants from different orientations and heights, and activate the body's nervous system through touch to create the sense of novelty, excitement and pleasure, thus improving mood and promoting all aspects of the body are fully coordinated to achieve the purpose of improving health [4].

Visual senses are the most direct way for people to perceive the environment. In the outdoor classroom area, colorful flowers and boundless farmlands are set up to provide people with a rich visual experience; different colors will cause people to have different levels of excitement, and exert adjustment and health care effects on people [5].
4.3. Wetland Reserve

We look forward to restoring the ecosystem's environment while enhancing people's contact with nature. In this area, people can experience the wetland’s functions of water quality purification and biological diversity maintenance. Through planting native wetland species, attracting birds and insects to increasing bio-diversity and stability. By setting up facilities such as corridors, bridges, and stepping stones which visitors can get close to the wetland.

4.4. Forest Conservation Area

Suburban forest conservation area plays a very important role in coordinating and protecting the urban and suburban ecological environment. Due to the high topography of the north of the site and the fact that there are already good forest vegetation resource, this area is planned to be a forest conservation area, where fruit trees and cash crops will be planted, effectively transporting oxygen to the city while also mitigating urban noise, light pollution, etc. It can also well conserve water resources and prevent soil erosion. Suburban ecosystems are vulnerable and sensitive. The design fully protects the suburban ecological environment and provides migration corridors for various organisms, especially animals.

4.5. Internal Staff Working Area

The internal staff working area is a number of office buildings. The people who work there are field managers, operators, professional horticulturists, representatives of village committees and so on.

4.6. Aborigines’ living Area

The design of the aborigines’ living area took full account of and retained the original texture of the villages such as its buildings, streets, and public spaces. Traditional villages are a type of heritage existing in life and production [6]. They are the vivid carriers of our country's history and culture. Traditional cultural landscapes in Chinese villages contain plenty of historical memories, clan cultures, idiom dialects, and rural township regulations [7]. The analysis of the village buildings and the reinforcement of the dilapidated buildings will help to preserve the village's texture, improve the infrastructure, increase the green space, and eventually improve the villagers’ life quality and the environment.

By planting local medicinal plants, villagers can enjoy high-quality therapeutic landscape resources. When villagers have minor health problems, they can pick up the medicinal plants and other herbs in this area. Planting wild edible plants can provide convenience for the villagers' life. These measures can not only help the villagers to pick up the medicinal plants by themselves and eat vegetables and fruits within this area, but also create a unique suburban landscape.

4.7. B&B Accommodation Area

Next to the aborigines’ living area, we set a series of B&B inns, combined with special food streets, suburban folk culture and creation exhibition halls and so on. This
design makes it convenient for tourists to fully experience the local characteristic culture. In addition, it can promote the economic development of the suburbs.

4.8. Land Claiming Area

This area mainly produces vegetables and fruits needed for the lives of urban residents. By land claiming, on the one hand, urban residents can harvest truly green, pollution-free fruits and vegetables. On the other hand, citizens can experience the joy and satisfaction of sowing in spring, growing in summer, and harvesting in autumn, so as to attract people into nature to participate in physical working and mental healing; at the same time, it can also promote economic development in the suburbs.

4.9. Picking Area

The cultivation of wild vegetables, fruits and other pollution-free organic food plants in this area can be enjoyed during the immature period and can be harvested during the ripe period. In the tea fields, visitors can pick up tea by themselves. When visitors walk into the teahouse, they can brew tea according to the recipes. Visitors' nervous system is stimulated by tasting and sniffing the leaves or fruits of different plants, which makes people feel happy and relaxed.

4.10. Forest Exploration Area

This area mainly includes rock climbing, jungle crossing, grass skiing, and outward-bound training. It mobilizes the public's body and achieves physical and mental healing functions during the event.

4.11. Agricultural sightseeing area

Horticultural working activities are provided in this area. Participants plant their own plants and irrigate, fertilize, and prune by themselves, which are easy to produce a sense of satisfaction and achievement, and promote the restoration of physical functions and stimulate positive emotions.

5. Plants planning

The topography is basically flat and the soil characteristics are homogenous. Thus there is no effect of soil on the land use pattern. The area is surrounded by reservoirs and lakes in all sides which provide water sources for fishponds and for irrigation of the farmlands. The plants planning is mainly divided into the following eleven parts:
1. The dominant landscape tree species: Cocos nucifera L.
2. The key landscape tree species: Cassia bakeriana, Bombax malabaricum DC.
3. Native tree species: Roystonea regia (H.B.K) O.F.Cook, Casuarina equisetifolia Forst, Cocos nucifera L.
5. Fruit trees: Drypetes cumingii (Baill.) Pax et Hoffm., Citrus maxima (Burm) Merr.,
Artocarpus heterophyllus Lam., Syzygium samarangense (Bl.) Merr. et Perry, Mangifera indica L., Dimocarpus longan Lour., Clausena langium (Lour.) Skeels, Litchi chinensis Sonn.

6. “Four Southern Herbal Medicines”: Areca catechu, Amomum villosum, Alpinia oxyphylla, Morinda officinalis, which have been widely used in the south part of China for a long time.

To a certain extent, all gardens have a certain convalescent effect. The difference between the therapeutic garden and general garden is the concern for users’ needs and preferences at the beginning of design. How to fully explore the recovery characteristics of garden space and to express them is the key point of therapeutic landscape design. Therefore, rehabilitation garden is an active association with nature and health [5].

6. Activity planning

There are two types of activities design in the site, including static viewing activities such as sit-in, viewing and slow-walking, and dynamic participation activities mainly including technical activities such as body-building and gardening work. These activities enrich leisure activities for urban residents, meanwhile it can also bring considerable economic benefits to the villagers.

Static viewing activities include: enjoying pastoral scenery, praying under ancient banyan trees, singing in colorful sea of flowers, enjoying the sunshine on green lawns, identifying southern herbal medicines and famous trees, taking outdoor classes, and jungle experience viaduct running; practical participation activities include: participating in gardening and farming, picking fruits and vegetables, picking tea and tasting tea.

7. Conclusion

Xianhe Village has a natural lake Xianhe Lake and the pastoral scenery, and has convenient access to the urban area. The establishment of the suburban therapeutic landscape can develop the ecological tourism industry and make it a new growth driver, and furthermore, change the industrial structure of the suburbs, and provide employment so as to encourage rural youth to return home [8]. In this way, the rate of empty nesters and left-behind children will be decreased, and the health and spiritual needs of urban residents can also be satisfied.

By means of therapeutic landscape, the suburban landscape displays a healthy, harmonious and stable state, transforming the traditional suburban pattern into a new suburban landscape model of “suburban
parks—the therapeutic landscape—providing high life for people”.

\section*{Abstract}

In Russia, one of the most important steps in developing a biophilic vision and including nature as an important component of urban planning and design was the development of special ‘academic towns’ (akademgorodok) in late 1950s-early1960s. Biophilic principles were perfectly expressed in the planning, design and management practices of such specially designed ideal towns. This was the first manifestation of Soviet progressive urban planning principles and of attempts to design sustainable green cities for the future. The vision had strong theoretical and philosophical foundations and aimed to create ideal living conditions for Soviet scientists, who would have daily contact with nature and receive emotional and physical inspiration (live in harmony with nature) and thus work productively and make scientific discoveries. A special urban planning department in Moscow and numerous botanical gardens (important scientific research institutions in Russia) dedicated their efforts to designing green areas for such new scientific towns. Green belts surrounding cities and forest patches of various sizes were included in all city zones.

The next step towards the truly biophilic city was the programme Ecopolis in the late 1970s. Its foundation was the principle of constructive ecology, which aims to help humans manage the natural environment as a tool in coherent evolution of nature and society towards the noosphere. One of the main goals of Ecopolis was to create an optimal ecological and socio-psychological urban environment that could also incorporate nature protection functions in urban areas. For the first time in Russia, urban ecology and sustainable design practices were
implemented in a real town, Pouschino (located 120 km from Moscow). Later, Ecopolis ideas emerged in other small, medium and large cities (Kosino, Korolev, Vologda and Uliyanovsk).

After 10 years of sweeping political and economic changes in Russian society in the 1990s, many cities revisited existing planning and design norms. In the past five years, a strong movement aiming to solve ecological crises has arisen in Russian megapolises (Moscow, St. Petersburg, Nizhniy Novgorod, Kazan, Novosibirsk, Vladivostok). Municipalities are revisiting planning and design policies and suggesting new visions for urban green infrastructure within their masterplans. In Russia, biophilia is traditionally associated with existing remnants of forests within city boundaries and protection strategies for these, especially trees. Concrete examples of using ecological design (design with nature) can be found in microdistricts of St. Petersburg and Moscow. Results from the research of academic towns, Ecopolis and examples from megacities are also discussed in this paper.

**Keywords** biophilic cities in Russia; academic town; academgorodok; Ecopolis; technopolis

1. Introduction

In this paper, we chart the development within Russia of biophilic cities, defined as cities that allow humans to connect with nature within urban environments on a daily basis [1]

In Russia, a very important step in developing a biophilic vision with nature as an important component of urban planning and design at all scales (from master plan through neighbourhood level to the gardens of multifamily houses) was the creation of special ‘academic towns’ (akademgorodok) in late 1950s-early 1960s. These were a special type of settlement mode within the ideology of socialism, with one of the postulates being to create a sustainable urban environment based on a harmonic relationship between man and nature [2]

Biophilic principles were perfectly expressed in the planning, design and management practices of Russia’s academic towns. They were the manifestation of Soviet progressive urban planning principles and of attempts to design sustainable green cities for the future. The vision had strong theoretical and philosophical foundations and aimed to create the most comfortable living conditions possible for Soviet scientists, who would have daily contact with nature, gain receive emotional and physical inspiration (live in harmony with nature) and thus work productively and make scientific discoveries [3]. Academic towns were also accepted the microdistrict (mycrorayon), the innovative Soviet urban planning concept, which intended to reflect the ideas of the socialist society where people should be tolerant and unselfish, respect collective bargaining, debate for the collective good and hold socio-cultural values and harmonious ‘brotherly’ living in high esteem. Microdistrict (microrayon), residential clusters of 30-50 hectares for 12,000-15,000 people, consisted of multifamily 5-7-9-12 storey houses, shops, laundries, cleaning and repair stores, dining-rooms, schools and pre-school facilities [4]. This unified and standardised planning, design and greening strategy included quite extensive green areas as an important tool for improving quality of life and
environmental health. Microdistrict principles were also used in the academic towns, but in more progressive interpretations because of the availability of native forests.

The task of providing a suitable environment for academic excellence demanded new principles of planning structure and use of a functional zoning system. Thus a working zone (where research institutes were located), living zone, public administration zone, a rest and recreation and a provision zone were suggested for academic towns [3]. The academic towns were designed by specialist urban planning units in Moscow (e.g. GIPRONII, All-Union State Institute for Planning Scientific Research of the USSR Academy of Sciences), with the help of numerous botanical gardens. In the Soviet era, botanical gardens were also under the umbrella of the USSR Academy of Science and were considered important scientific research institutions. They were responsible for developing theoretical knowledge, but also for the application of findings within biological science in practice, and were thereby called upon for drawing up planting design and plant material recommendations for the new academic towns.

It was recommended that the academic towns be located within or near pristine nature, but also in close proximity to public transport links to major cities. One of the approaches during the planning stage was preservation of existing patches of natural ecosystems and including them in different town planning zones. Academic towns were planned as “cities of a new type, which are closer to modern and future urban planning ideals” [5].

Biophilic principles also applied in the planting design. Drawing inspiration from surrounding native plant communities called for use of native species that could also sustain local climate conditions in the most effective way. One of the important principles of green infrastructure in scientific towns was maximum protection of surrounding native ecosystems and organising the network of protected reserves within the city’s boundaries. The list of plants for newly designed living neighbourhood also included decorative exotic species, which were intended to add a touch of interesting colour and texture, and thus reinforce the aesthetic appearance of novel urban vegetation.

2. Case study: Novosibirsk Academgorodok

One of the best examples of academic towns was Novosibirsk Academgorodok, located 30 km south of Novosibirsk city centre. The aim was to build an educational and scientific centre for Siberia. The site of the future town was on the shore of the Ob Sea (an artificially created reservoir on the river Ob), surrounded by birch and pine forests (Figure 1).

Fig. 1. Aerial view of Novosibirsk Academgorodok.

The town was founded in 1957, under the close patronage of the Academy of Sciences
of the USSR. In the 1970-1980s, the most prosperous years, Novosibirsk Akademgorodok was home to 65,000 scientists and their families. At that time the town had a good reputation and was a privileged residential area. Most of the population lived in nine-storey and four-storey multi-apartment buildings. Novosibirsk State University, 35 research institutes and a medical academy were located there, which created a good reputation and recognition of Novosibirsk Academgorodok as a truly ‘academic’ town.

In the general plan for the town, every aspect of planning was subordinate to clear functional zoning. The zones were established in a very logical, scientifically proven sequence, with a zone of research institutes, a provision zone, residential areas and a green protective zone, beyond which was a reservoir and finally a recreation area. Zoning preserved as much of the existing forest and open natural ecosystems as possible. The forest on the shore of the reservoir was saved as an important windbreak from the prevailing south-westerly winds and as a protection buffer from traffic noise on the transit highways passing the outskirts of the town [6].

The zone of research institutes was located in the north-eastern part of the town, where the institutes were clustered according their scientific interests and themes. This zone was built in an open spot where there was no existing forest, located on the leeward side of the residential area. The institutes’ buildings were positioned taking into account their transport connection with the provision zone. The provision zone was separated from the residential area by a protective forest belt. The residential zone was bordered by a large forest area. The concept of using a ‘green ring’ of protected forests and including green wedges in residential developments was very innovative and aimed to maximise everyday contact with nature. Green areas in the residential zone consisted of public parks and inner courtyard gardens. In each neighbourhood, optimal orientation and aspect of buildings was again ensured. One of the main planning themes of the entire town was preservation of natural forests and their use for recreational activities. The amount of green area allocated per person was very high, 26 m² of common green area and 200 m² of other types of greenery per person (Figure 2).

Fig. 2. Green areas in one of the microdistrict in Novosibirsk Academgorodok.

The recreation zone was placed along the shoreline of the reservoir (Ob Sea), where, as a result of shore protection works, a 2.5 km long beach was created. Part of the zone was located within the town’s administrative border, but the remainder continued further along the banks of the reservoir.

The Central Siberian Botanical Garden helped with designing the green areas. A specially created Forest Protection Station was made responsible for monitoring forest conditions, conserving, restoring and reconstructing forest ecosystems and helping with the greening of residential areas.
The architectural and planning structure of Novosibirsk Academgorodok can be seen as a very successful case of using existing natural conditions (topography, vegetation and hydrology) and including nature as a crucial structural element of urban spatial organisation. Another important outcome was the creation of a unified transport and pedestrian system, which provided convenient connections both between the city zones and within each zone, ensuring maximum safety for pedestrians, and excluded all types of transit through the territory of Novosibirsk Academgorodok. One of the positive features was organisation of cultural and consumer support services and creation of the novel architectural and aesthetic image of the city.

Taking into consideration its unique character as of one of the first academic towns and its special planning, architectural structure and urban development characteristics, in 2014 Novosibirsk Academgorodok was declared an object of cultural heritage (monument of history and culture) of the Russian Federation (cultural heritage of regional significance).

3. Case study: the Ecopolis programme and the academic town of Pushchino

The next step towards the truly biophilic Russian city was implementation of the Ecopolis programme in the late 1970s. Academics and scientists from Moscow State University were initiators of this project, the scientific foundation for which was the principle of constructive ecology, “which aims to help humans manage the natural environment as a tool in coherent evolution of nature and society” [7]. One of the main goals of Ecopolis was to create an optimal ecological and socio-psychological urban environment based on native landscapes and man-made plant communities. For the first time in Russia, urban ecology and sustainable design practices were combined within a major interdisciplinary project and implemented in the real town of Pushchino.

Pushchino (population 20,000) is located 120 km south of Moscow, on the bank of the river Oka. It was founded in 1963 as the Scientific Centre of Biological Research of the USSR Academy of Sciences. It brought together the following research institutes and centres: Institute of Protein, Institute of Biological Physics, Institute of Biochemistry & Microbiology, Institute of Photosynthesis, Institute of Agrochemistry & Soil Sciences, Scientific Computer Center, Constructor Bureau of Biological Apparatus and Radioastronomy Station. These were tasked with making breakthroughs in biological science in Russia.

The urban design concept applied for Pushchino was very innovative and had strong scientific foundations. The town was created as three parallel zones: an institute zone (working space) and a residential zone (living space), separated by a green zone (broad pedestrian boulevard). An additional (functional) zone was located at the periphery of the town. The green zone became the compositional axis of the town. The boulevard consisted of five groves (birch, pine, oak, larch and lime), which gave special ecological and aesthetic meaning to the whole town. Pushchino is
surrounded by native forests and meadows, while on the opposite bank of the Oka river there is a huge green ‘sea’ of Prioksko-Terrassny Biosphere Reserve (5000 hectares) (Figure 3).

Figure 3. Location of Pushchino and the view from the town to the Prioksko-Terrassny Biosphere Reserve.

Patches of native plant communities with high biodiversity value (e.g. unique native meadows, Figure 4) were included with the city boundaries and acted as the ‘skeleton’ of the urban green infrastructure system.

Fig. 4. Natural floodplain landscape at Pushchino (the Ostrov protected reserve).

Most indigenous vegetation patches were included in the network of urban nature reserves. The town is also very rich in cultural heritage landscapes. Just on its outskirts is the Teschilov Gorodische archaeological monument from the 12-14th century and a mansion house with the landscape park of the 18th -19th century. Nature is so close to residential areas in Pushchino that people can collect wild strawberries and forest mushrooms just 5 minutes’ walk from their homes.

The Ecopolis programme ran for 18 years (1978-1996) and since then there have been broad investigations of different aspects of its urban ecosystems [8]. The local community was actively involved in the programme. People participated in conferences, surveys, excursions, lectures, discussions on Pushchino themes, film showings and simulation games. With local government support and the participation of local citizens, there were numerous implementations of ideas in practice, for example the special decision on nature conservation, the establishment of new nature reserves, improvement measures for the town’s waste treatment system and introduction of ecological programmes in secondary and upper-secondary schools (Figure 5).

Fig. 5. Teaching session on botany in one of the nature reserves in Pushchino, 1991.

Later, Ecopolis ideas emerged in other small, medium and large cities in Russia, such as Kosino, Korolev, Vologda and Uliyanovsk.

4. Towards naukograd (technopolis)

The altered economic and political situation after 1991 resulted in re-evaluation of the approach to academic towns. In 1991, the new term ‘science city’ (naukograd) was introduced for the town of Zhukovski in the Moscow region, signifying the formation of a new Union for the Development of Science Towns. Since that time, science cities have emerged as targeted scientific and industrial complexes created specifically for the development of new science-intensive technologies. Such cities have to be based exclusively on close relations and interactions with universities and scientific and technical centres and with large industrial companies. Like the Soviet academic towns, the science city is designed as a special compact settlement with developed infrastructure that aims to provide productive and comfortable living and working conditions for researchers and
associated industrial staff. However, compared with the more idealistic academic emphasis of academic towns, the new technopolis is strictly pragmatic and orientated primarily towards housing scientifically progressive institutes and universities that produce new technologies and can contribute to economic growth.

Science cities are divided into seven research specialisations (aviation, rocket science and space research; electronics and radio engineering; mechanical engineering and instrumentation; chemistry, chemical physics and the creation of new materials; nuclear complex; power engineering; and biology and biotechnology). The size of science cities is not restricted and can vary. Pushchino town received the status of naukograd (among 13 officially recognised science cities) in 2005. The idea of the technopolis was taken from the West (USA and Western Europe). Nowadays the technopolis is a very attractive concept for many countries and is also reflected in current globalisation trends.

4.1. Case study: The town of Tsiolkovsky

One of the latest examples of using planning and design ideas for academic towns can be seen in the town of Tsiolkovsky (population 5000), a new settlement built next to the Vostochny space centre in Amur Oblast on the Bolshaya Pyora River, 110 km from the border with China. The most essential legacy of the classical Soviet academic towns, i.e. the interconnection with surrounding natural landscapes and the use of natural existing landscapes as part of the planning structure, is clearly visible in one of the proposed design of residential neighbourhoods in Tsiolkovsky (Figure 6).

This ‘city of the future’ uses modern technology and new innovative architectural and building construction techniques, together with more modern architectural forms and material. However, the main ideology of academgorodok is still evident, as Tsiolkovsky is intended to be a special place for living and creative work by people united by one ideal, performing research that derives inspiration from biophilic landscapes. The future for Tsiolkovsky town is as an innovative naukograd.

5. Understanding biophilia in modern Russian megapolis

After 10 years of sweeping political and economic changes in Russian society in the 1990s, many cities revisited existing planning and design norms. In the past five years, a strong movement aiming to solve ecological crises has arisen in Russian megapolises (Moscow, St. Petersburg, Nizhniy Novgorod, Kazan, Novosibirsk, Vladivostok). Municipalities are reviewing planning and design policies and suggesting new visions for urban green infrastructure within their masterplans. In Russia, biophilia is traditionally associated with existing remnants of forests within city boundaries.
and protection strategies for these, especially trees. For example, 15 specially protected natural areas occupying a total area of 6142.5 hectares have been established in St. Petersburg. In the past decade, examples of using ecological design (design with nature) at the fine level scale have emerged in the microdistricts of St. Petersburg and Moscow [9]. For example, green roofs and principles of integrated stormwater management (low impact design) have been implemented in the St. Petersburg suburb of Devyatkin [10]. One of the crucial concepts of modern masterplan strategies in megapolises is the green belt (involving urban forests) and green corridor and integration of all green and water-based elements into one united green-blue infrastructure system.

6. Conclusion

Recent decades have seen a tendency for reevaluation of the positive Soviet urban planning and landscape architecture legacy. Innovative practices of Soviet planning included the creation of microdistricts (microrayon), a unified planning, design and greening strategy using extensive green areas to improve quality of life and environmental health, and academic towns (akademgorodok), where nature was seen as an important planning and design element and a major socio-ecological tool in creating a harmonious relationship with nature. This biophilic approach, in combination with the concept of creating compact pedestrian and public transport-friendly settlements within a safe environment, can be seen as a progressive achievement of the Soviet planning system. Some of the academic towns from this era, for example Novosibirsk Academgorodok, have even been recognised as cultural heritage, mostly because of the unique zoning structure, abundant vegetation and proximity to natural forests giving an identity of whole city (“the town-forest”). The character and features of the academic cities were very much in line with the Soviet aim of creating a new generation of settlements that would fulfil the task of creating a good living environment.

- After years of turbulence and neglect of the past Soviet heritage in the 1990s, there is now a growing interest among urban planners and landscape architects in the academic town legacy. The new movement of the scientific city (naukograd) can be seen as today’s answer to market demand for advanced innovative technologies as an essential condition for societal progress. The scientific city model uses some ideas of academic towns, but the Ecopolis of co-evolution of man with nature has been subsumed within a more pragmatic model of technological development that is typical of a market economy.

Garden therapy in African slums

Mariusz Antolak

Department of Landscape Architecture, Faculty of Environmental Management and Agriculture, University of Warmia and Mazury in Olsztyn, Address: Prawocheńskiego str. 17, 10-720 Olsztyn, Poland,

Abstract

Horticultural therapy is a method of therapy in which garden work supports the healing process. It has been used more or less mindfully for many years. Thanks to the involvement of patients in the design process, performance and care of the selected space, their health and well-being are becoming improved. This conclusion is confirmed by the numerous results of research carried out with patients suffering, among others for autism, depression and senile dementia. This method of therapy is also used in resocializing prisoners and treating addictions. Patients participating in design process and gardening work are in constant contact with nature and become members of the community that creates the garden. Thanks to their involvement in the project process and its implementation, they are more likely to identify with and care for a given place. In January 2015, there was launched authorial project entitled: Global Garden Project. It is a scientific, artistic and educational project in the field of landscape architecture, horticultural therapy, urban gardening and social communication. The project includes, among others, workshops on designing process and setting up school gardens in places where people exposed to social exclusion are present. The students undergo a kind of garden therapy during this activities. They forget about the problems of everyday life and learn how to produce food on their own. The first garden of this type was created at the MCEDO School in the Mathare Slum in Nairobi, Kenya in January 2015. The main goal of the project was to jointly design and implement school gardens, in which students themselves grow edible and decorative plants. School gardens have many functions, among others: aesthetic, utilitarian and educational. Gardens can integrate local community, but also be a place where lessons in the open air and horticultural therapy take place. Students become very involved in the project, because there are no gardens in the immediate vicinity and many of them have not seen a similar place so far. While working in the school garden, they acquire an extremely important ability to work in a group, learn sensitivity to the surrounding space and produce food themselves, which is a basic good in the neighborhoods of poverty.

Keywords: urban gardening, sack gardening, slums, school garden, occupational therapy, outdoor activities, Kenya, Mathare Slum

1. Introduction and research method

The rapid increase in the population of African cities causes an increased demand for fresh food for the residents. The development of urban agriculture in the 21st century has become a good solution to this global problem [1]. School gardens have many functions, among others: aesthetic, utilitarian and educational. They can integrate the local community, be a place where outdoor lessons take place and in which food is produced. In January 2015,
there was launched authorial project entitled: Global Garden Project. It is a scientific, artistic and educational project in the field of landscape architecture, horticultural therapy, urban gardening and social communication. The first garden of this type was created at the MCEDO School in the Mathare Slum in Nairobi, Kenya. Main goals of the project were: implementation of an educational garden with a didactic function, mobilization of school pupils and popularization of the idea of urban gardening. The aim of the work is to present the results of this pilot project in the context of garden therapy in African slums. The initial stage of the work was the analysis of the literature of the subject of research and the library query. The next step was establishing contacts with NGOs operating in Kenya to find an appropriate teaching facility for pilot studies. The area of the study was inventoried and a master plan of the school garden was created. The next stage of the project was social research carried out among the participants of the project - a survey on the knowledge of basic issues related to gardening. Then, workshops on the design of green areas and workshops for setting up and nurturing gardens for school pupils were carried out. After these introductory activities, participants started to prepare garden. Plant material, fertile soil and drainage were obtained, the area was cleared of rubbish and debris from building materials, and basic earthworks were carried out - leveling the ground and bringing soil. The garden was established by school students.

2. Garden therapy in african slums

Slums are fragments of big cities inhabited by poor people, mostly immigrants or newcomers from rural areas. They constitute a big problem of the modern world, but at the same time they are also a global phenomenon [2]. For many years, attempts have been made to solve the problems that they generate [3], but these are not easy tasks. The external debt burden, high levels of inequality, unplanned and unmanaged urban growth, and the exclusionary nature of the regulatory framework governing the provision of planned residential land contribute to the prevalence of slums in African countries [4]. Considering that many of the slum dwellers had previously dealt with agriculture - applying the idea of urban gardening in the slums seems to be right. The problem of soil contamination was solved by using sack gardening. Thanks to it, we protect edible plants against soil contamination and we increase the production area. Sack gardening is popular in many African countries, among others in Kenya [5]. Work in the garden, in addition to traditional benefits in the form of food production is also valuable in terms of contact with nature. It is a kind of outdoor occupational therapy. Working in the garden helps you forget about the problems of everyday life. In the spatial structure of the slums, there are very few places covered with vegetation. Green oases are found mainly in areas that are not suitable for development. In the African slums, activities aimed at educating local communities have been undertaken for many years. Occupationally and artistically oriented activities are popular. However, it is also important to show how man can produce food himself, with a small financial outlay and in a small space.
3. A case study of Mathare Slum (Nairobi, Kenya)

3.1. Mathare Slum

Mathare Slum was developed around nine separate villages strung out along three miles of the Mathare and Gitathuru rivers. It is one of the largest areas of uncontrolled housing in Nairobi. This space has been extensively examined and for many years various research [6], planning [7] educational and artistic activities have been carried out here. There are also practical activities that activate the local community and organize the space. Some of them also concern urban agriculture and horticulture. They take place in the slums itself or outside its borders. In 1979, the Undugu Society of Kenya launched the Katanga Agricultural Project. The aim of this project was to reintegrate boys from slum in the rural society by educating them not only in academic subjects but also through education in agriculture, animal husbandry, crop cultivation and so on [8]. The Mcedo School located in the central part of Mathare Slum was chosen for the project. The area, which was designated for the garden, covers an area of around 60 m$^2$ and adjoins the school directly (fig. 1).

3.2. Social research and garden workshops

As part of the project, a survey was conducted among school students. It was prepared on a 7-meter print and was part of the presentation. Children together answered the questions (fig. 3). The person conducting the workshop moderated the discussion. 32 respondents were asked 10 questions. The first question was: What is a garden in your opinion? The following phrases dominated the answers: a fragment of the landscape in which we plant flowers; a fragment of the land that makes the environment more beautiful and prevents erosion; a place where we can find flowers and plants. Then, three exemplary photographs were presented to the respondents (fig. 2) and asked if there is a garden presented on each of them. Respondents' opinions were divided. 53% of children confirmed the answer, 47% denied that each of the pictures presents a garden. Then the children were asked to choose which of the pictures they liked the most. The answer to this question was unambiguous. As many as 94% said they liked the picture No. 2 the best. 6% indicated photo number 1. None of the respondents chose picture No. 3, presenting a rustic backyard, decorated show garden in front of one of the houses in the Polish open-air museum.
To the question: Must every garden comprise flowers? 84% of respondents gave positive answers. Only 5 people gave the opposite answer. All persons participating in the research stated that they would like to have their own garden. Another question was: What are the components of every garden? The most frequent answers include: flowers, vegetables, fruits, soil, trees, fresh air, water, humus, light, plants, shovel, gardener. Then the children were asked: What objects can be used to plant? Among the most popular answers were such items as a flower pot, paper bag, tin, bowl, sack, bucket or mug. To the question: Have you ever planted any plant? Everyone agreed that yes and up to 91% of pupils said it was difficult. The children were then asked: Where can you get soil for planting? Most of the children immediately pointed to the area adjacent to the school. When asked to extend the answer, they also mentioned: the area around the river, the water reservoir, the shore, the common (public) space, the field. At the end, the students were asked: Would you like to have classes in a garden? 94% of them gave a positive answer to this question.

Another element of classes at the school were workshops on the design of green areas. The task was to design a garden from prepared templates. The students attached elements of the garden equipment to the sheets on which the projection of the residential building was printed. During the workshops, they were informed about the basic principles of designing green areas. After getting acquainted with the theory, practical workshops on arranging green areas were started and the gardening process was started. The aim of the project was to show that with a little willingness and using local materials they can also make their own small home garden. They were also given the idea that useful plants can also perform decorative functions, and explained what functions decorative plants perform, which for the workshop participants have so far been exclusively shade plants.
3.3. The school garden

Work on the garden began with the inventory. The area is located in the direct vicinity of the school. On the western and southern side, it is fenced with a high wall covered with corrugated sheet, in which there are windows. The garden from the rest of the school grounds is separated by two large water reservoirs, located on the eastern side. At the time of the inventory, this separate space was the place where construction materials were stored and garbage collected. The soil present in this area was quite fertile, but it contained a lot of residues of building materials and rubbish. A big problem was the numerous boulders and stones that prevented the proper growth of vegetation. There were no woody plants in the study area. The area was overgrown by monocotyledonous plants communities with a small admixture of dicotyledons. The future garden is quite sunny for most of the day. An exception is a fragment adjoining the wall, which practically does not reach the sun's rays. A small shadow in this area appears in the morning due to the trees growing directly behind the fence. At the time of the inventory, the entrance to the future garden was located south of the water reservoirs. It was a small, several-dozen-centimeter gap between the water tank and the wall of the school.

According to the information obtained from the director and students, before the school was renovated, there was also a vegetable garden next to it and farm animals were raised here. However, it was completely destroyed, mainly due to the lack of fencing and improper care and lack of commitment of a gardener who was employed to take care of this place. The basic design assumption was to create a place where you can grow edible plants - vegetables and fruits.
In addition, the garden was to be a place where classes in "nature" could be carried out in the open air. It has to fulfill didactic, utilitarian and aesthetic functions. In the project were deliberately used not too expensive, local materials. Plants adapted to local habitat conditions were selected. The composition of the garden is simple and based on a grid of squares. In the central part of the garden there are two vegetable gardens (cultivation in the ground and in sacks). They were surrounded by other beds with edible and decorative plants. The composition of the garden has been underlined with local rock material and construction waste. In the garden there is also a gravel path leading to a boulder, which acts as a garden bench and a place of contemplation. The design uses decorative plants such as - thika palm, butterfly-bush, daylily, bamboo and fountain grass. In addition, on the wall surrounding the garden, the creepers were planted: bougainvillea, golden shower and jasmine. Along the border of the study, plants with edible fruits were planted: loquat, papaya and common figs. Also, vegetables such as kale, lettuce, onions, potatoes and spinach were sown and planted.

4. Discussion

A pilot study conducted at the MCEDO school in Nairobi shows how important role gardening can play in the education system. The new garden has become a place of integration and an additional class room in the open air. Students acquire an extremely important ability to work in a group, learn sensitivity to the surrounding space and produce food themselves, which is a basic good in the slum. After the completion of the project, the garden began to live its own life. The workshop participants started to make planning decisions themselves. For example one of the decisions was to use vegetable seedlings as ground-cover plants. The free spaces were filled with vegetable cuttings. There were new seeds sown and
harvested first crops. The key in this case was not only the composition, species selection, small architecture and surface. The most important in this type of projects is to infect the passion of creating and preparing a space that is friendly to its users. The students undergo garden therapy during this activities. They forget about the problems of everyday life and learn how to produce food on their own. The students of the school were very involved in the project. For most of them, the topic turned out to be interesting. Most of them treat the garden as a place of production of edible plants. The most interesting moments of the workshop were planting activities. Everyone wanted to plant them as much as possible, believing that after planting they would become his or her property. There are no gardens in the immediate vicinity and many of the children have not seen a similar place so far. Research continues in other countries.

Landscape: an approach to urbanism

Beverly A. Sandalack, PhD FCSLA RPP MCIP

University of Calgary, Faculty of Environmental Design, University of Calgary, Canada T2N1N4

Abstract

We are an increasingly urban species. The United Nations (2014) predicts that by 2050, over 66 per cent of the world’s population will be living in urban areas. Cities and towns, as human habitat, need to be addressing our needs in ways that are satisfying and sustainable. Urbanization was once viewed in terms of domination of nature, where the terms “urban” and “landscape” were in opposition. The reality is quite different. The city is complex - it contains both built form and natural form, and our changing values, combined with our increasing understanding of our world and our impact on it, now call for a more integrated approach in which development of land is coupled with environmental responsiveness.

Ideally, urbanism should be one of best expressions of good environmentalism, but in practice, cities are often hostile places for nature and for ourselves. The perils of the 21st century city now include the uncertainties of climate change, loss of species diversity, concerns about sustainability, threats to human health, and loss of sense of place. New tools, techniques and ways of understanding nature are required. Landscape, once thought of as a place of relief from the urban condition, should be viewed as integral with city form and process, and with important roles to play in sustaining life and giving cities greater resilience to withstand the unpredictability and extremes of climate that are now more common, in addition to providing places for recreation and entertainment or for aesthetic enjoyment.

A new and important landscape scale and approach could distinguish our current era, but we will require a revolution in environmental design at the impact and importance of the late nineteenth urban parks movement, which radically reconceptualized the relationship between nature and society. The intersection of the need for a landscape approach with interdisciplinary approaches may provide the framework for a new way of conceptualizing, and designing, urban landscape systems to address contemporary issues and to express societal values. The theories, tools and techniques from landscape ecology and urban ecology, with ideas of ecosystem services, could be combined for a new view of green infrastructure, where landscape and the public realm potently intersect. This implies the need for changes in the education of future professionals as well as adaptation of our current methods, processes, and regulations.

Keywords: Landscape; urbanism; public realm; resilience; climate change
1. Introduction

We are an increasingly urban species. The United Nations (2014) predicts that by 2050, over 66 percent of the world’s population will be living in urban areas [1]. Cities and towns, as human habitat, will need to be addressing more of our needs in ways that are satisfying and sustainable.

Ideally, urbanism should be one of the best expressions of good environmentalism, but in practice, cities are often hostile places for nature and for ourselves. The perils of the 21st century now include the uncertainties of climate change, loss of species diversity, concerns about sustainability, threats to human health, and loss of sense of place. The need is urgent: “this thin mosaic, the tissue of the planet, is in upheaval” [2].

New tools, techniques, and ways of understanding nature in the city are required. Parks and open spaces, once thought of as places of relief from the urban condition, should be viewed as integral with city form, having important roles to play in sustaining life, in addition to providing places for recreation and aesthetic enjoyment; these spaces are part of our very survival.

A landscape approach to planning and design is necessary and will require a revolution in thinking at the scale and importance of the late 19th century urban parks movement. Led by Fredrick Law Olmsted and other visionaries, it recognized the importance of urban parks to the health and welfare of city residents, radically reconceptualizing the relationship between nature and society. The practices of urban planning and landscape architecture were set on a strong path, epitomized best by New York City’s Central Park. With the new threats of the 21st century, another revolution in thinking is necessary.

2. Historic overview – landscape and public realm as reflection of values

How did we get here? The evolution of the city reflects the evolution of ideas and ideologies, and of changing theories and practices of urban design, landscape architecture, and planning. The values cultures place on the built and natural landscape are reflected in changing patterns of land ownership, land development, and environmental values, and consequently in the spatial, social, and ecological qualities of the public realm [3].

The first phase of urban development in many western cities, lasted up to approximately World War II and was marked by radical transformation of the landscape and by incremental urban change. New development usually extended and grafted onto the existing grid framework, and the street was considered a public space.

In Calgary, 1912 the Mawson Plan [4], influenced by William Pearce, an early Calgary visionary, viewed natural features as prime determinants of urban development, and Calgary was envisioned as a city of trees, with land along the rivers set aside for public use, all connected like links in a chain. Although representative of the urban and environmental design thinking of that time,
very little of this plan was to be put into place. For many decades, riverside land in the downtown was perceived to have low value, and Calgary’s river banks were the site of lumber yards and industrial uses that would remain until the 1960s. Tree planting occurred through the efforts of a few influential leaders, in the face of a shortage of water, desiccating Chinook winds in the winter, alkaline soils, insufficient funding, the absence of a comprehensive plan, and conflicts with utility companies.

Early public spaces included railway gardens (a distinct North American form located adjacent to the railway stations whose primary functions were promotion of the towns and advertisement of prairie fertility), as well as central memorial parks, public spaces associated with public buildings, and recreation parks. As the city expanded, Council required dedication of a minimum of five percent of proposed subdivisions for parks purposes, guaranteeing that all citizens would have access to open spaces, recreation areas, and playgrounds.

The second phase coincided with the period of economic growth following World War II, and corresponded with modernism, corporate development, and the institutionalization of town planning. History, tradition, and local identity were thought to be anti-progress and old-fashioned, and land uses such as parking were considered more important than the public realm. As a result, huge swaths of urban fabric were torn down and replaced with surface parking, eliminating many public spaces.

In Calgary, there was an emphasis on the provision of parks and open spaces for the booming post-war population, focusing on residential neighbourhood planning. The neighbourhood was the planning unit for suburban development, with school and park as the social and functional centre as the baby boom population reached the its teen years. This ushered in a shift from beautification, decorative parks, and playgrounds to family and athletic parks. As an unintended consequence, partly due to the growing requirement for standardized design and construction details, parks began to exhibit a more uniform design vocabulary. The diverse “natural” environment, which featured a range of environmental and microclimatic contexts, became more and more removed from what was built, leaving little indication of the original landscape.

At the same time, new ideas influenced society’s notions of nature, notably Aldo Leopold’s thoughts about environmental and land ethics [5], and Rachel Carson’s critique of pesticides [6], which helped to launch the environmental movement and pave the way for broad acceptance of ecology as a way of thinking.

The third phase, from the late 1970s through to the last decade or so, continued to include standard details and replicated park types, but it also included completion of several significant projects, such as Nose Hill Park and Fish Creek Park, two large environmental areas, which came about through the efforts of an increasingly engaged and ecologically minded citizenry.
The land along the rivers was also finally dedicated as publicly accessible open space in 1991 via the Urban Parks Master Plan and now includes more than 800 kilometres of pathways connecting the rivers and other water bodies, and another 300 kilometres of bikeways and cycle tracks.

We have now entered into a **fourth phase** of urban development. Ideas about sustainability and sense of place, together with a concern for the public realm, are part of the value systems of society and the environmental design professions and should be informing the public realm that we create.

There are currently two parts of the city that have somewhat different processes of park development: new suburbs, that are required to have ten percent of developable areas set aside for public amenities, including parks, and the process of re-urbanization in the developed areas. In an effort to counter suburban sprawl, redevelopment and intensification are encouraged in inner city areas. These new urban residents require open space and also have a greater expectation of urbanity in their surroundings, and ambitious public realm improvement programs are more common.

However, with increased urbanization comes associated environmental issues related to pollution, creation of heat islands, and the amount of pervious/impervious surfaces, and maintaining a healthy urban forest, achieving minimum recommended canopy coverage, and creating sustainable parks are challenges in the presence of fiscal constraints. Urban landscape projects are frequently conceived of as individual, stand-alone sites by those responsible for planning the city.

Climate change continues to emerge as a pressing issue and will have unknown impacts on our cities. Drought, flood, air quality, and water quality are now profoundly influenced by human actions; many of the ecological changes are “human-caused, rapid, and drastic” [7]. These climate events, which are likely to become more extreme and also more common, affect our parks and open space.

Resilience, a concept that has become more important as extreme climate events have become more common, can be considered defined as the capability of an organism (or a city) to adapt to change. The capacity for a city to cope with extreme climate events or other changes—its resilience—is affected in part by how well its parks and open spaces can absorb the impacts of change. The tendency to standardize details, species, and designs has likely been a negative process that should be addressed by embracing diversity. Parks and open spaces that function as systems rather than as discrete spaces—where they have a diversity of species, form and function—are more likely to be able to maintain ecosystem health and to offer a greater capacity for resilience [8].

Considerable research has shown how parks and open spaces are vital elements in improving the urban environment and mitigating climate change. As temperatures increase in Canadian cities, proper plant material selection becomes vital, since vegetation is important in regulating air temperature. The urban heat island effect, the phenomenon of higher temperatures in urban
areas due to the absorption of solar radiation by buildings and paved surfaces, is accentuated as more area is devoted to paved surfaces than to vegetated areas and water bodies.

In Calgary, what is often forgotten when flood events occur is that we are in fact living in a dry prairie landscape where water is the limiting factor to plant growth, and this calls for careful decisions in the selection of plant material.

3. A landscape approach to environmental design

Parks and open spaces are part of a more structurally complex environment and need to be thought of as more than just “green space”, a term that suggests a benign area with mown grass and ornamental plantings, irrigation-heavy practices that are significantly in conflict with the local and regional environmental constraints [9].

Have our approaches to landscape architecture and our methods and techniques kept pace with our values of sustainability, resilience, and ecological integrity? Are they sufficient to address the challenges of the 21st century, such as the uncertainties of climate change?

Our landscapes today will certainly not be those of tomorrow, and some forward thinking is necessary, and a bold framework for landscape architecture.

We have many building blocks for this approach:

- Ian McHarg [10] demonstrated that physical planning and design should be based on a thorough understanding of the ecology of the area, together with human values. McHarg once proposed that environmentally sensitive areas either remain in their natural condition, or be returned to that condition. He claimed that this single technique could address water quality, quantity, flood and drought control, and lead to “an immeasurable improvement in the aspect of nature in the city, in addition to the specific benefits of a planned watershed. No other device has such an ameliorative power” [11]. Hugely influential in environmental planning, McHarg’s ideas were, however, often considered to be anti-urban.

- Landscape ecology as a field considers regions in terms of a land mosaic, where landscape is understood as a network of patches and corridors. This approach provides a useful vocabulary, and could help to get away from thinking of individual parks as objects or discrete spaces, but is usually confined to the understanding of natural systems.

- The language introduced by Kevin Lynch [12] for understanding city form—as a system of paths, nodes, edges, districts, and landmarks—helps in understanding the public realm as a system as opposed to individual streets, parks, and other spaces.

- Michael Hough [13], in his detailed understanding of cities and the natural processes within them, proposed ideas of urban ecology as the basis for shaping cities, and also emphasized that in addition to increasing the amount of vegetated areas in the city, good design
practices need to be included. Sheltered, well-defined, and well-treed spaces are much cooler in hot weather, and also greatly increase comfort in winter. These ideally should be in the form of a “fine mesh of small spaces, distributed evenly over the whole city” rather than relying only on a few large ones. Anne Whiston Spirn [14], whose early writing coincided with Hough’s, similarly addressed the need for integration of urban living and natural processes.

• By combining the language of landscape ecology and urban design, the city can be thought of as an integrated system of urban and landscape, where parks and neighbourhoods are connected by corridors—like streets, linear greenways and rivers—within larger districts. It is within this combined system of urban and natural that habitats and species (including humans) can live healthily. Merging these vocabularies and theories also allows something typically thought of as purely “urban”, such as streets, to be considered as a part of the urban ecological framework, and something thought of as purely “natural”, such as the urban forest, to be considered as part of the city.

• The shifting bio-climatic regime that has been recently documented in the Climate Atlas of Canada [15] provides a sobering glimpse of the world that is coming, and suggests that our design approach, as well as the vocabulary of parks, domestic landscapes, and the public realm, should be radically re-thought, in anticipation of these changes.

The combination of our current values with the needs of today call for a renewed approach to environmental design and different ways of conceptualizing urban planning and design. It is likely that a new convergence of interests in a high-quality public realm, in public health and sustainability, and in the unknown future that comes with climate change, will help to further the agendas of good environmentalism and good urbanism. We are in a transitional state, becoming a different kind of city in many ways, with our tools and techniques needing evolution to evolve as well.

By examining the layers of the built environment, we can understand the important role that the landscape and public realm play [16]. Too often we have placed more value on the less permanent layers, such as buildings and decoration, rather than on the more permanent layers of landscape, parks, and public space.

Landscape and the public realm constitute the deepest layers of urban infrastructure, and are essential and fundamental, with even more importance if the need for resilience is considered. Viewed as part of the permanent infrastructure of the city, they cannot be viewed as afterthoughts, or as frills. They need to be understood as foundational for the city, and therefore deserving of higher profile, and increased emphasis in budgets.
Fig. 1 Pyramid of permanence (Sandalack and Nicolai 2006)

Layer 1 – the land
Landscape is the most permanent aspect of the built environment, with the greatest potential to contribute to ecological health and sense of place. Attention to topography, natural features, views, and connections is required as foundational knowledge. Good urbanism is good environmentalism.

Layer 2 – the public realm
The public realm—the shared city spaces made up of streets, squares, parks, and plazas—is part of the city’s connective tissue, providing space for circulation and gathering and helping to define the city image. Once established, block patterns, land uses, and creation of public spaces are difficult and costly to redevelop.

Layer 3 – buildings
Buildings are the most visible part of the urban environment, but not the most permanent—several generations of buildings will come and go within the life cycle of the urban structure, but they shape the edges of public space. The outsides of buildings form the inside wall of the public realm; all buildings have a responsibility to help positively shape public space.

Layer 4 – activities or program
Each individual building, and each neighbourhood, if its form is resilient, may be used for various activities or programs. Cities are at their best where there is a mix of uses, housing types, and people, and where they provide more opportunity for adaptation and continuity.

Layer 5 – trends and fashions
The least permanent aspects of the built environment, and of design activity, are the ephemeral trends and fashions, including colours, decoration, and public art. These add delight and contemporariness to the built environment and reference contemporary culture, and they can help to express the sense of place by reflecting environmental features or conditions.

This ‘pyramid of permanence’ helps in understanding the inter-relatedness of the built environment. Theories, tools, and techniques from landscape ecology and urban design, combined with more recent understanding of ecosystem services, also help to view the public realm as part of connected urban ecosystems, rather than discrete spaces, where landscape and urbanism potently intersect. Landscape and the public realm should be the deepest layer of urban infrastructure and need to be established first,
before roads, land subdivision, and building plans.

Complicating matters further, the anticipated future climate regimes should be included in the design process. Green infrastructure is all of the “natural, semi-natural and artificial networks of multifunctional ecological systems within, around and between urban areas, at all spatial scales” [17] emphasizing both the quality as well as the quantity of urban green spaces. Municipalities should incorporate practices that the urban ecology fields use “for measuring and managing urban land cover to maintain hydrological function, promote air quality, regulate microclimate, sequester carbon, and preserve species and habitat diversity” [18].

This requires a proper valuation of landscape and ecological function. The ‘natural capital’ of many places is often a major asset. Where capital is understood as any resource that can increase economic opportunity, natural capital means the resources that we rely on for life, provided by geology, soils, air, water, and all living organisms.

The notion that natural resources have capital value, leads to the concept of ecosystem services, which provides a way to evaluate parks and open space systems, determine their impacts, and then set measurable goals. Ecosystem services refers to “the benefits human populations derive, directly or indirectly [19], from ecosystem functions”

De Groot et al. [19] identified twenty-three ecosystem services that included biological, physical, aesthetic, recreational and cultural benefits. Many of them, such as climate regulation, water supply and aesthetic scenic properties, contribute directly to human health and wellbeing, but others, such as pollination and nutrient cycling, more indirectly contribute to sustaining ecosystems themselves.

Understanding the deep value of our city’s parks and natural landscapes, and the ecosystem services they provide, elevates the urban natural environment to a deserved position of importance and a higher priority for investment.

4. Summary

The planning and design of parks and open spaces through history have reflected the values that were held at the time, such as aesthetic criteria, practical needs, or demands for recreation. We have entered worldwide into a new phase where concerns about sustainability, resilience, public health, sense of place and an emphasis on the public realm, and the urgency of climate change—all topics within the domain of Landscape Architecture—are in the forefront, and this presents the opportunity to articulate a position and an approach.

We need a common vision for the future that emphasizes the importance of landscape and the public realm for all people and all places. The values that they provide go beyond the aesthetic or recreational—the ecosystem services that they provide, and the potential to adapt to more extreme conditions, will help ensure our very survival. In order for this landscape approach to the 21st century city to be realized, we need to address several urgent issues.
Climate change is going to have a profound influence on our physical environment and on our quality and way of life. The potential impacts need to be recognized and understood, and the role that parks and open spaces might play in increasing the resilience of our cities needs to be emphasized. This implies the need for changes in the education of future professionals as well as adaptation of our current methods, processes, and regulations.

Integration of new theories and new practices with some of our foundational theories and methods, and the recognition of the potential impacts of climate change, should become a priority for our profession, our education programs, and our local and national governments, as a matter of urgency. Too often, the limitations of training and legislation constrain many of the design disciplines, and consequently segregate the professions and result in discrete and un-related individual projects. However, if we can emphasize the inter-relationship of scales of thinking, rather than disciplinary concerns or boundaries, and focus on the quality of our environments and the quality of life of the inhabitants, there is a unique opportunity for Landscape Architecture to emerge as a stronger leader.

Acknowledgments

An earlier version ‘Green City: A landscape approach for the 21st century city’ by BA Sandalack was published in March 2017 by Park People in the Heart of the City papers.

Water traces in the coastal zone of Lake Biwa: toward reconfiguring cities with latent natural systems

Shuichi Murakami\textsuperscript{a}, Shinichi Todoroki\textsuperscript{a}

\textsuperscript{a} University of Shiga Prefecture, 2500 Hassaka-cho Hikone 522-8533, Japan

Abstract

Water traces are spatial elements that indicate that water areas have been changed into land areas owing to past developments. Water traces enable determining the original appearance of the land and examining the land allocation in the future. However, as society’s demands on the land change, further overwriting of the land is occurring and water traces are disappearing. Therefore, the objectives of this paper are 1) to comprehensively document the places wherein former water areas became land areas in this region, 2) to find elements of potential water traces at these locations and to catalog their characteristics, 3) to examine research methods to identify these elements as water traces to be preserved, and 4) to examine the possibilities for water traces when drawing future plans for these cities. Field survey based on a comprehensive map analysis of the water areas that changed into land areas showed elements that are likely water traces. Such elements include 1) height differences in the ground matching linearity of former shorelines, 2) outlines of land surfaces matching the recesses of former shorelines, 3) outlines of land surfaces matching the linearity of former creeks, and 4) height differences of the ground matching the outlines of former lagoons. To identify these elements as water traces, the details about the formation of these elements must be investigated. In addition, the existence of elements with a high risk of extinction emerged. A student-led study of ideas for incorporating these elements into the land history resulted in three methods to use and pass on the elements. These methods were 1) to make it easier for people to recognize the element, 2) to regenerate the water area, and 3) to apply a new program to the element and use it as a space.

Keywords: natural system, reclamation, remnant, land history, water area

1. Background

For a city to coexist with nature in future, it is important to reveal the latent natural systems obscured by the present urban condition. One of the key elements to excavate this hidden nature is determining the water traces. Water traces are spatial elements that indicate that water areas have been changed into land areas owing to past developments. For example, a previous study of a coastal city reported that the retaining walls of a residential land area indicated the locations of the original lake shorelines and that a road in the city had retained the shape of a filled-in river \cite{1}. Water traces enable determining the original appearance of the
Biophilic Cities

land (the former water areas) and examining the land allocation in the future. However, as society’s demands on the land change, further overwriting of the land is occurring and water traces are disappearing. The present condition of water traces should be recorded, and measures to preserve them and pass them on to future generations should be implemented.

2. Objectives

Many water traces are likely to be distributed in the six cities along the coast of Lake Biwa, which is the largest freshwater lake in Japan. This is because water areas, such as lakes, lagoons, ponds, creeks, and rivers, have been transformed into residential, industrial, commercial, and agricultural land via rapid developments in the modern era [2]. Some water traces have been reported; however, those in this area have not been completely identified. Therefore, the objectives of this paper are 1) to comprehensively document the places wherein former water areas became land areas in this region, 2) to find elements of potential water traces at these locations and to catalog their characteristics, 3) to examine research methods to identify these elements as water traces to be preserved, and 4) to examine the possibilities for water traces when drawing future plans for these cities.

3. Methods

This study was executed using the following methods.

1) The water areas that changed into land areas in this region were mapped out on a geographic information system by overlaying maps from 100 years ago on current maps.

2) Field surveys were conducted using the above-mentioned maps. The elevations of the ground and the outlines of land surfaces of the mapped out areas that matched the shapes of the former water areas were investigated. The positions, types, and conditions of such elevations and outlines were recorded as the possible elements of the water traces.

3) The recorded elements were classified based on the data obtained via the survey.

4) Research methods for identifying those elements as water traces to be preserved were considered.

5) The ideas were studied to use and to pass on some of the recorded spatial elements, and the possibilities for water traces were explored for future development.

4. Results and Discussion

4.1. Water areas changed into land areas

A map of the water areas that were changed into land areas was created by overlaying maps from 100 years ago on current maps (Fig. 1). This map showed that former water areas were distributed throughout the research area. These areas were roughly divided into those exhibiting linear and planar forms. The ones exhibiting a linear form were shorelines, rivers, and waterways. The locations that were once water areas around Lake Biwa had been filled in and constructed into ports, parks, levee beds, and roads adjacent to the former shorelines. The recesses in the shorelines (creeks and ship pools) had become farmlands and roads. The rivers and the creeks, in the forms of single lines, tree
Biophilic Cities

shapes, and meshes, had become farmland and roads. However, cases wherein the water areas had not completely disappeared existed but had remained as waterways along the roads. Water areas that had been lagoons and ponds had become farmland, building sites, parks, and landfills.

To understand the reason for changing these water areas into land areas, several development projects in the catchment area of Lake Biwa were cited. First, a River Water Control Project was conducted from 1942 to 1953. By controlling the weir at the exit of Lake Biwa, the water level of the lake was lowered by a maximum of 1 m and the discharge from the lake was increased to secure the water supply and industrial water in the downstream urban areas and to increase the amount of electricity generation. Some shallow water areas probably became land areas owing to the lowering of the water level [3]. Next, lagoon reclamation projects were implemented from 1944 to 1968 [4]. At Lake Biwa, 15 lagoons were reclaimed to increase farm production and eight of these lagoons were included in the research area. Further, the Lake Biwa Comprehensive Development Project implemented from 1972 to 1997 should be mentioned [5]. In this project, embankments were constructed off the lakeshore. The renovation of rivers pouring into Lake Biwa also advanced. In addition to these large-scale development projects that covered all of Lake Biwa, the development of fields was promoted in various locations and the development of residential lots and roads was promoted along with the expansion of urban areas; these were also considered to be factors for changing the water areas into land areas.

Fig. 1. Map of the water areas changed into land areas (red part)
4.2. Elements having the possibility of being water traces

The elevations of the ground and the outlines of land surfaces, which matched the shapes of the former water areas, were found via a field survey. Herein, these elements are classified according to their types based on the survey results. Moreover, research methods for identifying these elements as water traces to be preserved were considered.

4.2.1 Height differences of the ground matching the linear features of the former shoreline

Figure 2 shows a site of a temple surrounded by a masonry retaining wall. The height of the wall is 1 m. This temple is located in the residential area closest to the lake. An embankment with a road running along the top and a park with an artificial pond are located in-between the wall and the lake. These features were constructed during the Lake Biwa Comprehensive Development Project. The map from 100 years ago showed that the temple had been facing the lake and that there had been revetments between the temple and the lake (Fig. 3). The map symbol for the revetments continued not only in front of the temple but also in front of the residential area. The residential site adjacent to the temple was 1 m higher than the road on the front, with the retaining wall.

The method to identify the retaining walls as traces of the shoreline was as follows. The park in front of the temple site and the road in front of the residential site were 2 m higher than the standard water level of Lake Biwa. Despite considering that the water level had reduced by 1 m owing to the River Water Control Project, the ground contacting the retaining walls were higher than the water level recorded 100 years ago. This showed that the former lake had been landfilled and bulked. To determine whether the temple and residential sites had been bulked the background of the landfill should be investigated in detail.

Places wherein the retaining walls discontinued also existed. The slopes connecting the garages of the residential sites and the front roads cut into the retaining walls. Moreover, residential sites with no elevation difference with the front roads also existed. When renovating residential sites with a high elevation, the retaining walls might have been lost as the height of the grounds were adjusted with the surrounding lower residential sites.

Fig. 2. Image of a masonry retaining wall supporting the site of a temple

Fig. 3. Map showing the residential area 100 years ago [6]
4.2.2 Outline of land surface matching the recess of the former shoreline

Figure 4 shows an image of a turning space in a road passing through the center of a residential area adjacent to a fishing port; it is a rectangular space with a length of 65 m and a width of 25 m, and there is a small square and a bus stop at the center. The fishing port and a road bridge crossing over the fishing port are in-between the turning space and the lake. Both were constructed during the Lake Biwa Comprehensive Development Project. The map from 100 years ago showed that the shore had been indented in this region and had functioned as a fishing port until a new one was built (Fig. 5). An image of the old fishing port indicated that this area had been used as a ship pool (Fig. 6). Therefore, it is obvious that the turning space is the trace of the ship pool.

However, the following issue was cited as a factor for preserving the trace of this ship pool. When boats were used for daily transportation, this place was used as a ship pool. When vehicles were used for daily transportation, this place was used for car maneuvering, temporary parking, and as a bus stop. Thus, this residential area has always been a hub of transportation; however, the fact that this area was once a part of the lake cannot be neglected. Since this area is located 1.5 m higher than the standard water level of Lake Biwa, it is now leveled with the surrounding residential sites. Therefore, it is difficult to determine whether it had once been a water area.

4.2.3 Outline of land surface matching the linearity of former creeks

Figure 7 shows an image of a road unnaturally winding through the center of a residential area. The width of the road is 7–10 m, and its length is 350 m. The residential sites are lined along the meander on both sides of the road. The map from 100 years ago indicates that a creek had flowed through the residential area instead of the road (Fig.
Lake Biwa. In addition, no difference in height between the road and the surrounding residential sites is observed. No spatial elements that are necessary for using boats are attached to the residential sites along the road. Therefore, it is difficult to visually notice that the road had once been a creek.

4.2.4 Height Difference of Ground Matching the Outlines of Former Lagoons

Figure 9 shows an image of a grass-covered slope in the middle of a rice field. The height of the slope is 2 m. On the upper part of the slope, there are flat rice fields at an elevation of 85 m. At the bottom of the slope, there are rice fields at an elevation of 83 m, more than 1 m lower than the standard water level of Lake Biwa. On the map from 100
years ago, this had been a lagoon (Fig. 10). The lagoon had been reclaimed between 1944 and 1947 \cite{11}. The line of this slope coincides with the previous shoreline of the lagoon. Such slopes intermittently exist throughout the reclaimed land around the previous shoreline of the lagoon (red line in Fig. 11). In addition, the water areas had not completely disappeared but had remained as waterways along the top or the bottom of some slopes.

The method to identify the slopes as traces of a lagoon is as follows. Because the lagoon was a 1–2-m deep, flat-bottomed water area separated from Lake Biwa by sandbanks and sandbars \cite{12}, the slopes with a height of 2 m dotted on flat land that is at a lower level than Lake Biwa suggests the possibility of a trace of a lagoon. However, the shore of the lagoon had once exhibited a landscape structure from the land area to the water area, such as a waterside forest, a water extraction plant, a floating leaf plant, a submerged plant, or an open water surface \cite{14}. Therefore, not only the current slopes’ land surfaces but also their cross-sectional shapes are different from the original shore of the lagoon. Conditions wherein paths and waterways are located at the top and bottom of the slopes imply the possibility that the original shore was artificially altered during the lagoon reclamation project. In another lagoon reclamation project, to secure irrigation water to reclaimed land located at elevations lower than that of Lake Biwa, a waterway was established around the reclaimed land and embankments were built to prevent the reclaimed land from flooding \cite{15}. To identify the trace of the lagoon, the history of the lagoon reclamation and the improvements made to the fields around the lagoon must be understood.

The following issue was cited with respect to preserving and passing on the trace of the lagoon. At multiple locations, the slopes are interrupted (Fig. 11) and the elevations of the reclaimed land are the same as those of the surrounding areas (85 m). This land is used for agriculture and as a landfill. In both cases, the land was lifted, thereby eliminating the height difference with the surroundings and interrupting the slopes. Based on these circumstances, a detailed examination is necessary to determine how to deal with the elements of possible traces of the lagoons.

4.3. Possibilities for Water Traces when Imagining the Future of the City

Seven students studied the elements judged to possess the possibility of being water traces as a result of the field survey and investigated ideas to incorporate them as land history elements. Their design outputs were divided into three methods: 1) to make it easier for people to recognize the element, 2)
to regenerate the water areas, and 3) to apply a new program to the element and use it as a space.

4.3.1 Making it Easier for People to Recognize the Element

Lagoon-reclaimed land below the lake level that has been separated by levees from the lake. The surfaces of the levees will be covered with ground-cover plants, and rows of trees will be planted on them. Every season, the levees colored by the trees and the ground-cover plants, such as cherry blossoms and fall foliage, will highlight the edge of the lagoon that once existed (Fig. 12).

Fields have been created by landfilled wetlands in the water district. The appearance of the fields will change during the course of cultivation according to the season. A tree deck will be built on the fields so that people who visit can observe the seasonal changes of the fields (Fig. 13).

4.3.2 Regenerating the Water Area

A lagoon will be regenerated by flooding the reclaimed land. The area of an existing pear orchard will be expanded as well. The site will be developed into a park, a core space where people can enjoy boat rides and harvest pears (Fig. 14).

A sports park is located on a lagoon-reclaimed land. The view of the lagoon from the castle adjacent to the park is one of the important elements contributing to the historical value of the castle. After the big event closing, the coastal environment of the lagoon will be reproduced in the park and its surroundings. The sports park will become a legacy of the event in the midst of the wetland, thereby contributing to the castle’s historical legacy (Fig. 15).
4.3.3 Applying a New Program to the Element and Use it as a Space

The creek that flowed in the middle of a coastal village appears as a winding road. Ripple-like terrains will be built at various locations as an activity base for the residents, and covered pergolas that reflect the former water surface will be included throughout the area (Fig. 16).

A space for an exchange base in this region will be constructed on a wedge-shaped piece of land that exists between the outer edge of the reclaimed lagoon and the main road. By manipulating the wall, frame, roof, floor, and void in-between variables, possibilities of the forms in the space that inherited the trace of the lagoon will be explored (Fig. 17).

A center for education and landscape design research will be built on a lagoon-reclaimed land. The site will be subdivided by the size of the field that once existed. In each lot, infinite possibilities of the six element parameters, such as landform, water, surface, planting, circulation, and building, will be explored (Fig. 18).

5. Conclusions

Field survey based on a comprehensive map analysis of the water areas that changed into land areas showed elements that are likely water traces. Such elements include 1) height differences in the ground matching linearity of former shorelines, 2) outlines of
land surfaces matching the recesses of former shorelines, 3) outlines of land surfaces matching the linearity of former creeks, and 4) height differences of the ground matching the outlines of former lagoons. To identify these elements as water traces, the details about the formation of these elements must be investigated. In addition, the existence of elements with a high risk of extinction emerged. A student-led study of ideas for incorporating these elements into the land history resulted in three methods to use and pass on the elements. These methods were 1) to make it easier for people to recognize the element, 2) to regenerate the water area, and 3) to apply a new program to the element and use it as a space.

Why Designing for Neighbourhood Landscapes Matter - Overview of Research Project

Professor Tan Puay Yok
National University of Singapore
Singapore

Synopsis:
Neighbourhood landscapes are the quintessential forms of landscapes in most cities. These are the green spaces that buildings and infrastructures are embedded in – the myriad interstitial spaces between buildings, peripheral plantings at edge of residential plots, and increasingly, vegetated areas on buildings. Despite their small individual sizes, neighbourhood landscapes collectively constitute a rather large proportion of cities’ vegetative cover. As landscapes, they have the potential to influence the ecology and quality of the urban environment, improve the well-being urban dwellers, and forge identity, sense of place and care for the environment. This potential increases markedly for neighbourhood landscapes because of their large land uptake and proximity to the large majority of urban dwellers. But because of their mundaneness and small size, they are seldom the attention of designers compared to large gardens or green infrastructure projects. There is scant literature in the world on conceptual framework, approaches and design guidelines for the planning and design of neighbourhood landscapes, especially in the context of high-density estates which will increasingly need to house more people in the rapidly urbanising regions of Asia and elsewhere in the world. This talk presents highlights of the project undertaken in collaboration with the Housing and Development Board, National Parks Board and Urban Redevelopment Authority on development of a conceptual framework and guidelines that could maximize the potential of neighbourhood landscapes through urban ecosystem services.
Designing FOR Nature

Leonard Ng
Ramboll Dreistl Studio
Singapore

Synopsis:
Remember that famous landscape book by Ian McHarg – Designing with Nature? Much of modern cities has evolved beyond Ian’s compelling design philosophy. Many of our cities are urban jungles where nature is but a remnant of its former glory; almost an afterthought in this highly engineered environment. Nature must be more than bits of greenery draped onto buildings. Nature must play an equal role in the health of our urban environments so that future generations will stay rooted in their origins. This presentation will show some recent projects of efforts at reclaiming spaces for nature within our cities.
Standing on the Ground: Respecting the original topography

GyoungTak Park
Dongsimwon Design Corp
Republic of Korea

Synopsis:
The project title, standing on the ground is a poetic statement that denies the conventional design practice of flattening the original topography to build high-rise structures, which has been creating a typical landscape with similar appearance of blocks all over the city and substantially damaging the existing ecosystem and unique heritages of the site. The proposed design solution argues that the development of high-rise structures based on the respect of the existing topography and inherent natural characteristics is not only feasible but also the key to strengthening the identity of the site. The existing hills and low-valley area that are important natural assets of the site to be preserved, together with the proposed linear Park system described below, establish a strong interconnectivity for both human and nature throughout the site and becomes a framework for a new development plan.

Design Concept - Linear Parks
A series of long and narrow parks are designed to overcome the weakness of the conventional satellite park system of Singapore. The separated parks in the satellite park system does not only degrade the biodiversity of the region leaving each green patch isolated, but also weaken the bond among the communities neighboring each park. However, the proposed linear park system enhances the interconnectivity among the parks and communities of the region by creating a matrix of green corridors in various types and scales which include Main, Secondary, and Tertiary Linear Park and Green Necklace. The four ranks of Linear Park as green arteries, connecting important natural assets and running all over the site, maximize the extent of opportunity for people to access to all the parks, open spaces, amenities, and programed spaces.

Preservation Parks – Hills, Mountains and Low-Valley Area
It is suggested that the most important natural assets of the site are to be the Preservation Park and become the core part of the entire green network system of the site. Hills and mountains from 35m to 50m in elevation are one of such important natural assets of the site in terms of its rarity value in Singapore landscape. In addition, building HDB high-rise residential blocks in such high-elevation areas requires substantial destroy of the rare landscape. Hence, the design solution proposes that the hills and mountains are to be the Preservation Park surrounded by various buffer greens such as apiary, community farm, forest playground and etc. The Preservation Park together with the contiguous buffer greens around becomes a neighborhood park located at the center of a residential block. Within the residential block, School, hospital, and community center are located closer to the neighborhood park to more actively appreciate and utilize the natural resources.

Low-valley area is another important natural asset of the site due to its ecological value, rich nutrients and humid micro-climate. Hence, the design solution proposes the low-valley area with less than 5% degree slope to be Preservation Park. Two low-valley areas of the site designated as Preservation Park function not only as the ecologically important aquatic corridors but also as the waterways of the two watersheds for the western region of Singapore. Two large detention reservoirs are also suggested to mitigate flood risk and to support various water related leisure activities. These reservoirs are located at the boundary of the site, being used as water source for the waterfront of the suggested commercial area.
The Wenshan Oasis Project: Neighbourhood Landscape Design along the Waterway

Liu Po-Hung
Chairman
Classic Landscape Design and Planning, Ltd

Synopsis:
Singapore developed the Neighbourhood Landscape Planning and Design Framework (NLPDF) that guiding the design of neighbourhood landscapes nestled among residential buildings in the high-density, high-rise public residential estates. Taipei city is conducting similar projects that transform abandoned spaces into sustainable community shared space throughout residents’ cooperation.

Wenshan district is located in the suburbs of Taipei city and surrounded by several small hills. This topology brings abundance of ecological resources to Wenshan district. On the other hand, it also causes humidity and frequent flooding during rapid storm runoff. In order to ease the storm runoff, we conducted some field research to Wenshan district. We discovered that there used to be 4 main irrigation systems in Wenshan district, Liugong canal, Xingfu sub-canal, Wulixue canal, and Wansheng River. However, as Taipei city developed, the irrigation systems are covered in the underground. This not only limits its potential to adapt to climate change, but also left a lot of hidden back-alley ran zigzag between buildings.

The concept of “Wenshan Oasis” is to remodel these abandoned spaces into Rain Gardens and Bioswales that help absorbing the water runoff and lower the probability of flooding. Moreover, we intend to transform these spaces into community shared spaces that engage the residents and enhance community cohesion. The Wenshan Oasis Project aims to create community spaces that are ecological, flood-detaining and with local vibe.

Before remodeling the actual space, we held several residents’ networking events for everyone to interact face to face. There was a participatory activity of space-planning that used 1:1 scaled scenario props. There was an outdoor exhibition and a workshop about making models of urban design. There were community dinner parties that everyone was invited to, and we gave short talks at the dinner parties. We installed a playful “Water Wall” for children to have fun. We even designed a scavenger hunt – “To Find The Home of River God”. This game linked with local historic story and made the waterway issue entertaining.

We applied varies strategies in these events to make participants experienced how a vacant space could be transformed. Local residents started associating with the community environment through the activities. They discovered the correlation of their environment and its drainage systems, and they recognize the importance of this relationship. As local residents gradually care more about their environment, they are motivate to take action. They started to improve community shared space, creating an ecological, flood-detaining, and leisure environment.

Wenshan Oasis project echos to the concept of Neighbourhood Landscape Planning and Design Framework (NLPDF). The project focused on the topic of “disappearance of the waterway”, and remodeled the abandoned spaces into community space that are beneficial both ecologically and culturally.
Landscape Design with Ecosystem Services in High-Density Cities

Professor Liao Kuei-Hsien
National Taipei University

Synopsis:
In recent years, the concept of ecosystem services has become popular in the discipline of landscape architecture, which has increasingly applied ecology to open space design as sustainable design becomes a norm. However, how ecosystem services can be explicitly integrated into landscape design is still an area of early development, in both research and practice. Most existing literature on ecosystem services focuses on natural ecosystems. While it helps landscape architecture professionals understand the concept and basic science of ecosystem services, it provides little guidance to how to design with ecosystem services. The research on ecosystem services in the urban context, or urban ecosystem services, is highly relevant to landscape architecture. However, existing literature is still rather limited. The operationalization of the concept of ecosystem services requires a clear guidance to how to design with ecosystem services. Developed by an interdisciplinary research team, the Neighbourhood Landscape Design Guidelines (NLDG) provides a concrete methodology to explicitly design for multiple ecosystem services in neighbourhood landscapes in the context of high-density cities, where humans and nature intensively interact. Neighbourhood landscapes, or residential landscapes, refer to the open space in residential neighbourhoods. While they are a relatively underappreciated type of open space in landscape architecture, they account for a substantial amount of the total green areas in the city. Neighbourhood landscapes therefore can be considered the most common form of urban ecosystems, to which urban dwellers are exposed on a daily basis and which should be capable of providing multiple ecosystem services. The omnipresence of neighbourhood landscapes suggests that they can significantly affect the well-beings of the urban dwellers and the overall ecological quality of the city through the ecosystem services they provide. How neighbourhood landscapes are designed, used, and maintained would determine the quantities and qualities of their ecosystem services. Therefore, it is important that the design and management of neighbourhood landscapes are guided to optimize the provision of ecosystem services. As an example of how to design with ecosystem services, NLDG addresses seventeen urban ecosystem services that are identified to be more relevant in neighbourhood landscapes in high-density cities. For each ecosystem service, there is a suite of integrated design strategies for conserving, enhancing, or creating the service; targets for optimizing the service; and performance indicators for assessing the effectiveness of design. The details of NLDG is documented in a recently published volume titled “Nature, Place & People” authored by the research team (Tan et al., 2018). The objective of this presentation is to further explain the methodology behind NLDG. I will discuss the systematic approach to developing NLDG based on best available natural and social sciences. How to explicitly consider the tradeoffs between different ecosystem services will also be explored.
The Role of Green Spaces in Community Formation Depends on the Urban Context

Dr. Vincent Chua
National University of Singapore
Singapore

Synopsis:
There is growing recognition among scholars that green spaces are an important facilitator of community ties, but the specific conditions undergirding this link are less well understood. This study adds contextualization by asking when and for whom green spaces matter. Examining two neighbourhoods in Singapore, Punggol and Toa Payoh, our study finds an overall positive correlation between green spaces and neighbourly ties, yet uncovers some contingent effects. Singapore makes an interesting and relevant case given its high-rise and high-density residential contexts, its strong emphasis on greening, and its interspersing of urban and natural forms. We adopt the perspective that green spaces are simply one amenity among a broader range of other amenities (e.g., playgrounds, markets, shops, and the like) that coexist alongside green spaces to affect community formation.

Importantly, urban neighbourhoods incorporate both cultural and natural forms. On one hand, they are socio-ecological systems hosting a variety of commercial, industrial, and residential entities. On the other hand, they also host large swaths of vegetation cover and biodiversity, especially in biophilic neighbourhoods. The term garden city applied to Singapore captures the idea that urban and natural elements are interspersed. This being the case, the analysis of green spaces should be conducted while taking into account the broader socio-ecological mix within urban neighbourhoods, including their amenity mix and provisioning of other services. Depending on surrounding conditions and pre-existing provisions, green spaces can add to the provision of values and services to residents or be more contingent. This suggests a need for contextualized analysis.

We consider the following two possibilities: First, we venture that the positive relationship between green spaces and community formation might be attenuated among residents who already have strong place attachments to the neighbourhood. Second, this impact of green spaces (on community formation) might be less influential among residents who live in neighbourhoods characterized by a long-established network of amenities (such as provision shops, markets, food centres, libraries and the like) that already do a good job bringing residents together. Our findings justify our analysis and underscore a contingent view of the role of green spaces in community formation. First, we find that if residents are already well entrenched and have strong place attachments to their neighbourhoods, additional green spaces will do less, comparatively speaking, to strengthen their ties with neighbours. This is especially so if residents are part of neighbourhoods that are older, with a well-established network of social amenities that already do a thorough job bringing residents together. Second, analysing green spaces against a broader canvas of the neighbourhood as constituted by a range of amenities and pre-existing conditions allows us to determine the limits of what green spaces can be expected to achieve for neighbourhood communities. It is the mix, the interfacing of the man-made and natural structures that requires theoretical attention, not just one or the other.
Window View and the Brain: Can Floor Level and Amount of Green within the View Have an Effect on Mental Health and Well-Being?

Dr. Agnieszka O. Guizzo  
National University of Singapore  
Singapore

Synopsis:
Landscape views are a pervasive feature of urban areas which can restorative effect on mental health and well-being of urban dwellers. The quality of these landscapes and the visual connection with the natural elements (like greenness of the vegetation) constitute an important factor in the aesthetic values of a landscape - one of the landscape services in the socio-cultural (or People) category. In the high-rise, high-density context of residential estates, like Singaporean HDB, the window view provides to its residents, the most immediate and easily accessible way of connection with the neighbourhood landscape. This can potentially influence their quality of life, mental health and well-being, and it was important to us to explore to what extent this can happen through modulation of the brainwave rhythms. Evidence-based design emphasizes the use of data collected through various experimental techniques, including methods of neuroscience, to provide the scientific basis for designs of the built environment; it has emerged as an important study area. In this presentation we show the findings from the explorative study on how different window views may affect the pattern of brain activity of HDB residents who are passively exposed to them, depending on the floor level and the green cover within the view. To measure the brain response, we designed a simple passive-task experiment where 29 participants, in the controlled lab environment, were exposed to set of 36 photographs of different window views, while simultaneously the electroencephalography (EEG) signal was recorded, using the 14-channel Emotiv device installed on their scalp. Participants, HDB estate residents, viewed photographs taken from different floors (3rd, 6th, 12th and 24th floor) of a high-rise housing block, with varying extents of green cover within each view (minimal, medium and high green cover). The results showed that amount of green cover within the view captured at different floor levels had significant effect on the frontal alpha and temporal beta brain oscillations recorded while participants viewed photographs. These results suggest that the brainwave patterns commonly associated with positive emotional states, motivation and visual attention mechanisms are increased by the extent of green cover within the view. This phenomenon seems more pronounced on the higher than lower floors. However, window views from the highest floor studied (24th) appeared to stimulate the brain in a less positive way, but this was partially negated by increased levels of green cover within the view. Our results emphasize the importance of considering the quality of window views in the planning and design of urban high-rise neighbourhoods. Simply having a view of greenery can contribute to the mental well-being of urban dwellers.
Abstract

In the 1980s, Rachel and Stephen Kaplan conducted extensive research on the correlations between spending time in nature and mental concentration. The product of the Kaplan’s work formed the Attention Restoration Theory, a primary source of reference for landscape architects in creating Biophilic Cities. The Kaplan’s Attention Restoration Theory states that a physiologically restorative environment is made up of four components: ‘fascination’, ‘extent’, ‘being away’ and ‘compatibility’. This paper presents three case study projects within Singapore’s Biophilic context distinctly created with aspects of the Attention Restoration Theory: Jurong Lake Gardens West, Sungei Buloh Wetland Reserve and Jurong Eco-Garden.

Jurong Lake Gardens West (JLGW) is a new national gardens planned to open by 2019 located in the island’s western heartland community. JLGW embodies two dimensions of attention restoration: ‘fascination’ & ‘extent’. The Kaplans’ describe the value of ‘soft fascination’ (clouds, leaves in the wind, sunsets) in nature as able to hold attention while leaving the opportunity to think. Within the design of JLGW, ‘fascination’ is invited through the careful composition of plant groupings with consideration of views to the surroundings, along with targeted visual relationships between birdlife zone and the spatial experience of park visitors. The mental restoration component of ‘extent’ can refer to the experience of interacting with a historic artifact and gaining a connection to the past. JLGW was originally dominated by freshwater swamp forest with flora adapted to the unique intertidal habitats that characterized this area. Visitors will draw upon the restorative aspect of ‘extent’ as plant species of the park were specifically selected based on historical association with Jurong’s tropical lowland freshwater forest. Through the components of ‘fascination’ & ‘extent’, Jurong Lake Gardens West serves as a case study for the Biophilic values of psychological restoration.

Within Kaplan’s theory of Attention Restoration, the components of ‘being away’ refers to the value of releasing the everyday worries and stress of life through the feeling of getting away. These destinations are often natural environments such as shoreline beaches or alpine mountaintops. While Singapore has a highly urban population, Sungei Buloh Wetland Reserve provides an escape to a mangrove hinterland along the country’s northern shore. Here visitors can leave behind the burdens of city life and immerse themselves in a rich native tropical environment with Smooth Otters and numerous migratory birds.

The Jurong-Eco Garden provides a case study to the last component of Attention Restoration Theory: ‘compatibility’. Anchored by the overarching vision of the Jurong-Eco Garden as the first business park in a tropical rainforest, the central core was designed as the lungs and heart of the unique ecology of the site, a tranquil breathing space for visitors and office dwellers. Here
‘compatibility’ is achieved by providing the compatible setting to human inclinations towards roles such as locomotion through trekking or observation through bird watching.

These three Singapore landscapes showcase the city’s Biophilic context through the four components of the Attention Restoration Theory.

**Keywords:** Attention Restoration Theory; Directed Attention Fatigue; Restorative Environments; Singapore; Biophilia

### 1. Introduction

Compared to 30 years ago, our contemporary lives receive five times the amount of daily information due to advances such as the internet, 24-hour television, and smartphones. This figure is a fraction of the amount of information we produce through email, social media and text messaging. In the late 1980’s, the average person created approximately two and a half pages of information a day. Now our daily information output could fill six newspapers, which is a 200-fold increase [1]. As a result, more mental attention is required to process this massive amount of daily information. The increase of effort to manage more data comes at a psychological cost. Mental fatigue often sets in when we exceed the amount of direct attention we can provide on a given day [2].

This form of mental exhaustion is called Directed Attention Fatigue. It is most frequently caused by periods of intense or prolonged work. Directed Attention Fatigue can affect one’s ability to perform common tasks such as Selection, Inhibition & Affect, Fragility, Perception, Thought, Action, and Feeling [3]. While sleep provides one approach to Direct Attention Fatigue recovery, it can be insufficient as insomnia may develop before a full recovery is gained. Based on Kaplan and Kaplan’s research, a restorative experience within the natural environment can provide an alternative mode for directed attention restoration.

#### 1.1. Attention Restoration Theory

In the 1980’s & 1990’s an abundance of research was developed regarding the psychological benefits of nature. Natural environments were further understood to be specifically equipped with the robust values necessary for both attention restorative experiences and stress reduction [4]. At that time, the focus of environmental psychological research had situated the study of attention restoration apart from stress reduction [5]. Attention Restoration Theory sought to address the theoretical divide and shift towards an outlook on nature’s benefits to both stress and attention fatigue. Through this framework, an analysis was provided of experiences which led to recovery from directed attention fatigue [3].

The concept of restorative experience arose in the context of a research program in the wilderness by Kaplan and Kaplan in 1989. Several value traits were discovered through the study. The premise developed stated that attention restoration may be obtained through the experience of specific properties within the natural setting [2]. Four key components defined the restorative environment which may reduce the mental fatigue caused by directed attention [6]. These four characteristics are ‘fascination’, ‘extent’, ‘being away’ and ‘compatibility’. These traits of a restorative environment will
be described in detail through the following pages.

1.2. Singapore’s Biophilic Context

While the Kaplans were developing the basis for attention restoration theory, a book by Edward O. Wilson was published titled Biophilia. He is widely recognized as the first to coin the term Biophilia and described it as the inherited connection between humans and nature. Wilson describes our evolutionary history within the natural world as the cause for a human need to interact with nature [7].

The city of Singapore provides several case studies for how a Biophilic approach may be integrated into a major metropolitan area. The initial motivation behind Singapore’s nature integrated development began in 1963 when Prime Minister Lee Kuan Yew launched his vision for a ‘clean and green’ city. The campaign was conceived as a tree-planting initiative to improve air quality and brand Singapore as a ‘garden city’ [8]. Lee Kuan Yew felt deeply driven to create a garden city model within the Asian context. To exemplify his commitment to urban nature, Lee created the National Parks Board within the Ministry of National Development as a key agenda for the nation’s political focus. After Singapore's major industrial development, the Prime Minister Lee Hsien Loong reaffirmed the commitment to nature in the city: ‘in the next phase, our aim is to build a ‘City in a Garden’, to bring green spaces and biodiversity to our doorsteps’ [9].

2. ‘Fascination’ – 1st Trait of Attention Restoration Theory

The first of the four characteristics of Attention Restoration Theory as outlined by the Kaplan’s is ‘fascination’. Nature inherently hold several engrossing aspects of ‘fascination’ through both objects and processes. Examples of objects of ‘fascination’ in nature are flora, fauna, water or even a play of light. The processes of nature in which ‘fascination’ is held are elements of growth and succession along with the sequences of predation and survival. A prime example of process-based ‘fascination’ in nature is bird watching. These processes may be experienced in a variety of natural settings, such as clouds in the sky, sunsets on the horizon, snow patterns over the ground, or leaves moving in the wind [3]. Since these natural patterns seem effortless, they leave a certain room for the mind to wonder.

Fascination can be considered “hard” in the form of watching a car chase, which demands one's full attention. While “soft” fascination allows the opportunity for reflection in the possible form of a nature walk, which requires only partial attention. ‘Soft fascination’ holds one’s attention, although not in a dramatic fashion. In the mental state of ‘soft fascination,’ the mind is allowed to recover from direct attention fatigue through the processes of thinking, doing and pondering [2]. While ‘Fascination’ is a key component to providing restorative experiences, it does not guarantee rest or recovery without other characteristics of Attention Restoration Theory.
2.1. Singapore Case Study for ‘Fascination’: Jurong Lake Gardens West

Singapore’s new Jurong Lake Gardens is an excellent case study for ‘soft fascination’ within a natural setting. Along the western portion of the gardens, Jurong Lake Gardens West (JLGW), vegetation frames views towards elements of nature such as fauna habitats, birdlife feeding areas and the greater Jurong Lake. Benches provide viewing moments under mature shade trees to create resting spaces ideal for processes of thinking and reflection. Mental restoration through ‘fascination’ may occur through active processes such as: walking, running and even people watching. At JLGW, primary and secondary pedestrian routes are woven throughout the gardens to provide a diversity of experiences within nature. [10] People watching is welcomed at plazas near a variety of natural settings such as woodlands, grasslands and wetlands.

‘Soft fascination’ may occur in Jurong Lake’s rich ecological systems of native flora and dynamic fauna. While the history of the Singapore’s Jurong Lake landscape has experienced many transformations, it remains a vibrant sanctuary for birdlife [10]. Several biodiversity hotspots are concentrated along the banks of Jurong Lake. These natural areas are densely vegetated, comprising of large banyan trees and other plants which support a diversity of fauna such as small mammals, insects, and birds. The tall, dense crowns of the banyan trees serve as important resting sites for birds such as the black-crowned night heron, grey heron, and various species of egrets. Birdwatchers may visit to see the grey heron, a bird considered nationally threatened, nesting among the tall casuarina trees within Jurong Lake Gardens. The lake itself also adds an ecological niche to the terrestrial habitat, with aquatic and semi-aquatic species of fauna depending on the water body for survival. This range of habitats offers a vast range of potential opportunities for mental restoration through ‘fascination’ within the natural setting of Jurong Lake Gardens West.

3. ‘Extent’ – 2nd Trait of Attention Restoration Theory

The Kaplans’ second characteristic of Attention Restoration Theory is ‘extent’. While the element of ‘fascination’ relates to human engagement, ‘extent’ is in reference to more qualitative aspects of the natural environment. The most typical example of a space with ‘extent’ is a vast and remote wilderness. Although, to achieve the experience of ‘extent’ the size of the natural landscape and its proximity to urbanity is irrelevant. The spatial quality of ‘extent’ must provide the sense of a completely different world through environmental factors of richness, dynamics, and coherence. Watching a streaming video or even engaging in augmented reality is only a collection of impressions which may not provide enough for a full restorative experience. To gain the sensation of ‘extent’ a complete environment must be experienced to sufficiently preoccupy a better portion of the mind [2]. Three characteristics of an ‘extent’ experience are 1) its boundaries are not evident, 2) it has atypical properties from those of daily life and 3) it offers the
feeling of a real completely immersive environment.

It is not required to travel to a faraway wilderness in order to receive the mental restoration of ‘extent’. This may be created through a manipulation of scale such as miniaturization, an approach often used in Japanese garden design. Here landscape elements are intentionally dwarfed in size to create the perception of a larger space. ‘Extent’ may also be a conceptual idea through the interaction with historical artifacts or even reading a fantasy story [3]. These means of engagement can allow the mind to casually wander to a place where the stresses and fatigue of daily life recede away.

3.1. Singapore Case Study for ‘Extent’: Jurong Lake Gardens West

Jurong Lake Gardens West serves as an additional case study for the Attention Restoration Theory’s characteristic of ‘Extent’. Over an area of 53 hectares, JLGW is of a size which may engage the mind in a fully immersive environment. Also, by referencing the Jurong Lake's historical context the experience of ‘extent’ may provide an authentic interaction with the fresh water swamp landscape which once occupied the site.

Jurong's primeval ecosystem was rich in tropical lowland flora and diverse fauna. The first director of the Singapore Botanic Gardens, Henry Nicholas Ridley and his successor, Isaac Henry Burkill collected extensively from the area between the late 1800s to early-mid 1900s. From herbarium records, Jurong was covered with tracts of mangrove and freshwater swamp forests, comprised of a diverse palette of species. Trees with stilt roots that sit in intertidal areas, giant Pandanus that reach beyond 10m tall, pitcher plants that capture insects in their leafy cups, to myriads of orchid species that thrive epiphytically on the trees were all once part of the natural Jurong landscape [11]. Edred John Henry Corner conducted a botanical survey of the original freshwater swamp forest along Jurong Road 15th Mile right before the felling began in 1932. Within a tiny two-acre tract of the original freshwater swamp forest left, he identified 15 species which distinguished the Jurong freshwater swamp forest from the ones in Mandai, along with Pontian and Sedili in Peninsular Malaysia [12]. By June 1933 the whole swamp forest had been transformed into a pineapple estate.
Jurong’s historic freshwater swamp forest is comprised of plant life which has adapted to thrive in a unique intertidal habitat. The present-day Jurong Lake functions as a detention reservoir for storm water from the greater Jurong catchment via Sungei Lanchar and Sungei Jurong. This lake has an average fluctuation of about 500mm in weekly water levels. This presented an opportunity to use the changing water levels to mimic the intertidal effect necessary for the successful establishment of a shoreline character similar to the historic freshwater swamp. The plant groups were selected as part of a larger flora collection found within the lowland freshwater forest ecosystem. By using these plant species at various locations in JLGW the visitors are given a degree of ‘extent’ combined with ‘fascination’ to provide an environment suitable for mental restoration.

4. ‘Being Away’ – 3rd Trait of Attention Restoration Theory

The third characteristic of The Kaplans’ Attention Restoration Theory is ‘being away’. The experience of ‘being away’ is desired when one states “I need to get away for a few days”. This expression is used when travelling to a place of restoration. These ‘get away’ destinations are typically within the natural setting, such as beaches, mountains, lakes, forests, rivers or even meadows. When ‘getting away’ is mentioned it infers mental fatigue. In order to seek restoration from the fatigue, this need is stated as a desire to be away from the everyday task which is the source of exhaustion. When ‘being away’ is achieved, one is free from direct attention activities and is allowed to recover mentally [3].

While the desire of ‘being away’ often refers to a beach vacation, travelling to a faraway destination may not be possible or even necessary. The state of ‘being away’ may either be physical or conceptual. In the case of physical, one is required to physically be away from the setting and tasks which causes the need for mental restoration. The state of conceptually ‘being away’ may be obtained by simply pausing to peer out a window to receive a mental moment of feeling ‘away’ [2]. Since a majority of the world’s population lives and works in the urban context, close proximity to parks and gardens allows physical access to natural spaces for mental restoration. While conceptual access to ‘being away’ may be obtained through viewing a common space in a new way by shifting the position of perspective.

4.1. Singapore Case Study for ‘Being Away’: Sungei Buloh Wetland Reserve

As a resource for urban dwellers seeking the experience of ‘being away’ Sungei Buloh Wetland Reserve (SBWR) is a 202-hectare robust wetland sanctuary of mangroves, mudflats, ponds and secondary forest located at the Northwest corner of Singapore along the Johor Straits. The wetland reserve of mangrove species is particularly important as Singapore ranked 6th, out of 94 countries, for the richest number of mangrove species globally. Along with the rich range of mangroves, Sungei Buloh is also a key stop-over area for the international network of migratory shorebirds. SBWR has local and migratory birds with a range of nationally and
internationally endangered species [13]. The diversity of wildlife species, beyond numerous shorebirds, include Smooth Otters, monitor lizards and a range of aquatic marine life adapted to the reserves unique landscape character [14].

Since it’s opening in 1993, Sungei Buloh has played a significant role as a ‘being away’ destination within Singapore. Sungei Buloh Wetland Reserves has been created with the opportunity for visitors to experience distinctive trails showcasing the dynamics and diverse aspects of the wetland park [14]. SBWR provides visitors with the immersion into a unique natural environment conducive to mental restoration within the urban lifestyle of Singapore.

5. ‘Compatibility’ – 4th Trait of Attention Restoration Theory

‘Compatibility’ is the fourth and final characteristic of the Kaplans’ Attention Restoration Theory. The physical setting is a critical factor in one’s ability to carry out a given task. An environment's suitability for an intended purpose defines its level of ‘compatibility’. In a highly ‘compatible’ setting, an activity may be carried out comfortably with little to no obstruction [15].

The natural environment has an inherent capacity to be experienced in general as 'compatible'. When performing typical functions people tend to prefer a more natural setting over an urban, even when the city condition is familiar, as tasks seem to require less effort in a natural environment [16]. When a setting is not 'compatible' it adds to mental fatigue. Elements of 'non-compatibility' may be an obstruction in the environment, a desire to be in another setting, or a critical element missing from the present space. Within the natural environment, several activities tend to feel highly ‘compatible’ such as hunting, fishing, gardening, caring for pets, bird watching and even visiting zoos [2]. By engaging in these nature-based programs, mental fatigue may be restored through the experience of ‘compatibility’. 
5.1. Singapore Case Study for ‘Compatibility’: Jurong-Eco Garden

Singapore’s Jurong Eco-Garden (JEG) is a valuable reference for the trait of ‘Compatibility’. JEG was the first business park in a tropical rainforest designed for the site’s unique ecology and as a tranquil space for both visitors and office workers [17]. Here employees may take breaks to reconnect with nature as every building has a natural forested front on at least one side [18]. Underlying the holistic approach of JEG is a drive to work with a deep respect for nature. Through a host of surveys and studies, including topographic, geological, hydrological, botanical and zoological, the site in its original condition is fully considered in the Eco-Garden's layout. Through allowing a close proximity to natural spaces, JEG creates a ‘compatible’ environment for nearby office workers to gain moments of mental restoration through activities such as nature walks and bird watching while taking a break on a typical workday.

6. Conclusion

In the midst of the information age, Singapore is driven by strong growth and continued prosperity. This trend towards development often creates an intense life of 24/7 communication, stressful deadlines, and a seemingly endless pursuit towards progress. The repercussion of this constant effort is mental fatigue. Contemporary cities often look for elements of sustainability and sky rise greenery to create a more "natural" and healthy urban setting. These efforts to increased greenery and sustainable building credentials do not always address the social need for mental restoration. To provide psychological recovery from daily stresses, Biophilic cities should specifically create nature spaces with traits of ‘fascination’, ‘extent’, ‘being away’ and ‘compatibility’ throughout the urban context.

In Singapore’s urban evolution towards a Biophilic City, a new chapter is possible by developing into a 'city in a natural ecosystem'. Here urban escapes into the tropical wilderness can continue to be embedded throughout the city. A focus on creating increased human-to-nature interactions with traits of Attention Restoration Theory at the city's heart may expand. This authentic daily interaction with natural objects and processes is a valuable investment to advance Singapore's health and mental restoration.

Acknowledgments

I would like to thank Dione Tan for invaluable help in the process of the formation and writing of this article. In addition, I would like to thank Leonard Ng and Ramboll Studio Dreiseitl for the encouragement and support in the paper’s development. Special thanks to the National Parks Board and JTC Corporation in providing the reference works presented in the manuscript.

Growing fast and staying green – Vienna’s green space strategies

Thomas Knoll
Knollconsult Umweltplanung ZT GmbH, Obere Donaustraße 59, 1020 Vienna, AUSTRIA

Abstract

More than 50% of the Vienna city area are green spaces. This high share the city owes to its historic development. Large wood-areas and imperial parks were spared from urbanisation and clearance. In 1905, when Vienna’s population nearly has reached its peak, Vienna’s Wood and Meadow Belt was put under protection by the city council.

Today, more than a 100 years later, the generous green spaces are considered as one of the main factors for Vienna frequently being ranked amongst the most liveable cities worldwide. However, in the next decades Vienna again will face significant population growth. Recognising Vienna’s urban landscapes building the core of this city’s character and (life) quality, one of the city planner’s trickiest tasks is to still maintain natural areas and improve green space quality for all – existing and future – inhabitants.

Therefore recently a new set of instruments has been developed and implemented: Vienna’s Open Space Network now defines the city’s linear green connections to enable access of recreation areas for undersupplied quarters. The future goal is that every Viennese will be able to reach this network within a distance of 250 m. Balancing out the green space supply throughout the whole city area and all popular strata, the densification of the green infrastructure aims in a “green space equity”. Also, this close mesh ensures the networks accessibility for people of limited mobility. Furthermore the network links to the environs of the city and provides essential ecosystem services in the city.

Another new instrument, the “Local Green Plan” serves as a standardized planning tool for urban development areas to outline the green space demands for the master plan level and land use planning. Therefore 12 open space types can be used to define the required qualities of the new quarter whereas “green and open space standards” provide calculation methods to specify the amount of green space needed per future inhabitant or workplace.

In the tradition of Vienna’s “Wood- and Meadow Belt” from 1905, but equipped with these new instruments and the knowledge of today’s and future requirements and probable circumstances, on the large scale Vienna’s city planners currently are developing a new model and guideline for the entire city’s green space system, which aims in preserving Vienna’s high quality green spaces despite the predicted population growth.

To provide the city with an instrument strong enough to withstand the expected building pressure in the next decades, the model will rest on two solid pillars: On one side, the determination of green areas is based on a multi-layered GIS database of already approved
existing framework conditions (e.g. nature protected areas, agricultural zones, climate-relevant areas …). On the other hand Vienna is redefining its inviolable historic, functional and identity-establishing green space category “Vienna green belt” as interconnected major green areas of the whole city region.

The conclusively justified database and the transparency in decision result in an indisputable, legally sustainable and widely accepted instrument suitable to preserve Vienna’s green character for the upcoming decades.

---

1. **Introduction**

More than 50% of the Vienna city area are green spaces. This high share the city owes to its historic development. Large wood-areas and imperial parks were spared from urbanisation and clearance. In 1905, when Vienna’s population nearly has reached its peak, Vienna’s Wood and Meadow Belt was put under protection by the city council.

Today, more than a 100 years later, the generous green spaces are considered as one of the main factors for Vienna frequently being ranked amongst the most livable cities worldwide. However, in the next decades Vienna again will face significant population growth and many other challenges in terms of climate, energy and mobility. Recognizing Vienna’s urban landscapes building the core of this city’s character and (life) quality, one of the city planner’s trickiest tasks is to still maintain natural areas and improve green space quality for all – existing and future – inhabitants.

2. **A brief history of Vienna´s green space development**

Situated right at the junction of the Vienna Woods (“Wienerwald” - the eastern alpine foothills) and the riparian forests of the Danube, Vienna is naturally blessed with large greenspace-systems surrounding the city. Still, in the last 200 years Vienna’s green and open spaces took a huge development in terms of ownership, accessibility and functionality.

2.1. **Imperial Vienna**

Up to the 18th century the mayor green spaces around the historic city center have been strictly reserved for the aristocracy as representative gardens or imperial hunting grounds. [4] The opening of the Vienna Prater area (a large riparian forest area) to the public in 1766 was the starting point of a development of conversion of the green spaces to large leisure- and recreational areas for the Viennese citizens.

2.2. **Industrialization and new recreation and health necessities**

Like in many other western capitals industrialization in the 19th century and the rapid population growth brought about
urban densification, followed up by catastrophic living conditions and health standards. Between 1850 and 1910 the Vienna population nearly quadrupled from about 500,000 to over 2 mio. inhabitants. Due to the large amount of energy and space needed, Vienna’s green spaces and especially the Vienna Woods more and more were considered as endangered and this development soon called for counteraction.

Adapting an initial plan from architect Eugen Fassbender from 1898 [5] [7], in 1905 the peripheral “Vienna Wood and Meadow Belt” was defined by the city government for the “durable protection for the health conditions in our city as well as for the preservation of the attractive natural frame conditions”. So, the preservation of these large green areas mainly was founded on health considerations. This included the need to secure fresh air supply into the city, considering the heavily polluting industries at those times. Also, this periphal green belt fitted within a concentric city development model, promoted e.g. by the famous Viennese architect and city planner Otto WAGNER, which basically allowed an “unlimited” city growth (see Fig.1).

2.3. 20th century: the century’s catastrophes and stagnation in population growth

Soon after the beginning of the 20th century, the “endless city”-like growth came to a preliminary end with this century’s mayor catastrophes – World War I and World War II, which – together with the iron curtain – led to an overall stagnation in Vienna’s population growth until the end of the century.

Unlike its initial function as one of many recreational ring structures, to allow practically unlimited city expansion, now the Viennese green belt for the city planes
became like the green border, the ultimate limes for city development (Fig.2). Apart from traffic infrastructure, the areas surrounding Vienna, all of them within the province of Lower Austria, hardly were taken into consideration in terms of city planning and green space development. There was hardly any population growth and every infrastructural requirement should have been covered within the city borders.

With the Yugoslavian wars, after the fall of the Iron Curtain and with the European eastern countries applying for EU Membership, Vienna’s population started to increase again, mainly from immigration.

The city development concepts from that time (1995, 2005) accordingly show stronger reflection on the landscape outside of Vienna’s borders, the green- and open space concept from 2005 even shows Vienna’s green belt as a part of the 5 surrounding mayor landscape types (Fig. 3). Nevertheless, apart from the Vienna Woods (UNESCO biosphere park, founded 2005) and the Donau-Auen National Park (1996) there has been no real collaboration between Vienna and surrounding Lower Austria to commonly develop those shared green spaces.

3. Recreation and health – human needs that don’t really change through times

In modern city planning green and open spaces are considered equally important as other infrastructural necessities like mobility or energy supply. One of the core functions of those green spaces is to provide health promoting features. Green and open spaces contribute to the health of the citizens in different physical, psychological and social ways. Vienna’s city structure is strongly shaped by the 1905 established “Wood and Meadow Belt”, which to preserve was a decision basically for public health reasons. Today, the supply of public health and welfare services still is one of the main function of city green space infrastructure and needs to be adapted to challenges like fast population growth, overaging and climate change [2].
4. Green space equity

Vienna has a total of more than 50% green space. This high share of green space will be maintained in the future, which makes green space equity a vital issue: all citizens have the same right to high-quality provision of green and open space. However the green spaces of course are not equally spread over the entire city area. Some quarters are undersupplied with green spaces and some are extremely fortunate. The appropriate connecting elements should safeguard a consistent infrastructural supply with green and open spaces to the best possible extent. By developing a robust open space system and safeguarding the required areas, future generations will be provided with continuous access to high-quality green and open spaces in a growing city [1]. “Green space equity” is one of the main goals for Vienna’s green space development planning.

5. “Vienna City Region”: taking a new perspective on city growth

Green space equity as well as the preservation and improvement of green space qualities are the keys to better the availability of recreation possibilities and life quality for undersupplied city quarters. However with continuous population growth and densification potentials slowly coming to an end, there comes the point where the solution has to be broken down into one aspect: space.

Unlike in imperial times, when the empire’s capital just took the space it needed from its surroundings, today the administrative borders between the two equitable territorial entities Vienna and Lower Austria, are indisputable. Still, there is a traditional certain rivalry between the most (Vienna) and second most (Lower Austria) inhabited Austrian provincial states. It’s based on the common rivalry between urban and rural, different predominant ideologies and therefore traditional rivaling political parties leading the governments. So, the in many aspects vital collaboration between those provinces never has been completely frictionless.

Within today’s city region, administrative borders have lost their practical meaning in the people’s everyday life. Starting along the infrastructural axes the city slowly has blended into its surroundings and the region’s inhabitants care less and less whether they live in Vienna itself or just in the wider city region.

However, although it seems like the most logical and obvious way to address those
issues from the technical point of view – in a highly structured and organized western democracy like Austria, where each province has their own spatial planning authorities (and even laws), for local planners a collaborative approach to develop shared green spaces together appears groundbreaking.

For networking and coordinating common projects, in 2006 the joint platform “Stadt-Umland-Management” (SUM) was founded by the city of Vienna, the surrounding municipalities and the province of Lower Austria. Based on that platform many “cross-border” projects have been implemented but still there is need for general regional development policies.

So, Vienna’s green space planning department today wants to pick up that ball and aims in letting commonly developed regional green spaces be the first substantial collaboration in spatial planning between the Provinces of Vienna and Lower Austria.

6. New tools for Vienna’s green space planners

The Vienna city administration currently is developing the toolset for providing the necessary amount and qualities of urban green spaces for the future Vienna of 2 million citizens. Therefore, in 2014’s Thematic Concept “Green and open spaces” with methodical tools like the “Local green plan”, the 12 open space types and the green- and open space standards the basics have been set for quality assuring green space planning.

Being equipped with those tools and having gained experience on the local and district level, now Vienna’s city planners aim in setting up spatial tools to define Vienna’s green space development on a city-wide – or even wider – level.

Methodical tools

6.1. Local Green Plan

[6] The “Local Green Plan” is a planning method in which different types of open spaces are worked out, defined and assessed regarding their supply efficiency for the citizens. The “Local Green Plan” is a standardized tool for urban development planning which serves the collection of basic information for quality assuring procedures (competitions, cooperative planning procedures) and the design of land use plans.

Local Green Plans are based on 12 open space types: Open spaces in Vienna range from linear pedestrian zones to green axes to wide open, semi-public green spaces to protected areas. [6]
6.2. 12 open space types

6 linear and 6 wide open space types build the basis for green and open space planning of the city.

The types of open spaces are described regarding their form and functionality. If a space or a linear segment of the open space network has been defined as a particular type of open space, it has to fulfill certain functions.

The following functions are differentiated [1]:

- Function for everyday life and recreation
- Function for the structuring of the urban fabric
- Function for ecosystem services
- Function for nature conservation

The 12 open space types provide a uniform tool for green and open space planning in Vienna for expert departments, planning offices and politicians. They currently are mainly being used as the basic elements of Local Green Plans (6.1.) and the Vienna Open Space Network (6.4.).

6.3. Green and open space standards

[6] The development of new urban quarters requires the securing of green infrastructure such as parks in the neighborhood. These green and open spaces are anticipatorily secured in urban development competitions, in master plans and in the course of land use and development plans. The new standards regarding the supply of green space contribute to quality assurance in new urban
development areas. They contain minimum dimensions, as well as catchment areas.

Especially children and older people need recreation areas close to their homes, such as parks and attractively designed public spaces. They are the basis for social cohesion in the neighborhood and are crucial in making an active and self-determined life possible in their own urban quarters.

Together with the 12 open space types, the green and open space standards build the basic planning elements of Local Green Plans (chapter 6.1.)

**Spatial tools**

6.4. Vienna Open Space Network

To address the aim of “green space equity” (chapter 4), the city planner’s future goal is that every Viennese will be able to reach the closest segment of the open space network within a distance of approx. 250 m. The idea behind this is to build a network of high-quality green and open spaces of different characteristics. Large-scale green spaces, parks, smaller spaces of ecological importance, streets with green elements – they all will be connected to each other.

This network brings about many benefits, e.g. attractive thoroughfares which can be used on foot or by bike, an improvement of amenity and recreation quality in the close environs of residential areas or working places and a positive impact on the urban climate, as well as on the fauna and flora. The close mesh of green and open space connections ensures that people of limited mobility also have access to high-quality spaces of leisure and exercise in their closest vicinity.

The network concept also includes linking and connecting Vienna’s open space network to the environs of the city.

For determine the form and functionality of each green connection, the 6 linear Open Space Types are being used. [1, 6]

Fig. 9. Schematic scheme of Vienna’s open space network (open space types 0-6) connecting the wide open space types 7-12 [6]
6.5. 16 functional zones

For the development of the new city-wide green space model, the determination of green areas will be based on a multi-layered GIS database of already approved existing green infrastructure functionalities (e.g. nature protected areas, agricultural zones, climate-relevant areas …) (see Fig. 10).

This also includes city structural functions like the city’s green space department redefining an inviolable green space category “Vienna green belt” which founds in the historic, functional and identity-establishing city-wide importance of the interconnected major Vienna green areas.

Each of the 16 green-infrastructure functions provides the green planners with arguments to preserve those areas. Overlaying all 16 maps, some areas will serve with a couple of functions, some with only one. The amount and the types of functions of each area will lead to a certain assertion of the green space development department how to proceed with it within the Vienna’s redefined green- and open space system (see chapter 7).

7. The new Vienna green and open space system (2020)

Given the proper toolset the city planners now are able to define and conclusively justify Vienna’s green- and open space system for the next decades. It consists of
only 4 clearly defined, easy to understand and to communicate categories. Based on the amount and type of green infrastructural functions, one of the following categories will apply to each area:

1. **Green spaces of the city region**
   These large green areas are the commonly developed nature- and recreational areas in the city region. The areas crossing the administration border consist of “Vienna Green Belt”-areas and the bordering areas of the neighboring municipalities. Altogether they build up to a wide green ring structure around the city independently from the official city borders and beneficiary for both – Viennese and Lower Austrians.

2. **Open Space Network**
   The network of green infrastructure provides green mobility and green space equity for the whole city population, balancing out inequities between unequally equipped parts of the city. In many parts the Open Space Network already exists, in some measures are still required to increase their functionality according to their open space type.

3. **Vienna´s Gardens and Parks**
   Vienna´s publicly accessible historic and contemporary gardens and parks are used for recreation within the city in minor distances to the residential quarters. They also incomparably shape the face and the identity of Vienna.

4. **Vienna Landscapes – Next Generation**
   City planning is the process of continuously adapting the city to the current challenges. Therefore planning-reserves are needed. With the „Next Generation“-areas, the city preserves planning possibilities for its future (presently unknown) goals. So, the decision if those areas will host agriculture, recreation areas, residential or commercial zones is to be made by future generations.

   ![Fig. 13. Vienna´s open and green space planning model for 2020+](image)

   Fig. 13. Vienna´s open and green space planning model for 2020+

   The conclusively justified 4 green space categories and the transparency in decision result in an indisputable, legally sustainable and widely accepted instrument suitable to preserve Vienna’s green character and the life quality in the city region for the upcoming decades.

8. **Conclusion**
   Vienna’s worldwide acknowledged life quality to a large extent origins in its historic green spaces and the decisions and plans being made over 100 years ago to preserve and maintain them.
With the foundation on its green heritage, with the overall goal of “green space equity”, with a sophisticated quality preserving toolset, with the awareness of a city development not ending at the administrative border, and conclusively – with the acknowledgment and integration of green infrastructure functionality equal to all the other urban infrastructural needs, Vienna sets up the framework for a strong and consistent green- and open space system for the 21st century. – Good thing, knowing that many of the answers to today’s and tomorrow’s challenges like climate-change, energy revolution, changes in urban mobility, city population growth and aging can be found in the urban green and open spaces.

Abstract

Influenced by trends like Landscape Urbanism and Biophilic City, landscape architects find themselves playing more vital roles in reshaping cities nowadays. With the deepening of the study on Biophilic City by Timothy Beatley, Peter Newman, Angela Reeve, Ruth A. Rae and others, its definition, contents, characteristics and practice approaches are gradually clear. However, these researches mostly focus on cities in Europe, Oceania and North America. Asian cities, especially those in China are seldom mentioned. Actually, some Chinese cities are potential emerging biophilic cities. In this paper, we select Fuzhou, the capital of Fujian Province in the southeast of China, as the object of study. Fuzhou is a dense and land-scarce central city which is home to some 7.57 million people. Its good expression as a biophilic city in the coastal valley plain makes it worth studying. Benefiting from the superior natural environment, eco-friendly philosophy of living, widespread introduction of green development concept and successful landscape architecture practice, an increasingly complete green infrastructure network lead by landscape architecture has been gradually constructed. Nature can be found everywhere in Fuzhou. Citizens benefit a lot in daily life. In order to clarify its biophilic features and spatial framework as a biophilic city, we disassemble its green infrastructure network into the following three parts: extensive urban parks system, park connectors and suburban forest parks. Extensive urban parks system consists of some 150 all kinds of urban parks in various types and scales, occupying a total area of some 21.25km². Attached to many low hills with lush vegetation as well as lots of urban rivers, lakes and other water resources, these parks make it possible for all citizens to enjoy the benefits of nature after a some 15 to 25 minutes’ walk from every corner in this city. Among them, the West Lake Park is the typical representative. Several park connectors, providing elevated canopy walk to offer dramatic perspectives of the city, express another particular characteristic of biophilic Fuzhou. Awarded the International Architecture Awards 2017, the Fudao Park Connector designed by LOOK Architects is the most impressive one. This totally 19 kilometres long signature connector that provides public accessibility to indigenous hinterland
stretching north-east of Fudao signifies an awakened consciousness to improve lives of city dwellers by bringing nature within closer reach. Some 15 suburban forest parks of all kinds, total area of about 574.95km², are surrounding Fuzhou within a 30 minutes’ drive from downtown. Qishan National Forest Park and Fuzhou National Forest Park, as typical representatives, are of high biological diversity and have nice therapeutic function to the visitors. The study of Fuzhou’s success as a Chinese biophilic city may help us understanding the leading role of landscape architecture in improving our urban and natural environment in the context of a biophilic city.

Keywords: Landscape Architecture ; Chinese Biophilic Cities ; Green Infrastructure Network ; Extensive Urban Parks System ; Park Connectors ; Suburban Forest Parks

1. Introduction

Influenced by trends like Landscape Urbanism, Biophilic City and so on, landscape architects find themselves playing more vital roles in reshaping cities nowadays. Especially after the publication of two remarkable books which are Biophilic Cities: Integrating Nature into Urban Design and Planning and Handbook of Biophilic City Planning and Design by Timothy Beatley in the aspect of Biophilic City, we become more conscious in rethinking our discipline and the practice of landscape architecture in the context of rapidly growing cities.

With the deepening of the study on Biophilic City by Timothy Beatley [1-3], Angela Reeve [4], Ruth A. Rae [5], Emmanuel L. M. Wolfs [6], Sue Ruddick [7], CO Ryan [8], Peter Newman [1, 9], Jules Prettya [10], J Honey-Rosés [11], Germán I. Andrade [12] and others, its definition, contents, characteristics and practice approaches are gradually clear. “Biophilic Cities are sustainable and resilient cities. It provides close and daily contact with nature, nearby nature, but also seek to foster an awareness of and caring for this nature. It helps to foster social and landscape resilience, in the face of climate change, natural disasters and economic uncertainty and various other shocks that cities will face in the future [1].”

However, these researches mostly focus on cities in Europe, Oceania and North America. Asian cities, especially those in China are seldom mentioned. Only Chengdu and Tianjin were found in correlational research with brief and short introduction. As Timothy Beatley puts it, “The view of cities as spaces for cohabitation, shared spaces, is growing stronger, but much more needs to be done. We see these sensibilities and priorities expressed in cities in many other ways [3].” Actually, some Chinese cities are potential emerging biophilic cities. They are indeed worth studying.

2. Fuzhou as a Case Study in China

In this paper, we select Fuzhou, the capital city of Fujian Province in the southeast of China, as the object of study, Fig.1. It is in harmony with nature and seems to be a typical emerging biophilic cities in China. Its good expression as a biophilic city in the coastal valley plain makes it worth studying.
2.1. City Profile

Fuzhou lays on coastal hilly plain areas of Minjiang River estuary, Fig. 2. It is a dense and land-scarce central city which is home to some 7.57 million people.

Its rainy and moist subtropical marine monsoon climate, rich water resources, abundant flora and fauna together with plenty of low hills inside and outside the city construct an ideal foundation for the natural environment as a typical biophilic city, Fig. 3.

2.2. From a traditional “Shanshui City” to a modern biophilic city

Ancient Fuzhou is one of the best examples of widely accepted Chinese traditional “Shanshui City” under the strong influence of “Shanshui Culture” which is one of the most vital traditional Chinese culture emphasizing reaching harmony with nature in the living environment, Fig. 4.

Nowadays, Fuzhou inherited this tradition very well and has achieved a further development as a biophilic city under a balanced concept combining traditional ideas with modern theories of urban planning and landscape architecture.

Benefiting from the superior natural environment, eco-friendly philosophy of living, widespread introduction of green development concept and successful landscape architecture practice, an increasingly complete green infrastructure network lead by landscape architecture has been gradually constructed. Nature can be found everywhere in Fuzhou. Citizens benefit a lot in their daily life.
3. Biophilic features and spatial framework of Fuzhou as a biophilic city

In order to clarify the biophilic features and spatial framework of Fuzhou as a biophilic city, we disassemble its green infrastructure network into the following three parts: extensive urban parks system, park connectors and suburban forest parks.

3.1. Extensive urban parks system

Extensive urban parks system consists of some 150 all kinds of urban parks in various types and scales, occupying a total area of some 21.25km². Attached to many low hills with lush vegetation as well as lots of urban rivers, lakes and other water resources, these parks make it possible for all citizens to enjoy the benefits of nature after a some 15 to 25 minutes’ walk from every corner in this city. Among them, the West Lake Park is the typical representative.

West Lake Park, located in the central area of Fuzhou, has a history of more than 1,700 years and is the most complete classical garden in Fuzhou, Fig.5. Nowadays, it covers an area of 42.51 hectares, of which 12.21 hectares of land area, water area of 30.3 hectares. Liu causeway, Kaihua Island, Lagerstroemia Hall, Kaihua Temple, Wanzai Hall, Dressing Pavilion, Fujian Museum, West Lake Academy and so on are the main traditional and modern attractions. The local citizens treat it as a treasure of the city and will always pay a visit to enjoy their leisure time with friends and family in the park.

3.2. Park connectors

Several park connectors, such as Fudao Park Connector, Jinnishan Park Connector and so on, providing elevated canopy walk to offer dramatic perspectives of the city, express another particular characteristic of biophilic Fuzhou. The Fudao Park Connector designed by LOOK Architects, which is awarded the International Architecture Awards 2017, is the most impressive one, Fig.6.
The Fudao Park Connector is the first-of-its kind elevated steel pedestrian walkway system weaving through forested areas in China [13]. This totally 19 kilometres long signature connector that provides public accessibility to indigenous hinterland stretching north-east of Fudao signifies an awakened consciousness to improve lives of city dwellers by bringing nature within closer reach [14].

There are about 10 entrances of the Fudao Park Connector in total around the Jinniu Shan Hill, constructing an easy and accessible networks of conversion points from weary urban life to the embrace of nature. Several rest shelters, viewing decks, observation towers and teahouses are sited evenly and reasonably throughout the route. Use of steel grating for the walkway decks serves to bring natural light down to the ground plane, encouraging low-lying plants to thrive, Fig.7-8, [14].
Jinjishan Park Connector, another famous park connector which is situated in the north of the city, is a 2500-meter-long elevated pedestrian walkway stretching upon the Jinjishan Hill, Fig.9. Its other name is “Lancheng Walkway”, which means a park connector of embracing the city because of its shape and nice view of overlooking the city.

Fig. 9. Jinjishan Park Connector.
Source: http://tieba.baidu.com/photo/p?kw=%E7%A6%8F%E5%B7%9E&ie=utf-8&flux=1&tid=4532320599&pic_id=47982f2eb9389b50d54da6a8235e5ddd616666&pn=1&fj=2&sqc=1.

3.3. Suburban forest parks

Some 15 suburban forest parks of all kinds, total area of about 574.95km², are surrounding Fuzhou within a 30 minutes’ drive from downtown. Among them, 5 are national forest parks and the other 10 are provincial forest parks. Fuzhou National Forest Park and Qishan National Forest Park, as typical representatives, are of high biological diversity and have nice therapeutic function to the visitors.

Fuzhou National Forest Park with an area of 859.33 hectares, which was founded in 1960, is the first national forest park in Fujian Province and one of the top ten forest parks in China, Fig.10. It is divided into 5 sections: forest area, nursery, greenhouse, special park, and rest area. Due to the geographical environment and the protective effect of forests, a unique microclimate is formed in the park. It is warm in winter and cool in summer. The average temperature in summer is 3-5 degrees Celsius lower than inside the city. The forest releases a large amount of oxygen and negative oxygen ions, attracting many people to experience the “forest bathing” and is known as “the largest natural oxygen bar in Fuzhou” [15].

Fig. 10. Fuzhou National Forest Park.

Qishan National Forest Park, occupying an area of 35.87km², is located in the southwest, only 25 kilometers away from the downtown. In 2007, Qishan Forest Park officially launched the Forest People's Tourism Project. It is a new type of leisure tourism which is based on its good forest ecological resources and environment. It uses local forest farmers and large households as the main business and integrates forest culture and folk customs as one of the cities [16]. Besides, hot springs, Shisong Temple, Wanfo Temple, Shuixiang
Ancient Road and others are the main attractions there.

4. Conclusions

The research of biophilic city is especially important and urgent now, as Timothy Beatley puts it in his latest book: “As Planet Earth lunges forward toward a higher and higher percentage of world population living in cities, it is timely to rethink how these cities function and feel to those living in them … nature is not something optional, but, rather, absolutely essential to living healthy, interesting, and meaningful lives [3].”

In this paper, we select Fuzhou as a typical emerging biophilic city in the southeast of China and conduct a brief research of Fuzhou’s natural and cultural conditions to analyze its inheritance and development from a traditional “Shanshui City” to a modern biophilic city. Its biophilic features and spatial framework are mainly expressed as a comprehensive, ecological and robust green infrastructure network consisting of extensive urban parks system, park connectors and suburban forest parks.

The study of Fuzhou’s success as a Chinese biophilic city may arouse more scholars' attention and research on Chinese cities and help us understanding the leading role of landscape architecture in improving our urban and natural environment in the context of a biophilic city.

Acknowledgments

Special thanks must be given to my PhD supervisor professor Wang Xiang-rong and professor Lin Qing, who help me to conduct the comprehensive learning and awareness of Landscape Architecture. What’s more, there are many institutions and people to thank for help in making my academic trip possible and smoothly. Special thanks are due Dean Dong Jian-wen, College of Landscape Architecture, Fujian Agriculture and Forestry University to offer the significant financial support. Special thanks go to Que Chen-xi and Yan Chen for offering generous help during my conference registration and paper writing.

Abstract

Now hosting 32.4 million residents, Chóngqìng is the fastest growing inland city in China, and the most populous of the Chinese municipalities. Located at the confluence of the Yangze (Cháng Jiāng) and Jialing (Jiālíng Jiāng) rivers, originally named Jiangzhou in 316 BCE, Chóngqìng has historically served as a key economic node and centre of governance in China. The ancient city of Chóngqìng exists within the ‘mother town’ inside Yuzhong District today home to some 639,000 residents. The District offers unique archaeological records spanning over 3,000 years, and has experienced four distinct city wall construction movements that uniquely created a city analogous to the medieval walled cities of Europe. The first three wall-building movements resulted in a gradual expansion of the city’s footprint, while the latter wall-building movement was highly influenced by a Fengshui (Compass school) theory. The city’s urban tapestry is today interlaced and characterised by a unique semi-grid system of human and trade-movement mountain trails, possibly linking port gates on the Yangze and Jialing River edges. These rivers provided important water trade passageways and potable drinking water supplies for residents prior to the construction of a reticulated water supply. Once physically constrained within these walls, contemporary urbanisation has witnessed extensive industrialization and suburbanization on both sides of the rivers and in the larger valley, and massive urban rejuvenation projects within Yuzhong District. Considerable portions of this historic Yuzhong District tapestry exists today, and uniquely characterises Chóngqìng from other cities in China.

This paper considers the vision and planning process being taken in Chóngqìng to craft a unique greening strategy termed ‘Green Cultural Belt’. The overarching aim of this vision and planning process is to formulate a Greening Strategy and Master Plan focused upon the central Yudong District; for the ‘mother town’ area of Chóngqìng. Key elements of this vision include greening the image and character of the city; respecting and revealing cultural heritage values; mitigating the urban heat island effect and the occasional fog that veils the city; re-capturing and responding to the villages and mountain trails that interlace the ancient city; exploring and emphasizing pedestrianisation in the ancient city; and positioning Chóngqìng as a prospective Ecocity exemplar in China.

Involving a joint applied landscape planning research partnership between Chóngqìng University and Deakin University. The partnership is seeking to apply ecological
determinism theory and practice to inform the development of a strategy for Chóngqìng having regard to its historic and topographical characteristics. The research points to the potency of formulating a green city strategy unique for a city highly constrained and morphologically structured by its topography, as distinct from many urban cities. The findings demonstrate that an ancient-city-wide greening strategy can offer a successful ecological deterministic strategy for other Chinese cities. This Chóngqìng example confronts major challenges in addressing growth and its negative consequences, while crafting a strategy for a highly topographic and constrained city that will provide an enduring landscape planning legacy reflecting international best practice.

**Keywords:** City greening; Chóngqìng; Landscape architecture

1. Introduction

In translating human values to nature using Chóngqìng in China as the case study venue, this paper discusses urban ecological theory and archetypes, having regard to the current issues and potential ecological strategies for Yuzhong District in Chóngqìng -- the urbanized old town area of Chongqing. This investigation examines the cultural traditions and fabric of the District, and the existing human movement circulation system embodied in a unique ‘mountain-trail’ walking network. Both aspects are increasingly being negatively affected by over-sized infrastructure to service vehicle accessibility and movement needs despite District policy changes towards increasing walkability and the provision of green infrastructure. This contextual setting prompts a relevant and timely discussion about the position and contribution of the ICOMOS-authored Historic Urban Landscape (HUL) [1] approach and current discussions about biophilic design informing policy and design strategies that could aid the future conservation and greening of Chóngqìng and in particular, Yuzhong District.

In China, the number of people living in urban areas has now surpassed the number of people living in rural areas; this pattern is also replicable globally. In this context, the 21th century has become the ‘Urban Era’ reinforcing the potency of the built environment as the central domain for human activity and habitation.

Biophilic city design and planning indicators have been extensively canvassed [2], and there is a growing emergent body of biophilic city design case studies to inform and guide this shift in city design and planning [3, 4]. But such case studies are biased towards developed nation exemplars, retrofitting new and or old developed cities, and bear little advice on how to proceed in culturally and historically-rich places in Asia facing rapid changes in culture, place and habitat.

This paper considers the urbanized old town area of Chóngqìng, on Yuzhong Peninsula, in the burgeoning metropolis of Chongqing, in the south-west interior of China.

It offers a review of the town planning history of this landscape through the lens of human relationships to nature, revealed in its current relationship and treatment of nature to ecological development.

The urban ‘mountain trails’ or cultural trails of Yuzhong Peninsula, which used to link its old city gates and the water edges and mountains of the District, is a unique Historic Urban Landscape (HUL) [1] representing successive layers of meanings of this urban area. The landscape is also a significant potential venue for the creative
implementation of biophilic design and activities strategies.

For many historic cities, their origin and typology is based upon a deep respect and understanding of nature and the landscape that inform the physical siting of the village (now town or city).

This line of argument leads us to discuss the relationship between the increasingly dynamic cultural landscape conservation approach to Asian urban contexts and biophilic city design – an aspect missing in all the latter’s discussions and writings to date.

Figure 1: The location of Chongqing and Yuzhong District. (Source: the authors).

2. Biophilic Cities and Oneness with Nature

What is a biophilic city? As Beatley articulates it is:

... a city that puts nature first in its design, planning, and management; it recognizes the essential need for daily human contact with nature as well as the many environmental and economic values provided by nature and natural systems [2].
Included in this definition are indicators that include consideration of ‘biophilic condition and infrastructure’, ‘biophilic activities’, ‘biophilic attitude and knowledge’, ‘Institution and governance’ [2].

From our perspective as researchers and city participants, the nature of our practice involves two aspirations:
1. to embrace and insert more natural elements into the human environment, thereby increasing human contact with nature, and to intentionally re-share these spaces with other species; and
2. to improve integrations of human environments within larger natural systems, to improve cross-species habitat venues, ecological security and green infrastructure.

As a point of definition, our use of ‘natural’ recognises the definition that all aspects of the Earth have been modified by human activity, and that ‘natural’ in its true applied science sense does not exist today [5]. Instead, we reside within culturally modified environments and novel ecosystems.

For some ancient cities in China, the philosophy of town construction and landscape arrangement embodied a strong reverence of nature and subsequent adaptation to it. This action reflected the central theme of traditional Chinese philosophy that accentuates the relationship between nature and humans [6, 7]. This philosophy includes an “Oneness with nature”, requiring human beings to keep harmony and unity with nature, and for human beings and other species and elements in the natural world to share an ethical equality with each other [8]. This philosophy responds well to both sides of our understanding of biophilic design.

Interestingly, the evolution of Chóngqing as a village on the Peninsula is very much informed by this historical ‘oneness’ philosophy, as well as the more recent Fengshui. Fengshui theory is a representation of this historical philosophy, seeking to achieve harmonisation amongst heaven, earth and human beings by providing equilibrium amongst nature, building(s) and people [9]. Figure 2 below shows a Form-school Fengshui concept on the ideal siting consideration template for town location and construction, demonstrating the ideal relationship between humans and the natural environment.
3. Chóngqing and its Yuzhong Peninsula

Chóngqing, formerly known as Chungking, is located in southwest China, is the largest city in central China. With a history of more than 2,000 years, Chóngqing has functioned as the economic and financial hub of the upper Yangtze River catchment in China since the Qing Dynasty. Chóngqing’s pivotal status in China continues today because Chóngqing is one of only 4 direct-controlled municipal cities of China (the other 3 being Beijing, Shanghai and Tianjin). It is also the only municipality in China located away from the coast.

The urban area of Chóngqing is known as Central Chóngqing and covers approximately 5,473 km². Chóngqing. The Yuzhong District (“Central Chóngqing District”), with an area of 23.71 km², is the geographically central, historically oldest, and most densely populated district of Chóngqing. As the original site of the metropolis of Chóngqing, it is located on a peninsula confined by the major trade navigation routes of the Yangtze and the Jialing Rivers.

4. Reverence and adaption of nature

The major part of today’s Yuzhong Peninsula was where the ancient Chóngqing city was originally sited. Built on a mountainous landform, and as a port city confined by two rivers (the Yangtze and the Jialing), the urban planning philosophy of old Chóngqing city embodied a strong sense of reverence to nature.

4.1 The gate structure with Fengshui meaning

Figure 2: The ideal Fengshui mode for village and town construction. Source: [10].
Historically, there are 4 periods of ancient town construction of old Chóngqìng. The core historical period resulted in a town finally characterised by 9 water gates and 8 fire gates. The reference to water and fire alludes to this reverence embedded in Chóngqìng’s city structure (Figure 3). As part of this design theory, the symbolic role of ‘water’ is to control ‘fire’, (only 9 water gates can be opened and each links to water; the 8 fire gates complete the Fengshui urban structure theory).

Figure 3: The 17 gates of old Chongqing (map of Chongqing, 1891). (Source: http://cq.cqnews.net/shxw/2015-07/02/content_34646846.htm; accessed 1 July 2017).

Fire is a key archetypal value because historically Chóngqìng governance and citizens were always concerned with fire due to the predominance of bamboo and wood materials in building fabrication, and the close proximity of the buildings on the Peninsula. Similarly, the numbers 8 and 9 represent ‘9 palaces and 8 diagrams’, drawing reference to traditional Chinese philosophy, while also demonstrating defensive integrity and capability at the key juncture of two rivers. Further, the stilted timber buildings erected on the Peninsula followed the contours, accentuating the geographical character of the landform (Figures 4 and 5).
4.2 Self-adaptive trails

To cater for this unique geographical context, the trails historically evolved interlacing through this mountainous topography. The way these streets adapted to this uneven and often steep topography nonetheless resulted in the creation of flexible public spaces (Figures 4, 5 and 6), making these streets not only a space for transportation, but also venues and stages for social activities including small businesses, playing Majiang and chatting. This natural geographical environment historically formed the unique built environment space that is Chóngqing today, which also historically informed the nature of Chóngqing’s social activities and collective culture.

Figure 4: stilted buildings and old Chóngqing

Figure 5: the self-adaptive trails one hundred years ago.
Figure 6: Self-adaptive trails and public space. Source: the authors and Zhao (2003)

4.3 To ‘overcome’ nature

The contemporary emergence of high-rise buildings symbolizes Chinese people’s effort to overcome nature in Chóngqìng. Symbolically these new towers are seeking to break the historical limitations of vertical development and spatial capacity. As a mountainous city, Chóngqìng’s contemporary construction regulations have demonstrated softer requirements upon distances between buildings. In contrast, flat regions in China have a relatively strict requirement on the provision of daylighting and distance between new buildings. Instead, Yuzhong Peninsula, as a continuing Central Business District of Chóngqìng, has become filled up with candle-like skyscrapers (Figure 7). These towers not only destroy the harmonious visual relationship between mountain, river and built environment, but also are leading to a convoluted and vast mosaic of grey infrastructure and construction that is changing the original walking-based culture and main circulation structure of Chóngqìng.

This vehicle road construction is resulting in separated and imbalanced functions and social infrastructures. The first new vehicle road construction can be traced back to the 1920s when demolition of the original city wall defences commenced to facilitate city expansion. In recent decades, the process of vehicular road construction has increased, not only because of increasing population, but also due to imbalanced population, but also due to imbalanced strategic planning.

For clarification, the City of Chongqing and Yuzhong District, have their own five-year plans as official urban developmental strategies. In the 13th Five-Year Plan (2016-2020) [11] of the City of Chóngqìng, a requirement has been placed on the need to balance the functional development of city and to apply a cluster town planning model. This Plan emphasizes a cluster-node urban spatial layout and the need to balance working and living functions in each cluster, to reduce the unnecessary movement between clusters.

The development strategy for Yuzhong District, however, as the most significant central portion of Chóngqìng and its core function as a port area, highly emphasizes its commercial and business functions, which is increasingly breaking the balance of the historical functions of living and working harmoniously in the District.

This argument is evidenced in the Yuzhong Image Design Planning and Control Regulations [12]. Articles 6 and 7 of these Regulations are stated in Appendix A.
Further, the yearbook of Chóngqìng statistically evidences the practical application of these strategies that have resulted in a continuous reduction in the residential population of Yuzhong District in 2005, 2010 and 2015 (Appendix C).

4.4 To compromise with nature
Over the last 20 years Chóngqìng has experienced considerable growth in the construction of large-scale buildings to accommodate commercial, office or cultural activities. Figure 7 quantifies the construction of skyscrapers above 100m in height from 1998 to 2020, of which there are 79 buildings from 2005-2015 alone. Prior to this, only 15 such skyscrapers were built in 1998-2004. Among these new 79 skyscrapers, 26 were built in Yuzhong District, comprising a building footprint area of 0.4% of the Chóngqìng metropolitan area.

![Figure 7: Skyscrapers being built in Chongqing (source: http://www.skyscrapercenter.com/city/chongqing); accessed 5 April, 2018).](http://www.skyscrapercenter.com/city/chongqing)

Vehicle infrastructure construction has been an immediate outcome of this building construction to service and support this rapid and imbalanced development. Thus, vast new traffic infrastructure are needed to transport people from residential areas to Yuzhong for work and shopping, as well as to transport supplies of goods and materials for business and commercial activities. A substantial period of construction was legitimatised in traffic infrastructure planning heralded in the 11th 5-Year Plan (2006-2010) [13] of Yuzhong District aim is set out in Appendix B.

This vehicular infrastructure involves the construction of roads to surround the peninsula to stimulate the productivity of the District, and to supposedly increase the economic vitality of Yuzhong. However, many places in the District that previously supported local social activities have
vanished, especially along the waterfront area (Figure 7).

Figure 7: Layers of vehicle roads along Yuzhong waterfront have compromised access and social opportunities

5. To compromise with nature

Despite this change, there continues to be human inconvenience due to vehicle use and parking inside the mountainous landscape of the Peninsula. This is why successive Plans for the District have sought to include the revitalization of the extant walking system through Yuzhong Peninsula (Figure 8).
Of these Plans, the most well-known one is the *Yuzhong Image Design* [14]. This plan recognised 9 mountain-city trails (山城步道) as forming the key urban design framework for this landscape with an aim of seeking to utilize the traditional linear corridors and networks for both conserving the character of Yuzhong as well as to relieve the congestion of north-south vehicle transportation across the Peninsula. However, from data analysis through Chinese social media platform weibo.com, only a few of these extant mountain-city trails have been well recognized by tourists and local residents [15].

Special urban planning of the pedestrian system in *Yuzhong District Plan* (2017) [17] has separated up the walking system into two layers:

1. the fundamental walking system plan with pedestrian-transportation considerations; and,

2. walking trails plan with leisure and tourism considerations.

The 2017 plan has considerable modified this approach, seeking to appropriate spontaneous formed leisure trails by local organizations and peoples. But there is still a need to respond to and use and respect the natural and cultural environmental context of Yuzhong.

### 6. Understanding nature and people connections

The notion of a ‘cultural landscape’ represents a combination of human and natural values. The term ‘cultural landscape’ was recognized as a subclass of ‘cultural heritage’ by UNESCO through ICOMOS to better incorporate places that demonstrate ‘significant interaction between people and the natural environment’ [1]. ‘Cultural Landscape, in the associative sense, can exist at almost any scale’ [17]. Because
urban places are gathering venues for large populations of human beings, and often represent physical manifestations of human aspirations through space and time, there is an increasing recognition that cities also reflect or embody the interactions between nature and humans, making them a new type of a cultural landscape [18].

The Historic Urban Landscape (HUL) concept was proposed by ICOMOS to address a city-level systems context, thereby enabling the recognition of both a thing and a process, and their synergistic interactions. The HUL Recommendation [1] defines a historic urban landscape as the ‘layering of cultural and natural values and attributes, extending beyond the notion of ‘historic center’ or ‘ensemble … [that] include[s] the broader urban context and its geographical setting”. This definition puts an emphasis upon conservation and land development based upon an integrated pattern appreciation and knowledge of historic town and landscape under consideration, instead of putting strict definitional limitations between a heritage area and a non-heritage area.

Biophilic design requires us to understand and connect to nature. While the logic for many historic cities derives from such a connection and engagement with their natural environments, biophilic design emphasises the need to add green spaces and opportunities to connect with nature, as well as rebalance urban realms within natural environments. Thus, it is better for us to deeply understand the extant urban fabric and social clothes, its resources and its traditional knowledge about an old city area before proceeding with strategy formulation and practical actions.

In Chóngqìng’s case, to learn from the existing fabric and living culture can be a way to respond to the requirements of formulating a biophilic city model. There are a lot of parallel relationships between the HUL approach and the biophilic design approach for historic urban areas. Inspired by both of these theories, this paper proposes two visions for Yuzhong peninsula:

6.1 To revitalize walking-oriented urban spaces and biophilic activities

Yuzhong District today, as a compact city area framed by its traditional fabric, has good basis for enabling walkability. However, the accessibility of the existing pedestrian system has been reduced by poorly integrated pedestrian and vehicular systems and zig-zag footprint construction of vehicle roads within the Peninsula towards the two rivers. The situation is compounded by the narrow laneways arising from the cessation of a family-oriented cohesive social structure to curate these activities. These issues are reflected in the Yuzhong specific walking system plan [12].

Aside from providing a walkable framework inside the Peninsula, it is equally important to link the walking system to the outside of Yuzhong Peninsula. Secondly, there is a need for an integrated railway and walking trail system that links the recently installed underground metro railway stations and the walking trail system. Provision of a legible trail system from railway stations to
walking trails, and inside each trail corridor, should be developed.

High-rise buildings reduce the legibility of living within mountainous topography. Along with bridges for vehicle transportation, new buildings block many visual and physical connections between people, mountains and rivers. This is why people on Yuzhong Peninsula are increasingly valuing opportunities to view the two rivers, the mountains, and the sky.

Searching the key word “山城步道” (mountain-city trails) in the Chinese social media platform weibo.com many photos has been found taken the mountain and river views of this part of Chóngqing [18]. Many social activities centre around the mature Ficus virens specimens (a local tree offering shelter in intense heat of summer), evident in people’s comments (Figure 10) [18].

There is a clear need to conserve traditional lifestyles of peoples residing and or working along these trails – such as small businesses and outdoor activities – to encourage people to get out of their houses and to continue to partake in historical trail and street use culture.

We argue that strategies should include:

- building an integrated and interconnected railway and walking trail system to reduce vehicle use, with the larger vision of inspiring de-vehiculization of the place;
- prioritise the selection and design enhancement of trails establishing better access and legibility of water and mountain landscapes;
- Promote the conservation and celebration of traditional cultures and lifestyles encouraging outdoor engagement and activation; and
- Conserve local trees as part of Chóngqing’s heritage, as well as identify and implement new tree plantings.

Figure 9: Ficus virens and local people. Source: http://www.cq.xinhuanet.com/jrht/20140514a.htm, accessed 6, April, 2018
6.2 Possible solutions to building an ecological network after a de-vehicalization process

Continuing use as port area, the old town area of Chóngqìng continues to increase in density, thus presenting limited space for green infrastructure. The recent District Plan strategies seeking to reduce the resident population appears to be trying to alleviate the population density to the detriment of the historic and social fabric. In this high-density area of Chóngqìng, roads appear to have taken too much spatial prominence, to the detriment of provision of green infrastructure.

The ancient maps of Chóngqìng, evidence a network of Fengshui-inspired trails linking gates, water and the city, such a philosophical design strategy can work equally as an innovative culturally-responsive greening strategy, offering shaded and stimulating patches and routes for humans, corridors for animal migrations, and oxygenating air vents and conditioners for the old city of Chóngqìng.

In Chongqing’s case, along walking trails, micro-level planting can be undertaken to formulate a pedestrian-inspired greening system. At another level, if a de-vehicalization process works, there are several opportunities to change grey infrastructure into green infrastructure.

Acknowledgments

We are grateful for the assistance of Urban Planner Linxi Hui, for reviewing the

To conclude, strategies for this target include:
- take full use of existing walking trails for micro-level greening, to aid walking and outdoor activities; and
- turn grey infrastructure green, in synergy with or following any de-vehicalization process.

7 Conclusion

The idea that ‘Nature benefits humans’ is embedded in the subconscious common sense of individual and collective human beings. There are many ways to realize these benefits – new techniques, art and traditional wisdom. To be inclusive to this urbanisation change, it is important that we confront issues being presented by rapid population growth and associated urban structures and infrastructure, and the quietly profoundly emerging diversity of social values.

As human beings we need to respect the past to go forward. The corresponding relationship between these two terminologies tell us a possible truth rather than labelling any idea as a vehicle or policy for action. These include the need to respect diversify in people and context and to be inclusive to change for the betterment of people and their living environment.

Planning Policies and Guidelines outlined in this paper.

Biophilia and Berlin: how historical conflict establishes progressive biophilic landscape strategies and design.

Brent Greene

Royal Melbourne Institute of Technology (RMIT), Melbourne, 3000, Australia

Abstract

Biophilic design approaches emerge in the 1980s when advancing eco-philosophies, such as Wilson’s Biophilia, Clément’s Third Landscape and Kowarik’s Fourth Nature, began to manifest in literature and practice. Parc Henri Matisse (Lille 1995) and Natur-Park Schöneberger Südgelände (Berlin 2000), among others, represent some of the first instances where inherent urban systems, existing outside the influence of the designer, manifest in spatial practice.

This paper investigates attitudes towards biophilic projects today with a focus on Berlin, a city considered an exemplar of biophilic policy and design. The paper analyses Berlin’s key environmental policy and explores its impact on landscape practice. Additionally, by focusing on acclaimed landscape Park am Nordbahnhof (2009), the research comes to understand the expression of biophilia in contemporary practice. Drawing on a number of interviews, including: a city planner for Berlin’s Senate Department of Urban Development and Environment; an urban ecologist central to the creation of Natur-Park Schöneberger Südgelände; and the landscape architect responsible for Park am Nordbahnhof, this paper unveils the complex socio-political and eco-cultural conditions that inspire a positive engagement of urban systems through design.

The research suggests that Berlin’s ability to support biophilic practice is closely tied to its recent history. Complex socio-political conditions, in this case post-war recovery, inspire a new engagement of urban ecology in philosophy and landscape architecture. For example, it is suggested that World War 2, as well as the Berlin Wall, are catalysts in the development of a unique, and progressive eco-cultural dynamic that establishes the city as archetypically biophilic.

Keywords: Fourth Nature; wastelands; spontaneous urban ecology; Berlin; ecological philosophy; landscape architecture.
1. Introduction: from ecology to biophilia

The discipline of ecology first emerged in Europe during the 19th century and was understood as a scientific investigation into the 'relationship of the organism to the environment' [1]. Notably, European scientists, such as Alexander von Humboldt, examined intact ecosystems and focused on, among other themes, how species evolved and adapted within their environments.

The study of ecology diversified in the 20th century as new ecological positions continued to emerge. For example, in 1935 Tansley introduced the term ecosystem; and, in 1953 the Odums published *Fundamentals of Ecology*, a text that combined notions of systems operation alongside principles of ecological science. Coming a decade later in 1962, Carson's *Silent Springs* pushed ecological concepts into the mainstream consciousness. Notably, Carson explained how human actions, for instance the application of chemicals such as DDT, had agency to destroy entire ecological communities. Critically, Carson’s text introduced a new eco-framework that established associations between ecological and cultural systems. Bateson described this position succinctly, stating ‘We are not outside... ecology... we are... a part of it. Herein lies the charm and... terror of ecology - that the ideas of... science are irreversible becoming part of our own ecosocial system’ [2]. In this way, Carson and Bateson defined a system whereby cultural and environmental conditions are disparate, yet equal components, of the same system.

Building on these frameworks is Wilson’s *Biophilia*, a text that examined the complex interactions between culture and ecology globally. Wilson explored, among other concepts, biophilic associations between different cultures, ecologies and species which led him to conclude that ecological values can shift through time. As Wilson stated, ‘What is good... at this moment might easily sour within ten years... That is why any ethic worthy of the name has to encompass the distant future…. Values are time-dependent...’ [3]. Wilson identified the inherent complexities of ecological value systems and argued that biophilic relationships may evolve as new systems and perceptions emerge in the future.

1.1 Biophilia, ecology and design

Similar to the preceding philosophers, landscape architects, keenly interested in science and ecology, became more sensitive to ecosystems performance in the 1960s. Ian McHarg, for example, aimed to design the landscape as an integrated system composed ecological and cultural processes. As McHarg stated in *Design with Nature* 'the ecological method allows' the landscape architect to 'understand form as an explicit point in the evolutionary process' [4]. Similarly, Ian Laurie's *Nature in Cities* outlined new approaches to urban ecology and landscape practice. The book features Sukopp’s essay, 'The Soil, Flora, and Vegetation of Berlin’s Waste Lands' which studied the pioneer ecologies of Berlin’s wastelands and argued for the retention of ruderal flora through design [5]. Critically, these examples, among others, demonstrate...
how landscape architects began to engage dynamic systems as a primary design material in the 1960s and 1970s. Frameworks of ecology continued to diversify in the 1980s and 1990s with the introduction of eco-design philosophy which challenged many ideologies established in the 20th century. Notably, core principles were re-evaluated as the world became increasingly globalised and urbanised. For example, Gilles Clément (a designer) and Ingo Kowarik (an urban ecologist) utilised new theories of urban ecology through philosophy and landscape practice. Clément evolved eco-design thinking through the production of new ecological terms, namely the Planetary Garden, the Garden in Movement and the Third Landscape. While these positions are similar to some scientific principles of ecology (for example dynamism), Clément expanded established beliefs by acknowledging the role of politics and economics in a globalised ecosystem.

Fig. 1. An example of a Fourth Nature grassland at Tempelhof Feld, an abandoned airport in Berlin.

Similarly, Kowarik’s classification of a Fourth Nature ecology within Berlin (figure 1), which he defines as ‘spontaneous’, ‘novel’ and ‘wild’ [6] pushed the classification of species in ecological science beyond binary terms such as native or exotic. Read in conjunction with Clément, the novel philosophies represent another important progression in ecological thinking from the 1980s onwards.

The introduction highlights a shift towards a European acceptance of highly modified urban ecosystems in philosophy and design. The following section discusses the impact of this shift within Berlin. With a focus on Kowarik’s philosophy, and the design of Park am Nordbahnhof, this paper clarifies two points: first, how the legacy of World War 2 and the construction of the Berlin Wall produces Fourth Nature philosophy; and second, how Fourth Nature systems enhance biophilic associations through the design of public open space in Berlin.

2. The Berlin Wall and Fourth Nature: the emergence of biophilia in Berlin

In the 1970s and 1980s ecologists practicing in a divided Berlin were forced to examine unexplored landscape typologies as their primary sites of research. As Kowarik explains, West Berlin had become ‘an island… surrounded by the GDR’ following the construction of the Berlin Wall; and, having been denied the opportunity to examine traditional sites of research, such as
the wilderness, ecologists were forced to study urban environments [7]. This pivot from the exterior to the interior of the city shifted the ways in which ecologists perceived and understood natural systems. Critically, urban landscapes, which had been overlooked as valuable research sites [8], became the focus of ecological study in Berlin. As Lachmund notes, ‘ecologists… sought a reconciliation of city and nature…’, an impact he suggests ‘transformed into a more comprehensive view of different types of ecosystems… which had… some value or potential as nature’ [9].

For example, within wasteland spaces numerous ecologists, notably Herbert Sukopp, often discovered (unexpectedly) spontaneously evolved and biodiverse ecosystems. Sukopp’s discoveries were so remarkable that he advocated for the protection and enhancement of wasteland biotopes. As Sukopp wrote, wasteland species would be the ‘prevailing plants of the future’ owing to their abilities to ‘adjust themselves best to man-made sites’ [10]. Similarly, the ecologist wrote about a ‘great protective importance of these plants in cities…’ and argued to ‘preserve spontaneously developing’ systems as they often performed as ‘the last refuge of some species threatened elsewhere with extinction…’ [11]. In this way, Sukopp’s investigation of Berlin’s spontaneous ecosystems, later classified as Fourth Nature by Kowarik, reframed wastelands spaces as valuable ecological resources. Critically, as discussed in the following section, the evolved awareness was the epoch of Berlin’s contemporary biophilic system.

2.1 Contemporary biophilic association in Berlin

The perspectives of Kowarik, landscape architect Herald Fugmann, and Senate Department planner Holee Thierfelder reiterate the inherent biophilic relationship between the Berlin community and the city’s Fourth Nature ecosystem. Critically, Kowarik and Thierfelder refer to the notion of freedom, both cultural and ecological, when describing Berlin’s biophilic attributes. Similarly, Fugmann, who also describes a free condition, explains how the biophilic system impacts the design of Park am Nordbahnhof.

Kowarik and Thierfelder indicate that Berliners are inherently liberated and believe this attribute is derived from living in close proximity to Fourth Nature. As Kowarik states, ‘...it produces a feeling of being different… a feeling of natural approaches… that provides qualities that make… life richer because you have more direct contact with natural processes…’ [12]. Kowarik references the designed landscape of Park am Gleisdreieck to clarify his position, noting the park is valued ‘because it is a symbol of freedom, of natural processes in the heart of the city’ [13]. In this way, the quote suggests that Fourth Nature ecologies are a significant factor in the production of a liberal society within Berlin.

Likewise, Thierfelder describes a similar biophilic condition, defining the city’s residents as free and diverse. Nevertheless, unlike Kowarik’s viewpoint that the ecosystem produces a liberal society, Thierfelder implies the city’s Fourth Nature ecosystem is produced by the community’s
open-minded attitude towards cultural expression. As she clarifies, ‘Berlin had the idea to be such a free town and we have… not only the Fourth Nature, you have the bars and restaurants that are open all night… that’s what makes the people here and that’s what makes the Fourth Nature’ [14]. Critically, Thierfelder suggests that the attributes of liberty existed prior to the emergence of Fourth Nature; and, that Berliners’ inherently liberal attitudes led to the classification of a new type of eco-system in science and philosophy.

2.2 Valuing Fourth Nature in Berlin: protests and policy

Berlin’s biophilic system is supported by the city’s protest culture and numerous government policies that protect Fourth Nature from destruction. In reference to activism Thierfelder states that Berlin is a ‘protest city’ [15] and identifies Park am Gleisdreieck and Tempelhof Feld as two abandoned landscapes that have inspired political responses as a means to save Fourth Nature systems from destruction. Berliners, Thierfelder suggests, remain fiercely protective of abandoned landscapes as these spaces offer a ‘sense of freedom in our well organised world’ [16].

Similarly, multiple levels of government are committed to safeguarding Berlin’s Fourth Nature landscapes from processes such as residential development. For example, the Federal Government, Berlin State and the Senate Department for Development and Environment have a range of policies that safeguard Berlin’s Fourth Nature ecosystems. Notably, Berlin’s Biodiversity Strategy highlights ‘the importance of biodiversity for the… society of Berlin’ [17] and references numerous typologies of urban green space that are considered ecologically valuable. Critically, the strategy identifies Fourth Natures, defined as urban wilderness, as extremely important to Berlin’s eco-cultural system. As the document clarifies: ‘Current environmental psychological research… prove that city dwellers value urban
wilderness as much as traditional green spaces… For aesthetic reasons, but also for… biotope protection, it… makes sense to allow a permanent development of wilderness in some areas… in the context of species support programs and the biotope network’ [18]. Likewise, in *Specially Protected Biotopes in Berlin*, a resource outlining biotopes of principal interest, numerous Fourth Nature conditions are identified, for example; ‘gravel, sand and marl pits’ [19] and ‘lean and dry grasslands’ [20]. Notably, the document explains, among other points, how ‘rare or endangered plants…’ can emerge within wasteland spaces [21] (shown in figure 2) and establishes the ground of legal protection.

The examples of community activism and government protection reiterates the inherent biophilic relationship between the city’s ecological and cultural systems. Similarly, landscape architects practicing within Berlin are often driven by an ambition to protect Fourth Nature while foregrounding its ecological attributes through design. The following section discusses Fugmann Janotta’s biophilic approach to the design of Park am Nordbahnhof in the borough of Mitte.

### 3. Biophilia and Design: Park am Nordbahnhof

Park am Nordbahnhof was designed in two phases. The original scheme was the outcome of a 1995 design competition that Fugmann Janotta won in collaboration with architect Romuald Loegler. However, due to the Berlin’s constrained economic position in 1995 the proposal was never implemented.

Six years later the State Department flagged its intention to realise the project with significant design changes; the department had new ambitions which focused principally on the landscape’s ecological attributes. Fugmann explains that the Senate thought Nordbahnhof could perform *ecologically* as ‘compensation for things that happened in… other parts of the city… where nature and resources are destroyed’ [22]. In response, the landscape architects reconfigured the scheme with a strategic focus on the landscape’s eco-cultural history.

Fugmann recalls the experiential, structural and ecological attributes of Nordbahnhof’s pre-designed landscape. The designer notes that ‘it was a very special atmosphere… because you felt to be in the centre of the city… but you didn’t hear anything of it…’; similarly, he explains that ‘the Berlin Wall’ was a principal influence and describes the existing ecological condition being composed of ‘small band of scrubs and trees…’ and ‘very special… meadows… in the centre of the park’ [23]. As shown in the conceptual diagram (figure 3), each condition influences the configuration of the final design. Principally, the landscape architects understand Nordbahnhof as an opportunity to heighten the interface between Berlin’s urban ecology and its community. Fugmann explains that ‘these kinds of open spaces are very valuable for everyone who is living in the city… especially for children to see what nature in the city is and to visit these types’ of environments’; the design, he suggests, is a ‘kind of insertion… a director… setting up
an observation’ [24]. To promote interaction between the cultural and ecological systems, the designers inserted three islands into the central meadow, a ‘very artificial design’ that shows the ‘big contrast… to the nature’ [25] that evolved spontaneously within the landscape.

Within each island, shown in figures 4 and 5, is a disparate programmatic function designed to heighten the interaction between park uses and the surrounding ecology; whereas one island provides opportunities for children’s play, another includes spaces for picnicking and nature contemplation. Similarly, the clearly defined boundaries between the interior and exterior of the islands, constructed in concrete, intensify the visual and spatial distinction between the design and peripheral spontaneous environments.

Fig. 3. Nordbahnhof’s pre-existing eco-cultural conditions.
The islands are circumnavigated by a linear path system and interceding bridges which establish connections between the meadow islands and remaining landscape. Commenting on the performative capabilities of the path network the designer explains how they are perceived as devices to heighten the interaction between the Fourth Nature system and park users. Fugmann describes the railing as ‘very comfortable to put your hands on the top and to look and the vegetation’, to ‘think about what they… see in the area… to make people sensitive’ to Nordbahnhof’s spontaneous ecology [26].

Equally, the rails act as a barrier system to protect Nordbahnhof’s most valuable species. As Fugmann notes, ‘it was very important to build a line around the meadows’ as a means to limit damage to the environment; however, while protection is the design intention, he believes ‘there is no possibility’ to entirely secure the meadow from human encroachment [27].

Notably, several ephemeral tracks, shown in figure 6, are identified within the meadows as the barrier system is easily traversed. However, while the barriers, shown in figure 7, are traversable the designers do not necessarily perceive this as a failure. Alternatively, the landscape architects understand the rails as strategic moments where park users choose how they interact with the space and its ecology. Fugmann clarifies that the design encourages users ‘to be open to new experiences, for nature’ and ‘for history… we didn’t want… it to be a teacher or a guide… Everyone should make’ their ‘own experience… and… own discoveries’ within Nordbahnhof [28].

Fig. 4. The inserted island (left) and the pre-existing Fourth Nature system (right).
Fig. 5. Nordbahnhof’s path networks and islands.
the liberal approach to Berlin’s eco-cultural system previously described by Kowarik and Thierfelder. In this case, the railings, in addition to the islands, are loose design elements that provide park users a platform to contemplate, and interact, with the Fourth Nature system that dominates the landscape.

Nordbahnhof has proven to be a successful addition to Berlin’s open space network. It won the German Landscape Architecture Prize in 2011 which celebrated the park for its ability to ‘unite the fundamentally competing aspects of ecology and intensive park use in one overall concept’ [28]. Reflecting on the reaction to the design Fugmann recalls that Nordbahnhof ‘was an experiment’, and that he didn’t know ‘whether the public’ would react positively; but ‘the reaction was very positive: people… go to Nordbahnhof… looking for’ a novel atmospheric experience, ‘to see… nature, to hear the birds and the trees’ and to seek solace from the city [29]. In this way, Nordbahnhof presents a biophilic design response reflective of a culture that has developed a unique relationship with its spontaneous urban environments.

4. Conclusion

This research highlights how Berlin’s recent history establishes new approaches to ecology in design and philosophy. The creation of wasteland spaces through war and spatial division supported the emergence of a spontaneous ecosystem, notably Fourth Nature, which was later reconceptualised through science, philosophy and landscape practice.

Fig. 6. Ephemeral tracks produce by park users.
Fig. 7. Steel railing surrounding the central meadow.

Critically, the prominence of Fourth Nature in Berlin’s eco-cultural system typifies the city’s biophilic association. The ecology, among other performative capabilities, reinforces the community’s liberal condition; similarly, the freedom of the community supports an ecosystem which is inherently spontaneous.

The systems’ liberal attributes are celebrated through environmental policy and landscape architecture practice as a means to protect Fourth Nature for future generations. In the case of Park am Nordbahnhof, the intervention reinforces Berlin’s biophilic associations by establishing an interface between designed landscape and spontaneous ecology.

Acknowledgments

The author thanks Dr. Jillian Walliss, Dr. Heike Rahmann and Wendy Walls for their continuing support in the development of this research. Additionally, the author thanks Professor Ingo Kowarik, Herald Fugmann and Holee Thierfelder for taking the time to explain their understanding of biophilia and Fourth Nature ecosystems in Berlin.

The Landscape Recovery in Small Cities and Towns in China-Based on Liuying, Fengxiang County, Shaanxi

Zhang Weiping, Zheng Qili, Xu Riga

No. 13 of Yanta Road, Xi’an University of Architecture & Technology, Xi’an, Shaanxi, 710055, P.R.China

Abstract

Today, the environmental problems of the city is attracting more and more attention. Generally speaking, the environmental problem in large cities are more likely to cause people's attention. However, the environmental landscape of some small and medium-sized cities is not so optimistic, because the size of the city is smaller and the attention will be less. In small and medium-sized cities and towns, the investment level of the destruction of the environment pollution and the control of polluted productive activities are much less which leads to environmental problems in small towns is more prominent.

A balanced development with human settlement and cultural construction is the primary prerequisite for a city’s healthy development. Liuying, a small town famous for its clay sculpture in Fengxiang County, Shaanxi, is the case study in this paper which provide the possible measures for the effective coordinate between the development of local culture and the urban environment in small and medium-size cities and towns.

Keywords: small and medium-size cities and towns, clay sculpture, ecological restoration, sustainable development

1. Brief introduction

In recent years, with the acceleration of urbanization in small and medium-sized cities and the expansion of urban population, environmental problems are becoming more and more seriously. The sharp decline in air quality, water pollution, soil pollution, solid waste pollution and other problems are urgently needed to solve. At present, among the ten cities with poor air quality, the small and middle-size cities account for six. Sewage and industrial wastewater directly pollute rivers and lakes. Some small and medium-sized cities have serious soil pollution and low environmental quality. The comprehensive utilization rate of solid waste is low, and removing quantity of living garbage is insufficient. The air, water and soil pollution will affect the people’s health, and it also restricts the healthy
development of these small and medium-sized cities and towns.

Over disordered exploitation of landscape resources, the land lost capacity of recovery. This brought more serious lack of biodiversity and higher degree of environmental pollution. On the other hand, many environment deteriorated small and middle-size cities and towns will direct radiate its problems to the adjacent rural areas. Besides, small and middle-size cities and towns are less affected by the urbanization process, people's daily life combines more closely with local culture, the deterioration of the environment impact on people's lives are more obvious than in large cities.

Generally speaking, the development of small and medium-sized cities and towns exposes more prominent problems than the large cities, such as the poor quality of urbanization, the decline of the carrying capacity of environment and resources, the phenomenon of "urban disease", especially the lack of urban cultural construction, which has lost the soul of the city's development. With the economy improvement of living standards, people are having an even higher demand for the quality of living environment, especially for cultural aspects. The demand for culture construction is marked by multi-level, divers and multifaceted characteristics. A balanced development with human settlement and cultural construction is the primary prerequisite for a city’s healthy development. Liuying, a small town famous for its clay sculpture in Fengxiang County, Shaanxi, is the case study in this paper which provide the possible measures for the effective coordinate between the development of local culture and the urban environment in small and medium-size cities and towns.

2. The Fengxiang clay sculpture in Liuying, Fengxiang County, Shaanxi

Fengxiang County, is located in Guanzhong Plain, northeast of Baoji, Shaanxi. It is along the Qinling Mountain and has complex terrains. (Fig. 2.1) It is in the warm continental monsoon climate zone, semi humid and semiarid. Fengxiang has an area of 1179 square kilometers. It has 12 towns and 520 thousand population. Fengxiang has a long history of more than two thousand years. It is the famous for many of its folk arts and crafts, such as the folk poses, the clay sculpture, the boarding, the paper-cut, and the shadow puppet, etc. (Fig. 2.2)

Fengxiang clay sculpture is listed in China intangible cultural heritage. It is a kind of traditional folk art with unique local characteristics, and main produced in
Liuying town. The history of clay sculpture making could date back to the Ming Dynasty, which is more than 600 years ago. Local villagers purchase clay sculptures at home, to pray for children, spirits, houses, and good fortune. The making methods are handed down from generations to generations. Liuying is the main productive base for Fengxiang Clay Sculpture. There are a large number of clay making small factories and small workshops scattered in this area.

Fengxiang clay sculpture draws its inspiration from ancient stone carvings, New Year pictures, paper-cut and embroideries, with exaggerated shapes and colorful colors. The Fengxiang clay sculpture is modeled from dozens of processes such as fine blanking, coloring, thread drawing, color loading and glazing. The shape of the sculptures is realistic, rough, exaggerated, concise, generalized, colorful, and white drawn. The form is mainly for animals, birds and other mythological folklore modeling. (Fig. 2.3)

2.1. Environmental problems of Fengxiang clay plastic production

For over a decade, the ground soil excavation caused the destruction of vegetation, bare land, and the lack of self-purification ability. This is resulted in the pollution of water resources. The disorder and unrestrained development also leads to less and less high-quality soil resources for Clay Sculpture making and the production quantity is decreasing.

The Liuying clay sculpture is the most representative folk craft product in Fengxiang. The blinding expansion of production leads to serious environmental problems. The raw material of clay sculpture is taken from the nearby Dongfeng reservoir. The large area of unordered soil collection cause serious environmental problem. As the same time, the water in Dongfeng reservoir is polluted by the disordered discharge of industrial waste water and domestic sewage, the scattered solid waste make the situation even worse. The deterioration of the water land environment also leads to the lack of local cultural identity, the neglecting of suitable living spaces creation, and the reduction of people's life quality and happiness. (Fig. 2.4)

2.2. Soil erosion is caused serious clay figurines

The Liuying clay sculpture is made by six kinds of materials, the local black oil plate, white seal soil, fine cotton and glutinous rice, etc. The black soil is taken from the Dongfeng reservoir. In recent years, the economic benefit of the clay sculpture production has been highlighted. The demands for clay sculpture production has increased year by year, which leads to the unordered rising trend of the excavating of the raw clay material. The model of small workshop production is lack of overall arrangement, and lead to an individual behavior of soil collection. Over excavating
leads to the thinning and narrowing of the soil layer of the reservoir bank. The bank protection is very important in maintaining the ecological balance with soil and water, as well as the eco-environment in the reservoir area. The nudity bank has lost the ability to regulate the soil, and resulting in a large amount of soil erosion. The irreversible destruction trend lead to a serious destruction of the natural environment, the fragmentation of the landscape, the decline of the land productivity, and the limitation of sustainable development.

2.3. The wastewater discharge and solid waste cause serious water pollution.

The supporting sewage pipe network and connection in Liuying, especially in the Dongfeng reservoir area, is lagging behind. There are no sewage pipe network or the existence of plugging and breaking head in the areas of the basin, and a large amount of sewage is directly discharged into the reservoir. Due to the industrial waste water and domestic sewage, the water quality in the reservoir is extremely serious. The polluted water turns brown in dry seasons. There are no fish in the water and no grass growing on the land. The water quality is extremely worse and the local residents are unable to drink. The pollution has caused great inconvenience to local people's life and clay sculpture production. It needs to be improved urgently. (Fig. 2.5)

The shore edge protection of the reservoir is not well managed at all. The solid waste is dumped alongside the shore. After the pollution of the wasted sewage water, the reservoir water is polluted at the second time by the solid waste. The solid waste is exposed in the open air along the shore and caused chemical changes. The harmful gas is released continuously. The air pollution around the reservoir area is serious and the environmental quality is reduced as well.

2.4. Environmental deterioration leads to lack of local cultural identity

For centuries, in Liuying, the clay sculpture makers are basically staying in the traditional family handicraft workshops, with poor equipment. They still use the individually selling model, which is not only the wasting of time, but also limited the quantity of clay sculpture selling. This is greatly restricts the overall development of the regional clay sculpture making industry. The family style workshops lack of overall concept. Their corporative consciousness is weak. And therefore they lack of the initiatives to improving the living environmental quality. Because of the poor reproduction situation, the poor living environment quality, and the lack of local cultural identity, the development of
Fengxiang clay sculpture was once at a bottleneck. The foresight of high environmental quality and effective producing activities embodies the soft strength of the local development. Liuying is in its urgent need of taking effective measures to improve the overall environment quality, both in software and in hardware.

3. **The ecological restoration solutions for Fengxiang clay sculpture’s environmental impact**

3.1. **The government intervention to reduce soil erosion and sewage discharge**

We are trying to restore the local landscape in three steps. First, is to improve the local laws and regulations. That is to say, we try to reduce the clay excavation along the water areas, improving water quality, reducing water pollution by the ecological restoration of vegetation. The locals are trying to create a multi-layered defense system and ecosystem services in the surrounding landscape areas. We aim to restore the environment’s capability of breathing and growth, and then bring back the diversity of the biological improvement of surrounding areas.

Three years ago, the government of Fengxiang county has set up a three layer supervision and service system for environmental restoration of soil and water, specially in the area of Dongfeng reservoir. It is been considered as a pretty effective series of measures in changing the soil erosion and improving the ecological environment, as well as the agricultural production. These measures accelerate the pace of poverty relief and carry out the local sustainable development going further. The relevant laws and regulations are enacted to prevent the discharge of industrial waste water and domestic sewage been directly released into the reservoir area. A guarding system is established to prevent solid waste disposal which might lead to the second time pollution.

Along the water bank, the locals build a shrub and further a shrub forest in gully slope. They build a silt dam system which could combine the flood control, mud blocking and silt production altogether. This could stop the ditch erosion quite effectively. The local people expand the width of the natural vegetation area of the bank revetment, and carrying out a wide variety of natural species between the farm land and the water bank. Thus, the three layers of reservoir bank protection system is formed. (Fig. 3.1)
Other effective measures include expanding biodiversity, making full use of raw materials and native species with relatively low local maintenance and management costs, improving the current situation of soil and water losses, and gradually setting up a comprehensive management and development system for soil and water conservation. (Fig. 3.2)

Through working unit division and classified guidance, the environmental problem Liuying, the water and soil erosion in Dongfeng reservoir can be effectively reduced as well. The ecological environment in the region is improved. After proper management, the advantages of water and soil resources in Liuying will be brought back effectively in the near future, and the rapid development of local economy as well.

3.2. The process of ecological restoration bring in the promotion of cultural ide

Secondly, we are trying to combine the environment improvement with local culture which could better serve the local people’s life and clay sculpture production. (Fig. 3.3)

The most significant identification for different regions is the cultural difference, which is the unique spiritual and immaterialized wealth retained by every region in its own development. The inspiration from traditional culture and localization should be considered as the key issues to pursue the environmental protection and healthier quality. The Fengxiang clay sculpture in Liuying has its unique charm and connotation. The model making, billet, adhesive forming, fine
throwing, painting, drawing line, coloring, and polishing process of Fengxiang clay sculpture are all taken place in the local people’s yard or inside of the house. The clay sculpture making process is a symbol and be a part for local people’s daily life.

The purpose for improving the productive environment of the small workshop and build a suitable neighborhood environment is to achieve a better development of Fengxiang clay sculpture production, and then improve the living environmental quality of local people in that area.

3.3. Embedding cultural elements of clay sculpture and building green infrastructure.

Furthermore, the recovered landscape has become a green infrastructure of the town. In the recovering remodeling process of the environmental landscape, creating recreational and cultural spaces, thus strengthen the local characteristics of the area. (Fig. 3.4)

In the process of improving clay sculpture making spaces and the living environment qualities of Liuying, all specific problems have to be conducted individually with specific analysis. And the measures being taken have to consider the region’s own characteristics, such as geographical location, natural environment, history and culture, economic situation and so on. The ecological environment protection should be adopted properly. The construction of local green infrastructure also need to be combined with proper environmental management.

The possible measures would be the reforming of the houses’ front and back yard, the improvement of open and public spaces alongside the street. In recent years, Liuying has undertaken a series of reforming construction work. The clay sculpture museum has been built, the pedestrian street with the characteristic of clay sculpture was erected, and the folk craft research and development center was opened.

The possible measures would be the reforming of the houses’ front and back yard, the improvement of open and public spaces alongside the street. In recent years, Liuying has undertaken a series of reforming construction work. The clay sculpture museum has been built, the pedestrian street with the characteristic of clay sculpture was erected, and the folk craft research and development center was opened.

Other measures include, they build the farmland landscape with the function of tourism, leisure and environmental production as a whole.

Other measures include, they build the farmland landscape with the function of tourism, leisure and environmental production as a whole.
environmental transformation activities, etc. By taking all these measures, the Liuying clay sculpture production can be truly indivisible integrated into the people’s every aspect of daily life. (Fig. 3.5, Fig. 3.6)

4. The conclusion

In Liuying’s landscape reformation process, the significance is to draw attention of the marginalized small and medium-size cities and towns while they are facing with environmental pollutions and the destruction of vegetation. (Fig. 4.1)

The Liuying and its clay sculpture production is the epitome of hundreds and thousands Chinese small and medium-size cities and towns which has its own cultural characteristics. The study of the environmental, ecological and cultural solutions of Liuying which is aim in building a peaceful environment. Liuying, with its Fengxiang clay sculpture production, are an optimistic example and will provide reference for the refreshment of other small and medium-sized cities and towns with similar environmental and cultural remains to follow.

History and characteristics of urban parks those have been built on transportation infrastructure

Jisoo Sim

School of Architecture and Design Research, Virginia Tech, Blacksburg, VA 24060, USA

Abstract

Replacing old infrastructure with urban parks is wide spreading in the world. After the High Line, an elevated park, in New York has achieved success, many cities have proposed a new urban park to succeed. Infrastructure reached its lifespan now become a strategy to revive blighted communities and cities. This strategy which is redevelopment transportation infrastructure into urban parks is not only a fashion in recent but the part of a continued strategy for solving urban issues that have existed since the late twentieth century. Despite the importance of this type redevelopment, research on urban parks are limited. To use this strategy in right place and right type, research related to its characters and history are needed. This study aims to investigate its history and document its typology based on empirical case studies. At the beginning of twenties century, a lid park used to minimize noises from freeways. Since the twenty-first century, elevated parks have emerged as a practical case of landscape urbanism. Recently, a lower park starts to be built under overpass or underground. Type of urban parks built over (or on) a site previously used by transportation infrastructure can be divided into four types: (1) an elevated park, (2) a lower park, (3) a lid park and (4) a recovered park. Then, characteristics of each type and its cases will be explained in this study. This study will contribute to policy makers and urban planners who consider replacing their transportation infrastructure into parks and landscape architects who design urban parks over (or on) transportation infrastructure.

keywords: Urban parks; urban greenways; urban redevelopment; greening strategy; typology of urban park

1. Introduction

A paradigm of the freeway has changed from a way to connect us to a barrier that separates us! Although mobility, labor inputs and manufacturing outputs are enhanced [2], urban freeways also become urban issues such as air and noise pollution, lack of scenic value and environmental cost [3]. Many freeways which were built around the 1930s to the 1960s have reached their lifespans and need structural maintenance [4]. Urban freeways have become a subject of urban planning, whether through removal, repair or redevelopment of freeways. In planning, the redevelopment of freeways into urban parks is becoming a global trend around the world. This kind of redevelopment project covers not only freeways, but also all transportation
infrastructure such as railways and elevated roads.

To discover the impacts of replacing transportation infrastructure with urban parks, many researchers have investigated three categories: economic, environmental and social benefits. For example, the economic benefits of urban parks represent their impacts on increasing property values [5]–[7], tax revenue and jobs [8], [9]. For social benefits, urban parks contribute to improve health, enhance social interactions and ameliorate social inequity [9], [10], [12], [13]. Lastly, the environmental benefits of urban parks include improving biodiversity, providing wildlife habitat and managing stormwater [6], [10]. The positive impacts of the park over (or on) transportation infrastructure have been largely revealed. However, research on those parks related to their origins, history and features are lacking.

Understanding urban history and features is important to create appropriate proposals for cities. In this regard, this study aims to investigate the history of replacement of infrastructure with urban parks and create a typology based on empirical case studies. This study can be divided into three parts. First the greenway and linear park will be discussed as a theoretical background. Second, since the early 20th century to the present, the history of urban parks over (or on) transportation infrastructure will be investigated. Based on these background and historical reviews, types of parks and features of each type will be addressed. By understanding their origin, history and features, this study can help to find appropriate types when implementing urban parks over (or on) transportation infrastructure.

2. Background

The theoretical background of replacing transportation infrastructure with parks can be included under the term of greenway in terms of its functions and linear park in form. The parks built over (or on) transportation infrastructure are similar to those of greenways in that nearby residents can access easily and are convenient to use [10]. Looking at the morphological characteristics, this type of urban park is included in one of the types of linear parks [11].

A greenway is an “open space connector linking parks, natural reserves, cultural features, or historic sites with each other and with populated areas [12].” The economic, social and environmental functions of parks built on transportation infrastructure can be included in the same context as these functions of greenways. In particular, from a socio-environmental point of view, the greenway creates a place for leisure activities and alleviates pollution [10]. Especially those who live near a greenway gain more benefits because of greater accessibility [13], [14]. Coutts and Miles (2011) explained that greenways, unlike parks, contribute to neighborhoods’ interactions and connections.

Greenway planning in the United States originated at the beginning of the discipline of landscape architecture, and has had three phases in this evolution [15]: 1) the late 19th
Biophilic Cities

century, 2) the early 20th century and 3) post-World War II. Greenway planning in the late 19th century was led by Frederick Law Olmsted and Charles Eliot. In the second phases, the early 20th century, Olmsted and Eliot’s works were expanded. During the third phases, Ian McHarg and Phil Lewis led greenway planning [15].

Considering their physical characteristics, urban parks created on transportation infrastructure can be included in the category of linear parks. The linear space in the city is the edge where the most dynamic places in ecosystems occur [16]. It is also a habitat for the birds [17] and a trail for citizens [18]. Karl Kullann (2011) describes linear spaces in urban areas as a by-product of a plethora of cultural processes, and discusses and explains disused railways and freeways as examples. Highlighting connectivity and contextualism as dominant features of linear spaces, he accentuates the connections of adjacent communities and sequential experiences as features of linear parks [11].

3. Urban parks over (or on) transportation infrastructure

3.1 Methods

The study will focus on parks built on sites previously used as transportation infrastructure. From the 1970s to the present, a total of 36 cases in world cities were collected for this study. To identify the typology and compare with each type, three steps were needed: 1) investigating cases for classification, 2) developing a classification framework to define the type, 3) a comparison of each type’s features and 4) reviewing the history of each type. A case-study was chosen to capture the complexities of phenomenon and to divide cases into certain categories. From 1960s which a new lid park was completed to 2018, 36 highways have turned into urban parks. From the case study, it was concluded that urban parks on transport infrastructure fall into four categories.

The urban greenway park typology was designed as a way for planners to find an appropriate method to create parks, and for landscape architects to create a design strategy for specific sites. Types of urban greenway parks were divided into four types from the case study: lid parks, elevated parks, recovered parks, and underpass parks. The typological approach to urban greenway parks which was used in the study is not only to serve concrete typology approaches for categorizing urban greenway parks, but also has the potential to assist urban planners and landscape architects who intend to revitalize cities by replacing transportation infrastructure with urban parks. Different types of urban greenway parks were assessed in terms of former usage, replacement construction, and physical characteristics. Fig. 1 outlines various types of urban greenway parks and specific criteria derived from the case study. Four questions were asked to categorize urban greenways: 1) what kind of transportation was its previous usage? 2) what is the elevation of each transportation type? 3) was it torn down before replacing the park? 4) was a lid added for building the park? Each case was categorized in each category which was derived from each
question. Then four types were extracted from each category’s construction features (Table 2). After identifying four types, every case in each type was investigated to understand the features of the type.

3. 2 Types and features of urban parks over (or on) transportation infrastructure

Urban greenway parks were divided into four types, lid parks, elevated parks, lower park sand recovered parks. These types were defined by four features of their physical characteristics. The lid park is a park that has added a lid or cap upon a highway, so it can link to the ground level. The elevated park is a park which replaces an overpass and has limitations related to. A lower park is a newly emerged park in a compact city, and is a park under an overpass. The recovered park represents the most significant change among the other types. This type of park builds on the areas where a highway or overpass were torn down, and aims reclaim nature which has been polluted.

The main strengthen of the lid park is its level. Since it is built on the top of a highway, its level can be a connector in the city. When this type originated, it functioned as a noise prevention strategy by covering the highway. It also provides sports facilities for the neighbourhood. Today it can function as a space for festivals in the urban center and improves the livability of a city. The lid park also can link two communities which are divided by a highway.

The elevated park is a famous type of urban greenway park, since it offers not only an extraordinary experience but also contributes to tourism. Generally, an overpass is a long and narrow road that passes through a city. The elevated park which has replaced the overpass also shares the features of the overpass, which include continuity and connectivity.

The lower park is a park under an overpass, and is newly emerged type. Due to it characteristics of underway, the lower park is sometimes covered with concrete, i.e. is shaded. The lower park is used as a skate-board park since the noise from skateboarding is cancelled by road noise. Shade is a limitation of the lower park, but it can also be used to make a unique space in a city. For example, the lower park can be used as a gallery. The underpass park in Toronto is used as a gallery day and night, with lights and site-specific arts. The Lowline in New York City was approved and now funds are being raised for its construction. A lower park is a way to use dead space beneath.

The recovered park is a park that was built on a demolished road. The Südgelände Park in Berlin and the Cheonggyecheon in Seoul are exemplary cases of this type. This type can contribute to recovering its nature which has been polluted by a freeway or a rail road. To commemorate their origins, some parks retain a part of a rail road or overpass and use it as a design metaphor. Among the other types, only the recovered park has no limitations when they plant vegetation. The recovered park, like its title, aims to restore nature in an urban core. People can use this
park as a picnic area and a trail. It also contributes to revive a declined area by increasing visitors. Gyeongui park in Seoul leads the development of small business near the park, and generates revenue from park visitors. The recovered park in an urban core can offer a trail for residents, a picnic area for the citizens and can improve the bio-diversity for all.

3.3 History of urban parks over (or on) transportation infrastructure

The history of parks built on transportation infrastructure can be roughly classified into four phases: 1970s-80s, 1990s, 2000s and 2010s. Each period is a time when a unique approaches appeared to solve urban issues such as noise from transportation infrastructure, the deterioration of the infrastructure and lack of green spaces. The 1970s and 1980s covered highways and made parks on them to mitigate noise. In the 1990s, parks were built on railroads that were shut down. In the 2000s, highways, railways, and overpasses were torn down and parks were built on vacant lots to restore polluted lands. In 2010, parks with an elevated lower section appeared.

For the first phase, during the 1970s – 1980s, planning to cover highways and create the park on them was originated. During this time, urban parks built on transportation infrastructure were used to ameliorate noise and improve the aesthetics of highways. The most prominent example is the Freeway Park in Seattle. Opened in 1976, this park was designed by Lawrence Halprin, and ‘heal the scar’ was used as its vision [19]. Luther Burbank Park on Mercer Island is also a park built in the same way. Opened in 1985, the Luther Burbank Park has been providing benefits to connect disconnected communities and reduce noise and air pollution. One of the strengthen of this park is its relationship to the east side of Mercer Island as it connects communities to an expanded greenspaces in the future. Covering seven blocks of highway, this park is a typical example of a covered park and is a valuable early attempt.

In the second phase, the 1990s, the lid park continued to be constructed and the elevated park emerged. Due to the transition from rail to automobile, urban patterns changed [20] and surplus infrastructure emerged as a new issue [21]. The Promenade Plantee in Paris was transformed in 1993 from railways to a park. Conversion of disused urban railways to linear parks is a way to the reformatting of disused infrastructure [22]. According to Heathcott (2013), replacing disused urban railways to parks is a brilliant means of producing a new spatial condition in the city’s energy, connectivity and everyday life. At this time, interest in disused transportation infrastructure had begun to concentrate and urban parks emerged as a way to reformat disused urban infrastructure.

In the third phase, during the 2000s, cities have converted sites to parks that were previously used as railways or overpass. A recovered park has two main purposes: one is a restoration of a contaminated site to recover its natural ecosystem, and the other is to provide a green space to blighted area. The Cheonggyecheon Restoration Project in Seoul is an example that is most
representative a recovered park, which is a project to dismantle the overpass and freeway and restore existing rivers. This project has greatly improved the environmental issues of the city. Shiraki, et al. (2006) compared before and after air conditions to verify the effect of the Cheonggyecheon project on the air quality and found the NO\textsubscript{2} level was lower after the city restored the stream [23]. Also Shin, et al. studied the changing in benthic macro invertebrates in Cheonggyecheon and found out some species started to live in the stream [24]. Schöneberg Südgelände Park in Berlin is also one of the example of a recovered park which built on an abandoned railway. This park aims to being a spontaneous nature and making biotope in urban ecology. The idea of the park also aims to prohibit outside intervention and let nature follow its own systems [25]. In addition, it is noteworthy that during this period, parks have become a symbol of the city and the city’s economy has been revitalized. The High Line in New York (2009), the Olympic Sculptor park in Seattle (2007), the Big dig in Boston (2003) and the Cheonggyecheon in Seoul (2005) have been built and revived the cities’ vitality.

For the last phase, since the 2010s, replacing transportation infrastructure with urban parks starts to find an appropriate site in the compact city. As a result, a lower park emerged as a new type of urban parks. The Underpass park in Toronto (2012) and the Seart park in New Zealand (2010) were built under the overpass. These parks are built on hidden spaces in the city, and they are mainly used as space for exhibitions and leisure activities. Another feature of this period is that the park plans for urban regeneration have been announced and completed as learned in the case of the third period.

4. Conclusion

At the time many projects are proposed, this study provides a clue as to what type of strategy is needed in a city by looking at the type, features, and history of the park built on transportation infrastructure. Replacing the transportation infrastructure with urban parks has been developed for a long time as a way of solving problems of cities and give a new vitality to cities. From a lid park designed to reduce noise caused by highways to an elevated park that built on the existing structure, this type of parks changed its strategy according to the demands of the times.

Four types of parks are differentiated based on the physical characteristics of parks. A lid park has the advantage of physically linking disconnected communities to highways, but it is limited in that it is built on artificial ground. An elevated park is meaningful in that they utilize existing structures as they are, but they are limited in that accessibility is low and artificial grounds are used. The advantage of a lower park is that it uses an abandoned elevated lower section. Lastly, a recovered park has the advantage of restoring contaminated sites as a result of their transportation infrastructure.

This study has a limitation in that it did not consider the relation between the park and its surrounding context, although it is
significant in that it distinguishes and characterizes the kind of park constructed in the transportation infrastructure. In future research, we will be able to give some suggestions about the type of park in which contexts are needed, considering the relationship between each park and surrounding context.

In a speech in March 2016, Anthony Foxx, the nation’s top transportation official, said “Instead of connecting us to each other, highway decision makers separated us…We can’t change everything about the past, but we can certainly work as hard as we can today to repair our infrastructure to make it the connective tissue it ought to be [1, pp. 75–80]."

More than 50 parks over highways have been built or proposed in the United States [1, p. 76].
Strategies For The Recovery Of Threatened Natural Systems And Their Role In The Mitigation Of Rapid Urban Growth In Montes De Oca, Costa Rica

Laura Chaverri Flores\textsuperscript{a,b}, Luis Solano Monge\textsuperscript{a}

\textsuperscript{a}University of Costa Rica, San Pedro, Montes de Oca, Costa Rica
\textsuperscript{b}Tecnological Institute of Costa Rica, Barrio Amón, San José, Costa Rica

Abstract

Costa Rica is well known for its ecological and landscape diversity. Nevertheless, most of its cities have lost their natural richness due to uncontrolled growth in infrastructure. Urban development has caused surface waterproofing, air and water pollution, poorer landscape quality and a major loss of most native forests and the species living within them. This is the case of the county of Montes de Oca, birthplace of the most important university in the country.

The main campus of the University of Costa Rica comprises nearly 87 hectares and has conditioned urban growth in the area. It represents one of the few “green lungs” of the Metropolitan Region and is constantly being threatened by the construction of new buildings. This highlights the urgent need of an urban and landscape development plan. For this reason we made a proposal for its protection, focused on natural continuity, cushioning, ecological compensation and anticipation of future university expansion.

The landscape diagnosis analyzed water resources, slopes, runoff, flora and fauna. In 2017, the effects of “El Niño”, caused prolonged droughts and heavy rainfall in short periods of time, which resulted in flooding, high soil saturation and an increased risk of landslides. Green cover in the county is made up of patches of secondary forests linked to the University and Torres River, urban parks and isolated gardens. At “Finca 3”, the forest fragments represent at least 26% of the land. A detailed survey of its flora allowed us to characterize trees by shape, dimensions, color, as well as detecting the scarce, native, threatened species and the ones at risk of extinction to define the conservation criteria. We identified 209 tree species on 34 hectares, surpassing the records of larger nearby protected areas famous for their biodiversity, such as Cerros de La Carpintera (110 tree species in 2391 hectares).

At a regional level, we propose the integration of a green infrastructure network, through river corridors and landscape connectors associated with the rivers, linking natural spaces. Therefore, creating animal and plant crossings, nurturing ecosystem services such as carbon fixation and water quality improvement, and promoting outdoor recreation and the prevention of floods and landslides.

At the Campus level, the proposal is built upon four pillars: the Articulation System, which solves connectivity issues between the University and its environment considering mobility...
Biophilic Cities

factors; the Border System, which analyzes the relationship with the context, adding defined accesses and cushioning fringes; the Functional Units System, which groups homogeneous elements with defined identities; and finally, the Conservation and Ecology System, which promotes ecological and landscape connectivity through two components: water and vegetation. Green infrastructure acts as a natural public health system, favoring physical activity, establishing a bridge that unites forest patches and boosts ecosystem services responsible for preventing climate change. In order to mitigate flooding, there is a chain of lagoons in which water moves by gravity, accompanied by canals and rain gardens that delay water speed, improve its quality and enriches the user experience.

Keywords: Ecosystem services; landscape urbanism; green infrastructure; biodiversity loss; flooding.
1. Introduction

Costa Rica is internationally recognized for its extensive ecological biodiversity, as well for the beauty and variety of its natural and cultural landscapes. Its strategic location as a bridge between North and South America and its altitudinal fringes make it possible to combine landscapes from the humid tropical forest to dry tropical forest. In addition, since the end of the 20th century, the creation of the National System of Conservation Areas (SINAC), has helped recover part of the country’s forested area. According to SINAC [1], Costa Rica possesses 26.5% of the continental territory under state protection. However, parallel to the efforts of conservation of the natural patrimony, there has been uncontrolled urban growth in the Great Metropolitan Area (GAM) of the Central Valley that embodies the contradiction between an environmental discourse and a chaotic urban reality.

The county of Montes de Oca in the province of San José is one of the urban territories that has undergone a rapid transformation due to urban growth in recent decades. The county is considered the cradle of education in the country since it is home to a multitude of universities. The sparsely controlled growth and demand for buildable space have caused soils in aquifer recharge zones to become impermeable, increased pollution of streams and rivers; and have contributed to the loss of large quantities of forest.

The Rodrigo Facio headquarters of the University of Costa Rica (UCR) created in the 1940’s has also contributed heavily to the urban growth of the area due to its constant expansion with the acquisition of new land (Fig.1). The campus, from its conceptualization in the first overall design, was presented as an ECO-CAMPUS boasting a high percentage of green areas and protected forests, which is why it represents one of the few urban lungs left east of the GAM, and which in turn has been threatened by the construction of new buildings surrounding university spaces. Users as well as university authorities have made known the urgent need for a territorial urban landscape plan for both the campus and adjacent districts. This is why the proposal for the protection of the Rodrigo Facio headquarters was developed, replicable in other areas of the city, emphasizing the importance of the continuity of “green infrastructure” and of various natural layers superimposed upon urban use. This article presents a diagnosis of the area and proposes strategies for the recovery of threatened natural systems and the mitigation of urban growth within the Campus and the surrounding extent of Montes de Oca.

![Fig. 1. Campus and Montes de Oca Context. Source: Paul Vega Salas (2017). LANAMME.](image)

2. Methodology

As the first phase, several diagnoses were made that helped to better understand the current saturation of the Campus and its areas of influence. Using a process of
citizen participation with tools including flowcharts or evaluation sheets, it was possible to make a perceptual social diagnosis. Additionally, mobility, spatiality, the landscape and its natural systems were diagnosed along with the new buildings that are intended to be built at the University. For each diagnosis, their current situation and problems were analyzed to produce recommendations and guidelines for planning.

In this article, we will focus on the analysis of landscape and natural systems. For this process it was necessary to conduct field work in transdisciplinary teams. A thorough survey of the campus’ vegetation was conducted considering native and exotic species, deforested and newly sown trees, as well plant habitats. Examining historical aerial photographs and previous analyses made it possible to truly grasp the magnitude of the loss of forest cover and predominant urban expansion in the area. On the other hand, maps of the county were created emphasizing the area of the Torres River Biological Corridor according to maps of the Environmental Fragility Index of the National Electric Company (CNF). Finally, the information from the different diagnoses was cross-linked in order to generate mitigation guidelines and a landscape proposal. For this phase two participatory workshops were held: one with university personnel and another with surrounding neighbors and urban groups in the area (Fig. 2). We worked in a variety of scales framing the campus within its respective county, as well as the scale of the Rodrigo Facio headquarters in the University and other specific areas of the Campus.

3. Territorial framing

3.1. Montes de Oca

The county of Montes de Oca consists of 15.6 km² and is composed of 4 districts, San Pedro (4.82 km²), Sabanilla (1.79 km²), Mercedes (1.39 km²), and San Rafael (7.16 km²). San Pedro occupies 30% of the territory and is the second most densely populated district following Sabanilla, with 52% of the population while San Rafael only has 15.3% of the population and a large part of the protected forest area [2]. The Rodrigo Facio Headquarters of UCR holds nearly 87 hectares, occupying 15.24% of the territory of two of the districts in the county of Montes de Oca (Fig. 3). This county adjoins the northwest with the county of Guadalupe, the Torres River becoming a boundary or “back” instead of a blue infrastructure connector.
3.2. Impact of the University of Costa Rica in the county

UCR attracts thousands of students, professors and officials from all areas of the country on a daily basis as a meeting point and urban node, which gives the county its identity. University life has functioned like a magnet where internal and external uses establish a range of mutual dependence. Therefore, land uses have been modified as the expansion of the campus has enhanced the creation of services, commercial areas, rental housing for university students and a series of universities and educational institutions that are established nearby, increasing the educational vocation. As result, this has generated increased land value, causing displacement of permanent housing areas, the disappearance of traditional neighborhoods, coffee plantations and the remnants of riparian forests, producing a deterioration in landscape quality.

3.3. The Interurban Biological Corridor

Given the growing demand for built space, the system of green areas in the county has been drastically affected, decreasing urban parks and recreational areas. This is why rivers have reemerged, formerly invisible as an opportunity to protect biodiversity; as a strategy for the articulation of their scope of protection with small green patches, parks or forests scattered around the city, generating connectors that support continuity throughout the city and allow the transit of populations of flora and fauna established in these sites.

The Interurban Biological Corridor of the Torres River (Fig. 4) is an initiative led by the Hydrographic Basins and Biological Corridors Program of the municipality of San José with the support of other organized groups of neighbors and professionals. This project seeks to rehabilitate the protected areas, protect the urban environment and establish itself as the first urban ecological corridor in the county. Through the initiative, different ecosystem services would be obtained; defined as the benefits that humans obtain from natural ecosystems such as provisioning (obtaining water, food and natural resources); regulation (regulating floods and droughts); cultural (promoting spiritual values); and support [3].

The territory of UCR limits its northwest margin with part of this corridor along 745 m and restricts it to “Fincas” 3 and 4 with their margins of 33.667 m² that must be exclusively deemed riparian protection areas. This strip presents a great widening of the vegetal coverage in relation to the context for its vulnerability evidences even more the importance of protecting these tracks inside the university campus.
4. Diagnosis of Landscape and Natural Systems

As we have seen throughout this article, the Torres River Interurban Corridor, still protects an important segment of forest in contrast to the rest of the county and potentially allows the east-west articulation of strategic sites such as the Park of the East, the UCR, the Simon Bolivar Park and the Children's Museum. Within this dynamic UCR holds a relevant role in its consideration as a lung within the urban system for its density of plant cover, a condition that influences the surrounding natural landscape (Fig. 5).

Fig. 5. Location of Montes De Oca. Source: Own elaboration, based on Google Earth photo (2017).

The landscape analysis carried out considered a systemic approach, where the territory is understood as a complex relationship of articulated systems, for its study a superposition of variables combined with the cartography was proposed so that each component analyzed could be reflected in maps and identified within the system. In relation to this diagnosis, the following were analyzed: water resources and runoff, topography, as well as flora and fauna.

4.1. Slopes

At the topographic level, the county presents a very marked difference to the eastern sector, covering the San Rafael district. In this sector the slopes increase, becoming greater than 20% [4], due to the presence of mountains that are extensions to the faults of the Irazú Volcano, also generating the appearance of numerous rivers and streams (Fig. 6). On the other hand, towards the western sector the topography is more consistent except for some river basins that are forming mountains and occupy more depth in the area.

Fig. 6. Slope Maps of the County + Sports Facilities and F4, UCR. Source: Own elaboration (2017).
The central zone of the Sports Facilities and F4 has a more consistent topography with slopes ranging from 2.5 to 5% and up to 10%, where most buildings and infrastructure have been built. As one moves away from this central heart, the topography becomes more irregular responding to the different water channels that cross it, increasing the slopes from 10, 20 and up to 40% in the margins of the rivers. Through certain depressions, visual basins are also formed that allow observing the urban center in the distance (Fig. 6).

4.2. Hydric Resources

Within Costa Rica in 2017, the El Niño phenomenon generated significant variations in precipitation, causing shortages of rain on the Pacific slope and excess in the Caribbean. Although the fluvial system of the county of Montes de Oca belongs to the Pacific slope, torrential rains occurred, generating serious flood problems. The topography of the county with mountains that descend towards the populated sectors (Fig. 7), added to the loss of vegetation cover, pollution, possible earthquakes and saturation of soils and riverbeds. These factors increase events such as floods and landslides in urban areas.

At the campus scale, a study of directionality of surface runoff from the topography and slopes defined that most of the runoff vents to the surrounding rivers and streams, contributing to considerable water volumes. Some regulatory withdrawals such as those required for rivers that vary from 10m to 50m or the 100m perimeters for the springs restrict the construction of buildings for the protection of these water bodies, however sometimes these containment strips are not enough.

4.3. Wildlife, vegetation and forest cover

As for the system of life zones, Montes de Oca is composed of the Very Humid Premontane Forest in the eastern regions and the Montane Low Humid Forest in the middle section. The districts of San Pedro, Mercedes and Sabanilla are mostly part of the Premontane Humid Forest (Fig. 8), which has been reduced to small representative patches within the city due to deforestation and urban growth.

The few patches of significant vegetation cover, especially secondary forests, are associated with the Campus...
and the Torres River (Fig. 8). In the high zones of San Rafael the intervened forests abound and throughout the county exist various urban parks, vacant lots and isolated gardens, with certain vegetative wealth.

The Campus density study shows areas of high plant density correlate with bodies of water. The Campus has protected areas and a botanical garden in Plot 1. In “Finca” 3, for example, the forest patch represents 26% of the land. A detailed study of the flora of the site was made, categorizing the outstanding trees by form, monumental size, those possessing striking color, as well as native and exotic species. In addition, a meticulous survey of scarce and native trees, as well as threatened and endangered trees, clarified the conservation criteria of the species, detecting logging without planning in recent years. We identified 1,090 (59%) native trees and 510 (27%) exotic trees (Fig. 9). Of the native trees, 123 different species were identified in “Finca” 3 and 209 species throughout the Campus (34 ha), surpassing areas of greater extension.
and recognized for their biodiversity, such as La Carpintera (2.391 ha with 110 species). While the native trees predominate in the election of zingiberals, conifers and shrubs, exotic species prevail, a frequent phenomenon in the selection of urban species within the city. From the point of view of fauna, more than 120 species of birds were identified, as well as a diversity number of insects and mammals. According to studies by CICN (Institutional Carbon Neutrality Commission), the Campus represents an important contribution in CO2 capture, emitting 4,538 tons and capturing 56,219 [5]. In addition, the high level of appreciation that the community has regarding its natural areas is evident with participatory tools.

4.4. Conclusions and Issue

The irregular topographic condition of the county, with steeper slopes, produces numerous river channels that descend into urban areas. The pressure on its protection margins added to the loss of coverage, waterproofing and direct outflows increase risk conditions (Fig. 10). It was discovered that the different existing natural and water systems have degraded over time and continued urban expansion is generating natural dilemmas within the city. The need to produce new systems that are more strongly integrated with nature is imperative.

5. Results: Strategies for recovery

Biophilia is the deep-seated need of humans to connect with nature [6]. A biophilic city is at its heart a biodiverse city, a city full of nature, a place where in the normal course of work and play and life residents feel, see, and experience rich nature-plants, trees, animals [7].

For this project a proposal for environmental protection and urban landscape development is made where nature is the advocate supported by principles of biophilic design. One of the fundamental objectives was to anticipate the urban growth requirements of the campus and its immediate surroundings, based on principles of cushioning and ecological compensation. In this sense, Biophilic cities cherish what already exists (and there is much, as we have already seen) but also work hard to restore and repair what has been lost or degraded and to integrate new forms of nature into the design of every new structure or built project [7].
At the regional scale, the protection of water resources and the incorporation of green infrastructure that connects urban parks and the area’s most important green spaces are proposed. Emphasis is placed on the protection of aquifers located in elevated areas. Likewise, different green and landscape corridors are established along the two main rivers: the Torres and María Aguilar rivers, creating several linear parks, as well as regeneration parks that make up a large metropolitan river corridor. These corridors that act as pathways for animal and plant life, also provide ecological services such as carbon capture, water quality control, prevention of floods and landslides, recreation and sports areas, among others. The metropolitan park, La Sabana, and the University Campus function as excellent articulators between these two rivers (Fig. 11).

From the Campus scale, prototypes are proposed on a smaller scale that can serve as an example in the management and protection of corridors incorporating water sanitation, articulation of green patches and landscape and ecological integration within the urban context; schemes replicable in other potential sectors along the corridors.

5.1. Proposed systems

The proposal is based on four different systems vital to the Campus, which are interdependent, focused on achieving a balance between the current condition and the future development of buildings complemented by green areas to minimize their vulnerability.

The first, the Articulation System; resolves the connection of the Campus with its surroundings taking into account the pedestrian, cyclist, public transportation lines and private vehicles in a balanced system for each user. The Edge System studies the relationship of the Campus with the environment, incorporating well-defined access in some areas and incorporating a buffer layer in others. The system of Functional Units corresponds to the configuration of spaces with defined identities that group buildings and green areas producing small sets linked by the “articulator” system. Finally, the backbone of the proposal is formed by the Protection and Ecology System focused on facilitating ecological and passive connectivity through the reinforcement of the "green and blue infrastructure" (Fig. 12).

The Protection and Ecology System is composed of two components that complement and coexist: the hydraulic and the vegetative (Fig. 13). The green infrastructure becomes a natural public health system since it is interwoven with the mobility system, boosting physical and recreational activity (Fig. 14,16). Thus, establishing a corridor that highlighting the various forest areas and patches of regeneration and generating diverse ecosystem services capable of preventing climate change (Fig. 15). Some biophilic design patterns are enhanced by visual and non visual connection with nature. The latter is characterized by auditory, haptic, olfactory, or gustatory stimuli that engender a positive reference to nature [6]. Some expected results are the reduction of
runoff caused by storms and the generation of increased biodiversity. Likewise, trees with high maintenance and conservation priority are defined, according to the diagnostic criteria.

To compensate for the serious problem of flooding both on the campus and in the surrounding areas, an interconnected water system consisting of channels, compensation and macrophyte ponds, and rain gardens is proposed, which delays the speed of water evacuation and thus the pollution of the rivers by means of oils and hydrocarbons that were not previously treated. A new evacuation system is proposed with a succession of ponds that circulate by gravity towards the river, thus improving water quality and the experience of visitors.

Fig. 16. Proposed Boulevard in Finca 3. Source: Own elaboration (2017).
6. Conclusion

Throughout the article it was possible to observe the enormous landscape and ecological potential possessed by Montes de Oca, however we also detect many problems that must be solved. For the proposal, different design principles were used, where connectivity, education and diversity stand out, as well as biophilic design patterns as visual and non visual connections with nature and the presence of water. The proposal focused on ensuring a sense of identity by strengthening the ecological vision and demonstrating that it provides enormous benefits to the human population, such as offering an ideal environment for relaxation or providing water purification services. Biophilic design patterns have the potential to re-position the environmental quality conversation to give the individual’s needs equal consideration alongside conventional parameters for building performance that have historically excluded health and well-being [6].

Although this work has been well accepted by university authorities and neighbors who were invited to both workshops and the presentation of results, it is essential to be able to execute some of these proposals in order to generate a real user impact. It is imperative to involve local governments and communities in order for concrete actions to be carried out in our cities.

Acknowledgments

It must be recognized that the extended research and design work was carried out by a multidisciplinary team consisting of: Arch. Laura Chaverri (project director), Arch. Guillermo Chaves, Arch. Luis Solano, Arch. Nancy Corrales, Arch. Fernanda Barquero, Bio. Carlos Bolaños, Luis Fuentes, Sigrith Solera, Karen Badilla and Roberto Hidalgo.

We thank the Rector's Office and the Architecture School of the UCR, as well as the Architecture and Urbanism School of the Technological Institute of Costa Rica for the support provided to carry out this work. Also, we thank Paul Vega from LANAMME and Corey David Dodd, former exchange student in the Master of Landscaping and Site Design of the UCR for his help with the translation of this article.

SMART NATION
Cooling Singapore - Scientific Knowledge for Decision-Makers

Dr. Conrad Phillip  
Singapore-ETH Centre, Cooling Singapore  
Singapore

Synopsis:  
The UHI has become a matter for increasing concern because of its many, mainly negative, effects upon the quality of urban life. These include reduced thermal comfort for urban dwellers, and increased noise, air pollutants and greenhouse gas emissions. In tropical Singapore, increased temperatures due to UHI negatively affects the liveability and thermal comfort of residents. Many of these problems are likely to become more severe in the future, partly because of urban growth but also of the impacts of climate change upon cities.

Reducing the UHI effect will bring considerable benefits to Singapore, measurable not only in economic terms but also in the improved health and wellbeing of citizens. Achieving a substantial and lasting reduction, however, will be a complex undertaking that necessitates an all-of-government approach, since it will have implications for planning, transportation and construction, as well as patterns of individual consumption. Such an undertaking must be based upon the best scientific information, and new research will also be needed in areas where existing knowledge is insufficient. It will require a consistent commitment over an extended period and close coordination among stakeholders in government, the research community and private sector. Finally, addressing the issue of UHI will directly contribute to two of Singapore’s policy goals concerned with thermal comfort and meeting the COP21 goals to the reduction of greenhouse gases.

For all these reasons, Cooling Singapore project aims to develop a roadmap to guide the emerging strategy.
Green Intelligence - the future of plants and people!

Veera Sekaran  
Founder, Managing Director  
Greenology  
Singapore

Synopsis:
Mr Veera Sekaran would be exploring GI (Green Intelligence), a term he coined for the application of smart solutions on urban greening integrated with science and technology.

During his sharing, Veera will borrow from his own work that connects bio-sensors and softwares to urban greening and agricultural systems to showcase how we can get these micro natural habitats to ‘speak’ to us through data analytics and algorithms, and in turn receive regular checks on their well-being. He would also be addressing the pivotal roles played by architects, designers, practitioners and institutions in placing GI at the core of each project, as early as the conceptual and design stages, to realize built environments that are in better connection with nature.
Punggol Digital District - A New Approach to Designing Singapore’s Next Generation Business and University District

Aaron Tham
Director
JTC Corporation
Singapore

Synopsis:
Punggol Digital District (PDD) is the first district in Singapore to adopt a one integrated masterplan approach where we co-locate a business park and a university, which are supported by community facilities and public spaces from the planning stage. Such a holistic planning approach creates a vibrant and inclusive district to potentially transform the way we work, live, learn and play in the future.

The co-location of the Singapore Institute of Technology’s (SIT) new campus with JTC’s business park buildings will facilitate greater industry academia collaboration, through the cross-fertilisation of ideas and knowledge among students, faculty and industry professionals. New technological or business ideas conceived in SIT could be prototyped, tested and adopted by businesses in PDD, contributing to a higher rate of commercialisation success. Innovative enterprises affiliated with SIT’s strengths in applied programmes such as digital & cyber security, design, engineering, food technology, can also tap on SIT’s research capabilities for R&D and student pool for talent.

Housing key growth sectors of the digital economy such as cyber security and IoT, PDD will bring approximately 28,000 exciting jobs closer to residents in Punggol and the north-east region. Through the clustering of these growth sectors, we aim to create an ecosystem of open innovation and a conducive test-bed environment that will enable our businesses and community to thrive in a digital economy.

The District will not only be about technology and infrastructure, but an inclusive and green district for the community. The District is also planned to include green links to the waterfront and also more public spaces for the community to relax and unwind. For instance, the Campus Boulevard is a 800m pedestrianised street which will be a key gathering space that stretches between the SIT campus and JTC’s business park buildings. It will be designed for active mobility options such as walking, cycling and PMDs, with various retail and F&B offerings along the boulevard. PDD is also located beside the Serangoon Reservoir and this allows us to plan more community spaces such as a Market Village, which will offer retail and dining options for the community to relax and unwind by the coast.
Estimating leaf area index of urban trees from digital zenith cover photography: A framework on its application for urban practitioners

Ester Suen, Richard N. Belcher, Sacha Menz, Thomas Schroepfer

ETH Zürich, Future Cities Laboratory, Singapore-ETH Centre, Singapore.
Institute of Technology in Architecture, ETH Zürich, Switzerland.
Architecture and Sustainable Design, Singapore University of Technology and Design, Singapore.

Abstract

Urban vegetation is recognised as an important component in cities due to the benefits they provide, such as attenuation of the urban heat island effect; abatement of air and noise pollution; as well as human stress reduction. One method of assessing urban greenery is using the leaf area index (LAI), which is defined as the one-sided green leaf area per unit ground surface area, and is a measure of vegetation density. It is often used to infer various eco-physiological characteristics of plants, which determine their benefits, for example: evapotranspiration rate and shade provision (related to thermal comfort in urban streets, parks and rooftop gardens) and overall greenness (related to tree health or overall attractiveness). These benefits are often important to quantify for practitioners such as researchers, landscape architects, arborists and environmental consultants. Inexpensive, rapid and accurate estimates of LAI in urban areas are important, as often, practitioners’ time is scarce. While conventional methods for LAI are accurate they often require expensive equipment or disruptive measurements, and are not suitable for urban trees. Being one of the few studies to apply this method in an urban context, we show how the ground-based cover photography method (used in recent studies to quantify LAI of natural forests) meets the challenges of quantifying LAI in urban areas and present a framework for its application for different practitioners who work with urban greenery.

Key words: Leaf area index, urban, landscape urbanism, green infrastructure, design evaluation, landscape assessments

1. Introduction

The benefits of greenery in urban areas have been long studied and are well documented. Many academics and policy makers recognise that urban greenery and green structures are important due to their ability to help alleviate the urban heat island effect [1,2], improve air quality [3], reduce noise pollution [4], and aid in storm water management [5]. Urban greenery is also related to human perceived aesthetic
qualities [6] and health benefits of an area [7]. Thus, quantifying the extent and density of urban greenery is necessary for a variety of different application in cities. Urban practitioners need a reliable vegetation density metric to assess the health and success of landscaped areas, and to understand relationships between greenery and their benefits.

At broad spatial scales, landscape ecologists and planning researchers are interested in understanding the relationship between greenery, land use change and ecosystem services [8]. Thus, these urban researchers in cities often require accurate information of either species-specific traits, or individual tree-level measurements to produce accurate models to simulate these predicted benefits. To optimise the benefits provided by greenery, urban planners and developers are interested in increasing urban vegetation cover and density. At the local scale, practitioners working in the design, use and maintenance of green areas are interested in quantifying the foliage area and density of a space as these measurements are related to the general appearance and health of trees.

To date, greenery in urban areas is often quantified from satellite imagery-based canopy cover estimates. However, canopy cover only detects the extent of greenery and assumes that the vegetation is homogenously distributed. These remotely-sensed vegetation estimates from satellite or air-borne high resolution imagery do not yield suitable results for complex canopies [9,10]. While this may be sufficient for broad-scale analyses, it can be erroneous at smaller scales as it does not capture important species-specific information, such as branching architecture and foliage density, which are important for quantifying urban ecosystem services. The leaf area index (LAI) is a useful parameter that can be used to classify vegetation density in urban areas and can be suitable at multiple scales.

1.1 Definition of LAI

Leaf Area Index (LAI) is defined as the one-sided green leaf area per unit ground surface area [11]. It is a dimensionless number which characterises plant canopies and is used as a proxy to measure plant attributes such as gas exchange, rainfall interception, radiation interception, and carbon flux [9,12]. These attributes can be linked to ecosystem service provision in natural and urban areas.

LAI is used by forest ecologists to evaluate the health, stress, and productivity of forest stands or individual trees [13,14]. Another application of LAI is in agriculture to determine and model crop cover and yield by quantifying the light interception and potential energy flux balance in crop fields [15,16]. Although traditionally applied in these forest and agricultural settings, there has been a push to utilise LAI to quantify and assess greenery in urban spaces to provide quantification of the aforementioned benefits, and to compare greenery densities between buildings. For example, LAI is used in the calculation of the Green Plot Ratio (GpPR), which is defined as the average LAI of planted landscape in a building plot area [17] and is incorporated in many planning and building policies [18,19].

For these reasons, it is imperative to develop methods to accurately and efficiently measure LAI in urban areas. However, there have been few studies done in this field and conventional methods to quantify LAI are often expensive, laborious and time-consuming. This paper aims to (1) give a brief overview of the importance of LAI as an urban vegetation density metric, (2) detail a comprehensive working method...
to acquire LAI from ground-based cover photography in urban areas, (3) develop a framework on the potential of this technique based on the requirements of different urban practitioners, and (4) provide suggestions for future application and improvement of this method.

1.2 Relevance of LAI to practitioners in the urban environment

LAI is measurement of plant canopy attributes and greenery density, both of which can provide benefits to people as previously mentioned. Despite its extensive application in agricultural and forest settings, studies of its use in urban environments are scarce [2,12,20].

Where may quantifying this metric be useful in urban environments? Knowledge on species-specific LAI values, as well as on-site assessments of LAI, could be used by practitioners and planners to strategically plan the spatial configurations of urban trees and shrubs to best capture air pollution, reduce noise pollution, and increase the social and aesthetic value of an area.

It has been found that trees with higher LAI values have more surface area for the deposition of air contaminant particulates [3], with younger trees with dense canopies [21] and coniferous trees [22] performing the most efficiently in this regard. However, although large trees with spreading crowns and high LAI values may effectively capture pollution particulates, they may also limit particulate dispersion and increase local pollutant concentrations at ground-level when densely planted together [23].

Trees with higher LAI and denser canopy structures are also able to filter more solar radiation, reduce solar transmissivity, and increase shade area, producing more latent heating with their higher evapotranspiration rate [24]. The cooling potential of trees with similar LAI are comparable across species, regardless of species-specific trait differences such as leaf angle, leaf size, or branching architecture [2]. Trees with LAI of at least 3 are able to provide adequate shade and inherent cooling effects, and significantly reduce the probability of overheating occurrences [25]. In temperate regions, Hardin and Jensen [26] found that surface temperatures were reduced by 1.2°C for every unit increase in LAI, and that variation in surface temperatures was significantly related to LAI. In the subtropics and tropics, air temperatures under trees with higher LAI was found be up to 2.55°C cooler [27,28].

LAI is closely related to perceived benefits and aesthetics of spaces, and this is reflected in property prices in an area. Escobedo et al. [29] found that property values in Florida were positively related to high LAI trees, with every unit increase in LAI raising property values by US$9,348. Urban LAI is also found to be inversely correlated with household energy consumption [30].

1.3 Quantification of LAI

Evidently, the ability to rapidly and accurately quantify LAI in urban areas could be a valuable asset to practitioners. However, traditionally, LAI is directly measured by destructively harvesting and measuring the foliage area of a tree or shrub. Direct methods are the only measurements that calculate true LAI as only foliage area is included in the calculations [9]. While accurate, these methods are time-consuming, laborious, and are often only suitable for measurements in small areas or of crops due to its destructive nature.
Indirect methods are often used in place of destructive sampling owing to the challenges faced by direct quantifications of LAI. These methods are either based on allometry, radiation transmission theory or gap fraction theory. LAI calculated from allometric models utilise relationships between leaf area and certain measurements of woody plant elements, such as stem or branch diameter, and require a certain degree of disruptive sampling for verification [31].

Recently, remote sensing and light detection and ranging (LiDAR) scanning techniques have been employed successfully by researchers to quantify canopy attributes [32]. However, although these methods may produce precise and accurate results, they are very expensive and require special expertise to manoeuvre and retrieve data for reliable LAI values.

Other indirect methods commonly used rely on optic technology, and these include zenith cover, hemispherical and fisheye photography; and plant canopy analysers (PCAs). These methods are based on the proportion of crown gaps and crown area within the crown [9].

It is important to note that optic methods only quantify plant area index (PAI), or effective leaf area index (LAI_{eff}), as it includes all other physical elements of plant canopies such as stems and other woody elements [9]. For LAI estimates based on fisheye or hemispherical images, true LAI can be estimated by applying a correctional factor α, the ratio of woody area index to plant area index [33]. Conversely, it was found that the LAI estimates derived from disruptive sampling and uncorrected LAI estimates from cover images were comparable [34–36]. This was because the narrow view angle in cover images meant that the area of woody elements contributing to LAI calculation in cover images are considerably smaller compared to in hemispherical images [37]. For the purposes of this paper, “LAI” refers to both true leaf area index and plant area index.

1.3.1 Zenith cover photography

Cover photography is an optic method which has been successfully used by multiple studies to accurately acquire LAI estimates from forests. Like with other optic methods, it is based on the Beer-Lambert law, which describes and characterises the absorption of light as it passes through a semi-permeable membrane, in this case a forest canopy or tree crown. According to the law, a consistent ratio of light is absorbed as an incident light ray passes successively through foliage layers of a tree crown such that the its absorption rate follows a logarithmic pattern [38]. This law can be applied in optic methods to estimate LAI based on the proportion of gap fraction of the crown but must incorporate a known pattern of leaf inclination angles and an assumption of randomly-distributed foliage. Cover photography has been shown to be able to produce reliable LAI estimates in forest stands [34,39–41] and agricultural plots [36,42–44]. Due to its ease of use and flexible application, it could be a useful method for adoption by urban practitioners who incorporate LAI measurements into their work, or are interested in doing so.

2. Methods

We propose a qualitative assessment framework to determine the feasibility of cover photography as an appropriate method to assess LAI in an urban contexts based on the requirements of different practitioners.
2.1 Assessment framework

Academic literature, industry and government reports were used to identify five key groups of practitioners who work with urban greenery: urban ecologists; urban planners; contractors and developers; landscape architects; and arborists and park managers. These professions’ scope of work; and relevance and challenges of LAI application were compiled to understand whether it would be useful for them to use cover photography to assess LAI of urban trees. To enhance the assessment criteria, we also directly discussed these requirements with different practitioners. Based on the literature review and discussions, we created a qualitative assessment framework to determine the feasibility of cover photography to assess LAI for said practitioners (see supplementary materials for the compiled criteria).

During the review and discussions, we found that all practitioners prioritise speed when trying to measure urban vegetation densities. However, not all groups require the use of vegetation density metrics such as LAI. Urban ecologists and researchers prioritise precision and accuracy; whereas the other groups working in urban planning, design and maintenance prioritise ease of use and adoptability. Based on these responses, we measured the time it took for the data collection and analysis procedure, and qualitatively assessed the method’s ease of use and accuracy at assessing LAI in different urban scenarios.

2.2 Data collection

We took zenith cover images of different trees in the urban scenarios identified in the framework across a variety of sky conditions: uniform overcast, clear blue, and scattered clouds. We used a Nikon D7000 digital single-lens reflex camera with an 18-55 mm lens (Fig. 1). All images were taken with an 18 mm zoom to capture a wide angle of view and images were taken in FINE quality JPEG for highest resolution and detail. To ensure that all images are taken at zenith angle, a multi-axis spirit level is mounted on the camera’s hot shoe. All images are taken when the spirit bubble is centred within the horizontal plane.

To ensure that all foliage within the image is in focus, one zenith image is taken when the camera is first set to aperture priority mode (aperture \(f/9 \rightarrow f/11\) for a large depth of field) and ISO 400. A second image is taken at the same spot with one-stop underexposure in manual mode by varying the shutter speed while retaining the same f-step. To capture the spatial heterogeneity of foliage distribution, at least four images per tree are taken at various locations beneath its crown.
2.3 Data analysis

We sorted the images and, where needed, cropped them to remove urban features (such as buildings and lamp posts) such that only foliage area is retained in the images (Fig. 2).

Using MATLAB script developed by Macfarlane [45], the cropped images are analysed and the following parameters were calculated: gap fraction, foliage cover, crown cover, crown porosity and LAI. The script separates large between-crown gaps, and smaller within-crown gaps prior to the application of the Beer-Lambert law, which was found by Macfarlane et al. [41] to be able to accurately estimate LAI when compared to destructive sampling. The script requires an assumption randomly arranged foliage and a light extinction coefficient, $k$, which we have assumed to be 0.85 based on previous studies on leaf inclination angles and photographic image analysis [40,46].

3. Discussion

3.1 Findings

We found that cover photography was able to efficiently estimate LAI across different urban landscapes, provided there was no overlapping urban features or unwanted foliage in the canopy.

The automated image classification threshold is not sensitive enough to accurately distinguish between scattered clouds and blue pixels at times. Images taken in full sun conditions were not useable as the glare and reflection from the sun off the foliage can cause overexposure and an underestimation of foliage cover (Fig. 3).

3.2 Comparison with conventional methods

Zenith cover photography has a considerable advantage compared to other methods for quantifying LAI, owing to its affordability, the speed at which it can be
executed, and the ease of knowledge transfer. The operator only needs to understand some basic photography concepts (i.e. aperture, shutter speed) and from there, it is as simple as operating a regular point-and-shoot camera. The raw data can be acquired from a single tree within five minutes and post-analysis takes a maximum of 10 minutes per image. This is further expedited by the DCP software’s ability to batch process images such that hundreds of images can be analysed within approximately 15 minutes. However, the process is not entirely automated as it still requires the manual removal or urban features through cropping, as well as checking images post-software analysis to ensure that all images have been appropriately thresholded. Nonetheless, the short time taken for the entire process to quantify the LAI of individual trees (~15 minutes) is an asset compared to other methods. Based on reports of other methods, this is significantly less than destructive sampling, PCAs, and other optic methods [47].

Cover photography is a much more affordable option to estimate vegetation density indices compared to other methods. While commercial equipment, such as PCAs and LiDAR scanning equipment, generally cost anywhere between 50,000 USD to upwards of 100,000 USD [48], cover photography only require a DSLR camera, and a commercial grade computer equipped with photo-editing software such as Adobe Photoshop or GIMP (which is open source). These tools are generally commonplace and readily available.

Cover photography offers a simpler methodology and enables a wider working window as the operator can acquire suitable images over more varied sky conditions compared to other optic methods. Hemispherical and fisheye images often contain a higher proportion of mixed pixels due to their lower resolution and variable exposure, which may result in underestimation of true LAI [45]. Images can only be taken in overcast conditions to minimise mixed pixels, and this severely restricts the available time for data acquisition. In addition, these images require specific software for post-imaging analyses, which limits their speed and universal accessibility. Due to the wide view angle of these lenses, it is difficult to utilise these methods to estimate the LAI of isolated trees or in urban areas as they may invariably include large expanses of unwanted urban features [49]. PCAs, such as the LiCor LAI-2000, can acquire LAI estimates rapidly, but they possess the same disadvantages as hemispherical images as they rely on similar wide-angle lens technology. In addition, there is no way for the operator to check the accuracy of data collected in-field due to the lack of an interface for quality-checking.

3.3 Limitations of cover photography

The accuracy of LAI estimations from cover photography was compromised in conditions with bright sunlight due to the reflection from shiny foliage elements. This limits the practicality of this method as it only works most optimally in uniform sky conditions without direct sunlight. However, the cover photography method still provides a larger working window and is more tolerable to environmental

![Fig. 4. The cover photography method is not suitable for acquiring data from trees under these situations: (a) obstructed sky conditions with urban features dispersed among foliage; (b) large-leafed trees; and (c) mixed canopies with overlapping tree crowns.](image-url)
conditions compared to other optic methods, where the ideal conditions are only at dawn and at dusk.

The DCP software is not able to accurately detect plant pixels if urban features are dispersed among foliage (Fig. 4a). In these situations, LAI may still be determined through manual analysis as it allows for better control and subjectivity when distinguishing between plant and non-plant pixels [41]. It is not recommended to use zenith cover photography to determine LAI from the canopy of large-leafed trees (Fig. 4b), or of overlapping canopies of different species if the user is only interested in single species values (Fig. 4c). Estimations from cover photography of large-leafed canopies grossly violate the assumption of randomly distributed foliage, and will result in inaccurate estimates of LAI. For overlapping canopies, both automated and manual determination of foliage area of individual trees is near impossible due to the difficulty in discerning between green pixels of different species. In such cases, the overall stand canopy LAI can be determined and used instead.

3.4 Suggestions for application and improvement

There are multiple ways the LAI of individual trees can be applied to current industry and research purposes. For example, the total leaf area of individual trees can be acquired by multiplying its LAI by crown area. The total foliage area within a landscaped area can then be calculated by taking the sum of all LAI-weighted crown area. This gives a more robust estimation of the extent of greenery in an area, compared to conventional canopy cover estimates which do not recognise species-specific and individual-specific differences. Millward and Sabir [51] have incorporated LAI values to evaluate the health and age structure of trees in a landscaped park to determine their ecological and aesthetic benefits, and stressed the importance of utilising individual tree condition to determine accurate estimates of overall greenery benefits.

Accurate LAI estimates can be used together with information on tree location, abundance, spatial clustering, and species-specific traits (e.g. biodiversity-attracting attributes, branch architecture, leaf colour and size) to develop accurate and robust models to determine microclimate and perceived benefits of greenery. Information of total leaf area can be used to perform cost-benefit analyses of urban forests, street vegetation, and parks [29]. LAI can also be used in determining the potential leaf area index (PLAI), which is a measure of the carrying capacity of urban vegetation in an area and is based on the availability and configuration of growing space [52]. This parameter can be used by planners to identify areas that can be further enhanced by vegetation.

While this method is adequate in determining general trends for industry application, it is not robust enough for precise modelling of tree architecture (e.g. in research studies based around an individual or small clusters of trees). For this, we recommend manually determining the light extinction coefficient for more accurate estimates of LAI. We also recognise the limitations of this method with regard to complex urban greenery structures, shrubs and groundcover. We recommend more research to be done to refine and apply the automated cover photography method to estimate LAI of trees in obstructed sky conditions and of understory plants. Macfarlane and Ogden [50] have developed an automated software to detect green pixels to determine foliage
cover in understory plants. This software has been applied to successfully estimate the LAI of forest understory plants [40] and of isolated trees in urban areas with obstructed sky conditions [20]. However, more work needs to be done to fully automate the process.

4. Conclusion

LAI is an important parameter that can be used by a variety of practitioners working in urban areas. It can be used by: urban ecologists to evaluate and model ecosystem services provided by urban vegetation; urban planners, developers and landscape architects to design and assess the extent of greenery in an area; and arborists and park managers to assess the health of trees. For detailed modelling of individual trees, it may be more appropriate to use other methods such as destructive sampling to give more precise estimates. At large landscape scales, LiDAR coupled with remote sensing and spectroscopy are more appropriate LAI quantification methods. Nonetheless, cover photography has the potential to fulfill a specific niche in LAI quantification amongst practitioners that want site-specific greenery density measurements, or rapid inventories of trees. For example, in urban woodlots, landscaped parks, and along streetscapes.

Acknowledgements

We are thankful to Dr. Craig Macfarlane (CSIRO; University of Western Australia) for generously providing us with the DCP software and guiding us in its usage. We thank Ms. Srilalitha Gopalakrishnan (Singapore University of Technology and Design; Singapore Institute of Landscape Architects), Dr. Daniel Richards (Future Cities Laboratory, Singapore-ETH Centre), and Mr. Lahiru Wijedasa (National University of Singapore) for taking the time to share their knowledge and expertise about their professions. We are also grateful for the support of our colleagues, friends and families in writing this paper.

Abstract

The urban thermal environment has practical implications for energy consumption, human comfort and productivity, air pollution at street level, and urban ecology. Street tree view factor (TVF) is an important parameter of the urban outdoor environment that describe the tree canopy quantification, which plays a key role in the urban thermal environment. However, the previous study areas mainly focus on the cities where streetscape features are relatively simple with well-defined building and street structures. The feasibility and uncertainty of accurately estimating tree canopy at large-scale in such high-density urban areas, with much more complex streetscape structures, are still not clear. A typical street in high-density urban environment is characterized by large overhanging signboards, narrow lanes, heavy traffic, and high-rise buildings that block sunlight and air paths and provide very limited openness to the sky. An effective and accurate method for mapping the tree view factor of street canyons in this urban environment is therefore crucial for studying its urban climate and assessing the relevant outdoor thermal comfort.

This study aims on (1) developing an approach for automatically and accurately deriving tree canopy of street canyons in the high-density urban environments using the publicly available Google Street View (GSV) images and a deep-learning feature extraction algorithm for extraction of tree features; (2) verifying the accuracy of the developed GSV-based method using reference data of hemispheric photography from field survey; and (3) comparing the GSV-based tree view factor estimate of Hong Kong and Singapore, and investigating the impact factors for the discrepancies between them. As a result, TVF maps in high-density urban areas of two subtropical high-density cities are generated. Validation using reference
data of hemispheric photography from field surveys in compact high-rise and low-rise areas shows that the GSV-based tree view factor estimate has satisfying agreements ($R^2 >0.95$) with the reference data, suggesting the effectiveness and high accuracy of the developed method. The developed GSV-based method for analysing tree view factor in a 3D street environment makes large-scale tree canopy estimation possible. This will be playing an important role in relating science-based evidence for urban climatic studies and decision making in landscape urban planning and design processes.

1. Introduction

The urban thermal environment has practical implications for energy consumption, human comfort and productivity, air pollution at street level, and urban ecology [1]. It is influenced by the geometry of street canyons, street trees, building blocks and impervious ground covers [2]. Street view factor for tree (TVF) is an important parameter of the urban outdoor environment. View factor is a geometric ratio that expresses the fraction of the radiation output from one surface that is intercepted by another [3]. Tree view factor (TVF) is defined as the fractions of the overlying hemisphere as shown in a sky view image that are occupied by the tree canopy. A thorough quantification and understanding of the physical streetscape using view factors, including its features and dynamics, would offer great utility to urban planners and climatologists investigating the urban environment, its physical and social interactions [4], and implications for human well-being.

Street tree canopy, quantified by tree view factor (TVF), has instrumental ecological service functions such as urban heat island mitigation due to its contribution to reduce urban temperature [5], [6]. The thermal comfort benefit of trees that differences due to trees’ aspect ratio affect the physiological equivalent temperature reduction [7]. The trees’ cooling effect come from tree shading, which reduces the radiation reaching ground level [8], [9], and evaporative cooling from leaf surfaces [10]. In addition, urban street trees have been found to absorb airborne pollutions and therefore decrease road traffic emissions [11] and improve walkability of streets [12]. Therefore, the proportion of street tree cover can be used to evaluate the benefits from ecosystem service provisions at different areas of a city [13].

The purpose of this study is to develop an approach for estimating and mapping tree view factor (TVF) of street canyons with complex urban living environment context, like the high-density urban areas of Hong Kong. The approach is based on GSV images and a deep-learning technique for street feature extraction, and is validated using hemispheric photography measurements as reference data from field work. This validation is, to our knowledge, the first reported use of hemispheric photography for direct verification of GSV-based streetscape study. The developed approach represents a ground-based perspective of city streetscapes that cover complicated urban contexts, including tree canopy cover, building overhangs, and shade structures.

2. Methods

2.1. Study area

Hong Kong, situated at the coastline of south-eastern China, is one of the most densely-populated and built-up cities in the world. It has a population of over seven million living in around 262 km$^2$ of developed land [14], [15]. The climate of Hong Kong is subtropical maritime, which features hot and humid summers and warm winters [16]. Moreover, high-density urban areas of Hong Kong are characterized by high-rise compact building blocks and deep street canyons with a high H/W ratio. In these areas, tall buildings of some 40-60 stories lining narrow streets of 15-25 m width have been the norm with limited and high fragmentation landscape in built-up area [17]. Serious issues related to human thermal comfort [18], air pollution [19] and the urban heat island effect [20] due to its climate and urban forms have been primary planning concerns. As effective indicators for characterizing urban streetscapes, street view factors have been widely incorporated in modelling to address these concerns. However, accuracy assessment of tree canopy estimation, which is crucial for quantifying the uncertainty of models, is still lacking due to a lack of measurements.

2.2. GSV-based tree view factor estimates

Gong et al. [21] proposed an approach for accurately deriving view factors for the sky, trees, and buildings of street canyons in the high-density urban environment of Hong Kong using publicly available GSV images and a deep-learning feature extraction algorithm. In this study, we use publicly accessible GSV images to estimate the TVF of street canyons in high-density urban areas of Hong Kong and Singapore. Street panorama images sampled at 30-meter intervals are first collected using the GSV API [22], [23] based on the latitudes and longitudes of the sampling points. Extraction of features, including sky, trees, and buildings, is implemented using the scene parsing method in a deep-learning framework [24], [25]. We then project the panorama images from cylindrical to azimuthal projection to generate the fisheye images. From the fisheye images, TVF is calculated by applying the classical photographic method [26]. The workflow procedure for view factors calculations...
using this GSV-based method, and the detailed descriptions are shown in Gong et al. [21]

3. Results

3.1. Mapping tree canopy of street canyons using GSV images

This research quantifies spatial distributions of GSV-based TVF estimate in high-density urban areas in Kowloon and Hong Kong Island in Fig. 2 to compare their spatial variation and frequency distributions, as shown in Fig. 3. In general, we find the spatial patterns of TVF estimate are similar and consistent with the corresponding building height and density. Areas with higher density have lower TVF, and vice versa. The high-density residential areas, located in southern and western Kowloon and northern Hong Kong Island, which cover about 58% of the study area, are dominated by low TVF (0.0-0.2), because of the high-density construction and narrow streets that block sky visibility and limit space for greenery. The coastline regions and low-rise areas, which cover about 20% of the study area, show much median TVF (0.2-0.3), because of fewer buildings and more sky openness. In low-rise regions near country parks in the southern part of the study area in Hong Kong Island, where building density is low, however, the much lower sky openness, is mainly due to high tree cover (> 0.3) in this area, which blocks much of the sky visibility.

The mean TVF values of the whole areas and built-up areas of Hong Kong is 0.40 and 0.14, respectively, and there are small differences between Kowloon area (0.12) and Hong Kong Island (0.19). Fig. 3 shows the frequency distribution of the TVF and SVF in Hong Kong to investigate the frequency density of VFs. The TVF in the high building density area is dominated by values less than 0.1 and the mean value is 0.143. The low TVF is mainly limited by the high building density and narrow streets. This mean TVF is smaller compared with Singapore (0.26), a sub-tropical Asian city with high building and population densities (see Fig. 4).

![Fig. 2. Mapping of GSV-based estimate of tree view factor of street canyons in high-density urban areas of Hong Kong derived from 29,264 GSV images along streets at 30-meter intervals.](image)
3.2. Validation of GSV-based tree view factor estimate

To assess the accuracy of the scene parsing deep-learning technique in extracting street scenes, we randomly select 100 sampled street points, and collect their corresponding GSV images. Manual delineation on the images by eye inspection is implemented to extract the tree feature to generate a reference dataset (as truth). As a result, Fig. 5 shows the comparison of calculated tree canopy from GSV images using feature extraction based on the scene parsing deep-learning technique and based on the collected reference data. We can see the two datasets exactly agree with each other, with $R^2$ of 0.986 and RMSE of 0.025 for TVF. This agreement suggests that the scene parsing deep-learning technique is able to accurately extract the street-level features in high-density urban areas of Hong Kong.

The comparison of tree view factor estimates and direct measurements using hemispherical photography is a convincing way to verify the effectiveness and assess the uncertainties associated with GSV-based method for estimating tree view factor of street canyons. Here we use fisheye lens hemispheric photography to verify the applicability of GSV-based method in high-density urban areas of Hong Kong. Forty photographs were taken at 40 selected sample points (20 in the high-rise area of Mong Kok and 20 in the low-rise area of Kowloon Tong) in Kowloon. The photographs were taken at 1.5 m above ground level, using a digital camera, Nikon FM601, with an 8-mm circular lens. The results shown in Fig. 6 suggest that a GSV-based streetscape study is effective and accurate in high-density urban areas of Hong Kong, characterized by compact high-rise areas with complicated street environments.
and by low-rise areas with dense tree canopy. We compared survey-based reference TVF data and GSV-based TVF estimate. The GSV-based method we propose to use in high-density urban areas of Hong Kong performs much better in estimating TVF (see Fig. 6) with higher $R^2$ (0.987 versus 0.027).

4. Discussion

4.1. High-accuracy tree view factor estimate for better modeling of urban thermal environment

The climate of Hong Kong during hot and humid summers causes thermal discomfort and decreases the quality of living, and both effects are intensified by the UHI effect because of limited tree distribution in heavily built-up areas. There is a pressing need for high-accuracy estimate of tree canopy, which is effective indicator of the geometry and structures of street canyons for climatic study. This study proposes the use of publicly available GSV panorama images and a deep-learning technique to estimate the TVF at street level in high-density urban areas of Hong Kong. From the verification results against reference data (as truth), the GSV-based TVF show a satisfying agreement (with $R^2$ values larger than 0.95) with the reference data. This result indicates the high accuracy of estimating TVF using GSV images and the deep-learning technique. These high-accuracy estimates will improve the calculation of urban thermal radiation in modeling the street canyon thermal environment in Hong Kong. Moreover, the GSV-based method developed is capable of providing more detailed TVF estimates at various scales from a small site to an entire city. Since GSV images are available in many cities all over the world, this method provides a low-cost and effective approach to support global studies of urban thermal environments.

Fig. 5. Accuracy assessment of feature extraction using the pyramid scene parsing networks (PSPNet) in a deep-learning framework to calculate tree view factor from GSV images in high-density urban areas of Hong Kong. The $R^2$ and RMSE between the two datasets of view factors are also indicated.

Fig. 6. Scatter plot of TVF reference data from field survey and the corresponding GSV-based TVF estimates. The sampling TVF data include 20 samples in Mong Kok within high-rise building area (in triangles), and 20 samples in Kowloon Tong within low-rise area (in circles);
4.2. Temporal variation of street-level tree view factor

Hong Kong and Singapore are located in a subtropical monsoon region with little effect of seasonality on the variation of the street tree canopy. A specific assumption on the seasonality is that the leaf cover of street trees does not change during different seasons even though the acquisition time of GSV images differs. This is a reasonable assumption since Hong Kong is located in the subtropical monsoon region where the street trees can be maintained throughout the year [27]. Moreover, Hong Kong and Singapore are highly developed high-density cities where the built-up areas are limited and therefore very little change has taken place during recent years [15], [28] that will significantly affect the street skylines.

However, for temperate climate regions, the seasonality of TVF will be a big issue, given that the street trees will be in an annual cycle of greening during growing seasons, and turning yellow and falling during the autumn and winter seasons. The change in color of tree leaves poses a challenge for tree view factor studies using conventional tree detection method based on the traditional spectral (RGB) information. The developed deep-learning method in this study, on the other hand, extracts street features based on local and global context information independent of spectral information. Therefore, it has an advantage over the traditional pixel-based spectral method. The developed method in this study can be used to address the problem of VF seasonality by first training the deep-learning module with tree image samples from different seasons and then applying it to GSV images grouped into different seasons.

5. Conclusions

This study focuses on (1) developing an approach for accurately deriving tree view factor of street canyons in the high-density urban environments using publicly available GSV images and a deep-learning feature extraction algorithm; (2) verifying the accuracy of the developed GSV-based method using reference data of hemispheric photography from field surveys; and (3) comparing the GSV-based tree view factor estimate of Hong Kong and Singapore, two subtropical high-density cities. The following conclusions can be drawn:

- Street tree canopy maps in high-density urban areas of Hong Kong and Singapore are generated. The mean TVF values in the whole Hong Kong and high-density areas of Hong Kong is 0.40, and 0.14, respectively. The mean TVF is smaller compared with Singapore (0.26).
- The spatial patterns of TVF estimate are similar and consistent with the corresponding building height and density. The TVF is dominated by values less than 0.1, which is limited by the high building density and narrow street environment.
- Verification using reference data by hemispheric photography from field surveys shows that the GSV-based TVF estimate have a satisfying agreement (with $R^2$ value larger than 0.95) with the reference data. It suggests the effectiveness and high accuracy of the GSV-based method.

The developed method for analyzing tree canopy in a 3D street environment will play an important role in relating science-based evidence for urban climatic studies and
decision-making in landscape planning and design processes.

Abstract

The urban flood potential analysis associated with land use measure, a non-engineering approach, can manage urban storm and runoff water and draw creek’s upstream and downstream areas intelligently, and more important, spatially distribute flooding potential or predict areas inundated for land use suitability through the lowest spot of major or sub-drainage outlet. This study looks at upstream rural and downstream urbanized urban flood potential areas, and collaborates with local geographical information system (GIS) with consideration of resident sustainability in compliance with flooding potential constraints and opportunities. This study applies Taipei Da Gou Creek Park inundated site as a case and ex post facto examines the data tracing back 1961 through 2009, documented by Taiwan Metrological Service Bureau data, and the data published on 1977, Highway Bureau Service drainage research, with local Taipei City Water Resources Service’s data up to 2008. Land use suitability diagrams for Taipei urban flood disaster adaption of most likeness or of improbability precipitation volume are indicated. An normal admired urban storm and runoff water intensity is set to have design storm by an equivalent of 2-year recurrence year with a 2-hour precipitation duration time; An extraordinary one, flooding design precipitation applies an rainfall intensity by recurrence of greater than 25 year or by an equivalent to 50 to 100-year recurrence, 2 hour design rainfall duration intensity is examined. Analyzing anticipated peak rates of upstream and downstream inundated areas, the study clarifies study site terrain with soil and slope conditions and set up schematically site storm management and area inundated land use suitability for detention park accordingly. This study is to suggest construction proposal of park and its adjacent areas avoid inundated areas or eventually only create recreation or retention land use and stay away from occupancy of flood-prone residence land use.

Keywords Flooding Potential Analysis; Inundation; Area Inundated; Human Occupancy Land Use; Inflow or Outflow hydrograph; Storm and Runoff Water Storage Diagram; Ecosystems Services Land Use Suitability; Taipei Da Gau Creek Park;
1. Introduction: Purpose and Significance

The Disaster Prevention and Protection Act (DPPA) for Taiwan Area, Section 7, Article Number 22, defines flooding as a real disaster. Indeed, people shall review flooding potential and its corresponding hazardous outcomes, foresee inundated area, and propose adopting and mitigating for better quality of life accordingly.

This study chooses Taipei Da Gou Creek Park as a case of application for redeeming such the said ecosystem service for human well-being through the prediction of urban storm and runoff water volume and possible storage for urban stream catchment.

The Park, after opening to the public on 2009, the Da Gou Park is getting more and more advertised, as a theme of governmental achievement for multi-use of flooding detention, prevention, and recreation. The Park becomes not a due compensation for the flooding loss but a true implemental tool for flood management example. The authority asserts that the current detention for prevention flood is good enough. Any improbability of extra precipitation is not necessarily going to happen in any predictable time soon. The public media, news and internets are also showing a lot of success stories related to this Park.

Does such optimistic judgment stay unyielding? Could the Da-Gou Park work as a suitable, “spongy or resilient” detention park-land use for public good? Does the Park a hydrological icon where partly detention in the upstream area and partly retention in the downstream area catch flooding problem? This study is then to clarify and reconsider the land use suitability or inundation at the downstream area at Da Gou Creek man-made outlet. A quick pilot calculation draw as an inflow, outflow, and possible storm and runoff volume storage diagrams though their perception hygrograms. The results are to verify the applicable areas inundated for land use policy.

2. The Site for Flooding Potential Analysis

The study site, a 340-hectare area with most of woodland covered, averagely 17.5 percentage slope, has an about 3,500 meter long stream and has a hierarchical network of channels. It takes shape of the catchment and drains storm and runoff water from small rills through gullies to creek and to the destination retention Da Hu (Great Pond). It eventually has suffered receiving powerful typhoons which cause severe downpours that causing a great deal of discharge fluctuation for the stream.

Where the study site at downstream area was a field of swamp, it now becomes an impervious blanket for highway and luxury condominium high-raises urban area. No particular flooding happened before when the site was swamp; Now it did flood after the high-raises and buildings constructed.

The community then has solicited to request deterrence or prevention of detention constructed facilities no matter whether the area inundated was chosen inappropriate or developments created the flooding.

The amount of sediment has built up gradually in the flat bottom of developed urbanized area. The drainage area, or catchment, is adjacent to the major, much bigger Da Hu (Great Lake) catchment. The Figure 1 and Figure 2 show the site and its surrounding’s topographic grades and hydrological storm and runoff water routing.
This study reviews current climate change indicating possible storm and runoff water volumes back to the probability of values greater or changes and for possible flood-prone areas less than design storm management design rainfall intensity. It applies recurrence analysis through hydrological, not hydraulic, approach via current and historical recorded precipitation data documented by Taipei Meteorological Bureau.

The study predicts the Park’s inflow and outflow storm and runoff water to be retained by the detention facilities at the existing channels, weirs and orifices beyond the creek’s lowest spot at outlet.\(^\text{[12][13]}\)

There is an estimate of rainfall volume and duration time held in the pipes and channels into the adjacent streets between the park and its surroundings with or without overflowing credentials. The study calculates storm and runoff water volume by determining the rates and volumes of storm runoff, using rational and modified rational methods for upstream and downstream two areas. It investigates existing high points, low points, ridges, valleys, swales, points of concentrations. The study checks whether storm drainage systems exceeds the rate of flow or not, and reviews the existing and original drainage volume with and without Da Gou Park. It is comparing possible storage volume prior to and after the development in the end.

The coefficient value, C,\(^\text{[4]}\) is decided separately by existing land use types, slopes and topographical characteristics. The urbanized downstream area is high impervious. See the Figure 3.

Whole site is a portion of hill slope down to the flat gentle valley slope and ended up with connection of intersection at main streets to the Da Hu (Great Lake) detention pond, the average c value is as high as to 0.5 to 0.7. The cumulative percent frequency or probability of annual precipitation at Taipei, 1961-2009, shows a straight line indicating the annual precipitation values are normal distributed.\(^\text{[12]}\)

The storm frequency, defined as the number of years during which the design storm, or a storm exceeding it, is based on the Taipei Central Meteorological Services’ survey of probabilities for 49 years. That is, the annual perception data from 1961 through 2013, as shown in the Figure 4. This study discovers, from the governmental web site information, that the Da Gou Creek has
a 20-year design storm with responding frequency and duration respectively for storm water management system according the above-mentioned DPPA Act and other regulations as well.

3. Method and Analysis

Learning from the cumulative percent frequency or probability of annual precipitation at Taipei, this study find out that normal 2.0, or 2.2 year recurrence of the design storm frequency\[8]\[9] is around 2,249 mm per year. The representative mean value of average one is around 2,250 mm. However, this 2,249 annual rainfall in mm per hour (mm/hr) shall be considered as only a possible range. The flooding potential shall be examined the range at least up to or within one standard deviation above the mean stays additional 34 percent of all occurrences represented by the frequency distribution.\[10]\[11]\[12] The Figure 4 indicates the cumulative percent frequency as followed. The details, see the Figure 4.

![Figure 4 Cumulative Percent Frequency or Probability of Annual Precipitation in Taipei](image)

4. Storm and Runoff Water In-Flow, Out-Flow, and Storage

The calculation of Da Gou Creek Park drainage area is based on the mean average value around precipitation of 2, 250 mm per year and transmits into 80.93 mm per hour as calculated by Log-Person III’s method (1976), or 84.55 mm/hr by Chow’s method (1976) with a 2-hour short rainfall duration time. The Table 1 compares and shows Taipei design rainfall intensity with a particular precipitation frequency by possible recurrence for peak runoff rate calculation.

The modified rational method, with an antecedent precipitation factor in rational formula, has determined the Da Gou Creek Park’s lowest spot’s inflow and invert outflow volumes. The method (MRM) allows runoff for storm duration shorter or longer than the time of concentration, and that is applying in this study case. Applying hydrograph diagram as indication that is a plot of flow rate (q) versus time (T), more particular, the tabular is representative of plots showing the estimate of hydrograph...
distribution. The Table 2 shows the results as followed.

By measuring duration of rainfall events, this study has produced a set of hydrographs, by the duration time of storm and runoff water. Specifying the flow rates (q) of upstream area at any time during the storm and runoff water volume process by hydrographs, the total estimate of storm and runoff water volume from upstream area can be identified. It is about 133,900 cubic meters at a 25-year recurrence. ArcGIS’s spatial analysis with volumes of cut-and-fill modelling is to clarify that. Probability of precipitation values rate of Taipei is for double reference.

The following Da Gou Creek Park’s inflow and outflow hydrograph by particular 2-, 5-, 10-, 25-, 50-, and 100 year recurrence is listed. Each Figure shows the storm and runoff water inflow, outflow, and storage volumes respectively.
5. Result: Area Inundated and Determining Suitability for Detention Park Land Use

Whether people are aware of the risk of residence in a flood-prone land subject to flooding, developments of high-rise luxury apartments and dwellings are still to be located on the Da Hu (Great Lake) Section where Da Gou Creek stream running through. This study has analyzes the area inundated, which is the best or highest “suitable” or land use “suitability” of detention park land use; yet it is the worst or least “suitable” for land use “suitability” for other, non-detention park land use such as residence, factory, or commercial use.

In this case study, land use situation or “suitability” may further be compromised or complicate if the topographical grade, slope, soil, vegetation and land use associated with increasing flood hazard potential to downstream areas outside the study site, when climate change may happen dramatically and significantly. The Table 3 shows an initiative pilot evaluation method for the evaluation.

Started studying and got immediate result shows that an analytic hierarchy processing with expert opinion analysis for ecosystems and human well-being regulating flood, the assessment designate the most possible flooding potential area, or the most area inundated land use type, at upstream and downstream areas. The calculation results indicate land parcel of study site and place an average high, or much lower or higher index value of function level of of detention preventing park. It is a kind of suitability mapping yet only on and along Da Gou Creek Park, the stream and its surrounding district with another larger watershed included.

In detail, the index system includes three levels: first, level of the index complied with the fundamental requirement of M1, regulating flood; second and third, M2 and M3, the index for ecosystem...
services. Second, the level of index is the provisioning: N1, flood potential; and N2, Slid hazard potential; N3, de-vegetation; N4, runoff routing; N5, soil deformation; and N6, landscaping accessibility. After being weight of the said level’s index, the study reaches an overall integrity of flood potential or area inundated as listed in the Table 4, and in the the map of the Figure 8 as will be discussed in the end.

Started studying ecosystem assessment framework with Arcgis’ modelling and mapping and got final results show, this study specifies Da Gou Creek Park potential flooding areas by design storms and runoff water recurrence, and compares volumes of inflow and outflow by different hydrographs, for the valley bottomlands and the channel of Da Gou Creek above the reservoir retention facility at Da Hu (Great Lake) District.

The study specifies inundated areas by mapping of the flood potential based on the above discussed results organized on Table 4, and based on the analyzed by design storm of 25 recurrence year, presented at three levels of inundate storm water height: first, 0.0 through 0.5 meter; second, 0.5 through 1.0 meter; and third, 1.0 through 3.0 meter. Figure 5 and Figure 6 indicates the map under three different inundated height levels.
through the above-mentioned analytic hierarchy process (AHP) method, or single integrated factor analysis, with expert opinion analysis, the Figure 5-a, 5-b, 5-c, 5-d, 5-e, and 5-g have shown a series single-purpose suitability land use map for proposed detention-park, according to first, by inundated land distribution; second, by topographical slope, third, by region’s vegetation forms; fourth, by potential runoff routing distance; fifth, by soil types including silt loam and clay soil; and six, by landscape accessibility or distance to access.

All mappings designate the land-use suitability for Da Gou Creek park and its surroundings upstream and downstream inundated areas for detention park land use, where are certain that the most likeness of the site and place can be used for detention or retention facilities as well.

In detail, the flooding potential levels are indentified as first, the a flood-prone scale at 1.71 through 2.64, the less detention; second, the scale at 2.64 through 3.58, the medium suitable for detention; and third, the scale at 3.58 through 4.5, the most suitable for detention. That is, the last or third scale vale, the most significantly represents the most likeness of area inundated, and the first scale value represents the least possible area inundated; the second scale vale represents the medium area inundated between the last and the first scale area values.

Multi- or six- single integrated factor analysis mapping indicates the the most likeness of the site and place can be
used for detention or retention facilities as shown in the Figure 6.

**Figure 5-a** Single factor analytic hierarchy process method, or an integrated analysis of eco-systems service flood regulation suitability assessment for flood detention park land use for Da Gou Creek Park and its surrounding area by area inundated land, or inundation potential distribution.

**Figure 5-b** Single factor analytic hierarchy process method, or an integrated analysis of eco-systems service flood regulation suitability assessment for flood detention park land use for Da Gou Creek Park and its surrounding area by topographical slope.

**Figure 5-d** Single factor analytic hierarchy process method, or integrated analysis of eco-systems service flood regulation suitability assessment for flood detention park land use for Da Gou Creek Park and its surrounding area by potential runoff routing distance.

**Figure 5-e** Single factor analytic hierarchy process method, or integrated analysis of eco-systems service flood regulation suitability assessment for flood detention park land use for Da Gou Creek Park and its surrounding area by soil types.

**Figure 5-f** Single factor analytic hierarchy process method, or integrated analysis of eco-systems service flood regulation suitability assessment for flood detention park land use for Da Gou Creek Park and its surrounding area by landscape accessibility or distance to access.
Figure 6 Multi-factor analytic or integrated analysis of eco-systems service flood regulation suitability assessment for flood detention park land use for Da Gou Creek Park and its surrounding area by the index of urbanized or rural inundated area.

The urban flood potential analysis associated with land use measure is a sound non-engineering approach: it adapts two or three-dimensional mapping for zoning. It reviews urban development with man-made detention and retention facilities for both urban and rural areas. Yet, this study see the fact that when the flood lapses, and the evidence of flooding damage immaculate, the hazard threat fades. The perception of flood urgency swifts from attention until next one, a 50-, 100- or 200-recurrence year storm, is to come.

With respect to information of environmental planning and design, land use suitability or area inundated mapping data should be opened, yet it is somehow obscured by dishonest, if not corrupted, politicians, land developers, or the others with interests in socio-economic growth and local pride. Thus, has thoroughly been lined up with ecosystem services among human services and GPS modeling, this study clarifies flood potential of Da Gou Creek at Park and human safe fit for security concerns. It provides a typical eco-indexing of systems of human well-being services such as the calculation of closed drainage system and flooding potential.

The results imply that further examination and mapping is highly recommended, particularly, for the areas where highly possibly inundated at the starting outlet, through lower open outlet surrounded by developed urbanized areas and ended up at Da Hu (Great Lake) retention facility pond.

What is validity of drainage is to examine the research site that needs free from logical flaw or free from data validities; That is, the study suggests empirical checks of rational or modified rational method which the drainage area is normally less than 80 hectares[12][13].

In this study, the drainage area is as big as 340 hectares and still likely appeared to be applicable because of the allowable calculation measure which listed the drainage area for calculation to the maximum of 1,000 hectares, according to the Disaster Prevention and Protection Act (DPPA) of Taiwan rural area.

The study recommends, first, inspection of precipitation shall be within one standard deviation above and below the mean which lies in 68 percent of all occurrences such as represented by the frequency distribution and further compare at at least a 30- or more year recorded data in calculation and
combine data with uncertainty flooding possibilities:

Second, focus on examining flood probabilities responding to micro-topographical contours with larger scale. Any emergency evacuation such as avoiding typhoons and extreme, torrential rain occurrence shall be further weighted and considered into the calculation and mapping.

Third, examine typical current drainage structures which appear to be short in the site and off-site in terms of drainage regularities. The storm and runoff surface drainage collection shall modify its maximum amount of average plus the flooding potential, up to the range at least within one standard deviation above the mean stays additional 34 percent of all occurrences represented by frequency distribution.

In addition, the peak runoff rates for the Da Gou Creek Park’s hydraulic structures, culverts and reinforced concrete channel waterways must fit into the storm frequency more than by 25 year recurrence and up to at least a 50- year recurrence with at least 12 hour duration time. So does the connection piping with pumping on the top of bank.

Existing off-site disposal to the Da Hu (Great Lake) shall also seriously review its maximum volume in compliance with this climate change requirement. The designed reconstructed storage pond and detention reservoir with stepping stone for recreation need to reconstruct to fit additional rainfall intensity which exceeds a 50-recurrence design storm rainfall intensity.

In the end, three things, for collecting, conducting, and disposing storm and runoff water systematically all together into one shall be considered as a major framework critically to fulfill; It shall be never be overestimated whatsoever.

Abstract

With the continuous improvement of the ageing in our country, how to deal with the healthy problems of the elderly has become one of the hot issues in the whole society. Urban community parks are one of the main spaces of physical activities for the elderly. The construction of community parks which is suitable for the elderly's outdoor activities has positive significance. Based on theory of environmental activities, the research takes the physical activities of the elderly as an object and selects a representative community park in Harbin as a research site. Scanning observations and semi-structured interviews were used to collect data. The data was digitally visualized through GIS software. From the perspective of time and space, the amount of the elderly, types of activities, spatiotemporal distribution, and environmental characteristics were studied, to provide reference which build the urban park. The Research found that: (1) The physical activities of the elderly in community parks mainly include 8 types of Physical Fitness Activity, 3 types of Social Interaction Activity, 5 types of Leisure Recreational Activity, and 4 types of Static Rest Activity. (2) The park activity shows a trend of two lows and three highs over time, forming a peak period of three healthy activities. It has obvious time effect. (3) The outdoor activities of the elderly are balanced in spatial distribution and have obvious boundary effects. Different types of activities have obvious domains.

Fund Items: National Natural Science Foundation of China (No. 51578173); National Natural Science Foundation of China (No. 51678180)
1. Introduction

With the continuous improvement of the ageing in our country, how to deal with the healthy problems of the elderly has become one of the hot issues in the whole society. Research in the public health field shows that regular participation in physical activity can bring many health benefits [1][2]. Urban community parks are one of the main spaces for physical activities for the elderly. The construction of urban community parks which is suitable for the elderly’s outdoor activities has positive significance.

After years of development, there have been some achievements in the field of elderly. At the policy level, the World Assembly on Ageing report in 2002 states that “the dwelling and its surroundings are particularly important for the elderly. Consideration should be given to provide important mental and psychological security for the elderly.” [3] The 12th Five-Year Plan for the development of China's aging undertakings in 2011 emphasizes: “Accelerate the construction of old-age activity venues and facilities, and focus on improving the living condition of the elderly. Make use of public spaces, such as parks, green spaces, squares, to open up sports and fitness facilities for the elderly.” [4] Wang Z (2010) found that different environmental and other individual specific factors were found to be significantly related to meeting recommendation within either walking for transport or walking for leisure [5]. J. Eronen (2014) investigated the factors affecting the physical activity of the elderly through random interviews and questionnaire surveys, and found outdoor recreation facilities is an important factor to promote outdoor physical activity [6]. Kalevi Kor-pela (2017) and others found that happiness is positively correlated with the frequency of physical activity in nature, which fully demonstrates the importance of physical activity outdoors [7]. Kirs E. Keskinen (2018) investigated the relationship between the environment and the physical activity of the elderly through questionnaires and interviews and found that the spatial diversity is positively correlated with the frequency of physical activity of the elderly [8]. Zhao Xiumin (2016) extracted environmental elements in various types of space to analyze the relationship and extent of the impact of environmental elements on outdoor activities [9].

Studies on the outdoor activities of the elderly have achieved certain results, but most of them are based on theoretical discussions of the needs of the elderly for outdoor activities. However, few studies based on empirical investigations of the elderly's outdoor activities to ascertain their actual needs. Therefore, based on the behavior observation, this study analyzes the differences in the temporal and spatial characteristics of outdoor activities of the elderly from the time and space of the activities, and aims to provide reference to design the sustainable outdoor activity space for the elderly.

2. Research Methods

2.1. The research site

In this study, Beixiu Park in Nangang District of Harbin City was selected as the research site. The park has a long history...
Smart Cities

and is an important part of the city's texture. As one of the few community parks in Nangang District, the park had a survey. The users are mainly elderly people, and their use rate and activity are high. The garden area is about 150 meters long, 80 meters wide, and covers an area of 1.2 hectares. It consists of green space and central activity space. The park is surrounded by urban roads and is surrounded by residential areas. With convenient transportation, the elderly can easily walk from the residential area to the park.

2.2. Research Methods and Data Collection

In this study, taking the behavior of the elderly as the object. Through behavior observation, the physical activity of outdoor elderly people in the park was comprehensively recorded by mapping. The physical activity of the elderly is digitally visualized through the GIS and analyzed by SPSS. From time and space, the study was conducted on the amount of elderly people visiting, activity types, spatiotemporal distribution and environmental behavior characteristics. The data was collected from March 28th to April 1st, 2018(except March 31th). The observation time was controlled every 10 minutes, covered every area of the park. All observed behaviors of the elderly would be recorded on the plan of the park through the GIS (Figure 1).

3. Data description

The total number of physical activity was 17868 in the park, the data of male was 10037, the data of female was 7831. There are 23 kinds of physical activities for the elderly in the park.

Based on healthy perspective, we classified the physical activities into four types, they were Social Interaction Activity, Leisure Recreational Activity, Static Rest Activity, Physical Fitness Activity (Table 1).

There are 23 kinds of physical activities for the elderly in the park, of which more than 1500 were standing with talking, sing fitness equipment, playing poker, square dancing, sport walking, watching. The activity data 500-1500 were standing, sitting, sitting with talking, accompanying children, walking though, doing tai chi, playing chess, playing shuttlecock, ballroom dancing, walking with talking. Less than 500 activities included standing with sports, walking the dog, writing calligraphy, lying, running, playing balls, singing. in the activities of the elderly, males main activities were watching、playing pokers、using fitness、standing with talking and females mainly did square dancing and sports walking (Figure 2).
Through analyzing the various types of activities data, it was found that among the four types of activities, the number of Physical Fitness Activities were the most, accounting for 41% of the total data, followed by Leisure Recreational Activity, Social Interaction Activity, Static Rest Activity. The proportions were 22%, 21%, and 16% (Note: The four types of activities don’t include walking through, the same as below). It was found that the gender had an influence on the choice of outdoor activities for the elderly on Independent-Samples T Test by using SPSS (P=0.003, P<0.05). Males more likely to do Leisure and Entertainment Activities such as playing pokers, while females mainly choose Physical Fitness Activities such as square dancing. (Table 2).

4. Temporal characteristics of physical activities

4.1. Temporal Features at Different Time granularity

Though analyzed the elderly's physical activities data in a whole day, it was found that the physical activities data of the elderly has changed significantly over time. The peak period of healthy behavior formed at 9:00-10:59, 14:00-14:59, 18:00-19:59 (Figure 3). We do the variance analysis by using SPSS in whole day, found that the

</tbody>
</table>
The variance of the data was relatively large, indicating that the number of physical activities of the elderly was obviously limited by time.

4.2. Temporal Features of different types of physical activities

With the change of time, the elderly in the park show different tendencies on the types of activities. The period 7:00-7:59 and 18:00-19:59, were mainly doing Physical Fitness Activity, both accounting for 64%. The data of Social Interaction Activity and Leisure Recreational Activity increases at 8:00-11:59, the proportion is about 60% totally. At 13:00-16:59, there were mainly Leisure Recreational Activity and Physical Fitness Activity, accounting for 61% totally (Figure 4).

Among the static rest activity, sitting was the most popular activity. The participation rate was 52%. The following were standing and accompanying children, accounting for 38% and 10%. The data of lying was rare.

Static Rest Activity data began to increase at 8:00, the peak periods were 10:00-10:59,14:00-14:59,18:00-19:59.

Analyzing the reasons, it was found that the temperature of cold cities is low in the morning and the sunlight was more abundant after 10 o'clock. In the afternoon, the sunshine is the most abundant and the temperature kept rising. The number of people who had a rest in parks reached the maximum (Figure 5).

In Social Interaction Activity, the main behavior was standing with talking, the participation rate was as high as 58%. Social interaction activity has changed markedly over time. The three peak periods were 9:00-10:59,14:00-14:59,20:00-20:59. Standing with talking mostly occurred at 13:00-15:59 and 18:00-20:59. Standing with talking often took place at 9:00-10:59 and 14:00-14:59. Walking with talking mostly occurred in the 9:00-10:59 and 20:00-20:59 (Figure 6).

In Leisure Recreational Activity, the main activities were playing pokers and...
watching. The participations were 46% and 42%. The activity data were 1,709 and 1,561 times. The total data of writing calligraphy, singing and walking the dog was less, only 1.8%. The three peak periods were 9:00-10:59, 13:00-15:59, 9:00-19:59. 13:00-15:59 is the highest peak period in a day. Writing calligraphy and singing had a timely use of the site, mainly occurring in the morning and occasionally occurring in other periods. Playing pokers and playing chess have been happening since 8:00, mainly focus on 9:00-10:59 and 14:00-14:59, only few people played pokers in the evening. (Figure 7).

In Physical Fitness Activity, the main activities were Square dancing, sports walking and using fitness. The participations were successively 33.31%, 27.75%, and 25.96%. The total data of playing balls, running, standing with sports, accounting for 1.08%, only 74 times. In Physical Fitness Activity, the three peak periods were 7:00-7:59, 14:00-14:59, 19:00-19:59, 19:00-19:59 is the highest peak period in a day. Ballroom dancing and square dancing had a timely use of the site. mainly occurring in 13:00-15:59 and 18:00-19:59. Doing Tai Chi, playing balls, and running also mainly occurred during the early morning, it rarely occurred in other periods. Sports walking and using fitness been occurred all the day. Sports walking mainly occurred in 9:00-10:59 and 18:00-19:59, using fitness equipment were mainly occurred in 14:00-14:59 and 18:00-18:59, 18:00-18:59 was the highest peak period in the day.

4.3. Period characteristics under different genders

During the activity period within a day, elder people of different genders have changed significantly over time. The number of men who participated in the activity in the morning was higher than that of women, and they rose continuously after 8:00 and reached the maximum at 10:00-10:59. In the afternoon, female data increased, reaching the first small peak between 14:00-14:59, but the overall data was more than men. At night, both male and female data reached the highest peak of the day between 18:00-19:59. The overall data was slightly higher than that of men. Analysis of the reasons
revealed that there were plenty of sunshine in the morning and there were more male seniors who came to the park to play poker. The increase in female data in the afternoon and evening was due to the increase in female seniors who came to the park to dance square dances (Figure 9).

5. Spatial characteristics of outdoor physical activity

5.1. Spatial agglomeration characteristics

In the spatial distribution, the elderly had the obvious tendency of using the space in the park. The tendency was that the activities were in the north of park more than the south, the east were more than the west. The use of square space had obvious boundary effect. The obvious imbalance in the spatial distribution of the elderly reflected the different ability that support physical activity in different areas in the park. (Figure 10).

5.2. Spatial characteristics of different types of activities

Using the GIS to do the Point Density (Figure 11), it was found that the Social Interaction Activity almost covered the whole park, but the main areas were the stone table on the north side of the park, the landscape tree pools and the landscape bench surrounded by plants on the south side.

Static Rest Activity was mainly distributed on the north, south and east sides of the park, while the west side was less. Sitting and lying mainly relied on facilities, while accompanying children and standing were mainly carried out in the outer areas of activities.

Physical Fitness Activity formed a number of core gathering areas in the park, main areas were the middle of the park, the open space in the east park, and the fitness facilities, while the space utilization rate in the west of the park increased. According to the observation, it was found that the fitness activities were highly dependent on the sites and facilities, they required fitness equipment. The site had a low limit on playing shuttlecock, the elderly can carry out it at any small open space. It is necessary to pay attention to the non-slip surface of the
floor. Green shade and seats are required on the outside of the activity. Square dancing, Doing Tai Chi and ballroom dancing are generally multi-person group activities or dozens of people's collective activities, which are mainly conducted in open squares. The sport walking had a low dependence on the site and obvious boundary effects, the elderly mainly walked around the boundary of the park.

5.3. Spatial Features at Different time periods

The physical activities of the elderly in the park formed the peak of healthy behavior at 9:00-10:59, 14:00-14:59 and 18:00-19:59. In the spatial distribution of total data, at morning rush hour 9:00-10:59, it was a significant north-south boundary effect, the distribution density of activities data gradually decreasing from north to south of the park, mainly distributed at the stone table on the north side and the seat on the south side. At afternoon rush hour 14:00-14:59, the boundary effect on the north side was obvious, the data on the south side was reduced. At evening rush hour 18:00-19:59, the distribution of activity data was

Fig.11-1. The spatial distribution characteristics of the Social Interaction Activity

Fig.11-2. The spatial distribution characteristics of the Static Rest Activity

Fig.11-3. The spatial distribution characteristics of the Physical Fitness Activity

Fig.11-4. The spatial distribution characteristics of the Leisure Recreational Activity

Fig.11. The spatial distribution characteristics of different types of activities

Leisure Recreational Activity mainly relied on rest facilities. Watching caused by playing chess and pokers was an important type of activity for the elderly. Therefore, there should be sufficient seats in the surrounding areas. Playing chess and pokers relied on the park landscape seats, stone tables and chairs, landscape installations etc.
relatively balanced, the data on the west side increased, the boundary effect was intensified, the central activity gathering area moved westward, located under the device with lights.

Discuss

Ann Forsyth said that small urban parks should provide opportunities for the elderly to socialize and be close to nature. The aging population is the main user of the urban community parks in China. With the continuous improvement of the ageing, the demand for outdoor activities will be strengthened. More and more attention has been paid to the research of the relationship between the park’s environment and the elderly’s. The design of park environment has also paid more and more attention to the healthy demand of the elderly.

(1) There were a various of physical activities of the elderly in the park, based on healthy perspective, we classified the physical activities into four types, they were Social Interaction Activity, Leisure Recreational Activity, Static Rest Activity, Physical Fitness Activity. The demands for the environment of these activities are different, the organization and distribution of the activities are obviously different. According to the survey, it was found that there was mutual interference in various activities in the park. There was a spatial overlap between walking along the border and the activities located at the rest-seat area on the border of the site. Based on the guiding role of active facilities, the design of the site and facilities should be based on the type of activities for the elderly. For example, according to the boundary effect and the diversification of activities, the edge space should be planned in a hierarchical manner and the layout of the facilities should be distributed, to divide the activities of elderly people and reduce interference between activities, improve the quality of the activities.

(2) The park activities had obvious temporal effect, the peak periods of healthy activities were 9:00-10:59, 14:00-14:59 and 18:00-19:59. The multi-periods of activities reflects that the climate in the cold region...
Smart Cities

and the schedule of the elderly have influence on using the site. The morning rush hour shows that after the temperature of the park has risen and the commuting period, the elderly began to carry out intensive outdoor physical activities. In the afternoon, the temperature at 14:00-14:59 was the highest in the whole day, the elderly began to carry out intensive outdoor physical activity after the nap. The environmental factors such as sunshine and wind speed had an obvious influence on the outdoor physical activity of the elderly in winter area. Except the safety factors such as antiskid surface, In the winter, The elderly has special requirements for the landscape environment on the light transmittance of plants and the containment of space.

(3) The boundary effect of activities in the park was obvious, and the utilization rate of open space at the center was low. The activities would be carried out only at specific periods. At other times, the activity was mostly walking through and few elderly people would stay to have activities. The square dancing which appeared in the specific periods is the special fitness way for Chinese elderly people. It is a typical manifestation of the collective life style of Chinese young people to the old age period. At the same time, the playing chess, playing pokers and watching are also a special culture of the Chinese elderly people. These characteristics announce that the culture has influence on outdoor physical activities. Therefore, at the planning of outdoor healthy environment for the elderly, outdoor facilities and space planning should be conducted on respecting the cultural connotation of the elderly and studying the cultural structure of the elderly.

7. Research limitations

The data from observing activities of the elderly, it is impossible to effectively identify the age group of the elderly, so it is impossible to analyze the characteristics of the elderly at different ages. This study recorded the activities as point data, it may be difficult to capture for fast moving activities.

8. Conclusion

The elderly in the park were the subjects in the study, Through behavior observation, a comprehensive record of the outdoor physical activity (PA) of the elderly in the park was conducted by using map annotation. And spatial behavior characteristics of the elderly were explored from different time granularity and spatial scales.

The Research found that:(1) The outdoor physical activities of the elderly in community parks mainly include square dances, walks, jogging, standing exercises, tai chi, equipment fitness, dancing balls, playing dice, and social interactions., sitting, chatting, accompanied, walking, entertainment, playing poker, playing chess, calligraphy, watching, walking a dog, resting leisurely activities, standing watching, lying and taking children, physical fitness activity is mostly the main type of activity. (2) The park activity data has changed significantly with time passing. The overall trend of the park is two lows and three highs. The peak period of healthy behaviors was formed mainly at 9:00-10:59 in the morning, 14:00-14:59 in the afternoon and at 18:00-19:59 in the evening which has
an obviously time effect. (3) The outdoor activities of the elderly are unbalanced distributed and have obvious boundary effects. Different types of activities have obvious domains. Physical Fitness Activity has a high degree of dependence on the site, not only on the site’s scale and paving, some activities need to be set up with fixed facilities before it can be carried out; other Social Interactions Activity, Leisure Recreational Activity requires the least in site facilities, It can be carried out around the activity site and rest facilities.

Study on Urban Bicycle Greenway Planning Based on Big Data Analysis of Shared Bicycle

Xixi Chen\textsuperscript{a}, LiangLi\textsuperscript{a} and Danzi Wu\textsuperscript{a}\textsuperscript{*}

\textsuperscript{a}Beijing Forestry University, (No.) 35 East Qinghua Road, Beijing and 100083, China

Abstract

Chinese greenway construction will enter a new period of development. Related research and practice are mostly focusing on the construction of regional greenways. However, considering the urban traffic congestion and the worsening air pollution problem, urban bicycle greenway should be high-ranked in the future greenway construction in China. Because it is mainly located in the urban built-up area, the selection of line is influenced by complicated factors, such as the existing urban land use layout, the network structure and the usage demand. At present, China greenway line selection is mainly based on the analysis of the suitability of the value as well as potential of urban land use, but has rarely emphasized the daily use demand of citizens. With the increasing popularity of sharing bicycles, the big data reflects the daily usage demand of urban bicycle residents.

The research considers both two aspects, big data of shared bicycle social behavior and potential of green space utilization. By sharing the cycling OD data, we can get the intensity degree of the shared bicycle destination, establish the evaluation index system by using the entropy method to get the landscape utilization potential of the green space node, and sum up the suitability distribution of the greenway node, finally choose 47 greenway connections node. Also, by sharing the bicycle track data to get the most used roads of the shared bicycle, the linear green space distribution is extracted by remote sensing visual interpretation to obtain the potential of the greenway corridor based on the greenway connection, and the two are overlaid to obtain the greenway connection suitability distribution map, which become Greenway routing cost grid based on the cost path model.Finally, the lowest cost path is obtained by connecting nodes and cost grid, the initial route selection of greenway is determined, and the route selection model is optimized according to the status quo of land as well as other economic, social and cultural factors. This article suggests to organize the greenway systematically and divide it into two greenway systems: the integrated greenway system and the commuting greenway system.
Keywords: urban greenway, bicycle greenway, big data of shared bicycle, least-cost path, route selection, entropy method;

1. Urban Bicycle Greenway

With the rapid development and expansion of cities, urban population continues to increase, and urban problems such as traffic congestion, air pollution and fragmentation of green spaces are gradually intensified. The demand for improving the urban space quality is getting increasingly prominent. The construction of the greenway, which connects the broken green spaces in the city, provides a comfortable slow-moving experience for the urban residents and improves the living quality of the residents, providing a new development mode for urban stock renewal and sustainable land use.

Since the 90s of the last century, China has entered a rapid development stage of greenway research and practice. Today, with the continuous progress of urbanization in China, there’s a conspicuous shift of regional development from high-speed expansion to refined innovation. Greenway construction practice will also bring about new changes.

According to the spatial distribution feature, greenways can be mainly divided into three types: area-type, city-type and community-type. Regional greenways are mainly for the connection of key ecological land at the regional scale. Urban and community-based greenways are mainly for the connection of the main places of activities for residents, such as urban parks, street green spaces, schools and businesses within the built-up areas.

Compared with the regional greenway, the urban greenway construction is restricted by the land use for the built-up area, more emphasis is placed on the excavation of the potential of the urban space and the daily needs of residents. Compared with the community-type greenway, urban-type greenway can solve the problems of urban landscape and traffic more systematically in the urban space system [11-13], which is of great value to today’s urban construction in China. At present, the research and practice of greenways in China mainly focus on regional greenways instead of urban greenways [14], and the method of line selection mainly focuses on the evaluation of suitability analysis based on multivariate land value [15-16]. This paper discussed the urban greenway planning in China, focusing on the methods of line selection and layout within the city connected to the various functional groups.

Greenway mainly carries three kinds of slow traffic manner, walking, running and cycling [17]. Demand for bicycles, as one of the important functions carried by urban greenways, is an important factor in route selection [18]. The construction of urban bicycle greenway will provide a more comfortable and convenient experience for work commuting and daily life service, which is of great significance for encouraging green travel and alleviating urban traffic congestion. Especially in China's mega-cities such as Beijing and Shanghai, bicycles are becoming an important choice for intra-city travel, and form a complete urban public transport system by connecting with public transport and subway.

Urban bike greenway line selection mainly considers two key elements: First, the potential of the built-up area. According to existing research, the construction of urban greenway relies mainly on urban road corridors and various types of linear green space [19]. Second, bicycle usage needs and space model.
ow social life and day-to-day commuter links to reflect the social preferences of cycling. Therefore, this study attempts to combine spatial potential with big data analysis of social behavior to explore a new approach to greenway line selection.

2. Big data of shared bicycle

Big data has the following four characteristics: volume, variety, velocity, and value [20]. With the rapid development of information technology, the data show an explosive growth, and the use of big data has caught more interests of the public. In recent years, big data has been widely used in urban planning research, especially for the studies of social behavior. By interpreting big data properly, the daily rules of public social behavior shall be effectively reflected, which provides the basis for our decision-making concerning urban planning. Moreover, with the continuous accumulation of data, the persistent improvement of extraction, analysis and visual interpretation technologies will further enhance the accuracy of the analysis [21-23].

The explosive development of shared bicycles makes their big data have extensive research and application prospects. 《The 2017 China Share Cycling Market Research Report》 shows that the number of shared bicycle users is expected to reach 209 million in 2017. As of mid-March 2017, the total number of bicycle-sharing vehicles in the country has exceeded 4 million [24-25]. Relying on the shared bicycle positioning system, the data analysis of origins, destinations and riding routes can accurately and intuitively identify the resident's riding behavior and high-frequency use space, which brings a revolutionary breakthrough in the public participation in urban planning [26]. With the increasing amount of data, the accuracy of research results can be accordingly improved. Meanwhile, this is also the main service function of an urban greenway, since sharing bicycles primarily addresses the last kilometer of residents' public trips. Sharing Bicycles Big Data shows the high frequency areas, providing an prominent basis for planning a greenway network that is convenient for citizens to bike and optimize the layout of the urban land.

3. Bicycle Greenway Planning Technology Based on Sharing Bicycle Big Data

This paper utilizes big data of shared bike and potential value analysis tool to explore the needs of urban bicycle greenway and the route selection of urban bicycle greenway. This route selection method can bring urban space of high-frequency use into the greenway connecting patches to meet the daily needs of residents and maximize convenient service for residents' living, work-traveling.

Based on the least-cost path model, this paper selects the connection nodes and cost grid of urban bicycle greenway from the two aspects of sharing bicycle big data and the potential of green space utilization. The first step is the selection of the connecting nodes. Firstly, from the aspect of shared bicycle big data, through analyzing and interpreting the OD data of bicycle sharing, we can get the region of high bicycle usage frequency as the important
connection node of the greenway. Secondly, from the perspective of the potential of green space utilization, ArcGIS software was used to analyze the spatial distribution of existing urban green space. The entropy method is used to establish the evaluation index system, and the importance and carrying capacity of the green space are analyzed. The potential of landscape utilization of the green space node based on urban greenway is obtained. The two are overlaid to obtain suitability distribution of the greenway connecting nodes, and the green space connecting nodes are selected according to the regions’ rating of suitability.

In the second step, the social demand and the existing green space corridor are taken as the cost measure factors to generate the greenway alignment cost grid based on the cost path model. First, through the fitting of the riding track data and the current road space, the road and the linear space with high travel frequency of the bicycle in the research area are analyzed. Secondly, extract the linear green space distribution by visual interpretation of remote sensing to obtain the potential of the greenway connection. The two are overlaid to derive the greenway connectivity suitability map and generate a greenway alignment cost grid based on the cost path model.

Finally, the least-cost path is obtained by combining the connection node and cost grid, and the initial green line selection is delineated. From the perspective of commute demand, leisure experience and other aspects of the alignment to optimize the greenway selection, dividing it into two types of bicycle greenway system, comprehensive type and commuting type, thus complete the urban greenway selection for bicycles.

![Fig. 1. framework for bicycle greenway planning](image)
4. Urban Bicycle Green Route Selection Planning of Beijing Haidian District

4.1. Data Sources

This research data includes:

(1) The "secondary data" of Mobike shared bicycle usage records in Beijing, including the OD data and the fitted road data based on the trajectory data. The raw data come from Maui Technology Co., Ltd. from September 1, 2016 to September 30, 2016 One-month raw data of bicycle use, including cycling ID, starting time of bicycle use, starting point of riding and end of riding. This paper studies the use of motorcycle cycling big data, with the largest user base and stable and reliable positioning data. These data are based on users 'completely spontaneous cycling behavior, which can objectively reflect citizens' riding behavior characteristics and space requirements.

(2) Based on the remote sensing images of high score II in Haidian District, Beijing, the spatial distribution of green space in Haidian District was collected by visual interpretation, including the park green space, the protective green space and the urban road space.

4.2. Analysis and Selection of greenway connection node

The greenway connection node is an important part of the greenway route selection. It is a high-frequency destination for citizens to daily-travel or has valuable green space. From two aspects of the citizen bike travel high-frequency destination and green landscape service potential, we conduct a comprehensive analysis, select the connection node. Through the greenway these high frequency node space to connect, so as to meet the daily needs of commuters and commuting needs, which is in line with the service function of the urban bike greenway.

4.2.1 hotspots of shared bicycle use

Origin-Destination data, referred to OD data for short, includes location information that shares the starting and ending location of a cycling ride. Through the analysis of OD data, the distribution characteristics of the shared bicycle trip space are obtained, reflecting the spatial movement of residents using the shared bicycle trip and the main demand area of the urban shared bicycle [27]. The big data information includes the running records of all the shared bicycles in Beijing for one month. Each record contains the vehicle ID, On point, Off point, and so on. Through the analysis of visual data, we generate the distribution map of hotspots of shared bicycle use on weekdays and holidays (Figure 2), and obtain the high frequency
spatial distribution of shared bicycle use.

In ArcGIS software, OD data of working day and OD data of weekend are overlaid, and the activity space and intensity characteristic of shared cycling are analyzed to determine the node space with high usage frequency. As shown, the color from blue to red, the more reddish area sharing bicycle the greater the use of density. The activity space and intensity characteristics of the shared bicycle OD data can more accurately reflect the spatial distribution characteristics of citizens’ travel, covering important office, residential and commercial functional areas and important transport hubs such as the subway stations and the bus stations.

The shared space for high frequency use of cycling in the study area mainly includes two major regions: one is Zhongguancun, Peking University and most of the east of it. As the center of Haidian District, it has important industrial R & D, office and commercial service functions, with the most densely populated and distributed colleges and universities. The second one is the surrounding areas of Shangdi, Xierqi and Zhongguancun Software Parks. Mainly for large residential and office space. Important nodes in the first area include Peking University and Zhongguancun area surrounded by Line 4 and Wanquanhe Road; a section of Chengfu Road near the exit of Peking University's East Gate Subway Station; a section of line 13 from Haidian Bridge to West Tucheng; a section of the North Third Ring Road. Important nodes in the second area include: Shangdi Subway Station, Xierqi Subway Station, and Sina Headquarters Building.

4.2.2. Green space node potential analysis

Select the existing park green as an important landscape service node for the greenway connection. The research uses the entropy method to make a comprehensive evaluation of the existing park green space, establishes the evaluation index system, and generates the evaluation level spatial distribution map. Evaluation index is divided into ecological value, landscape value and cultural value. Based on the principle of integrity and principle of authenticity, we used Expert Scoring and Public Participation to calculate score of parks, and we chose the entropy method to calculate the weight value of the value index [29-30] (Table 1).

Table 1. The cost values and weights assigned for the analysis of entropy method.

<table>
<thead>
<tr>
<th></th>
<th>ecological value</th>
<th>Landscape value</th>
<th>Cultural value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ej</td>
<td>0.98</td>
<td>0.98</td>
<td>0.99</td>
</tr>
<tr>
<td>dj</td>
<td>0.02</td>
<td>0.02</td>
<td>0.01</td>
</tr>
<tr>
<td>wj</td>
<td>0.30</td>
<td>0.44</td>
<td>0.26</td>
</tr>
</tbody>
</table>

Based on the weight of each index obtained, the greenway-based park green space evaluation score is calculated by weighted calculation (Appendix A).
Based on the above evaluation results, we link the score of each green space with the vector map of the spatial distribution of green space through the attribute table link in Arcgis, and re-classify the score of each green space to obtain ten levels. The green space-based park green space service value hierarchy map (Figure 3) is obtained.

![Fig. 3. Distribution of the green space node value in study area](image)

4.2.3 Selection of greenway connection node

By overlaying the citizen's share of the spatial distribution of intensity levels of cycling destination and the potential spatial level distribution of green landscape nodes, the suitability distribution map of greenway connecting nodes is obtained (Figure 4).

![Fig. 4. The spatial distribution of greenway connection node suitability](image)

As is shown in the figure, the adaptability of greenway route connecting nodes shows a positive correlation with the overlay scores, while the areas with reddish to blue color and the more reddish areas indicate that the suitability of greenway connecting nodes is higher. By filtering out the highest level area, set 47 connection nodes (Figure 5).

![Fig. 5. Map of greenway connection node selection](image)
4.3. Analysis of greenways corridors suitability

4.3.1 Road Usage Analysis of Shared Bicycle Based on Trajectory Data

The trajectory data is the data information obtained by sampling the movement of the moving object. The shared cycling trajectory data can be matched to the real road network through the key preprocessing steps in the location service [30]. By fitting the cycling track of the shared bicycle to the existing road, the preference of the road selected by the bicycle travel can be obtained as the route selection guide of the urban bicycle. Through data visualization, a road map of the shared bicycle use is generated (Figure 6) to reflect the distribution of high-frequency road used by the shared bicycle.

Fig. 6. density distributions of shared bicycle using road

The frequency of shared bicycles’ using varies on different roads, and even varies on different areas on one road. The using ratio of road space near major residential, commercial and office areas is noticeably higher. The frequency of use around the metro stations also increased significantly, showing a tendency to radiate outward from the metro stations. To a certain extent, it tells that shared bicycles is better suited to solve the "last kilometer" problem of residents traveling, which is in line with the main service functions of the urban bicycle greenway.

4.3.2. Green space corridor utilization potential analysis

The linear green space is an important bearing space for the connection of greenways, and is also an important green corridor in the city. The spatial distribution of the linear green space in the study area is identified through visual interpretation through remote sensing, and a spatial distribution map of the space potential of the green space corridor is generated. (Figure 7).

Fig. 7. Distribution of the current linear green space in study area

4.3.3. Greenway corridor suitability analysis

The overlay analysis of the distribution characteristics of road intensity connected to citizens' bicycle trips and the green space utilization potential of the greenway was used to obtain the suitability map of green line selection (Figure 8). Based on the social demand and the existing green space corridors as the cost metrics, the green line selection costing grid based on the cost path
model is generated to establish the least-cost path model for path selection.

Fig. 8. The density maps reflect potential utilisation of greenway corridors

4.4. Urban Bicycle Greenway line selection

4.4.1 Create least-cost path

The “cost path” tool in GIS is used to identify the 47 important connecting nodes of greenway as the starting and ending points. Through cost-weighted distance functions that are generated by use frequency of road intensity connected to citizens’ bicycle trips and the green space utilization potential of the green space corridors, the minimum cost path between the corresponding connecting nodes is obtained (Figure 9).

Fig. 9. Create least-cost path

4.4.2 Initial line selection of the greenway system

Based on the analysis of the minimum cost path of greenways obtained through the analysis of big data combined with ArcGIS, a coherent, multi-functional and vibrant green network is formed to maximize the satisfaction of citizens' commuting needs and guide healthy travel modes. An initial selection line of the urban bicycle greenway in Haidian District is finally formed (Figure 10).
4.4.3 Greenway Selection Optimization

Considering the current status of land use conditions, leisure needs of residents, and different levels of existing roads, the initial greenway system was optimized and divided into two different levels of greenway systems, i.e., integrated greenway systems and commuter greenways. The system will eventually form the overall greenway route selection plan for Haidian District (Figure 11). While ensuring the continuity of the greenways, the two systems give different features to the greenways from the perspective of the existing natural environment, road system, landscape style, commuting needs, and walking experience.

1) The integrated greenway system
To build an integrated greenway based on the selection of green lanes that have large flow of bicycles, can connect existing high-quality park green spaces. The integrated greenway meets the needs of daily cycling and jogging. It also integrates existing fragmented green space, connects various important park green areas, and provides ecological service functions. It also provides recreational facilities in the greenway system to meet residents' daily fitness, entertainment, social and other needs. The overall integrated greenway system has formed a multifunctional system that integrates ecological landscape features, historical culture, social economy, and citizen commuting functions.

2) The commuter greenway system
We sort out the other lines that have a large flow of existing bicycles, mainly responsible for work and life commuting services, and plan commuter-type greenway systems. The system makes full use of high-frequency use of urban secondary roads and
branch roads to meet the current commuting needs, thereby improving residents’ bicycle travel experience and promoting daily low-carbon travel of urban residents, which alleviating the growing pressure of urban private motor vehicles.

5. Conclusions

This article analyzes the spatial distribution of cycling in Haidian District through shared bicycle big data, mapping the spatial characteristics of citizens’ cycling. At the same time, based on the characteristic that green space corridors are the main space carriers for the construction of urban greenways, the appropriate spatial distribution characteristics of routes plan for urban bicycles greenway are explored. The research uses big data to analyze social behaviors, and implement a scientific and precise greenway route selection plan from the bottom up, which provides all new approach for greenway route selection planning. In the context of urban renewal and smart development, this new method can be enlightening both theoretically and practically.

Materialising Microclimates: designing with data for thermal effect

Wendy Walls

The University of Melbourne, Melbourne, 3010, Australia

Abstract

The thermal condition of a landscape is a powerful determinant of social and ecological engagement with a site. Despite this, designing for thermal performance remains largely unexplored in landscape architecture. The last ten years have seen extensive scientific research in measuring and quantifying external thermal comfort, mapping urban heat islands and predicting new climatic conditions. Frequently this research concludes with recommendations for better links with urban and landscape design and planning. This paper will explore potential methods of data-driven design for outdoor thermal performance. Taking thermal sensation as an example of complex and irregular variables, the research draws on technological advancements as well as new theoretical influences, including big data and performative design, to inform landscape specific design methods. Illustrated with design work from masters’ studios run at the University of Melbourne, Australia, these investigations demonstrate emerging opportunities for designers to embed data in their practice. The project discussed uses designer led data capture and simulation of wind and temperature as creative methods for working with change through design. By addressing thermal sensation in design, this research demonstrates the value of maintaining habitable external space for people in cities. This is a necessary focus for landscape architecture as the challenges of climate change, including warming cities, become ever more apparent.

Keywords: Design method; environmental data; thermal comfort; thermal sensation; microclimate

1. Introduction

The experience of heat in a landscape greatly influences how a space can be used. Extremes of hot or cold weather significantly deter users from external space. As climate change continues to disrupt normal seasonal cycles, there is convincing evidence that temperature change, notably heat is a major challenge for urban environments [1]. Cities are especially vulnerable to warming where greater energy use and hard surface materials further contribute towards the urban heat island effect. Increasing urban temperatures diminish people’s engagement with external space and in extreme conditions can be dangerous to human health, causing heat stroke, sickness and death in vulnerable populations [2].

Strategic responses to the problem of urban warming range from energy reduction to broad scale tactics for reducing overall city temperatures [3]. However, plans for very large-scale temperature mitigation require an
extensive scale of intervention. For instance, a 2015 study of vegetation for cooling the city of Melbourne found that typical summer temperatures could be reduced up to 2°C ‘by replacing the Melbourne CBD with more vegetated suburbs and planted parklands’ [4]. Whilst this scale of response has the potential to significantly cool the city, it lacks viability as an implementable solution.

The scale of external urban site interventions is an important component in understanding how to manage outdoor thermal performance. Smaller scale interventions may have less impact on overall temperatures, but when positioned as an effect on human thermal sensation, smaller site design can offer strategic opportunities for supporting people in urban spaces. As Norton argues, ‘people’s experiences of the climate and high temperatures occur mostly at the micro-scale, in the layer of air between the ground and the top of roofs or trees’ [5].

Recent scientific research of microclimate conditions using real-time data provide important opportunities for better addressing thermal behaviors in urban sites. However, these often-detailed measurements must be understood alongside the more subjective qualities of thermal sensation. Designers hoping to use this information must address complex dynamic environmental phenomena alongside equally complex human experience.

2. Experiencing temperature

Addressing temperature at a human scale is a different ambition to reducing the temperature of an entire city. Human thermal sensation is influenced by the constantly changing interactions between air temperature, wind flow, radiated heat, solar exposure and humidity. Whilst these factors overlap with the conditions that produce ambient air temperature, such as material mass and wind, thermal sensation additionally deals with human physiology and subjective experience. Table one shows the relative environmental, physiological and psychological factors that produce human thermal sensation.

</table>
An individual’s experience of temperature depends on personal metabolism, activity, clothing values and subjective preference. For example, the thermal experience of someone jogging is different to someone who is stationary. Equally, someone who is more accustomed to the heat will have a lower tolerance for relatively cooler conditions. In *Architecture of the Well-Tempered Environment* Reyner Banham [6] gives the example of British troops in Aden, Yemen in the 1960’s who were accused of subtly torturing their Arab detainees by running the air conditioners at ‘full cool’. Banham points out that this torture could have simply been the British preference for coolness in the hot dry desert climate. Some of the earliest research on thermal sensation and heat stress was developed for the military as North American and European troops were sent into unfamiliar and often hot environments.

There are now over 100 different indices for measuring combinations of thermal sensation, thermal comfort and heat stress. Many of these simply express the interaction of air temperature with a secondary parameter such as wind, though the complexity of indices has increased in recent years [7, 8].

The majority of thermal sensation indices are designed for internal environments, where environmental factors can be tightly controlled to produce specific and ideal temperature ranges. Influencing the thermal experience of outdoor environments remains challenging due to the lack of absolute control over significant variables. Whilst internal environments are often maintained in consistent ‘steady state’ conditions, it is impossible to reproduce this consistency in outdoor spaces [9].

Many existing data driven thermal sensation metrics rely on assumptions of quantified control. However, in external sites, precise calculation does not necessarily lend itself to suitable design responses.

In external sites, design strategies can address relative temperature changes rather than reproducing internal static ideals. It is possible for design interventions to reduce thermal fluctuation or sudden change by moderating thermal transitions. Alternatively, design can aim to heighten experience, to enhance moments of difference, using contrast as a generator of experience. In each of these propositions, understanding the behaviour of site temperatures is essential. Site specific temperature data can provide real-time information about temperature fluctuation; including daily and seasonal change as well as critical environmental and material influences on thermal change.

3. Designing with Data

Landscape architecture has a long heritage of using data to inform design. From the development of Geographic Information Systems (GIS) at Harvard in the 1960’s, the collection and analysis of site data has been central to landscape design. However, use of data often relies on reductive methods. For instance, existing site conditions are drawn from single site surveys prior to the process of design where data is treated as static, representing one condition in one moment of time. The recent rise in accessible technologies, such as real-time environmental sensors offer new scope to these traditional methods.

As new data sources have become available, including satellite, GPS and local sensors, the quality of site data has changed to include unprecedented
Smart Cities

accuracy and detail. Emerging technologies have contributed to the information-based paradigm shift of high quality, rapidly producing data streams, known as big data.

The mass, detail and real-time speed of big data proposes alternative interrogations of temporality and dynamics [10]. Michalatos further suggests that big data changes traditional statistical analysis from means and averages to include both the ordinary and the exceptional [11]. Consequently, big data is producing methods for understanding the world that are not reliant on reductive processes but can incorporate updateable and changing information. For design, this suggests an expanded conceptualisation of data from analytics into a tool for research-based speculation.

Sensing environmental data further clarifies the value of big data for landscape architecture. Environmental big data includes meteorological, hydrological and atmospheric information. Sensors can record external phenomena including temperature, humidity, pressure, air speed, lux, barometric pressure, air particles, radiation and decibels. Beyond the collection of explicit data sets, this information can be made relative to one another. Accordingly, environmental systems can be interrogated for relative performative attributes, exposing complex dynamic processes and how they are subject to influential and relational change. Thermal sensation is an important example of an interactive physical system, where comparative and relational data can expose both behaviours and influences.

The last ten years has seen extensive scientific research in measuring and quantifying external thermal sensation, mapping urban heat islands and predicting new climatic conditions in different geographic regions. Whilst these studies have highlighted the importance of context specific information, design specific methods for climate responsive generative outcomes are rare [12]. Often this research concludes with recommendations for better links with urban and landscape design and planning or guidelines of singular tactics such as more trees and fewer hard surface materials. For instance the 2017 Australian Cooperative Research Centres (CRC) Guide to Urban Cooling Strategies offers a selection of interventions including shade, permeable paving and additional evaporative cooling mechanisms to be applied in different Australian cities [13].

These approaches offer evidence-based technologies for cooling urban environments; however, the generic application fails to address relationships between environmental variables. Further, there are no recommendations for working with specific qualities for human inhabitation or use of space. The nomination of guidelines leaves designers with little space to explore the possibilities of dynamic thermal spatial design.

The following project demonstrates a series of data driven methods used in developing a speculative design for a new ‘student precinct’ at the University of Melbourne, Australia. In this project, the use of data addresses creative methods for understanding site specific thermal behaviours and generating novel user based spatial outcomes for improved thermal sensation.

4. Student Precinct 2.0

The new student precinct at the University of Melbourne, Australia is the redevelopment of an existing campus plaza as shown in figure 1. The new external open space is conceived as the student heart of the campus [14]. Students will use the outdoor space for study, meetings and
gatherings throughout the year. The significance of the outdoor area for occupancy means that the climatic performance of the external space is fundamental to the success of the project.

The speculative design proposal ‘Student Precinct 2.0’ uses thermal sensation within the climatic context of Melbourne as a core design provocation. Melbourne is known for unpredictable and rapidly changing weather [16]. Whilst considered a temperate climate, an average Melbourne day can change from cool to uncomfortably hot over very short periods of time. The urban microclimate is influenced by differences in hot northerly wind and cooler southerly wind in addition to intense solar exposure. These highly changeable climatic qualities challenge single tactic design methods, subsequently, this project engages with the distinctive attributes of Melbourne’s unpredictable weather to generate a series of potential thermal experiences throughout cycles of days and seasons.

4.1 Designer led data capture

Initial design research used temperature data collected by the designers themselves to map existing on site thermal gradients. Designer led data capture provides quantified information of ambient air temperature variations as well as first-hand experience of relative thermal sensation. These comparative measures allow the designers to interrogate the site through temperature change and transitions, with an emphasis on opportunities for amplifying or modifying thermal experience for users.

Using iButton temperature sensors, the designers walked through the site following specific transects. The walks produced a thermal mapping of temperature change, moving into and out of buildings and across different landscape surfaces and conditions. The resulting axonometric map of the site shown in figure 2, provides the designers with a basis for observing user behaviour in conjunction with environmental phenomena such as sun, shade, wind and noise. As a site survey device, the focus on transitions highlights points of relative change in time and disparity between conditions rather than absolute measurements.
Fig. 2. Data driven atmospheric axonometric mapping of environmental site phenomena and user behavior on site.
As an empirical method, the combination of real-time data with on-site observation allows the designers to test their assumptions about thermal performance. For instance, the influence of shadow was assumed to reduce heat build-up over a day. After the mapping, the designers note for one heavily shaded area; ‘It is hotter even under the tree shadows by 5pm, consequently, natural shade in this instance does not equate to a cool environment. It does however, minimize the residual heat maintained by the ground material’[17]. Thus, the spatial differences between the sensor and the human body offer insights into the behaviors of heat across small areas, further allowing the designers to re-test their own hypothesis. Accordingly, data capture becomes an integrated part of the early design process as the designers work with existing conditions to understand drivers for new thermal relationships.

This example of designer led data capture does not offer a generative design response, however, the process of data capture and atmospheric mapping suggests rules for a design intervention. The relative combinations of wind, sun, shade and landscape materiality provide an onsite benchmark of relational effects for producing temperature difference. These physical rules are well established in thermal comfort science, however the diversity of conditions in external space give a contextual example of how people engage with different combinations of thermal difference, providing designers with a broader palette of opportunities. Using the knowledge gained from existing site processes, the designers engaged predictive methods of simulation to test potential design interventions.

4.2 Simulation as proof of concept.

Using the rules of thermal transitions generated by the on-site data capture, the designers simulated potential future atmospheric conditions. The digital simulations tested combinations of wind, solar exposure with new spatial form and materiality with the intention of highlighting preferable thermal performance at different points in the day. Here, the shift to generative design utilises data to show many possible atmospheric conditions. Rather than attempting to produce a single or ideal thermal state, the simulations operate as a proof of concept, revealing the greatest potential for creating a variety of desired effects over days and seasons [18].

To predict longer term climatic conditions including seasonal changes, the designers accessed open source data sets from the Australian Bureau of Meteorology. These larger data sets address some of the limitations of working with small site-specific data and providing a secondary source of validation. Using multiple data streams offers greater rigour as results become further verified through each data driven test and design exploration. Consequently, the accrual of data builds confidence in the results of simulations and models [19]. Furthermore, localised data becomes more ‘big data like’ as it produces inter-related outcomes which are responsive to the design investigation [20].

Simulating possible wind, solar exposure and seasonal temperatures generates potentially endless combinations of microclimate conditions. To control variability, the designers worked at critical moments during summer and winter. The simulations were overlain with expectations of user engagement with the site as an important refinement to atmospheric outcomes. Illustrated in figure
3 are simulations of foot traffic, dominant wind flows and heat at 9am and 4pm during summer and winter. These time points are important moments for student movement on site as people arrive and leave campus but also offer the greatest differences for understanding site microclimate variability.

Fig. 3. Winter and summer comparisons of temperature differences across site combined with dominant wind behaviours and likely pedestrian traffic flows.
The diagrams shown in figure 3 are a distillation of multiple digital simulations generated from computational fluid dynamic (CFD) modelling and grasshopper plug-ins. The combination of multiple simulation tools provides a comparative metric for the designers to reflect on potential new conditions and modify the design response. This non-linear design process utilising simulation as a predictive method has become more common as digital design practices facilitate the incorporation of environmental data with generative design [21]. Developments in accessible technology including sensors and digital simulations make the integration of performance criteria, such as thermal sensation into the early stages of design, more accessible.

Furthermore, designers can interrogate performance criteria of a site at a range of scales. For instance, a whole site can be conceived as a series of thermal transitions which simultaneously can be examined as distinct moments of user experience, understood through the immediate interactions of the body in space, within a moment of time.

The final design speculation for ‘Student Precinct 2.0’ illustrated in figure 4 is a fluid landscape highlighted with discrete microclimates designed to perform across a variety of seasonal conditions. The ‘arcade / under croft’ is a sheltered area of thermal mass for winter but also a deeply shaded refuge during the heat of summer. The space engages with the adjoining building to maximise the internal – external thermal boundaries by limiting the ‘hard edge’ of temperature change between inside and outside. Importantly, the range of microclimates across the site offers users diversity of experience and choice in the many possible conditions of Melbourne’s seasons. By engaging with thermal sensation as a relative condition within the variable Melbourne climate, the designers generated a nuanced site design featuring thermal performance as an attribute of inhabitation.

The methods for utilising data described here demonstrate creative applications of quantitative measurements. New sensor and simulation technologies offer designers unprecedented insight into site dynamics and behaviours; however, these findings also require a theoretical foundation that enables design as a creative discipline.
5. Conclusion

This research highlights critical questions for designers working with climate data. The reframing of thermal performance from an optimum static condition to moderating relative changes offers a design specific perspective on climate control. By addressing thermal sensation through design methods, this research aims to demonstrate the value of external space for people by offering more than generic guidelines to cooler cities. As the new challenges of climate change emerge, including rising temperatures, the role of landscape architecture and design is important in providing innovative and quality open spaces.
Acknowledgements

The author would like to thank Dr Jillian Walliss for her continued and generous support and guidance. In addition, Dr Joseph Barrins and Ravi Bessabava for their help with data capture and analysis. I thank The University of Melbourne and Student Precinct Project team for supporting the onsite data collection. I also wish to acknowledge the Landscape Architecture Masters students who took part in the 2017 ‘Designing for Heat in the Public Domain’ elective subject, with special thanks to Chengyue Jia, Chen Jiayi, Morgan Kennedy, Yanfei Wu and Daud Wijaya, whose work is discussed here.

Big Data Analysis for Cultural Ecosystem Services in Landscape Research

Lilan Jin, Kihwan Song, Jinhyung Chon

*Department of Environmental Science & Ecological Engineering, Korea University, 145 Anam-ro, Seongbuk-gu, Seoul 02841, South Korea

Abstract

Ecosystem services are the benefits of nature provided to human society. Among the ecosystem service categories defined by the Millennium Ecosystem Assessment, cultural ecosystem services (CES) relate most to the intangible nature of ecosystems. With the emergence of the 4th industrial revolution in recent years, the role of big data in capturing and providing insight into people's perceptions of the environment is increasing. Landscape architecture improves quality of life by creating, planning and designing a natural environment. Therefore, it is necessary to grasp the CES to people in parks through various data provided in real time through the use of big data in the field of landscape architecture. The aims of this study are to analyse the reviews of users of urban parks using big data analysis and to present the values of CES reflected in these reviews.

First, we used an open source program, R 3.4.4, to extract keywords related to CES. We read through reviews related to parks on the TripAdvisor website to extract keywords. We studied the period from May 2014 to December 2017 for Olympic Park, Seoul Forest, Han River Park and Namsan Park in Korea. Then we analysed the value of CES as determined in previous studies through a literature review and a comparison using CES keywords extracted during the previous step.

The result of this study: First, regarding park reviews, 350 reviews of Olympic Park, 191 of Seoul Forest, 771 of Han River Park, and 813 of Namsan Park were extracted from TripAdvisor. To reviewers of Olympic Park and Seoul Forest, recreation was the most important factor. Users of Han River Park and Namsan Park tend to have a greater interest in aesthetic services than recreation factors. However, CES should include a variety of inspirational and heritage services as well as recreation and aesthetics. These parks also need to make efforts to increase user awareness of a wider variety of CES. Second, this study also analysed urban park user reviews and compared it with the value of existing CES and the value of urban park CES. In CES research carried out between 2010 and 2015, rather than
assessing CES by measuring people's perceptions, studies focused on measuring areas, components, and facilities of the natural environment. However, the value of CES as determined in this study utilizes the concept of post occupancy evaluation, which is continuously accumulated and updated, and the data constructed by the intention of those who used the spaces examined. In the planning, design, and management of urban parks as well as other landscape spaces, results of this study will be present as an efficient way to update visitors' awareness immediately and continuously.

Keywords: Big data ; Ecosystem servies ; Social media

1. Introduction

Resource depletion and biodiversity reduction due to climate change and human environment activities have led to a need to evaluate environmental resources and their value [1], and consequently the concept of ecosystem services has emerged. Ecosystem services mean the benefits of nature to provide services to human life [2]. Ecosystem services grew out of the concept of “natural capital” in the 1970s. Ecosystem services concerns itself with human interaction with ecosystems. It expanded to include ideas related to the value of the natural environment and sustainable services in the marketplace in the fields of the environment and economy in the 1980s and ecology and economics in the 1990s [3]. Since then, the concept and research surrounding it have continued to evolve, from the Millennium Ecosystem Assessment (MEA) published by UNEP in 2005 to The Economics of Ecosystem and Biodiversity (TEEB) published in 2010 by the European Commission [4].

The most commonly defined concept of ecosystem services is the process of viewing ecosystem services providing benefits or deriving benefits from natural environment [5]. However, over time, ecosystem services have come to be recognized as not simply providing benefits but recognizing a collection of functions, services, and benefits [6]. There are four categories of ecosystem services.

This study focuses on cultural ecosystem services (CES) for human wellbeing under the concept of ecosystem service mentioned above. The MEA defines the concept of CES as “the nonmaterial benefits people obtain from ecosystems through spiritual enrichment, cognitive development, reflection, recreation, and aesthetic experience” [5]. CES are spoken of as part of cultural services [2], life-fulfilling functions [2], information functions [1], amenities and fulfillment [7], cultural and amenity services [8], socio-cultural fulfillment [9]. In a rapidly urbanizing world, securing long-term quality of life becomes a major challenge. In an industrialized society, CES are more important than other ecosystem services, such as provisioning, regulating, and supporting [10]. As a result, the demand for CES is expected to increase at a time when the 4th industrial revolution has arrived [11].

In 2005, the MEA clearly linked the field of biophysics with human well-being in a study of the consequences of ecosystem change. Of the major ecosystem service categories defined by MEA, CES are the most closely related to the intangible properties of ecosystems [5]. The provisioning service aspect can be measured in the form of food, water, etc. In the case of regulating service, it can be measured by the amount of carbon sequestration and the quality of the water. In the case of supporting service, it can be measured in the form of biodiversity and landscapes. However, CES has features that are...
determined by intangible values [12], and research has been carried out to evaluate them before [13]. According to the European Landscape Convention, the landscape has an important public interest role in the cultural, ecological, environmental, and social fields, which are key elements of individual and social well-being [14].

Human decisions and preferences play an important role in the formation of urban spaces [15]. Landscape architecture improves the quality of human life by planning, designing, by creating buildings and natural environment (www.asla.org). Ecosystem services are provided in the process, and landscape spaces such as urban parks are important in terms of providing CES to people. In the existing landscape architecture field an effort was made to determine values by short-term interview [16] or the questionnaire method [17] and to use the results for the design of the landscape space. With the advent of the 4th industrial revolution in recent years, a discussion has arisen about the utilization of big data, which aims to instantly grasp and reflect people's perceptions of the environment [18]. Big data analysis is used in various fields as a method of collecting and utilizing atypical and various data in real time, and this has not been done before. Therefore, it is necessity to grasp people’s perceptions of landscape spaces or CES by using a lot of data, provided in real time, from existing evaluation methods in the landscape architecture field. Big data analysis, which utilizes a lot of data provided by various people online, may be somewhat less feasible than existing research process and methods. Nevertheless, as diverse social data provided in real time accumulates, the feasibility of using it will be higher. Therefore, in the landscape area, it is necessity to recognize the data provided by various people along with the necessity of CES and utilize it as big data.

Therefore, the purpose of this study is to analyze the reviews of users of urban parks using big data analysis and to present the values of CES reflected in these reviews. First, in this study, opinions of users on four representative urban parks in South Korea were analyzed using text mining, a big data analysis technique. Second, the value of users according to the categories of CES and the improvement plan of landscape space through comparison with existing studies were suggested. The result of this study is expected to be a starting point for the design of future landscape spaces considering CES by continuously reflecting the needs of users.

2. Methods

First, for data extraction, this study used an online review website called TripAdvisor. This website is the largest travel community in the world, with approximately 439 million reviews by approximately 390 million individual visitors per month. The reviews cover 6.8 million tourist attractions, accommodations, and restaurants in a total of 49 countries [19]. These features make it ideal as a source from which to extract valid data regarding the evaluation of landscape spaces. In order to crawling CES data, this paper used the open source program named R 3.4.4. R is a good open source language for scientific calculations and has been
recognized as a reliable software tool for statistical modeling, but now it is also being used as a powerful tool for data mining and analytics. Of these, R Studio is most commonly used and can display editor, console, command, and package management on one screen and link it with the source code management system. In addition, it can support multiple platforms such as Linux, Mac, and Windows, and it has a built-in feature called R Markdown [20], which can easily combine code and documents and enable replicability analysis. This study used R Studio. The study data search covered the period from May 2014 to December 2017, when TripAdvisor entered the South Korean market. TripAdvisor selected four city parks (Olympic Park, Seoul Forest, Han River Park, and Namsan Park) in Seoul which showed at the top of page. Second, for cleaning extracted data and presenting term frequency, R Studio was used to extract the data from sentences identified at the first step according to the frequency of words used and to exclude irrelevant words.

From Olympic Park, the following words were derived: walk, bicycle, tree, family, show, mat, exercise, date, picnic, famous, rest, children, grass, rabbit, autumn, stadium etc (Fig 1). In reviews of Olympic Park, from the list of words, the word walk was the most frequently used (43 times), indicating that for user of this park, walking was the main interest. In addition, exercise, show, date, and other terms appeared in the reviews of Olympic Park, indicating that users were interested in the recreation of the CES. In addition, it was found that people think about the aspect of aesthetics in relation to Olympic Park, since they used words such as amenity, happiness, relaxation, quiet, and interest, though these words did not appear with the frequency of the word walk. In addition to recreation and aesthetic terms, which are most often seen in CES, the use of terms such as exhibition and history suggest that Olympic Park can provide diverse CES. Although it is currently recognized by people to be lower than other services, it is considered necessity to provide various CES.

3. Results and Discussion

3.1. Analysis of reviews by urban park users

At this stage, TripAdvisor crawls reviews from people from four city parks (Olympic Park, Seoul Forest, Han River Park, Namsan Park) in South Korea, refines the data, and analyzes the term frequency. In all, 350 reviews of Olympic Park, 191 reviews of Seoul Forest, 771 reviews of Han River Park, and 813 reviews of Namsan Park were extracted.
From Seoul Forest, the words walk, cherry blossom, date, deer, night view, bicycle, etc. were derived (Fig 2). As in the case of the Olympic Park, the most frequently used word used in reviews of Seoul Forest was walk (116 times), and the proportion of the words date and bicycle is high, indicating that users are most concerned about recreation. The most remarkable point is that the proportion of the mention of cherry blossoms in Seoul Forest.

This means that not only aesthetics but also inspiration of cherry blossom viewing by people in the spring season can provide various CES. In addition, the famous deer, the Han River, ponds, and various plants, animals and natural and environmental factors were mentioned in reviews of Seoul Forest, meaning that people find an impressive sense of beauty in the park.

From Han River Park, the words bicycle, walk, exercise, night view, etc. were derived (Fig 3). Unlike Olympic Park or Seoul Forest, the word bicycle is the most important word in reviews of Han River Park (16 times). Indicating that people are more aware of recreation there than other aspects. In addition, terms such as night view, rest, relaxation, and moonlight were found to be more important in the Han River Park than other CES. The terms such as night view and rainbow, which are often mentioned in reviews of Han River Park, show that a variety of CES are generated by providing inspiration to various people as well as aesthetic service. The park is directly adjacent to the Han River, and it can be seen that the terms swimming pool and canoe are used widely by reviewers.
Lastly, from reviews of Namsan Park, variables such as cable car, tower, walk, night view, autumn, and maple are derived (Fig 4). The cable car (mentioned 370 times), which occupies the largest portion of word usage in Namsan Park reviews, is considered to be the result of recognizing the interest of people who frequent the park, which is built in Namsan, in the center of Seoul. In addition to the cable car, the Namsan tower is recognized as being significant to users both in recreation and aesthetic aspects. In addition, in terms of aesthetic, maple and cherry blossom were mentioned frequently by users, and it was found that Namsan Park was the main place in terms of both active and aesthetic aspects.

Unlike other parks, Namsan Park has shown that the maple is more frequently mentioned than the cherry blossom. Maple is a keyword that does not appear in other parks, and this is because of the park’s unique maple landscape, which suggests that Namsan Park provides various aesthetic values.

In conclusion, to reviewers of Olympic Park and Seoul Forest recreation was the main factor. Among them, the high proportion of the term walk is due to the large size of the Seoul Forest and Olympic Park and the well-developed places for walking. However, the Olympic Park commemorates the opening of the Olympic Games in South Korea, and in the case of the Seoul Forest, it is a historic place that was a racecourse in the past. It can be concluded that CES need to be provided with a variety of inspiration and heritage services as well as recreation and aesthetics, and people's perceptions needs to be improved. In addition, Han River Park and Namsan Park have a higher proportion of aesthetic service interests than recreation factors. This can be seen as related to the fact that these city parks are adjacent to mountains and rivers. These parks also need to make efforts to make users aware of a wider variety of CES.

3.2. The value of CES and comparison with previous studies

This chapter analyzed the urban park user reviews and compared it with the value of existing CES and the value of urban park CES. CES have been slightly differentiated
in detail since the MEA in 2005, but they have been largely divided into learning and inspiration, physical and psychological experience, and spiritual.

Studies that have measured existing CES have been in place since 2010 and continue to be in place (Table 1 for CES categories and indicators) [21–32]. Studies of CES measurements from 2010 to 2015 dealt with the classifications of recreation, aesthetics, and inspiration. However, the method of measuring indicators of the CES that were provided differed from one researcher to another, and in most studies, CES were measured by focusing on recreation. Most of evaluation that is continuously accumulated and updated. The value of ecosystem services recognized in this study is not measured by refined data. However, it is the data constructed by the intention of those who used the spaces examined in this study (Table 2 for CES value of urban parks in the studies that measured recreation focused on activities (walking, jogging, etc.) and the number of users [33]. Aesthetic service was intended to be measured by asking people about abstract ideas through a questionnaire or by directly evaluating the natural environment [34]. In CES research carried out between 2010 and 2015, rather than assessing CES by measuring people's perceptions, studies focused on measuring areas, components, and facilities for the natural environment. However, the value of CES identified in this study is not a measure by evaluation of facilities or objects, but rather a concept of post occupancy (Seoul). Also, it can be said that such data can be update according to the perceptions and values of the people who use the city parks continuously, which makes it more valuable for our purposes that temporary utilization data.

Table 2. CES value of urban parks in Seoul

4. Conclusion

The purpose of this study is to analyze the post occupancy reviews of urban park users and to compare them with previous researches so as to find ways to improve CES in the landscape space continuously. First, based on the information of the TripAdvisor community, we selected four city parks in Seoul, South Korea (Olympic Park, Seoul Forest, Han River Park, Namsan Park) and analyzed reviews of park visitors. Second, we analyzed the value of CES by comparing the reviews with existing CES research. The results of this study will be presented as an efficient way to update awareness of visitors immediately and continuously in the planning, design, and management of urban parks as well as other landscape spaces. Future research will suggest various ways to design and manage a sustainable landscape space by systematizing the method of measuring the value of CES to urban parks as well as various landscape spaces based on the big data analysis used in this study.

Smart Investigation: Evaluation of Beijing Olympic Forest Park based on Online Big Data

Jiang Xin,*, Lin Qing,*, Wang Xiangrong,*, a

a Landscape Architecture School of Beijing Forestry University, No.35 Qinghua east road, Beijing 100083, China

Abstract

With the rapid development of the Internet and the application of big data technology, a series of concepts like urban informatics, social media and cloud sourcing have become more and more popular. As for a totally new investigating method, analysis with online big data is smarter than before to get visitors' evaluation after visiting city parks. By collecting, screening and making detailed analysis of these digitalised data, the study quantifies park effects and puts forward related suggestions to promote it, so as to provide new ideas for the sustainable development of city parks.

This paper takes Beijing Olympic Forest Park completed in 2008 when Beijing Olympic Games held as a case to make an investigation based on online comments data. Beijing Olympic Forest Park is one of the most popular parks in Beijing for recent years. Visitors leave a huge amount of comments data on the websites after their visiting, which provides basic support for analysis based on big data. In addition, there have been changes in many aspects in the past 10 years since 2008. It is also facing enormous challenges brought about by rapid urbanization and social development. Therefore, the case study on Beijing Olympic Forest Park is typical and representative even to other city parks.

The evaluation system is divided into two parts: comprehensive evaluation (including keyword analysis and sentiment analysis) and single-factor evaluation. In single-factor evaluation, the study tries to build an evaluation system from 4 indicators (landscape, facility, accessibility and management) based on 631 online comments from an authoritative website. By screening and scoring these data with information-grasping software, the study gets the results of evaluation.

The results show that Beijing Olympic Forest Park is overall good especially in landscape factor. But there are also much discontentment exposed by visitors, especially in green-space, landscape infrastructure, internal transportation and management level. According to the results of the investigation, the paper proposed corresponding improvement suggestions for Beijing Olympic Forest Park. Firstly it should integrate the surrounding resources and attach importance to construction of greenway and green network. Secondly, strengthen the maintenance of landscape infrastructures and transportation facilities. What more, it should tighten up the management and create comprehensive benefits through a variety of marketing methods.

This investigation is a totally new attempt to make online comments data applied to the evaluation of urban park planning and landscape design, it will assist improving parks better according to the analysis of extracting relevant information selectively.

Keywords: urban informatics; big data; landscape architecture; Beijing Olympic Forest Park; evaluation
1. Introduction

Online comment is a mode of third-party assessments with mobile clients using the mobile Internet, combined with the geographical position and personalized consumer demand, providing information of catering, shopping, leisure and life service areas anytime and anywhere, such as business information, consumer preferences and evaluation of consumption released by interactive platforms\(^1\). As the user's experience feedback, online comments data has been widely used in commercial industry, service industry, tourism and other industries after-use of the evaluation system. For example, Wu Hangdong (2015) used online comments data to evaluate the theatre usage, it obtained audience’s attention and satisfaction with the theatre\(^2\). Zhong Mingming (2016) made an evaluation of the usage of the Heaven Scenic village, from 5 aspects of tourism experience, tourism facilities, tourism services, tourism safety, and tourism environment, the problems existing in the development of scenic spots were analyzed\(^3\). Ding Yusi (2014) scheduled for analyzing evaluation of five-star hotel service. Comparing the evaluation content with the hotel service quality assessment index, the quality of five-star hotel service was analyzed\(^4\). But at present there are a lack of cases which apply online comments into the field of landscape evaluation after-use.

Compared with the traditional questionnaire survey, online comments data not only has the advantage of easy-getting, but also can reflect the visitors' preferences and satisfaction of the park better due to

online comments are filled out by visitors spontaneously. However, there are many disadvantages in this method. For example, visitors' comments are more subjective and have personal feelings to parks. So there may be some errors in data semantic analysis. Learning from past experience of evaluation methods which are presented, on the basis of using the software analysis and combining with artificial interpretation screening, this study tries to build a set of reasonable evaluation system to enhance the accuracy and objectivity of evaluation results.

Fig. 1. Aerial view of Olympic Forest Park

Fig. 2. Layout of Olympic Forest Park
The paper takes Beijing Olympic Forest Park as a case, which is regarded as the “green lung” of Beijing. It originates from the design concept of “Axis to Nature”[5]. The park covers an area of 680 hectares and is divided into the South Park, North Park and some other facility zones, providing leisure and recreation services for millions of surrounding residents. There has been a lot of researches on the Olympic Forest Park since it was built. Most of the researches are conducted from the planning and design of the park, plant collocation, water system planning, etc. Of course, there are also cases of after-use evaluation. For example, Zhao Jingyun (2014) evaluated the southern wetland of the Olympic Forest Park using post-evaluation methods (POE) through questionnaires and interviews[6]. Hao Xinhua (2016) analyzed the southern area of Olympic Forest Park with the help of multi-source data (microblogging sign-in POI data, Baidu map LBS data), getting the distribution of the park crowd and the degree of preference[7]. These researches have significant implications for this paper.

2. Methods

2.1. Evaluation system

The data of this study comes from the authoritative public comment website in China (http://www.dianping.com/). Until to March 2, 2018, a total of 631 visitors comments were collected. The evaluation system is divided into two parts: comprehensive evaluation and single-factor evaluation. The comprehensive evaluation includes keyword analysis and sentiment analysis. It tries to obtain visitors' general impressions and feelings about the park through semantic analysis software. At the same time, according to the analysis results and Baidu thermal diagram, generating visitors favorite map; Single-factor evaluation is mainly based on four indicators (landscapes, facilities, accessibility and management) for more detailed single analysis, the evaluation system is divided into three parts of data filtering, score assignment and calculation. First of all, in the data filtering step, because the visitors' comments on the park are often too subjective, the description of the problem is often mixed with personal emotions, so the invalid information needs to be eliminated first. Secondly, selecting comments on specific assessment factors of a keyword index by using information software. Then according to all valid comments on detailed semantic analysis, corresponding scores are given according to the degree of satisfaction of the reflection (1 point: not satisfied, 3 points: general, 5 points: satisfied). Finally, it will get a score of certain evaluation factor according to the calculation of the average.
2.2 Single-factor evaluation

In the single-factor evaluation system, the specific evaluation indicators need to be determined first. The online comments data obtained on the Internet is published online by visitors in the form of words or pictures, which reflects the perception and evaluation of the visitors after the visiting. Through the preliminary screening and making analysis of these data, combining with suggestions of professional landscape architecture experts, the study divides the evaluation factor into 4 categories (B1 - B4), and 11 detailed evaluation indicators (C1 - C11).

The study can preliminary calculate the comprehensive score of the Olympic Forest Park by making a weighted summation of all factors.

The frequency of different indicators in the comments can represent the importance of an evaluation indicator to visitors. By this way, the study gets the weight of every factor in the figure, the data indicates that plant, water, public service facility, infrastructure maintenance and internal transportation which have a high weight are the most concerned indicators to visitors.

3. Results

3.1. Comprehensive evaluation results

The figure 4 shows the word frequency distribution status of the Olympic Forest Park generated by the word frequency analysis software. It can be seen that most of the words show the satisfaction and praise of visitors such as “good”, “suitable”, and “great”. Among the words related to landscape and green space, “forest”, “sunflower”, “wetland”, “cosmos” and “ginkgo” appear most frequently, indicating that the forest landscape can represent the general landscape style of the park, while the plants with ornamental characteristics such as flowers and autumn leaves are deeply loved by visitors; Among the words related to activities, “running”, “exercise”, “photograph”, “fitness” and “tent” show that

Tab. 1. Single-factor evaluation indicator & weight
the activities in the park mainly consist of physical exercise, especially running. It benefits from the wide and comfortable ring runway set in the Olympic Forest Park; In terms of words about places and things, “south gate” and “subway” indicate that the south gate of the park is the most concentrated area for visitors, and the convenient subway is one of the most commonly used transportation facilities. “Weather” and “air” indicate that the air quality in the park is significantly better than the surrounding area, benefiting from the various types of vegetation planted in the park.

In addition, combined with the Baidu thermal diagram, the paper draws a map showing degree of visitors' affection to the Olympic Forest Park. The figure 5 shows that visitors in the southern part of the park are significantly more than those in the northern area; the entrances and exits of the park are crowded, particularly in the south gate area; the ring runway around the park is significantly more crowded than the inner area; the lawn area, the lake and wetland area, and the flower field area are more attractive than the mountain forest area. Obviously, the densely populated areas are also the visitors' favorite activity areas.
The figures 6-8 reflect how positive or negative the visitors' evaluation is through the sentiment analysis software. The score is divided into half by 0.5 points, positive comments are above 0.5 points, and negative comments are below 0.5 points. The result shows that 77.51% of the comments are positive, 22.49% are negative, and the average score of comments is 0.52 points, which means that the overall comments are positive.

In perspective of the time dimension, from 2013 to 2018, both of the evaluation score and quantity assumes a gradual growth trend, especially during the period from October to December 2017. At that time, the park was hosting the Cosmos Flower Show. And during the autumn, the Ginkgo biloba was turned yellow, so the beautiful plant landscape attracted a large number of visitors to take photos and visit, which resulted in blowouts of the comments number.

3.2. Single-factor evaluation results

In the single-factor evaluation, visitors' attitude to each factor can be revealed more clearly through quantitative analysis. The results in the table 2 shows that most indicators get 4+ such as C2 plant, C3 water, C4 ecology, C7 external transportation, C9 activity. There are also some aspects not well like C5 public service facility, C6 infrastructure maintenance, C8 internal transportation etc. Overall, the
A comprehensive score of the Olympic Forest Park is 4.01 points (5 points are the total points), which reveals that the park achieved success in general. The following will analyze the results from these four aspects specifically.

In terms of landscape factor, all four indicators are above 4 points, showing that the beautiful natural scenery of the Olympic Forest Park is attractive to visitors. Comparing with some small parks of the inner urban area, the Olympic Forest Park has different kinds of landscape types, including mountain, grassland, wetland, lake, etc. The wetlands in the northwest with pastoral scenery are deeply loved by people especially. Moreover, many birds and other wild animals are attracted by the natural environment here. After decades of development, a stable ecological chain has been formed, and the natural ecology has reached a balance. Every autumn, the golden leaves fallen everywhere in the park lawns become the symbolic landscape of the park.

During the past ten years since its completion, the Olympic Forest Park has become a green core in the north of Beijing, providing residents with a good place to relax and play. But there is also much discontentment exposed by visitors: In C1 green space indicator, more than 20% of visitors reflect that the green space is less connected to the surrounding area and some space is not well utilized. For example, due to the inconvenience of surrounding transportation and the backwardness of the surrounding area, the visitor number of the north park is obviously less than the south park, which makes the south park crowded during the holiday while the north park silent. Many of the sports venues around the park are abandoned after the games and are rarely used.

In terms of facility factor, visitors are not satisfied with the two indicators of C5 public service facility and C6 infrastructure maintenance. There are 35% of visitors complaining about lacking of landscape

Tab. 2. Single-factor evaluation results
infrastructure such as toilets and service rooms, due to the number of toilets are insufficient and the distance is too far since the beginning construction of the park. Many enquiry service facilities are not open at ordinary times. In addition, the large size of the park has caused the desolation of facilities in many remote locations. However, there are quite a few visitors who have expressed their positive attitude towards the park facilities and believe that it is much better than most of other parks in Beijing.

In terms of accessibility factor, visitors have the opposite attitude towards C7 external transportation and C8 internal transportation. It is very convenient to get the Olympic Forest Park because it has direct subway and public transportation after its completion. However, inside the park, external vehicles including bicycles are forbidden, causing inconvenience to many visitors. 42% of visitors reflect that the park forbids cycling which is inconvenient to riders. Since the park is too big to walk, bicycle riding is very necessary. But there is only charged bicycles and electric cars inside, ordinary bikes are not allowed in.

In terms of management factor, C9 activity gets a very high score, this is due to the rich variety of events organized by park managers such as the marathon, rainbow run, flower show, etc. Especially, running has become the special feature of the park, the surrounding residents like running in the park on the weekend or after work, the park sets up a comfortable red plastic runway which is very comfortable to runners. Besides, 28% of visitors complain about the low-level management in the park. The park lacks sufficient management, the landscape is often not maintained timely.

4. Suggestions

According to the conclusion of the investigation, the paper proposed corresponding improvement suggestions for Beijing Olympic Forest Park. First of all, the park should continue to maintain the existing good landscape, and promote the balance of the development between the north park and the south park, especially enhance the popularity of the north park. For instance, the north park countryside features can be enhanced through activities such as hosting land art exhibitions and cross-country experiential events. At the same time, the park should open some sports venues freely to meet the public sports needs. Secondly, the park should strengthen the maintenance of the infrastructure, increase the service inquiry facilities, it can add recreational facilities and children playgrounds appropriately. Thirdly, the park should set up dedicated bike lanes and

Fig. 9. Beautiful scenery, comfortable runway, colorful activities
multiple entrances to surrounding visitors. With the popularity of “sharing bike”, parks should be accessible to bicycles. Last but not the least, park managers need to change their ideas, improve the level of management and service, integrating into the market-oriented operation system continually[8].

In addition, parks should establish a set of evaluation system based on the evaluation of visitors through the regular survey or Internet survey like online comments data in the future, which would be benefit to find their own problems in time, and then deal with these problems pointedly. Forming a good interaction between visitors and parks will be a new direction for future park evaluation research.

5. Conclusions

It is a new attempt and exploration to evaluate the park based on online comments data. As a kind of big data, online comments data applied to the evaluation of urban planning and landscape design after use will help to realize the application value of big data to guide practice according to the analysis to extract relevant information selectively[9]. Of course, there are many deficiencies in this study. For example, the evaluation data from visitors is subjective sometimes and lacks of professionalism and objectivity. The selection process of the online comments data should be more scientific and rigorous, and the subjective interpretation may make the final calculation result in a certain error. But as a new way of park evaluation, its analysis process and the results have a certain innovation significance and reference value, can provide a new train of thought for subsequent park development.

Through the study of the online comments data evaluation of the Olympic Forest Park, it can be seen that visitors’ recognition of the park is still relatively high after many years. It is hoped that the park will establish a good interactive relationship with visitors, and the suggestions and evaluation of visitors will be applied to the improvement of the park.

Acknowledgments

This study was completed while the author was a master degree candidate in Beijing Forestry University, under the supervision of Professor Wang, Professor Lin, Professor Li and with the support of the National Natural Science Foundation Youth Science Foundation (31600577); Fundamental Research Funds for Central Universities (2015ZCQ-YL-02).

Denser, Greener, Smarter

Professor Thomas Schroefper
Professor and Founding Associate Head of Pillar, Architecture and Sustainable Design
Singapore University of Technology and Design
Singapore

Synopsis:
Contemporary architecture and urban design practice in Singapore and beyond is increasingly exploring the integration of green spaces in buildings, producing innovative building types for high-density urban environments that include public spaces, extensive sky terraces, sky bridges, vertical parks, roof gardens, and other ‘green’ components. Combinations of all these, often applied to mixes of residential, civic and commercial programmes, conjoin at times to produce ‘vertical cities’ in which the built sections become part of larger urban ecosystems such as parks, gardens and river networks. Density and sustainability here are not seen as contradictory, but rather as mutually dependent and synergistic.

The presentation discusses Dense and Green Building Typologies, a five-year research project at the Singapore-ETH Centre Future Cities Laboratory (SEC-FCL), in collaboration with the Singapore University of Technology and Design (SUTD). The research explores innovative dense and green buildings through a systematic study of their urban, architectural, environmental, social, urban and economic benefits in high-density cities. The presentation further introduces FCL’s larger High Density Mixed-Use Cities research ‘scenario’ that the project is part of. The scenario develops new integrated planning approaches, research methodologies and implementation processes to support higher population densities, higher standards of environmental sustainability and enhanced liveability.

The presentation provides an overview of the project by discussing aspects of five of its areas of research:

Urban Design and Architecture Benefits explores design strategies that mitigate the negative effects of high density.

Environmental Benefits studies the performance of dense and green building types in terms of thermal comfort, heat gain, urban heat island effects, air quality and noise pollution.

Social Benefits investigates dense and green building types in terms of use and appropriation as well as psychological comfort.

Economic Benefits examines the role of dense and green building types in land value appreciation.

Design Strategies integrates all work packages to develop innovative approaches to future high-density urban design and architecture.
Dense and Green Building Typologies is conducted by a multidisciplinary team of researchers. These work synergistically with other research teams at FCL and bring together expertise in urban planning and design, architecture, landscape architecture, building technology, social science, ecology and economics. Beyond FCL, the research team has established a number of important collaborations with Singapore Government agencies, including the Urban Redevelopment Authority, the Housing and Development Board, the Building and Construction Authority, the National Parks Board and the National Environment Agency, as well as clients and practitioners. International collaborations include the Swiss Federal Institute of Technology Zurich (ETHZ), the Politecnico di Milan and the University of New South Wales. The research findings of Dense and Green Building Typologies have been presented at international conferences and symposia and published in journals and books including by Springer Nature. The project is currently exhibited at the Venice Biennale 2018. A book titled Dense and Green Cities: Architecture as Urban Ecosystem is slated for publication by Birkhäuser in 2019.
Using Data Analytics and Geospatial Modelling to strengthen parks planning

Huang Zhongwen
Director
Digital planning Iap Department
Singapore

Synopsis:
To develop a City in the Garden, Singapore has adopted over the decades a continuous series of innovations in how we plan for green and blue spaces, as well as policies to encourage urban greenery. In recent years, URA with agencies have also been exploring the use of data analytics and GIS to further strengthen the way we plan for parks and greenery. The sharing will highlight ways in which it has been applied to enabled a more data-informed way to plan for parks and green spaces to create an even more livable environment and achieve better planning outcomes for people, while also optimizing the use of land and other resources.
Connecting Landscaping and Human Well Being
Design for Outdoor Comfort in tropical climates

Wolfgang Kessling
Partner and Principal
Transsolar
Germany

Synopsis:
The intensity of outdoor activities is one of the basic parameters which defines the urban social sustainability - the number of people and the time they spend outdoors in the streets, plaza, markets places, playgrounds, etc.. Outdoor activities are influenced by the availability of protected open spaces in the neighbourhood. High thermal comfort on an urban space will elevate urban sustainability, increase density of activity and social contacts, promote local business and reduce energy use and CO2 emissions. But first and foremost, design for outdoor comfort will improve microclimatic conditions for a healthy environment in cities.

In the context of rapidly growing cities designing performing landscapes gain more and more attraction in the professional community of landscape architects. Landscape architects play a role to overcome compromised critical infrastructure systems in the city. Designing for resilience, giving back space and function to ecological systems within the city, activating layers of green and blue infrastructure can counteract the impact of urban heat island effects and climate change.

Advanced Human-Biometeorological parameters support the understanding how climatic conditions and environmental parameters are perceived by people. Given a site and local climatic conditions, what is the combined impact of sun and wind, humidity and air temperature on people's outdoor comfort. What is the impact of dedicated strategies? What if conditions would be so and so? Tools and methodologies, developed to quickly link strategies to local climatic conditions, have proven to give powerful design advice. Modelling in detail the performance of landscape elements, location and extent of shading, trees, water features is useful to inform design decisions how to improve outdoor comfort considering the specifications of materials and elements of nature.

Also in humid tropical climates, elevated air speed can be combined with Dry Mist Technology to create human comfort also. Dry Mist technology targets basic human needs by improving micro climatic conditions to create a healthy and comfortable outdoor environment. The technology can be integrated into the design of public spaces, streetscapes, markets, playgrounds and parks and integrated with well-watered green areas to mitigate urban heat island effects on a local human scale.

In outdoor environments people have many adaptive choices to find thermal comfort. In indoor environments for some decades high comfort was only attributed to a very static mechanically controlled thermal environment. In tropical architecture increasingly, architects and landscape architects work beyond their disciplines to develop concepts of Breathing Architecture for buildings which offer an intense connection of indoor and outdoor spaces and embrace green and nature. Designing for adaptive comfort can reduce technical systems and energy demand by about 50% without sacrificing thermal delight in the tropics.

Examples of interventions include Gardens by the Bay (Singapore), MASDAR (Abu Dhabi), Heart of Doha (Doha), Installations of Dry Mist Technology (Singapore, Cayman, Milan) as well as the Floating University of BRAC (Bangladesh).
Living Digital in Smart Cities

Professor Poon King Wang
Director
Lee Kuan Yew Centre for Innovative Cities
Singapore

Synopsis:
Discussions on smart cities and innovation tend to focus on technological innovations and the ecosystems that support them. Just as important, but less discussed, are how cities need to innovate in their social and economic institutions of work, education and healthcare. These build human capabilities for people to live flourishing lives, but are now under stress from social, economic, political and technological disruption.

How we respond will determine whether our citizens and cities thrive or struggle. Drawing on the recently published book Living Digital 2040: Future of Work, Education and Healthcare, this presentation will share how taking a human, social and technological lens can help us develop practical policies and strategies to lift lives, often with the same technologies that are disrupting them. It will also share how we can draw strength from our human and collective capacity to innovate together and create better lives for each other.
Cities & Innovations, Smart Nation Track
How information technology and data analytics may provide insights into the design processes by better quantifying our understanding of the environment.

Adam White
Director
Davies White Ltd
United Kingdom

Synopsis:
The world we live in is changing – urban environments are under unprecedented pressure from urbanisation and increasing population. In the UK, more than eight out of ten people live in cities. Landscapes are increasingly being looked to, to help relieve pressures on key issues such as sustainability and health and wellbeing.

We can see this through the rise in the gross value added in the sector – it’s estimated that in 2016 the UK landscape profession contributed £948m in aGVA (average gross value added), a 15.9% increase since 2010. Technology is changing the way in which our profession works and has been playing an increasing role in helping design, deliver and manage these more resilient landscapes.

The landscape profession is leading the way in using new technology and innovation to create stronger connections between people, place and nature across the UK and beyond. Digital skills – including virtual, augmented and mixed reality, sourcing and use of spatial data and digital collaboration are transforming the way the profession designs, manages and plans environments. It also has the ability to transform how we use, communicate, educate and move through a landscape.

Adam White, President of the Landscape Institute, and himself an award winning Landscape Architect will be sharing case studies of leading examples of information technology and data analytics from across the landscape profession. Adam will discuss:
• Our profession is responding to new technology and its use
• Tools for better collaboration & community engagement
• Innovations in construction, 3D printing & design
• Collection and interpretation of landscape data
• Latest trends in visualization of landscape

Adam will also offer perspectives from his area of expertise linked to the importance of play in the landscape – health benefits and better appreciation of the environment. He will also offer the Landscape Institute’s latest thinking on equipping the profession with the skills needed for the future. Those working in landscape should be front and centre in this new world, given their appreciation and ability to consider and resolve environmental issues at both the large and small scale.
The Digitisation of Vegetation: From Solitary Trees to Whole Forests.

Dr. Ervine Lin
National Parks Board
Singapore

Synopsis:
During the adoption of smart technologies in cities, an integral component that makes cities liveable cannot be ignored – vegetation. Yet the two, vegetation and the digital world, are often segregated due to gaps in the technology or knowledge required to unify the two seemingly opposing domains. The risk of inadequately integrating vegetation into the digital realm is that it would ignored completely thus omitting any possible role vegetation has to play in urban planning, design or other forms of data analytics.

The current method of bridging this gap is to utilise Geographical Information Systems (GIS) to serve as a two dimensional (2D) record of vegetation. This occurs in the form of raster and vector maps which are derived from satellite imagery or ground surveys and provide information on the location, size, and density of this vegetation. These methods have proven to work and will continue to be further refined and developed but are inherently two dimensional in nature and are difficult to translate directly into a three dimensional (3D) space required when we start digitising the rest of the city in 3D.

One advancement that is helping to bridge this gap is the use of reality capture technology – specifically photogrammetry and laser scanning. While each of them have their own merits and limitations, it has provided a means to digitally record objects in the real world – such as vegetation – into a digital one thereby inverting the typical method of generating 3D models to represent reality. These technologies can allow us to digitise across multiple scales from a single seed pod up to a whole nation depending on which sensor is used.

However, capturing the data is only the first step and the captured 3D models are only useful as a visualisation tool if there is no other means to access that data. A much more challenging process is to be able to efficiently extract useful information from these scans that can either enrich existing databases or form the basis of further decision making processes for the respective stakeholders. This talk provides preliminary insights into how this can be done from the scale of a single tree to an entire forest and exposes both the limitations and potential uses of this technology.
Applications of Unmanned Aerial Vehicles Remote Sensing Technology in Landscape Architecture

Weijie Han, a Yilan Wang, a Wei Guo a*

Beijing Forestry University, No.35 Qinghua east road, Beijing 100083, China

Abstract

Accurately acquiring information of the site is crucial for landscape architects. Since satellite remote sensing and GIS (Geographic Information System) techniques have been widely used in landscape architecture for decades, various kinds of satellite images and open source data have become an important way for landscape architects to acquire site information. However, the limitations of traditional satellite-based remote sensing images such as low spatial resolution, long image update period and cloud cover often lead to the information obtained not accurate and comprehensive enough to meet the needs of landscape planning and design and research. UAV-based remote sensing technology provides a new method to acquire the site information, which is flexible, efficient and free from the limitation of time, space and resolution, and can provide the latest high-resolution image data of the site at any time. This study briefly introduces the classification of UAVs and the types of sensors they carried, then it divides the application of UAVs in landscape into two aspects: aerial photography and aerial photogrammetry. UAV aerial photogrammetry technology, such as orthophoto maps and oblique photography, are highlighted, then it explores the various uses of UAVs, carrying different types of sensors such as thermal imaging sensors, hyperspectral sensors and LiDAR in landscape planning and research. Finally, some potential hot applications of UAVs in the field of landscape architecture are discussed in the hope of enlightening the relevant research.

Keywords: UAV; remote sensing; aerial photography; aerial photogrammetry; landscape planning and research

1. Introduction

With the rapid development of information technology, the future world is becoming more and more digitized and informatized, and the use of digital technology is gradually deepening into all aspects of the landscape architecture industry. [1] As a part of the "Smart Cities", landscape architecture will eventually be incorporated into the entire intelligent system and become a "Smart Landscape." As the first step of landscape planning and design, the acquisition and analysis of site information is the basis for all subsequent
work. Accurate access to site information is crucial for landscape architects.

Remote sensing images and data are important carriers of site information. Since satellite remote sensing and GIS (Geographic Information System) technologies have been widely used in the landscape field for decades, various satellite images and open source data have become one of the most important ways for landscape architects to obtain on-site information. However, the early satellite remote sensing images were limited by the resolution and revisit period (for example, Landsat data spatial resolution 30m, access period 18d), it is difficult to meet the needs of small and medium-scale landscape design and research. In recent years, some large commercial companies have developed some new satellite sensors capable of acquiring high-resolution remote sensing image data within 10m, such as IKONOS, Quickbird, World View, Gaofen, etc. But these data cannot avoid cloud disturbances, especially in cloudy mountainous areas, and the acquisition cost is high.

UAVRS (UAV Remote Sensing) technology has the characteristics of high resolution, no period limitation, no influence by clouds, so it has great potential in both commercial and scientific applications. In recent years, UAVs have appeared in the civilian field frequently. Some small and light UAVs have the advantages of flexible takeoff and landing, low operating costs, and being less affected by the weather. They are therefore widely used in many fields. For the application of UAV remote sensing technology in various industries, the predecessors have carried out many reviews: such as Colomina et al. [2] reviewed the application of UAVs in surveying and mapping; Zhiming et al. [3] reviewed the application of UAVs in landscape ecology; Jiaojiao et al. [4] reviewed the application of UAVs in urban planning; Zhang et al. [5] reviewed the application of UAVs in agriculture. Although UAVRS technology has a certain application in landscape architecture, it is relatively less mature than the above industries. The author combines his own practical experience to introduce and summarize the application of UAV in landscape architecture.

2. UAVRSS (UAV Remote Sensing System)
UAVRSS is an aerial photogrammetry system that uses UAV as a platform, loads various sensors as a payload, and flies at a height of several kilometers (military up to 10km or more) to obtain remote sensing images, video, and other data. [6] At present, mature and complete civilian UAVSS is mainly composed of three parts: flight platform system, payload system, and ground station system. (Fig. 1)

2.1. Common UAV types

There are many types of civilian UAVs on the market and there is no uniform classification standard. They can be divided into multiple types in terms of power, usage, control method, structure, range, and aircraft weight. For example, according to the structure can be divided into fixed-wing UAVs, rotor UAVs, unmanned helicopters; according to the weight of the aircraft can be divided into micro, small, medium, large UAVs; according to the control mode can be divided into radio controlled UAVs, pre-programmed controlled UAVs, radio and programming mixed controlled UAV. [6] At present, small and micro-unmanned UAVs are most popular in the landscape industry. Small rotor UAVs are most commonly used with great distinctive feature of achieving target hovering and being suitable for small and medium-sized site information acquisition; Followed by is small fixed-wing UAVs, its flight range is generally within a few kilometers, faster than the rotor UAVs, longer flight time, often used for large-scale site information acquisition.

2.2. Common sensor types

The UAV is a flying platform, which can meet the needs of different tasks in various industries through combination with different types of cameras and sensors, and achieve very convenient and practical observation of the ground. Such as RGB digital cameras, small airborne LiDAR...

The application of UAVRS in landscape architecture can be roughly divided into two aspects: UAV aerial photography and UAV aerial photogrammetry. The UAV aerial photography is the simplest and most common application of UAVs. It just uses UAVs to take ordinary photos and videos without remote sensing image processing. The UAV aerial photogrammetry is more sophisticated than the aerial photography. It is essentially a surveying mission accomplished by UAVs, and it is mainly used to acquire centimeter-level ultra-high resolution orthophoto maps and establish 3D models in landscape architecture.

The UAV aerial photography only performs primary operations such as photographing and video recording. The products are relatively simple, only ordinary photos and videos. In terms of flying platforms, consumer-level rotor UAVs are mainly used, such as the DJI quadrotor small UAVs, Phantom series and Mavic series; In terms of sensors, only the most basic single-lens digital cameras can meet the needs; In terms of ground station, use the radio remote
control as a control platform, randomly formulating route flight.

3.1.1 Get Aerial View Photos

Currently, the most used application is to take aerial view photos and videos. The aerial view provides information that is not visible from the conventional perspective. Most of the traditional site surveys rely on hand-held cameras to record the site information with single photo, which only presents partial scenes. UAVs can be used to take aerial photographs and videos of the site, so that landscape architects can more comprehensively obtain site information for analysis. (Fig. 2) After project completed, photos and videos from aerial view are also very useful for project display and promotion. Many government projects use UAVs to film videos.

3.1.2 Construction Management Supervision

In the digital management of architecture or landscape engineering, UAVs play the role of project managers’ eyes in project supervision. Through UAV aerial photography, project progress information can be acquired intuitively, comprehensively, and in real time, which is an indispensable tool to realize building information management and intelligent building. (Fig. 3)

3.2 Application of UAV Aerial Photogrammetry in Landscape

UAV aerial photogrammetry is a true sense of UAVRS technology with more sophisticated application method, cause its relatively complicated operation and difficult to master, and involving knowledge and technologies of Surveying, Remote Sensing, GIS and other multi-disciplinary. In terms of flying platforms, due to the more diverse and complex sensors that are required to be deployed, higher requirements have been placed on the load and stability of the flying platform. Professional- level six-rotor UAVs, eight-rotor UAVs, fixed-wing UAVs and the likes are the most commonly used; In terms of sensors, multi-lens sensors are commonly used, such as five-lens digital cameras; In terms of ground station, aerial photogrammetry needs to completely cover the target area and requires a certain image overlap rate. Therefore, it is necessary to pre-program the route design so that UAVs can autonomously fly according to the instructions, or they can use flight control software such as Pix4Dcapture, Altizure and other auxiliary route design software.

3.2.1 DOM and Its Application in Landscape
The DOM (Digital Orthophoto Map) is a remote sensing image with orthographic projection properties. It is an image data generated by correcting, mosaicking, and cutting aerial photographs or remote sensing images with DEM (Digital Elevation Model), and it is a kind of map with both the geometric accuracy and image features. The resolution of DOM is generally between 1cm to 5cm, which is much higher than the resolution of satellite remote sensing images. Simply put, the DOM produced by UAV aerial photogrammetry can be regarded as an ultra-high-resolution satellite image. (Fig. 4) UAVs can produce DOMs with ordinary digital cameras. The principle is simple, firstly, using UAV to fly according to programmed routes and take photos, secondly, using the coordinate data of some control points and the POS (Position and Orientation System) data of the UAV for aerial triangulation to get DEM, finally, orthophoto correction and mosaic cutting were performed on the photos with DEM to obtain DOM image data.

Remote-sensing image data acquired by UAVs is automatically processed by specialized software to obtain DOM. Common UAV RS image rapid processing software includes: Bentley Context Capture (Smart 3D), Pix4Dmapper, ERDAS-LPS, Altizure, Datumate, Inpho, etc. The most commonly used software such as the Swiss Pix4D series includes Pix4Dcapture, Pix4Dmapper, and Pix4Dcloud. Pix4Dcapture can be downloaded to terminals such as mobile phones and tablets to connect UAVs for route planning; Pix4Dmapper can quickly analyze and process thousands of image data and automatically generate corresponding high-precision 2D image or 3D model data; [7] Pix4Dcloud can upload image data to the cloud, eliminating the user's concern about the lack of performance of the local computer.

After Pix4D processes the original
photographs taken by the UAV, the DEM, DSM (Digital Surface Model), and DOM can be generated. DEM data is widely used in the preliminary analysis of landscape planning and design, and its importance does not need to be described in detail. DSM is based on DEM and includes elevations such as ground buildings, bridges, and trees. It is mainly used in areas that require analysis of building height and trees cover. For example, the DSM captured by a UAV can record the changes in the amount of earthwork in different construction phases in real time, and guide the shaping of the terrain more precisely and economically. By overlaying the DEM at the construction site with the design DEM, the difference between the construction and the design can be more accurately reflected. For example, the green area in Figure 5 indicates that the construction elevation is in accordance with the design elevation; The bluish region indicates that the design elevation is lower, and the reddish region indicates that it is higher than the design elevation. The construction managers can appropriately adjust the construction according to this map to make it more in line with the design.

The biggest feature of the DOM is that it is no longer limited by the spatial resolution of traditional satellite remote sensing data, and its centimeter-level ultra-high resolution meets the needs of landscape architects for site analysis and research. Using DOM can even achieve a certain degree of recognition of plant species. Mora et al. [8] used the DOM images acquired by UAV to perform vegetation identification and mapping on the river impact fan area in Adventdalen. The results showed that at the species level, Gramineae, Salix and some bryophytes could not be distinguished, but it can be well separated from other land cover; Di Chen et al. [9] based on high-resolution DOM images taken by UAV to extract the location and crown of the trees, using the 3D tree-crown volume formula calculates the 3D green volume of different trees and achieves a quantitative analysis of 3D green volume. Ting Liang et al. [10] used UAV data to extract orthophotos, water quality parameters, physical and chemical indicators of water and land use types, and assessed the health of river ecosystems in the mainstream of the Liaoh river nature reserve.

3.2.2 UAV Oblique Photogrammetry and Its Application in Landscape

UAV oblique photogrammetry is currently an emerging aeronautical photogrammetry technology, which has changed the limitations of previous aerial photogrammetry can only be taken from the vertical direction, the essence of which is to carry multiple sensors on the same flying platform, (Fig. 6) and photographing the ground objects from multiple angles (vertical and oblique angles). [11] At present, the UAV oblique photogrammetry technology is mainly used for real-time 3D modeling in a landscape.
Establishing a real-time 3D model with high accuracy requires a multi-lens digital camera (single-lens cameras can also perform oblique photogrammetry with a low degree of accuracy through surround photography). The larger the number of lenses, the higher the accuracy of the model. Commonly seen in the market is a five-lens digital camera. As shown in Figure 7, the lens in the center can be shot vertically downwards to acquire DOM data, and the four-lens shots can be taken from four directions to acquire ground images at multiple angles. The UAV oblique photography takes a dedicated route. To establish a three-dimensional real model, the overlapping degree of the lateral direction needs to reach more than 50%, and the degree of heading overlap needs to reach more than 70%. The route planning can also be accomplished by software such as Pix4Dcapture.

The remote sensing image data processing for generating the real-time 3D model is also using software such as Smart 3D, Pix4Dmapper, etc. The principle is to perform aerial triangulation operation based on the control point coordinates and POS data, and then generate a point cloud data to build model. Take Smart 3D as an example.

This is an almost fully automatic 3D modeling software. You only need to prepare the multi-angle oblique photos, POS data and control point coordinates, and the software can automatically perform aerial triangulation calculation to generate dense point cloud data. Finally, it completes model mapping to generate a real-time 3D model. The 3D model made by oblique photogrammetry can measure the actual space distance of any two points, the actual surface area of any area and the actual volume of any object in the model. It is a truly digital sand table and can play an important role in landscape planning, design and research. (Fig. 8)

Jiazhong et al. [12] used the UAV oblique photogrammetry technology to establish a real-time 3D model of the design site through Smart 3D, and the model was...
used to perform sunshine analysis, visual line analysis, and profile analysis of the site simulation. Finally, the design is displayed on the basis of the real-time 3D model, which truly shows the effect of the design plan. Wei Wang et al. [13] used the UAV aerial photogrammetry to acquire the DOM and the real-world 3D model of the site, and according to these digital model simulations, the hydrological analysis was conducted to obtain the catchment area and use it as a basis for flood prevention landscape design. Qingping et al. [14] used UAV oblique photogrammetry technology and Ground LiDAR to establish a real-time 3D model of Suzhou Suiyuan, and studied the application of digital mapping technology in Chinese classical gardens.

3.2.3 Application of Other UAV Airborne Sensors in Landscape

In addition to visible light digital cameras, small airborne LiDAR, hyperspectral sensors, multi-spectral sensors, thermal imaging sensors are also useful in landscapes.

LiDAR can obtain ultra-high-density point cloud data and complete more accurate DEM, DSM, and 3D models than RGB digital camera photogrammetry. However, due to the high cost, there are fewer applications in the landscape industry. Wallace [15] used LiDAR-equipped UAV to obtain point cloud data and DSM from the study area, and processed point cloud data to obtain information such as tree position, canopy, and canopy traits in the study area. Hyperspectral sensors and multi-spectral sensors can collect invisible spectral information. These information can indirectly reflect some of the physiological functions of plants, and can be used to analyze and study the spatial patterns of garden plant physiological characteristics and pests and diseases. Gen sheng et al. [16] used visible light and near-infrared images acquired by UAVs to realize the identification of pines and trees by using weighted support vector data description and other multi-classification algorithms, and to study the spatial distribution pattern characteristics of pests and pine trees. Compared with traditional manual survey or aerial satellite image recognition, it has the advantages of low cost and high operability. The thermal imaging sensors can obtain the surface temperature map. Nishar et al. [17] tried to use UAVs equipped with thermal imaging sensor and RGB digital camera to obtain image information and thermal information for monitoring the surface temperature of the environment. Zarco-Tejada et al. [18] used the thermal imaging camera and hyperspectral camera mounted on the UAV to monitor the citrus orchard and obtained the crown temperature, the optical index of leaves and the chlorophyll fluorescence index, also made correlation analysis combined with data of the leaf stomatal conductance, moisture, etc. Finally, these physiological characteristics data were reflected in the spatial temperature map.

4. Conclusions

UAVs can be equipped with a variety of sensors, so it is possible to obtain low-altitude aerial remote sensing data of various types, high timeliness, high space, and high resolution, especially numerous aerial orthophotos, radar images, and hyperspectral image data. However, these aerial images of UAV have problems such as large data volume, high degree of overlap, large directional variation, and influence of terrain and UAV flight stance, which brings great challenges to data processing and interpretation of UAV remote sensing images. However, these will inevitably
promote rapid development of UAV remote sensing data processing, interpretation and analysis.

At present, the sensors carried by UAVs are mainly RGB digital cameras in the landscape industry, while the use of other types of sensors is less, bringing great potentials. For example, UAVs equipped with multiple sensors can be widely used in urban landscape unit extraction, urban heat island effect monitoring, urban microclimate measurement, city pattern change and landscape evaluation. The use of UAVs in landscape architecture started relatively late, and overall it is still at a relatively elementary stage of application. However, with the progress of digitalization and the construction of “smart cities”, the application of UAV remote sensing technology in landscape will have more possibilities.

Abstract

Ian McHarg introduced the polygon overlay operation to landscape planning in Design with Nature (1969). Since then, combining spatial information geographically with overlaid composite maps has become an essential method for multidisciplinary analysis in spatial planning and design. Recently, with the rapid development of computer technology applied to them, Geodesign tools are considered as promising support for more ecological landscape planning and design, especially in data-rich environments such as America. This Paper uses Hutchinson Island in Savannah, Georgia, the USA as a research context to illustrate how the use of Geodesign tools in landscape planning and urban design could support decision-making for ecologically compatible solutions, mainly from following three perspectives: 1. Application of Geographic Information System (GIS) to hazard mapping helps to visualize the affected areas of flooding and surge due to climate change; 2. GIS and related visual media enable a better understanding of Savannah’s world-renown historic urban fabric for the future urban development; 3. Analyses using Geodesign tools help urban development foster solutions to or otherwise solve environmental problems that will come with urban expansion including SHEP (the Savannah Harbor Expansion Project).

Keywords: Geodesign; Spatial Planning; Visualization

1. Supported by Guangdong Natural Science Foundation Project (Grant No.2015A030310356), China.
1. Introduction

In 1969, Design with Nature by Ian McHarg was published and gained an excellent reputation for the ecological view it promoted in the design profession. Based on McHarg’s cross-disciplinary practice and critical inheritance of the arguments from earlier environmentalism [1], Design with Nature contributed systematic ecological analysis and design principles to landscape planning and design. These principles initially assisted landscape architects in getting complex geographic information layered and combined for the development of ecologically compatible solutions, and its influence soon went beyond landscape field to all spatial planning and design professions [2]. McHarg’s theory which advocates multidisciplinary cooperation adopts and refines research methods from all related fields, creating a working framework to ensure the core value of ecological planning, “integration, synthesis and evaluation” [4].

The most renown “layer-cake” method in the book formed the basis of Geographic Information System and other Geodesign tools that derive from it. Correspondingly, Geodesign tools ensure the possibility to achieve the goal of “Designing with Nature”.

There are mainly two different views about the definition of Geodesign. Some are biased to seeing Geodesign just as a planning and design method that could couple the design proposals with impact simulations informed by geographic context1. Carl Steinitz of Harvard University regarded Geodesign as an operation method that intervenes surrounding geographic context for human’s desired uses by “changing geography with design”[5]. Others consider Geodesign as a technical framework that integrates different geographic information to provide real-time analysis and feedback for synergetic spatial design. “Geodesign brings geographic analysis into the design process in which initial sketches are instantly vetted for suitability”. This on-the-fly analysis equip the land use planners, civil engineers, transportation planners, and other involved practitioners with a tool to leverage geographic information in their design workflows”[6]. The latter opinion highlights the dynamic feedback between geographic analysis and design. Despite different perspectives, these two views both emphasize the crucial role of Geodesign in connecting spatial design with geographic information technology.

Urban design is the process of designing and shaping cities, towns and villages. It considers problems beyond individual buildings, dealing with groups of objects at a larger scale to make the urban environment more functional, exquisite and sustainable2. Mumford regarded urban design as an effort of combing art and science[7]. Indeed, urban design involves analysis from different professions shaping urban form to elaborate as richly and as coherently with the lived experience of the inhabitants[8]. In this regard, the advantage of Geodesign that enables cross-disciplinary collaboration

could be made the most of in urban design workflow.

This paper illustrates the contributions of Geodesign to urban design in a data-rich environment through the study of Hutchinson Island in Savannah, Georgia, USA. The study is based on the urban design studio instructed by associate professor Douglas Pardue at the College of Environment and Design, the University of Georgia and is further conducted using updated open public data.

2. Towards “Design with Nature”

2.1. Design with Nature

In Design with Nature, McHarg demonstrated that living environment in the context of industrialization was no longer as natural as it used to be, there is a conflict between the modern production methods and the natural environment. He insisted that instead of separating themselves from the natural world, humans must coordinate with it.

Virtually, in ancient times, human ancestors chose their settlements, most of which were adjacent to a river, according to their evaluation of the surrounding geographic environment. Since then, human learned to remake nature for subsistence resources and live in harmony with nature for sustainability. This is the initial version of the practice of designing with nature.

McHarg built his theory on ecological science and developed a set of design frameworks, drawing people’s attention back to the ecological wisdom that human has long used. Apart from just focusing on form, function and aesthetics, he advocated more notice to ecological security, living environment and the balance between development and nature.[9].

2.2. The Geodesign Framework

Geodesign innovated the tools and workflow of spatial planning and design. The most widely recognized framework for Geodesign was the “four groups of people”-“six models”-“three loops” one put forward by Carl Steinitz. (Fig. 1.)

Among “four groups of people”, people of the place mainly play two essential roles of presenting design intents and reviewing the impact of design proposals. Scientist group includes both natural and social scientists, such as geographers, ecologists, economists, sociologists. Design professionals refer to experts from subjects such as urban planning, urban design, landscape architecture and architecture. People of information technologies focus on dealing with information processing and application of GIS.

The “six models” clarify six main tasks of Geodesign. Specifically, in representation models, the context should be described from dimensions of both time and space. In the following process models, the structure and functional relationships of inter-elements should be observed. The evaluate models assess the current situation of the study area to help determine, in the fourth model (change model), what policies or actions need to be taken for the changes at which time or which place. Afterward, impacts that resulted from changes mentioned above would be simulated and given to people of the place for decision-making in the last two models (impact models and decision models). The “four
groups of people” have their own tasks accomplished in corresponding steps of “six models”.

The "three loops" is virtually the workflow of “six models”. Firstly, the top-down loop, from the representation model to the decision model, explains why the study should be conducted. Secondly, the bottom-up reverse loop, from the decision model to the representation model, demonstrates how to carry out this study. Finally, another top-down loop determines what, when and where to study. “Three loops” makes the dynamic feedbacks between geographic analysis and design possible. Upon the accomplishment of all three loops, a compatible proposal could be made [5].

Compared to McHarg’s theory that promotes multidisciplinary collaboration merely by using overlay operation, Steinitz’s framework is a decision-oriented and multi-solution design workflow that could propose and evaluate different scenarios for the particular context and the results are optimization outcomes. Although the framework is based on landscape design theory, it could be applied to all spatial planning and design professions for its technology-independence.

3. The Hutchinson Island(Savannah) Case

3.1. Background

The city of Savannah is located in Chatham County on the eastern coast of the State of Georgia. It used to be a strategic port city in the American Revolution and during the American Civil War. Today, the port of Savannah is one of the busiest containerization cargo ports in the world which, to a certain extent, contributes to Savannah's status as a regional industrial center1. Apart from the port, the historic district in Savannah enjoys a same excellent reputation. It attracts millions of tourists from all over the nation and the world.

Hutchinson Island lies in the middle of the Savannah River and is at a distance of about 800 feet (240 meters) across from historic Savannah. Until recently, most parts of the island were vacant land. The undergoing urban development proposed a major mixed-use project which contains the Westin Savannah Harbor Resort, the Savannah International Convention Center and some retail and residential properties.

There is a massive project, the Savannah Harbor Expansion Project (SHEP), on the Savannah River in the city administrated by the US Army. SHEP needs to regularly deepen the harbor and the associated shipping channel to allow larger, more efficient container vessels to use the East Coast’s second busiest container harbor with less weight and tidal restrictions 2. The project has been a significant part of the city’s development and has dramatic impacts on both economy and ecology of Savannah city and Hutchinson Island annually.

3.2. Methods

The study on the Hutchinson Island mainly followed the workflow of “six

1. en.wikipedia.org/wiki/Savannah_Georgia
2. www.sas.usace.army.mil
models” in Steinitz’s framework for Geodesign.

In the representation model, the primary focus was to build a database that could be operated and analyzed to help form a comprehensive description of the island. Data from online resources such as SAGIS (Savannah Area Geographic Information System) and site survey were gathered in terms of a wide range of aspects including ecology, geographic, economics and history.

In the process model, a series of mapping operations were conducted to examine the urban systems initially at regional and urban scales, then zooming in, to the island scale. By overlay (vector-based) and algebra (raster-based), data regarding different disciplines from the first model was integrated and illustrated on maps to demonstrate how different urban systems operate. (Fig. 2.)

Setting up indicators for assessments was the main focus of the evaluation model. The evaluation phase involved the “four groups of people”. Site visits enabled adequate interviews and communications with “people of the place” which helped understand design issues and objectives. Discussions with professionals from scientists and information technology experts defined the metrics, analysis methods and a set of common values. Conclusions for this stage could be summarized as follows:

1) Design objectives:
   a) To overcome the flooding problem on the island for appropriate urban development;
   b) To bring popularity and dense to Hutchinson Island;
   c) To find a wise way to deal with dredge from the SHEP.

2) Common values:
   a) New development on the island should worship the urban pattern of Savannah historic district;
   b) Dispersed SCAD (Savannah College of Art and Design) campus in downtown area fostering innovation industry is a valuable experience for urbanity;
   c) Natural process and ecological benefits should be maintained despite the urban expansion.

In the second half of Steinitz’s “six models”, the question of how the context could be altered in the change model virtually refers to “design” in the ordinary sense of the word. The main purpose of this model is to propose different scenarios of the site for tests in the impact model, tests are based on the relevant indicators and common values in the evaluation model. Finally, in the decision model optimization outcomes are supposed to be produced and presented.

In the Savannah case, some modification was made to change model and impact model according to the findings in the first three models. The study integrated evaluation process of the impact model into the change model. As mentioned above, the design intents and related constraints are mostly related to flooding and ecological conditions. Specifically, the general goal is to foster urban development (with the succession of old urban fabric) in flood-free areas on the island and protect the eco-environment at the same time.

Technically, simulation of ecological benefits on the island was classified with
Geodesign tools (mainly GIS) and was marked in different colors along with the affected area of flooding on the maps. These instrumental mappings were later used as a guide in the change model to help alter the context for a suitable medium between urban development and natural environment. In this case, the outputs fulfilled the evaluation measurements in the impact model and could be directly delivered for decision-making.

3.3. Analysis

In the integrated evaluation-change model, three analysis methods (based on Geodesign tools) were adopted as follows:

3.3.1 Hazard Mapping

Geodesign tools, such as GIS, have been employed in hydrological analyses for many years. Notably, the application of GIS to flood disaster management has drawn worldwide attention. The integration of hydrological data and spatial analysis in GIS makes it a powerful analytical tool for flood risk assessment, which could significantly improve the accuracy and efficiency of evaluation and prediction. From the 1950s, America began mapping the flood hazard national-widely, till the beginning of this century, the National Flood Insurance Program (NFIP) had made more than 90,000 flood hazard maps, covering about 19,000 communities, 389,000 square kilometers of the floodplain. Japan started the job in the year of 1995, after decades of effort, flood hazard maps of more than 180 rivers have been completed. England and Wales have published the 1:50000 scale flood hazard map by the United Kingdom Environment Agency and established a Web-GIS based flood management system on the official website[10].

Geographically, Savannah lies on the Savannah River, approximately 20 mi (32 km) upriver from the Atlantic Ocean. Because of its location in the Georgia Bight (the arc of the Atlantic coastline in Georgia and northern Florida) along with the tendency for hurricanes to recurve up the coast, Savannah is prone to flooding. Five canals and several pumping stations have been built to help reduce the effects. The most recent Hurricane Irma passing by the city in 2017, with no exception, brought heavy rainfall and flooded parts of the city. Specifically, low-land topography on Hutchinson Island makes it barely possible to survive through flood and surge.

According to the general geographic condition, the overarching task of urban design on Hutchinson Island is to recognize the potential hazard zone. This study took two main factors would affect the flooding risk on the island into account, topography and water system. With DEM data, the standard deviation of elevation could be calculated in GIS. A larger impact value was assigned to a certain point if the elevation was lower and the standard deviation of elevation was smaller, which means it is more likely to get flooded. The impact of the water system was represented by drainage density index. By integrated analysis of

1. Federal Emergency Management Agency
2. Georgiainfo.galileo.usg.edu
3. www.savannahnow.com
spatial and attribute data, the flood hazard map was produced. (Fig. 4.)

3.3.2 Landscape Ecological Security Pattern

In 1995, inspired by the traditional Chinese Game “Go”, Chinese scholar Kongjian Yu proposed the theory of landscape ecological security pattern. He illustrates that landscape elements in different forms of point, line and area play different roles in natural processes. The portion and location of these landscape forms are also significant to natural processes. The spatial pattern composed of different landscape elements in a certain proportion and location is called landscape ecological security pattern, which typically includes five parts: source, buffer, corridor, radiation and node. By identifying, establishing and protecting it, the natural process of the context could be efficiently maintained and the ecological benefits could be conserved [11].

The theory of landscape security pattern has been applied to guide landscape planning in numbers of cases, such as Yu KongJian’s practices of Magang Village in Guangdong and Xiangshan Ski Resort in Beijing. These two projects succeed in maintaining the natural process while providing more building land, which was of great meaning with limited availability of land in rapid urbanization [12]-[13].

Based on the research of ecological environment on Hutchinson Island, this study regarded the wetlands and lakes as essential ecological “sources”. Afterward, buffer zones were then identified and were divided into high, medium and low landscape security, according to the distance from the sources. The wider buffer zones are, the higher landscape ecological security would be achieved. Similarly, with integrated analysis method in GIS, the landscape ecological security was simulated and mapped. (Fig. 5.)

3.3.3 Space Syntax

The application of space syntax to street network analysis enables a comparatively scientific understanding of the urban fabric. It simulates and predicts the flow of people and traffic by calculating the relevant characteristic variables and extracts the axes of the street network for the analysis of road accessibility. [14].

Savannah’s world-renown historic fabric consists of twenty-four wards that extended from the riverfront under the supervision of James E. Oglethorpe. The unique fabric makes significant use of the squares to create series of rhythmically placed open space, giving a wonderful sense of space in a solidly built townscape[15]. Its vestiges could be found even in contemporary planning. Savannah East Riverfront Extension, the winning project of 2010 Honor Awards for Regional and Urban Design, traced the history of the city, seeking experience and wisdom from the past. It transformed the old urban fabric into urban development that meets new social needs[16]. (Fig. 6., Fig. 7.)

Under the assistance of GIS, a space syntax analysis on the street network of Savannah historic district was conducted in terms of accessibility and stability for a better understanding of the Oglethorpe’s urban fabric. The old fabric’s value was proved again from a scientific view. Thus, the study convinced the future urban development to evolve the old urban
development wisdom for today’s new needs on the island. (Fig. 8.)

3.3.4 Results

With the application of Geodesign tools, following urban design strategies for Hutchinson island were developed:

(1) Productive Dredging

The dredge from SHEP is now being deposited on the South Carolina side of Savannah River, which is costly and time demanding. This study proposed to use dredge from the SHEP to raise the elevation of some flooding parts of the island for a synergy of the harbor expansion and flood disaster management. Under the guidance of flood hazard map and landscape ecological security pattern, areas to be lifted up were selected among high eco-security and low flood risk zones.

(2) Urban Ecological Matrix

To enlarge ecological benefits and to higher the landscape security pattern. The new urban fabric was developed by connecting spotted squares of old urban fabric into corridors. Again, these green corridors were arranged along with the landscape ecological security pattern on the island. (Fig. 9.)

(3) SCAD Eco-Campus

The “Spot-Line-Area” developing mode of SCAD campus in downtown Savannah has been proved to be a success in bringing innovation industry along with urban vitality to the city. This study proposed a strategy to conserve and enhance the “source” elements of the landscape ecological security pattern on the island by building eco-campuses around them. Eco-campuses could enable development with low environmental impacts, which would help achieve a balance between ecological benefits and urban development. Plus, the SCAD’s potential in bringing urbanity to the isolated island would help the undergoing development get out of the struggle of attracting people from the other side of the river. (Fig. 10.)

4. Discussion

As illustrated in the Savannah case, Geodesign tools applied in urban design helped recognize values or risks scientifically by quantitative analysis. However, when it comes to issues that cannot be easily quantized such as urban vitality, urban aesthetics, and social fairness, conclusions were mainly made based on designers’ experience and intuition.

In other words, under the framework for Geodesign, it would not be a big challenge for practitioners to achieve an ENVIRONMENTALLY NATURAL solution because most of the environmental analyses are based on quantitative features. However, to foster design solutions that should meet HUMAN NATURE needs better, designers need to establish comprehensive analysis-evaluation systems by quantizing intangible features, which calls for further inter-disciplinary collaboration in the future.

Acknowledgments

Thanks are due to Associate Professor Douglas Pardue at the University of Georgia for his forward-looking vision and instruction in the study, and Mr. Wei Chen from AECOM for his generous help and suggestions.

Abstract

The advancement of data-driven design and construction process is reflected in the increasing importance of BIM in the whole AEC industry. In this context the landscape design professional practice is turning into a digitalized environment as well. The central element of such digital environment is an intelligent virtual model, which holds both the information of the existing conditions and the proposed project deliveries. The virtual model is built on various data sources, including satellite remote sensing, photogrammetry and LiDAR scanning. It contains also parametric 3d-models from different disciplines and their specialized software. Data of different sources reveals different features of the object. However, the lack of coordination and synthesize among data brings obstacles to operate an integrated modeling and analysis. The increased amount of data doesn’t necessarily bring efficient information. To adapt to the digitalized working context with the variety of data, it is important for landscape design practice to achieve an integrated information operation. Under such background, it turns to be important research topic to develop technological approaches that produce multi-source data fusion for landscape design process. In this paper, such approaches is realized with a workflow of data processing in a Landscape Information Modeling (LIM). The workflow defines the approaches to achieve multi-source data processing for a project with the regards of the scale of site, the purpose of the analysis, the stage of the project’s lifecycle. The outcome of the workflow is a 3D LIM model carrying the information that the project needs for analysis, design, documentation and performance analysis. The project of Jade Well Park in Pingtan, Fujian Province, China, serves as an empirical research case for this paper, in which a 3D LIM model is built with the fusion of various data sources. For the landscape design, the model provides information to support grading analysis, watershed analysis, wind protection performing analysis as well as the calculation of material quantity and design proposal visualization.

Keywords: Landscape Architecture, Landscape Design, Workflow, Landscape Information Modeling, Photogrammetry
1. Introduction

In the architecture engineering construction (AEC) industry, the advancement of data-driven design and construction process is reflected in the increasing importance of BIM (Building Information Model). In such context the landscape design professional practice is turning into a digitalized environment, as well. Digital design practice refers beside BIM or LIM (Landscape Information Modeling) also to algorithm based parametric modeling, simulation for comprehensive understanding of effects and performance of the design as well as for digital fabrication, for example 3D machine control systems for grading.\(^1\)

The central element of these forms of digital practice is an intelligent virtual model. This model holds the information of the existing conditions as well as the proposed design and project deliveries and planning documents as well as the data for machine control.

Such virtual model is built on various data sources. For the existing conditions and their analysis, data sources including that from satellite remote sensing, photogrammetry, LIDAR scanning are becoming common inputs to landscape design projects, besides traditionally used maps and survey drawings. Through the design process, various new data, the most of which is in form of parametric 3D-models from different disciplines and their specialized software, get accumulated in the model.

The increased amount of data doesn’t necessarily bring efficient information from which design process takes advantage. On one hand, data of different sources reveals different features and potentials of the site. On the other hand, it brings obstacles to operate an integrated modeling and analysis when the coordination and synthesize among the various data is inadequate. Only when the fusion of data is achieved in a proper way, can the design process be optimized with information input.

To adapt to the digitalized working context with the variety of data, it is important for landscape design practice to achieve an integrated information operation. Under such background, it turns out to be important research topic to develop technological approaches that produce multi-source data fusion for landscape design process.

2. Objectives

Data selecting principles, data processing approaches and the fusion of multi-sources data are discussed and studied in this paper. They are of the objective to enable landscape architecture studios and institutes to work with Landscape Information Modeling Workflow (LIM Workflow) in the digitalized working context.

In the increasingly digitalized working context, when data driven practice is rapidly developing in AEC industry, landscape architects have to face the tasks of information operation in daily work. If the technological approaches of information operation are not developed and applied in landscape architecture profession, landscape architects have to turn to engineers or experts from other professions to accomplish their own daily work. Therefore, it is of great significance for landscape architects to master tools such as BIM.

Under current circumstance, there are still obstacles for landscape architects to fully adopt BIM tools.\(^2\) But, when it is with proper organizational management and cooperation, a workflow of information modeling for landscape architecture can be achieved by using a combination of BIM
and GIS software[^3], which is known as LIM. Most of these software are accessible and familiar for common landscape architecture studios and institutes.

LIM workflow does not only empower the landscape architects to collaborate with different disciplines, but also allow the landscape designers to directly operate with information within the design process.[^4]

The core of the LIM workflow is an intelligent virtual model within which data of different sources are stored, processed, shared and computed.[^5] To optimize the workflow for landscape architecture practice, it is necessary to standardize the process of operating the workflow in terms of data selecting, processing and the fusion of data.

3. Methods

3.1. Workflow-orientated data sources selection

Data sources selection defines the data input and influence the data proceeding of the LIM workflow. To form a standard workflow that every participant in the design process is able to exchange information in a interoperable manner, the data sources is to be selected and formulated as the first step. The increased data and information input from the ongoing design process need be considered also as type of data sources. And it should be selected in order to keep the dynamics of the workflow.

From the practical point of view, the selection of the data source is not only a matter of technology but also that of legality and efficiency.

As the design basis of a project, the fundamental data of the site should be approved by the authority or the authorized agency. The additional data input should be accessible either through the open source channels or from the market with the reliable quality. The cost have to be considered. The conditions of hardware, software and the team’s capability influence the process of data processing and computing. It is necessary to count in these conditions when deciding the selection of the data sources. Therefore, the selection of the data source follows the principles of legality, reliability, accessibility, cost-controllability as well as computability.

With the above principles, the following data sources may be options for a landscape design project.

3.2. Standardization-regulated data process

The process how data from the source system are loaded in to the federated model is in Data warehousing commonly known as
ETL (Extract, Transform, Load) or ELT (Extract, Load, Transform). The transformation work in ETL takes place in a specialized engine, in ELT the transformation occurs in the target system. The Extract step covers the data extraction from the source system and makes it accessible for further processing. This can be initiated by the source system (push) or by destination system (pull) after an update notification.

In the Transformation stage, a series of rules or functions are applied to the extracted data in order to prepare it for loading into the end target. The data transformation that takes place usually involves various operations, such as filtering, encoding, deriving, de-duplicating, validating, joining and splitting data. An important function of transformation is the cleaning of data, which aims to pass only "proper" data to the target.

Plans, models and maps from different sources are often using different coordinate systems, therefore re-projection to an appropriate geographic coordinate system is an critical transformation in order to see elements in the context of landscape models.

The load phase process the data into the federated model, updating the model as well as archiving the previous model.

The following list gives an overview about major data sources of a landscape virtual model.

a. Satellite remote sensing data (DEM) and satellite map  
b. Topo-Map  
c. Surveys  
d. Photogrammetry model and LiDAR data  
e. Architecture and MEP Model  
f. Infrastructure model  
g. Planting plans  
h. Landscape improvement model  
i. Irrigation plan  
j. Landscape lighting plan

For each data source, the following processing methods are regulated as a standardization.

a. Re-projection from WGS84 to the national coordinate system for planning
b. Reorganizing drawing elements into layers based on their GIS-Code; Extracting height information (points, contours, break lines) for creating DEM (Digital Elevation Model) in a separated drawing; Extracting building footprints, putting them to right elevation, translating number of floors to building height; Extracting land use and vegetation information
c. Merging survey information with the information from Topo-Map
d. Geo-referencing the photogrammetry model by reference points from the Topo-Map; Extracting DEM from DSM (Digital Surface Model, bare ground surface) by filtering out objects; Merging with DEM from Topo-Map
e. Geo-referencing the building based on shared reference point with coordinates; Filtering to relevant parts of the model (outer hull, openings, entrances)
f. Pass through information, no transformation needed
g. Converting 2D to 3D elements, moving elements on to the graded surface; Deriving plan surface from Final surface and planting soil thickness
h. Converting models from legacy data formats to parametric models
i. Connecting with MEP model  
j. Converting 2D to 3D elements with elevation information and projecting photometric maps to surface

Through such a standardized data processing procedure, the following information can be harvested for the design process.
3.3. Federated-model-based data fusion

A central intelligent virtual model, known also as federated model is essential. The process of data input and multi-source data fusion is depending on the algorithm embedded in the modeling software. Generally, in the design process, the data fusion is computed on feature level and decision level. \[^6\]

The significance of the federated model is to provide a digital base that data of different sources can be input, stored, transformed, exchanged and distributed among participants and participating disciplines through the process of landscape design. In other word, data is converted to information within the federated model.

According to the variation of the category of projects, the model can be various. For the project that covers bigger area, Autodesk Infraworks model is a good choice to play the role of federated model. Because it has powerful capability to process GIS data and has the outstanding performance of real-time rendering, especially when the scene ranges across different scales. For the project that closely related to the architecture, Autodesk Navisworks works in advanced effects as the federated model, because of its sophisticated BIM features. For most of the landscape design project, Autodesk Civil3D model is a proper option to act as the federated model. The reason is that Civil 3D is powerful on dealing with terrain model, which is one of the most important elements for landscape architecture that every other element relates on. When operated in a data management server environment, Civil 3D can have even better performance as a federated model.

4. Results

4.1. LIM workflow for landscape design in the project Jade Well Park

The project of Jade Well Park in Pingtan, Fujian Province, China, serves as an empirical research case for this paper in which a 3D LIM model was created and managed in Autodesk Civil3D based on a terrain model (DEM, Digital Elevation Model) derived from the topographic map issued by the Ministry of Land and Resources of the PRC. (Fig. 1)

![Terrain model (DEM) derived from the topographic map](image)

In the first step the model was extended with data from open source DEM (GDTM30m), urban planning and infrastructure data. The DEM and the mapped satellite imagery was created in Autodesk Infraworks and projected in to Xi’an 80 coordinate system in which the
officially perimeter (redline) of the project was given.

As different analysis needed models in different scale and size, smaller areas with higher resolution closer to the site where nested in to the larger area and coarse resolution model.

For the process of determining the projects coordinate system and adding additional large scale DEM and satellite images with other projection we created a manual with step by step instruction.

The model also included existing and new planned infrastructure (roads) as well as land development information.

With this model we performed initial analysis of the site conditions for grading, watershed and microclimate (especially wind exposition) as well as analysis of the urban and ecological context of the project. It was also used to discuss initial design concepts by mapping hand drawings on to the surface, enhanced with simple masses for proposed buildings.

Additional survey and a photogrammetry model was carried out to update and detailing the model as the quarry operation was ongoing since the last update of the topographic map.

With the progress in the design detailed models where produced for landscape (grading, hardscape, softscape, retaining walls, stairs) with Autodesk Civil 3D and for the building with Autodesk Revit.

Integrating the design models with the existing site model and surrounding allowed analysis of design performance (wind protection, drainage) as well as the calculation of material quantity and design proposal visualization.

The virtual model also served the construction documentation and will allow digital stake out with GPS.

4.2. Photogrammetry enhanced dynamic data fusion

The model was built up on 200 photos taken on a site visit. These photos where processed to a Point Cloud. (Fig. 2)

This point cloud is then calibrated by well-known reference points (from the topographic map) to the right size and position inside Autodesk Civil 3D.

From this point cloud we extracted a DEM by filtering out buildings, structures, cars and other non-ground data). The DEM extracted from the photogrammetry improved our terrain model in critical design areas. By comparing it to the DEM build from the topographic map we could quantify the fills of loose material.

4.3. Information driven design solution

Landscape as well as architecture design was done with BIM tools as parametric models.

In the landscape design grading, paths and retaining walls are dynamically linked to each other and the existing surface. We are using our own plug-in for parametric staircases and dynamic blocks for planting design containing all relevant information of the plant (name, size, phenotype).

For most of the landscape design features no additional data transformation was needed as there was created with same
software that manage the federated model. Only the planting design data needed a transformation by projecting the blocks to the final graded surface and adding 3D representation to them. (Fig. 3)

The building model was extracted from Revit into a plain 3D-Autocad file, filtering out detail information and referenced in to the landscape model, vice versa the landscape model was referenced into the Revit model, making design changes for both design teams transparent and promptly.

We established a procedure for creating a shared base point in Autodesk Revit to ensure information transferred from there into Autodesk Civil 3D or vice versa ends up in the correct location. The ability to create a shared coordinate base point between Autodesk Civil 3D and Autodesk Revit is since version 2018 built directly into the software. In versions prior to 2018, this was available as a subscription add-on. (Fig. 4)

4.4. Performance analysis

Including the existing site condition, the design solution and the surrounding of the site allowed us to do several performance analyses: earthwork (cut/fill balance), storm water management (analysis of flow lines, catchment areas and run-off analysis for checking the swale as detention/infiltration systems) and performance of the wind sheltering. (Fig. 5, Fig 6)

The analysis for earthwork and drainage are performed directly within Autodesk Civil 3D. Our office standard includes templates for performing this analysis consistent and efficient.

For the wind sheltering performance the model was exported to Phoenics.
5. Conclusions

The data is not equal to the information. Data transforms to information only when it is processed to reveal the facts of the site, to evaluate the design proposals, and to support the decision making process.

This paper articulates an approach of multi-source data fusion by means of Landscape Information Modeling (LIM) workflow. It is based on the fundamental data. To one direction, it is integrated with satellite remote data and geographic information data to support the analysis to the site in a broader context. To the other direction, it includes data from photogrammetry, laser scanning, and additional surveys with a lot more details to support design decision making.

The LIM workflow is a dynamic process based on the federated model, in which data of various sources keep accumulating and computing. In accordance with the requirements of each specific design stage, and for each participating discipline the data is exchanged and distributed in different formats and at different levels of detail (LOD), which leads to various outcomes, such as topographical and ecological analysis, water catchment analysis, design proposal emerging, performance evaluating, visualization producing, construction documentation as well as the project’s integrating delivery.

Such a workflow was experimented in the project of Jade Well Park in Fujian Province, China. The workflow is not emphasizing on specific software. Instead, its focus is on efficient management of the data and organizational processes to provide useful information for and during the design process. It is important that the data processing is operated in a standardized way. Data processing manuals and operation instructions are necessary to guarantee the outcome in the expected quality, even the specific processing procedure is customized according to the varying project typologies.

Abstract

Landscape designs evolve from measurements taken of the site. Rather than to rely on datasets collected by government agencies or remote-sensing companies, it is becoming common practice for designers to personally gather the necessary information with the support of laser scanning devices. With point-cloud editing software it is now possible to sketch directly on the digital site and to develop a project referenced in its context. The workflow is not only time and cost effective, but allows to refine design criterions for a site-specific approach. The Rail Corridor in Singapore is taken as a case scenario and the workflow was applied during a joint workshop between the ETH Institute of Landscape Architecture in Zurich and the SUTD department of Architecture and Sustainable Design in Singapore. The workshop prescribed to work exclusively on the point-cloud medium and introduced the following questions for discussion: 1. The direct relation between site and landscape architectural design thinking. 2. Effectiveness of the point-cloud medium to communicate design intentions.

Keywords: digital design method; landscape architecture; physical modelling; terrestrial laser scanning; point-cloud

1. Introduction

Landscape designs evolve from measurements taken of the site. Rather than to rely on datasets collected by government agencies or remote-sensing companies, it is becoming common practice for designers to personally gather the necessary information with the support of laser scanning devices [1]. By strategically defining a set of scanning positions in the field, it is possible to compose a detailed point-cloud model that replicates with high fidelity the spatial configuration, allowing to articulate a landscape architectural intervention that relates extensively to site-specific conditions. The point-cloud model goes beyond its strong aesthetic, as each point corresponds to an exact coordinate in space and geo-locates every landscape feature, regardless of scale and detail. In the process of a landscape architectural design, gaining topological understanding is key and lays the foundation for taking design decisions [2]. Point-cloud editing software allows to recognize landscape features in the datasets and to sketch directly on the digital site, developing a project referenced in its context. With the ability to personally collect, append, add
detail or update site-specific data as the project progresses, the workflow with data directly taken from the field has the advantage to adapt to new conditions while being time and cost effective [3].

Architectural and landscape architectural design informed by point-cloud datasets have the potential to reform the approach, sensitivity and criterion for a site-specific design. The application of the laser-scanning technology in landscape architectural design opens the possibility to a new language for information and communication. The evolution in both academic and professional sectors may shift the design approach from a foremost planar approach of the site involving CAD drawings and mapping tools, to an augmented spatial representation of the reality. To support this research for design, the 24km-long Rail Corridor in Singapore is used as a case scenario. The implementation of fieldwork-based design could make an essential contribution to the development of urban landscapes and play a significant role in the long-term strategy of metropolises.

2. Methods

2.1. Terrestrial laser scanning in complex environment

Laser-scanned point-clouds are at present the most accurate virtual models to represent the spatial qualities contained in a landscape, urban or rural as it may be. Digital landscape models derived from this technology come within millimeters of reality in all three X, Y and Z axes. Each set of coordinates may hold additional information such as color, refraction, heat - depending on the scanning sensor used to record the material space. The unequivocal quality of the point-cloud model is to be an exact replication of the physical landscape, in which each object is a unique representation of its real counterpart.

Landscape Architects do not necessarily have a professional training in surveying, but a basic knowledge is sufficient to operate laser-scanning devices that are rapidly improving in ergonomy and portability. However, it is key to understand how to employ the instrument. Large sites can easily be covered in a few days of field work on flat unobstructed terrain, but in a dense urban landscape such as in Singapore, laser-scanning meets significant difficulties with a high number of objects occluding the laser beam and with a tropical vegetation difficult to penetrate. A variety of scanning modes can be exercised, each requiring a set of specific instruments and each resulting in different outcomes in term of precision, detailing and density of datasets (fig. 1). A first surveying mission was conducted with a small team of researchers from the Future Cities Laboratory.
employing a long-range laser scanner\textsuperscript{1} to scan 8 kilometers along the Rail Corridor in Singapore, from the Buona Vista MRT station to the Tanjong Pagar railway station at the southern end. For security reasons it was not possible to employ an unmanned aerial vehicle to fly over the dense urban environment and the aerial laser scanning was therefore simulated by scanning from the rooftop of HDB housing. The team individuated 30 buildings along the Rail Corridor that would give an appropriate wide-angle view towards the corridor and its context and would allow to assemble a complete model of the site.

The Rail Corridor evolves along a heterogeneous landscape, from dense urban areas in the Tanjong Pagar district to more vegetated areas after splitting with the AYE highway. Its former function as railway causes its edges to be segregated from adjacent areas by vegetation, infrastructure and topographical breaks. This situation results in an interruption that visually separates the interior of the corridor from the exterior. To cover both parts, the strategy was to set-up a high number of scanning positions along the corridor with a medium resolution of points in order to complement the void of scanning occlusions in other scans\textsuperscript{2}. The scanning angle also played a major role as the rays can best record the topography when coming from a high angle of incidence and when aligned with the corridor. The full operation succeeded in collecting more than 50 scanning positions from rooftops along the Rail Corridor.

2.2. Reconstruction of a navigable model

Assembling the individual point-clouds scans required a compute-intensive process before appearing into a final composite. The clouds contained minor amounts of stray points caused by reflective surfaces like glass or metal. A coarse cleaning was done manually to avoid a loss of true points from an automated filtering. Moving elements created little interference with the rest of the model and were kept as scanned, figuring as low noise from vehicles on roads and as duplicates from moving cranes in the harbor or on construction sites. The scanning conditions did not allow to employ registration targets and the separate scans were therefore assembled through a semi-automatic registration computed from overlapping landscape features.\textsuperscript{3}

The point-cloud dataset quickly revealed that general assumptions about the site were wrong. The integrated GPS and levelling sensors of the scanner are not precise enough to level the data in centimeter precision on the whole length of the model. The idea was to straighten the pitch and roll axis by using blind walls of high buildings, assumed to be vertical. A detailed analysis proved impossible to determine a shared Z axis from facades, for every building had a slight and visually unperceivable tilt, presumably caused by shifting terrain or construction

\begin{itemize}
  \item \textsuperscript{1} We employed the 3D terrestrial laser scanner VZ-1000 by Riegl with a measurement rate that reaches up to 122,000 points/sec at a radial range of 1400m, and a mounted DSLR camera to capture color information.
  \item \textsuperscript{2} The runtime of one scanning position was about 20 minutes, a compromise between time and resolution. Each scanning position had an average of 25 million points.
  \item \textsuperscript{3} All processing tasks were accomplished with the open-source software CloudCompare 2.8, 2017. The registration ensued from a manual alignment and a fine registration with the Iterative Closest Point (ICP) algorithm. At the end, a subsampling of 5cm was applied to avoid an unnecessary high resolution in areas of no particular interest.
\end{itemize}
imprecision. The final solution was to adjust the orientation of the data using an integration method with a 3-years-old geo-referenced LiDAR dataset [4].

The substantial difference between using point-cloud data in remote-sensing applications and in landscape architectural design is the qualitative appreciation of the space, rather than its quantitative evaluation. This fact implies new requirements in visualizing data for which navigation becomes more significant than mapping and partly explains the technological lag since visualization is more resource-intensive than analysis. To navigate the composed point-cloud of 350 million points, we implemented a recently developed web application that enables interaction with gigantic datasets [5]. The application allows to quickly develop an affinity with the laser-scanned environment and to gain a precise understanding of the urban landscape along the corridor. The application allows to instantly read features of the point-cloud, determining water flow directions by measuring the height difference in water channels and topography, to compare the height of buildings or to discover unique characteristics, like existing breezeways through vegetation or topographic traces from former infrastructure. Such visual analysis enables designers to take game-changing decisions early in the design process and to work with rich micro-topography, vegetation patterns and other existing landscape features.

Because of their particle structure, point-clouds are well adapted to segmentation in the form of sections, classifications or cut-out objects. This property allows to place sections in real time throughout the model and examine them separately, exposing the inner structure of the landscape where ground, plants, buildings can be recognized as distinct features (fig. 2).

2.3. Rapid manipulation of the site

A second surveying mission took place during a joint workshop week of two design research studios working on the shared objective of developing urban landscape typologies along the Rail Corridor that could mitigate the urban climate. The workshop started with a field exercise that consisted in familiarizing the students with the site and the procedure of laser-scanning. The goal was to densify the first dataset employing short range Terrestrial Laser Scanners in order to develop a detail design. Twenty new

---

4 Two design studios with bachelor and master students in architecture were launched at the beginning of 2018 at the Swiss Federal Institute of Technology in Zurich under the guidance of Prof. Christophe Girot and at the Singapore University of Technology and Design under the combined lead of Prof. Joshua Comaroff and Philipp Urech.

5 We used two laser scanners with a maximum range of 300m for the detail scanning: ScanStation P40 by Leica and Focus3D X330 by FARO.

---

Fig. 2. The point-cloud model helps to read the spatial configuration of a site. Orthographic projections in plan or section show that topographical and vegetation features are clearly recognizable along the Rail Corridor (arrows).
samples were recorded from the ground in three predetermined locations of interest with an increased resolution and with overlapping areas that allowed the fine registration. Three days of scanning and processing were sufficient for increasing the detail of the sites, each on an area of 500 x 500 square meters (fig. 3: top image).

The fourth day involved modeling with the point-cloud dataset and implementing a simple design concept within the urban context. The assignment consisted in using the software CloudCompare as a 3-dimensional sketching tool to extract and assemble landscape typologies and to reshape the landscape of the corridor in a local setting. The typological transfer allowed to quickly test and discuss variations by rearranging previously extracted landscape elements and by composing a new meaning. Reading the site through the scanning exercise and the resulting virtual models allowed the students to refer to site-specific findings that could be included into the manipulation of the landscape. The proposals had to include principles of cooling strategies such as ventilation, shading or new edge conditions in contact with green cooling areas.

3. Results

Laser-scanned data is commonly considered a “raw” source that needs to be filtered and translated in secondary forms, such as terrain models or elevation grids, before being manipulated by end users. The results presented at the closing of the workshop week included plans, sections and axonometric projections developed exclusively with point-cloud data and demonstrated that the raw medium is well suited to directly operate on the site in short time and with high specificity towards the existing situation. Representative qualities of point-clouds for landscape architecture have been proven to be efficient, especially for sections and elevations [6]. The medium was indeed highly efficient to explain before-and-after situations of the design concepts and to easily decompose them into a series of sections illustrating the intricate urban situation. The visual representation met difficulties where the point density was not controlled with care, resulting either in loose graphics with a low density of points or in clamped colorings on sections represented with an excessive depth. Another risk in visual communication is that point-clouds
may confuse the reader with unorganized information, when the project is not distinguishable from its context or shown from an ineffectual perspective. Successful presentations were able to choreograph views and projections that were communicating clearly their design intentions.

3.1. Further editing potential

Software solutions like CloudCompare are suited to manipulate point-clouds and to realize minor manual modifications, but are not adapted to develop large-scale projects for which modelling and cloning tools are necessary to represent the extensive construct of a landscape architectural design. The workshop was an experiment part of a design semester that addressed the Rail Corridor as a whole on a large scale. In subsequent steps, the 3D modelling was refined with a workflow that draws from the topological information retrieved from point-cloud datasets. The initial condition of the site is built by extracting, filtering and meshing the point-cloud in the specific locations where the intervention will take place. From there, designers manipulate all elements relevant to their project, reshaping the topography and defining planting schemes that confer to their intervention a spatial presence. Finally, the tailored design is reconnected to the unchanged context (fig. 4).

4. Conclusion

For any architectural, urban or landscape architectural project, the site plays a primordial role and must be understood with transparency. The point-cloud medium brings the site closer to the designer as the laser-scanned samples represent literally a cast of the reality that lays the foundations for a site-specific design. “Designing from the field” complements the thinking through physical modeling and brings the act of designing closer to the reality of the place.

By combining datasets collected with various laser-scanning procedures it becomes possible to address the high spatial complexity of the landscape at multiple scales within the same model. The datasets have the potential of refining the designer’s choice and of enhancing his sensibility in any kind of environment ranging from bare topography to dense vegetation or to highly urbanized land. The simple modelling approach experimented in the workshop can be transposed with the right tools to vast extents, amalgamating the rationale of the topography to the intelligence in the shape of the design. Landscape architectural design thinking will evolve accordingly, linking scientific and qualitative approaches in the same model.

The point-cloud medium is not only efficient as modelling input, but proves to be a valuable support for the site reading, during...
the design development and for communicating design intentions. The representation of landscape design is a consolidative part of the design process and the increasing sophistication of visualization tools opens opportunities for the designers’ creativity. In fact, visualizations of landscape architecture shall not only be an aesthetic and atmospheric composite, but need to work as a structural expression of the place, where the detailed foreground of the image relates to the entire landscape. In a traditional design process, the visualization is composed in a concluding effort to represent the final version of the design. The workability and the strong aesthetics of point-cloud models could shift the spatial appraisal of the design to an earlier stage and propose a faster feedback loop in which design decisions are being taken.

Intelligent landscapes: information modeling for a new generation of flood control strategies in São Paulo City, Brazil

Abstract

If landscape can be featured as more or less intelligent according to its capacity to respond to multipurpose and variable requirements, the ideal framework to enhance the intelligence of landscape is to acknowledge it as a soft system with complex, open organisms that can adapt to changing circumstances and work with the rhythms and pulses of human settlements, especially of large urban sites. This assumption meets in the concept of green infrastructure a novel approach. Through its focus on quantifiable phenomena and its internalization of new ecology principles of adaptation, resilience, and disturbance, green infrastructure possesses the potential to grapple with rapidly changing climate, resource scarcity, and shifting cultural values. This potential is the utter ability of adaptation, it is intelligence and it finds in today’s information modeling technology a promising field of research and practice that enables complex simulations of how proposed solutions respond to specific challenges. If we understand landscape as a technological soft system, it may be evaluated through mathematical and computational models as much as any built infrastructure. However, instead of rigidness and sterility, green infrastructure provides a living and adaptive support to urbanity with greater social and aesthetic values. This approach has been examined in the Jaguaré Creek Revitalization Project, a pilot plan for a tributary watershed that corresponds to 1/10 of the total 270km² drainage area of Pinheiros River, one of the two main watercourses crossing the Greater São Paulo. In addition to strategies for water quality improvement such as non-point source pollution mitigation, waste recycling and sewage collection and treatment, the Project addressed flood risk management by identifying priority areas for flood control through hydrological simulations of the watershed. Considering 100-year flood events and their consequences on runoff and river flow, the retention volumes have been determined for each inline or offline reservoir along the Jaguaré Creek. One of these facilities is presented in this paper as a prototype evaluated not only for its volume capacity but also for its performance as a water landscape and a stormwater Best Management Practice (BMP). To integrate these abilities, computer-aided parametric modeling, using software such as AutoCAD, Rhinoceros®, its algorithmic modeling plugin Grasshopper and a Computational Fluid Dynamics (CFD) plugin, offered new ways of investigating landscape performances and
experimenting design. This functionality allowed a greater freedom of design, which corresponds to the water landscapes of anastomosing rivers with changing and waving forms and variable depths adapted to the dynamics of different water flows, to slowness and to phytoremediation. In this research, the principles of information modeling and simulation have been examined in landscape design through international cooperation between the University of São Paulo and Cornell University, with the contribution of the Federal University of Ceará. Applied to a case study in the City of São Paulo, this work points towards an innovative and prospective tool to deal with issues of urban water management and represent a practical reflection to advance in the experimental field of LIM – Landscape Information Modeling.

---

**Introduction**

*Intelligence is the ability to adapt to change.* This quote is not properly sourced, but it has been widely referenced to the brilliant theoretical physicist and cosmologist Stephen Hawking. In this metaphysical definition, intelligence has enabled human civilization to evolve. And if we consider landscape as the most complete artifact of mankind [1], with current challenges of climate change, water collapse and humanity crises, adaptation is a key tenet for its planning and design.

Although landscape is not a sentient being by itself, there has always been a demand for it to behave as an entity with responsiveness and adaptability, which are direct attributes of intelligence. Thus, landscape can be featured as more or less intelligent according to its capacity to respond to multipurpose and variable requirements. This theory assumes that the ideal framework to enhance the intelligence of landscape is to acknowledge it as a soft system with complex, open organisms that can adapt to changing circumstances and work with the rhythms and pulses of human settlements, especially of large urban sites [2].

This assumption meets in the concept of green infrastructure a novel approach. Through its focus on quantifiable phenomena and its internalization of new ecology principles of adaptation, resilience, and disturbance, green infrastructure possesses the potential to grapple with rapidly changing climate, resource scarcity, and shifting cultural values [2]. This potential is the utter ability of adaptation, it is intelligence and it finds in today’s information modeling technology a promising field of research and practice that enables complex simulations of how proposed solutions respond to specific challenges, considering time, phasing and entropy [3]. If we understand landscape as a technological soft system, it may be evaluated through mathematical and computational models as much as any built infrastructure. However, instead of rigidity and sterility, green infrastructure provides a living and adaptive support to urbanity with greater social and aesthetic values.

In this paper, the principles of information modeling and simulation are examined in landscape design through international cooperation between the University of São Paulo (Faculty of Architecture and Urbanism and Polytechnic School) and Cornell University (Department of...
Landscape Architecture), with the contribution of the Federal University of Ceará (Department of Architecture, Urbanism and Design). Applied to a case study in the city of São Paulo, this work points towards an innovative and prospective tool to deal with issues of urban water management and represent a practical reflection to advance in the experimental field of LIM – Landscape Information Modeling.

1.1. São Paulo’s unintelligent urbanization

If landscape intelligence directly corresponds to its ability to adapt to changes, then rigid, monofunctional gray infrastructures of the twentieth-century urbanization were never intelligent, although they have had their historical time of importance and efficiency. Urban waters are an undeniable indicator of this lack of adaptation and, therefore, of cities’ unintelligent development. From initial settlements to great metropolitan areas, water bodies have shifted from resource providers to drainage and sanitation accessories as their behavior, performance and landscape were significantly modified with unaffordable costs to society, economy and environment, beyond the lack of resiliency and (biological, aesthetic, and social) diversity (Fig. 1). From main support for ecosystem dynamics, water has been the target of most impactful transformations: rectified and channeled rivers and streams, landed ponds, and over all, the progressive imperviousness of urban territory led to unprecedented changes in hydrology and intricate issues concerning water quantity, as to flood risk management, and quality, as to pollution mitigation.

The City of São Paulo is representative of this model of influence and urbanization. The fast transition from rural to urban especially in the last century has brought serious consequences to landscape and environment. From 31,000 in 1872, the City of São Paulo has grown seven times in population until the end of the 19th century and became the most important metropolis in South America in the first half of 20th century and this number already outraged 11 million [4]. Along this shift, urban development considered hard engineered and massive construction works as a symbol of prosperity, despite of occupying and transforming relevant environmental landscapes into a road and street system under expansion that often matches what once belonged to water (Fig. 2).

Conversion into gray infrastructures has especially disturbed the hydrological cycle and natural processes chained to it. With the combination of complete artificial management of stormwater, imperviousness and rapid runoff conveyance, streams and river channels have been more likely to overflow, aquifer recharges have decreased, and drainage infrastructure has been over demanded while its longevity and efficiency was reduced. Beyond the issue of stormwater volume, São Paulo has serious concerns about the quality of its waters. The former combination of drainage solutions also increases the pollution discharges that flows into surface water resources, which accelerates environmental deterioration and gradually prevents streams and rivers to be restored and perform as a multifunctional infrastructure, embraced by city population. Today, São Paulo’s greater rivers, Tietê and Pinheiros, are reflections of this unintelligent process. Mostly channeled and
heavily polluted, their waters carry significant load of domestic and industrial sewage and other non-point sources as well (Fig. 3). Their tributary creeks are also mostly seen as obstacles, instead of being a source of civic pride, identity, territorial organization or connection.

1.2. Opportunities for landscape infrastructures

In São Paulo, the overlapping of unaccomplished urban plans, misappropriated investments, and compromised decision making with progress at any cost resulted in channeled rivers to serve an extensive system of marginal roads of great relevance for economy and transportation. Historically, there has been a failure to prioritize the opportunity for a green metropolitan infrastructure, which today requires corrective and adaptive action to reclaim river landscapes and functions. As to flood risk management, public administration has lately invested in centralized compensatory solutions and implementation of detention reservoirs, commonly known as piscinões, that form a network of monofunctional engineering structures without any connection to people or landscape (Fig. 4).

In the other hand, since flood resilience is mandatory and will demand the construction of more reservoirs, there is a unique chance to adapt open spaces, with emphasis on strategic remaining floodplains within the urban fabric, to enhance runoff slowness and stormwater retention, treatment and infiltration. From a range of available technologies, this work examines Best Management Practices (BMP) to access flood control due to their suitability to green infrastructure principles, such as multifunctionality, connection, biodiversity, esthetics and resilience [5]. Considered as Natured Based Solutions (NBS), BMP represent a more efficient and cost-effective approach to development than traditional approaches [6]. When based on bioremediation, they are also able to improve water quality and mitigate diffuse pollution. In this sense, applying a simple organic matrix, composed of vegetation, planting soil and a discreltional layer of bedrocks for runoff retention has been proved to be efficient in reducing loads of nonpoint source pollutants [7].

2. Strategies for intelligent flood control landscapes

2.1. Landscape as technology

The ability of landscape to react and work as a framework to urban resiliency depends upon a new concept to assess, plan and design the support of ecology in cities. This original theory has reached a promising field through data processing and artificial intelligence [3]. This approach found a unique testing opportunity at the Jaguaré Creek Revitalization Project, a pilot plan for a tributary watershed that corresponds to 1/10 of the total 270km² drainage area of Pinheiros River, one of the two main watercourses crossing Greater São Paulo. An extensive analysis of the Jaguaré basin [8] estimated the pollution loads discharged into the creek through land occupation pattern and a system of BMP was then proposed to improve water quality and deal with flood risk control. Beyond strategies for water quality improvement, such as non-point source pollution mitigation, waste recycling, sewage collection and treatment, the project addressed water volume issues...
by identifying priority areas for flood management through hydrological simulations within the watershed. Considering 100-year flood events and their consequences on runoff and river flow, the retention volumes have been determined for each inline or offline reservoir along the Jaguaré Creek, and one of them has been selected for the pilot parametric prototype presented in this research.

A new generation of flood control infrastructures or new piscinões have been explored in Jaguaré. Over four years members of the research team conducted fieldwork, developed methods and workflow, and analyzed existing strategies and conditions. This culminated with a three-day workshop and symposium in Cornell University (Ithaca, NY) held in April of 2017 that brought together geographers, engineers, policy makers, hydro-ecologists, and designers to identify key design principles (Fig. 5).

From these principles two strategies were subsequently articulated and tested to implement the principles: the anastomosing retention reservoir and the phenotypes. These strategies stand as the working conclusions to this research that are informing final reports for the government agencies and non-governmental organizations interested in the possibility of rethinking the river infrastructure of São Paulo in relation to its urban communities, human and ecological. The strategies are:

2.2 Anastomosing retention reservoir

An anastomosing river has two or more interconnected channels that enclose flood basins (Fig. 6). This definition combines floodplain geomorphology with river channel pattern to appropriately capture the intent behind a site-specific approach to new retention basins (Fig. 7). Instead of the conventional solution of detention reservoirs in geometric volumes conformed by flat surfaces - the dreadful piscinões - a research hypothesis was adopted that takes advantage of the forms that are naturally given and adapt to variable water flows. The form of anastomosed channels, with the successive branching or multiple channels that are separated and recombined, were given by an input of parameters for a digital modeling with the use of algorithm, in constant iteration with the previously intuited forms.

The process of developing the algorithm was divided into three stages: 1. understanding the problem; 2. elaboration of a prototype; 3. openness to generalizations. The initial stage was defined by the apprehension of the geometric patterns that constitute the specific landscape language (Fig. 8). The later phase dealt with the decomposition of the design language's logic and its translation into the computational environment. This stage aimed to reproduce a logical reasoning mediated by the computational tools of the Rhinoceros software and its plugin, Grasshopper. Given the complexity of the forms involved, a typological decomposition was performed, aiming the restitution of the geometric patterns from less complex elements.

2.3 Landscape phenotypes

The biological concept of phenotype is particularly apt for this approach, as it grants primary agency to the landscape itself and its dynamics, emphasizes transferability and empirical characteristics, and allows for an understanding of form. This frame has lead us to a working definition of landscape form which was not only shape (the literal
geometry) but also pattern (distribution of geometry across spatial scales) and process (distribution through time).

An analysis of existing river landscape phenotypes includes but is not limited to those found historically within the São Paulo region and the Tietê or Jaguaré basins. This is in part because the processes of making are political-economic and technological as much as they are hydro-geological now. The rivers and their landscapes have fundamentally changed. These are hybridized with the forms and structures already present in the city; the drainage culverts, flood walls, and revetments. Many of these formal types can be found when studying anastomosing rivers.

Rather than reasoning by analogy such as the building of scaled digital and physical models, this strategy focused on reasoning by analysis. In this study we generated phenotypes that we expected to produce desirable effects in relation to water flow if they were used in the river channels, in the detention basins, or in floodable zones immediately adjacent.

We were able to generate these studies within a modeling environment that also accounted for more conventional urban design and landscape architectural elements. This workflow allowed us to quickly ask multiple questions of the forms in relation to both river design and urban landscape design. Moreover, the studies were relatively fast, allowing for a wide range of options to be studied before final designs are chosen for more expensive and precise scenario modeling using hydrodynamic software (Fig. 9).

**Accomplishments towards landscape intelligence**

Advances in both strategies evolved in parallel, however, results display an opportunity to be further explored and combined into a single tool, in which phenotypes can collaborate to model anastomosing reservoirs. Focusing on flood risk management, landscape has been investigated and experimentally designed through responsive information modeling, which demonstrated specific strengths/weaknesses for both methods:

2.4. **Intelligent reservoirs**

Designer intervention was performed mainly by manual sketches of the sinuous channels within digital environment and the connection of these geometries with algorithm functions (Fig. 10a). This approach aided the transition of experienced users to traditional CAD software, requiring less training for the algorithm operation.

The anastomosed axes of the reservoir were divided into two categories: the primary ones, which derive from the inflow and outflow points of the original channel; and the secondary ones, whose affluent points have been determined by the algorithm itself and which necessarily connect to the main axis. Firstly, the algorithm required the insertion of the primary axis, which automatically altered the initial topography to a new situation. This, in turn, redirects the flows of surface runoff and regions of greater or lesser slope, requiring, therefore, a new iteration of analyzes and simulations. In a second moment, the algorithm performs an analysis of the concentration of rainfall trajectories on the surface and detects the highest concentrations at the edge of the
intervention area. These points identified the secondary paths, requiring the sketch of curvilinear axes that, in their projection, intercept the main axis (Fig. 10b).

By crossing the main axes and the secondary axes, a series of formal treatments and analyzes specific to computer graphics determined suitable regions within the limits of the reservation area to model new meanders in order to enhance water flow slowness and retention. These new 3D surfaces were distinguished between small reservoirs (submerged) and small isles (emerged) (Fig. 10c).

In the last steps of the algorithm a cloud of points was generated by a decomposition of the main and secondary axes as well as the meandering regions. In addition, the points referring to the edge of the intervention area and original topography in the urban environment (Fig. 11a) were also added to this grouping. The cloud resulting from this overlapping was used to define a final topographic surface (Fig. 11b).

For the calculation of the retention volume, the surface was extruded down, generating a complex shaped solid, called a closed brep. From this moment, by means of boolean operations of form subtraction, it was possible to identify and calculate the volumes retained in the small reservoirs of the meanders, as highlighted in Figure 11c in white. The calculation was performed automatically by the algorithm.

2.5. Intelligent slowness

The concept of the phenotype study was centered on form as an abstract idea with specific intention to recover the complexity of water flow. The development of the prototypical forms and the use of Rhinoceros Computational Fluid Dynamics (CFD) enhanced the comprehension of how these 3D shapes change flow vectors in the modeling/simulation environment. These forms were also built parametrically, creating a feedback loop between changes of flow and form. From all possibilities, two forms were chosen for further experimentation (Fig. 12).

The cresant was selected for three main reasons: 1. with simple variations to its baseform it allowed a wide range of performative effects; 2. the shape was clearly intentional and easily produced a pattern that would be recognizable to users or maintenance workers; 3. it might function out away from the bank as a low-flow obstruction. Different flow scenarios were used to analyze the performance of variations of this phenotype. The variations could be set from the start or induced through material choice and flow force over time. In each case the form produced an elongated zone behind.

The teeth were chosen for two main reasons: 1. while the form didn’t change it allowed us to easily question relations between forms; 2) the shape would easily attach to banks and provide physical access for recreation or maintenance. To analyze the performance of variations of the phenotype, we searched for useful formations by running multiple flow scenarios and comparing outputs with the understanding that every form was different. The number and sizing of the obstructions has been formulated to not cause a difference at a large scale, but to produce micro-topographies and areas of slower water at a smaller scale.
Conclusion

When examining the design process for a new generation of flood control strategies in São Paulo, the water space has been adaptively and intelligently remodeled for reservation and flow discipline purposes, relying on the sophistication of natural systems. This approach presented an expected difficulty to be reproduced efficiently by digital artificial tools, which has been overcome once the design strategy was determined: the curvilinear language of anastomosed river channels.

Regarding fast manipulation and adherence to performance criteria, this work investigated the definition of an artifact based on information technologies and capable to assist the design process, not only to provide an automated modeling of formal structures but mostly to provide feedback on the performance of the researched solutions. The resulting system was able to grant a series of information that guided the proposal translation, and yet it allowed manifestations of manual expressiveness.

By combining performance with computational design, this work has reached a prospective language for landscape architecture in balance with the requirements of hydraulic engineering, social use of open spaces, urban governance and biodiversity. An innovative tool morphology for retention reservoirs was capable to integrate the diverse functions that are expected for urban spaces, such as areas that combine the role of infrastructure with the needs of social and aesthetic use and that stimulate more vibrant and valued urban landscapes.

Assessment of the structural connectivity of green spaces to identify stepping stones for garden city development of Quezon City, Philippines

Aicel Mae J. Alvarez, Nappy L. Navarra
University of the Philippines, Diliman, Quezon City 1101, Philippines

Abstract

With the construction of MRT 7 in Quezon City, domino effect of the urban development is anticipated to grow exponentially, threatening the natural environment in the city. The removal of 1,858 trees to pave way for the MRT line can possibly lead to loss of natural habitats and further landscape fragmentation which will go against the goal of the city government in creating a garden city. The major challenge is how to create ecological network when La Mesa Nature Reserve which is 55% of the city’s total area of green spaces is located only in the northernmost part of the city and is separated from other ecological cores by the MRT line and wide highways traversing the city.

Using aggregation metrics, the landscape texture of Quezon City is assessed to evaluate the connectivity between the ecological cores. With GIS tools, a resistance weight, a structural connectivity index and an ecological barrier effect index, the needed area for stepping stones to form greenways are identified. This study helps shorten the distance between urban green spaces and offer a spatial-planning strategy to increase the green space connectivity in Quezon City.

Though further analysis may be necessary, the results give indication on possible paths of stepping stones necessary for creating ecological connectivity.

Keywords: Geo-design, Biophilic City, Urban Ecological Network, Stepping Stones, Ecological Connectivity

1. Introduction

As a result of urban expansion, fragmentation decreases ecological connectivity, increasing isolation of habitats and loss of green spaces. The movements of organisms and the resultant flows of ecosystem services are shaped by landscape connectivity. Therefore, conservation of green space connectivity through ecological networks in rapidly expanding cities is needed to protect the biodiversity in urban area. Connectivity is key to how landscape functions ecologically. It is a particularly critical issue in urban areas because these typically comprise very large numbers of, often small, habitat patches separated to varying degrees by impermeable surfaces and barriers (i.e. buildings and roads).

Connectivity can be categorized into two: Structural and Functional. Structural connectivity pertains to the underlying landscape geometry, such as corridor width...
and distance between patches, whereas functional connectivity seeks to consider the specific needs and behaviors of a target species or species group [1]. Studies of structural connectivity in urban settings have highlighted its importance and utility as an aid to planning [2] [3].

1.1. Statement of the Problem

Assessing connectivity for developing an ecological network by using efficient models is essential to improve these networks under rapid urban expansion. Thus, this study answers the question how can ecological connectivity be strengthened between ecological cores of Quezon City?

1. How dense are green spaces in Quezon City?
2. What are the current ecological connectivity values of green spaces in Quezon City?
3. Where should stepping stone corridors be established to create higher ecological connectivity values between ecological cores?

With those questions in mind, this study aims to develop the ecological network between the ecological cores of Quezon City through addition of stepping stone corridors. To achieve this goal, the following objectives are set in place:

1. Locate the green spaces in Quezon City and determine its density
2. Compute the current connectivity value of green spaces in Quezon City
3. Identify the locations where stepping stones should be added to create connectivity between ecological cores

The results of this study can improve not only the ecological health of cities, but also the quality of life for human urban residents through the provision of bird interactions and other encounters with nature.

This study provides examples on how combining models can contribute to the improvement of ecological networks in rapidly expanding cities and demonstrates the usefulness of such models for biodiversity conservation and urban planning. Not only will this help the garden city development of Quezon City, this will also serve as a reference for students and professionals who are studying landscape architecture, urban planning, and other relevant fields.

1.2. Review of Related Literature

Connectivity analysis of green spaces in urban landscapes has recently been one of the main steps in urban planning especially in high-density cities. One example is the study by Tian et al [4] where they analyzed the relationships between the connectivity index of green spaces and green cover, elevation, building density, and population density using GIS tools and different landscape indices. The target species in the study were humans. The results indicated that low connectivity usually occurs in both old and new town centers with high building density and low green cover, and in areas occupied by land uses with a high resistance weight.

In another study by Nor et al [5], three areas in Southeast Asia (Kuala Lumpur, Malaysia; Jakarta, Indonesia and Metro
Manila, Philippines) were assessed to model connectivity for the two bird species: Eurasian tree sparrow (*Passer montanus*) and Yellow-vented bulbul (*Pycnonotus goiavier*). The approach identifies potential priority corridors for ecological connectivity networks. The study combined circuit models, connectivity analysis and least-cost models to identify potential corridors by integrating structure and function of green space patches to provide reliable ecological connectivity network models in the cities. Same as the study of Tian et al [4], this study used relevant parameters such as landscape resistance and green space structure (vegetation density, patch size and patch distance).

The two mentioned studies above, as with many other studies that used connectivity index, considered the building footprint as one of the barriers in ecological connectivity. It was also considered as one of the barriers in measuring connectivity as indicator of City Biodiversity Index (endorsed by the Convention on Biological Diversity in 2009). In the study done by Deslauriers et al [6], they applied these barriers in analyzing the ecological connectivity in Montréal and Lisbon. Railway lines were considered as connectors in Montréal but these were barriers in Lisbon. Depending on the policies in the location, the barriers can sometimes be connectors in the ecology.

2. Methodology

This study had three major steps for obtaining the goals and objectives: Ecological Patch Mapping, Application of Landscape Metrics, and Analysis of the Maps.

First, the green spaces of Quezon City were identified through creation of polygons in Google Earth Pro. The view was set at the range of 2.4-2.7km altitude and the green spaces more than 5000 square meters (sqm) were identified. These were then categorized into different land covers. Table 1 shows the different land covers identified in Quezon City.

Table 1: Land Cover Classifications found in Quezon City

After identification of the green spaces, the kml file from Google Earth was transferred to ArcGIS 10.4. The connectivity value was then computed by using the below formula from the City Biodiversity Index [7].

\[ \text{Indicator}_2 = \frac{1}{A_{\text{total}}} \left( A_1^2 + A_2^2 + A_3^2 + \ldots + A_n^2 \right) \]

where \( A_1 \) to \( A_n \) represent the sizes of the natural areas, from natural area 1 (\( A_1 \)) to natural area \( n \) (\( A_n \)), \( n \) is the total number of distinct natural areas and \( A_{\text{total}} \) is the total area of all natural areas. This measures effective mesh size of the natural areas in the city. \( A_1 \) to \( A_n \) may consist of areas that are the sum of two or more smaller patches which are connected. In general, patches are considered as connected if they are less than 100 meters apart.

However, exceptions to the above rule include anthropogenic barriers such as roads (15 meters or more in width; or are smaller but have a high traffic volume of more than 5000 cars per day), rivers that are highly modified and other artificial barriers such as heavily concretized canals and heavily built up areas, and any other artificial structures that the city would consider as a barrier. For the purpose of this study, only the roads were considered as barriers. The building footprint of the city was ignored as barrier, because this study recognizes the potential of sky-rise greenery especially green roofs as stepping stone corridors.

By creating a 50-meter buffer on each patch and then identifying the patches which connect to each other, the connectivity value of the city was determined. Figure 2 shows the green spaces that are ecologically connected when the buffer was applied.

After knowing the status of the connectivity of the patches, the ecological cores were identified depending on the area, edge density, and land cover. Edge density was computed by getting the quotient of the parameter of the patch over the patch area. Table 2 shows the weights attributed on the parameters for determining the ecological cores. Those with the highest points were chosen as the ecological cores.

![Fig. 2. Connected Green Spaces when the buffer of 50m was applied to each patch](image-url)
The study proceeded with the analysis of their connectivity through the use of several indices under Aggregation Metrics which refers to the tendency of patch types to be spatially aggregated; that is, to occur in large, aggregated or "contagious" distributions. Structural connectivity index and an ecological barrier effect index were then applied in ARCGIS with use of different spatial analysis tools. The models used came from the proposal of Tian et al [4] which is detailed below:

Barrier effect index was calculated using the Cost Distance module in ArcGIS. The barrier effect index (BEI) was modeled as follows:

\[
BEI_i = \ln\left(\frac{d_i - d_{\text{min}}}{d_{\text{max}} - d_{\text{min}}} + 1\right)
\]

where, for the given area, \(BEI_i\) is the barrier effect index; \(d_i\) is the path distance; and \(d_{\text{max}}\) and \(d_{\text{min}}\) are the maximum and minimum path distances, respectively.

Table 2: Parameters used to identify core areas

In addition to the barrier effects, travel cost and time consumption are also important factors affecting the connectivity of urban green spaces. The nearest neighbor distance (nd) between different green spaces is calculated by analyzing the distances between the centroid of one piece of green space and the centroid of the nearest green space. For a given region \(j\), the DI is modeled as

\[
DI_j = \ln\left(\frac{\text{nd}_j - \text{nd}_{\text{min}}}{\text{nd}_{\text{max}} - \text{nd}_{\text{min}}} + 1\right)
\]

where \(DI_j\) is the total distance between different urban green spaces in region \(j\); \(\ln\) is the average Euclidean distance from the centroid of one piece green space to the centroid of the nearest green space; \(\text{nd}_j\) is the summation of all average Euclidean distances from the centroid of one piece of green space to the centroid of the nearest green space in region \(j\); and \(\text{nd}_{\text{max}}\) and \(\text{nd}_{\text{min}}\) are the corresponding maximum and minimum distances between different urban green spaces in the given area, respectively. The ecological barrier effect index (EBEI) is then formulated by summing BEI and DI. For the given area, the ecological barrier effect index is modeled as follows:

\[
\text{EBEI}_j = \sum_{i=1}^{n} BEI_{ij} + DI_j
\]

where \(\text{EBEI}_j\) is the ecological barrier effect index between different urban green spaces.
in region \(j\); \(BEI_j\) is the barrier effect index in region \(j\); and \(n\) is the number of green spaces in region \(j\).

For structural connectivity index, it is modeled as

\[
CI_j = 10 - 9 \ln\left(\frac{(BEI_j - BEI_{\text{min}})}{(BEI_{\text{max}} - BEI_{\text{min}})} + 1\right)
\]

where \(CI_j\) is the structural connectivity index of green spaces in region \(j\), where the value of \(CI\) ranges from 0 to 10; and \(BEI_{\text{max}}\) and \(BEI_{\text{min}}\) are the corresponding maximum and minimum ecological barrier effect indices in the given area. The resulting maps showed the possible areas for installation of greenways that will connect the ecological cores of Quezon City.

3. Results and Analysis

After identifying the green spaces of Quezon City via Google Earth Pro, the below data were captured:

- Total number of green spaces: 273
- Total Area of Green Spaces: 47,916,678 sqm
- Total Area of QC: 165.33 sq km
- Green Space Density: **28.98%**

The green space density of Quezon City is relatively good considering that it is highly-densed with commercial and residential areas. However, this does not mean that all the green spaces offer good ecosystem services. It must be pointed out that 55% of these green spaces is La Mesa Nature Reserve alone which is located at the northernmost part of the city. Thus, it is a challenge to connect this area to other green spaces of the city to create an ecological network that can distribute the biodiversity all over the city.

For further assessment of the patches, the land covers were identified. Majority of the green spaces are open forests (See figure A1 in Appendix A). Theses spaces are mostly man-made landscapes like residential areas where trees are planted only on the sides of the roads. This further highlights the need to connect the open and medium forests to the closed forests in order to have a richer and well-distributed biodiversity in the city.

With a high density of green spaces, a relatively high connectivity value was also captured. Based on the City Biodiversity Index, the highest point is given to a city...
when its connectivity value is greater than 1500 hectares. When the connectivity value of Quezon City was computed, only the major roads with greater than or equal to 15m width were considered as barrier. The building footprint was ignored, and this resulted to a value of 1483.154 hectares. This connectivity value shows a potential for buildings to serve not as a barrier to movement of species but as corridors to other green spaces by redesigning them with skyrise greenery e.g. green roofs, vertical gardens.

When the ecological cores were identified, five patches stood out: La Mesa Eco Park, UP Diliman, Arboretum Park, QC Circle, Ninoy Aquino Parks and Wildlife Center, and a private land with closed forest near UP Diliman. Table A1 (See Appendix A) shows the corresponding weights of these green spaces.

Figure B1 (See Appendix B) display the distributions of the distance index (DI) between different urban green spaces and the connectivity index. Distance Index displayed that Districts 1, 4, and 3 have higher values of DI than other areas. However, Connectivity Index indicates that the spatial pattern of green space connectivity differs among districts. The southern part of Districts 3 and 4 have extremely low connectivity of green spaces.
Fig. 5. Identified least cost path considering the roads as barriers

In Figure B2 (See Appendix B), connectivity and least-cost path analysis were used to identify the potential corridors to connect green space patches for ecological connectivity networks. The approach identifies and assess optimal corridors in urban environments under current and future development scenarios. In such a rapidly evolving, heterogeneous and highly fragmented landscapes, the identification of corridors which should be prioritized is important to better design, preserve and can improve ecological networks. These networks of multifunctional ecosystems are undoubtedly crucial for nature conservation and human well-being as well, since they support biodiversity, ecological processes and services in urbanized landscapes.

4. Conclusion and Recommendations

The approach identifies potential priority corridors for ecological connectivity networks. The study combined circuit models, connectivity analysis and least-cost models to identify potential corridors by integrating structure and function of green space patches to provide reliable ecological connectivity network model in Quezon City.

The landscape metrics allowed the assessment of connectivity of green space structure revealing the potential corridors and least-cost pathways for bird species at the patch sites. The implementation of improvements to the identified corridors could increase the connectivity of ecological corridors. Moreover, eco-bridges can be constructed between ecological cores that are separated by major highways to create connectivity.

Urban planners could encourage installation of vegetated roofs on buildings near larger green spaces, directly supporting ecological land use connectivity designs. Green roof organisms likely contribute to urban metapopulations, being colonized by individuals from the larger urban population as well as colonizing other nearby areas. With an increased focus on ecology in urban planning, structures could be arranged intentionally to encourage interaction between patches and promote gene flow and migration, thereby increasing habitat resilience and supporting all aspects of urban biodiversity: ecosystem, species, and genetic diversity.

Abstract

Recently, there have been movable and changeable architectural structures adapted to climate and environment such as dynamic façades. The landscape architecture, on the other hand, though it is a field dealing with living things, rather than nonliving things, has been limited to a fixed vision. Planting, which is more sensitive to seasonal changes than any other material, shows an everyday change in forms, colors, and texture. Yet, a sense of season is lacking when you observe bird’s eye views and perspective drawing in landscape design. The most important reason for such a phenomenon is the absence of landscape architecture libraries. Therefore, designers make an error related to seasons by using a 3D image of unidentifiable trees when making a bird’s eye view and perspective drawing or they do so in the process of editing and retouching images using Photoshop. To solve the problem of the absence of planting libraries, Speed Tree and Autodesk 3D Max were used for creating trees that reflect seasonal changes. Unlike the previous 2D images or 3D animations, Speed Tree and Autodesk 3D Max, which give a seasonal sense to the images by using a compatible game engine (Unreal Engine4), can visualize seasonal changes through VR. The purpose of this research is not just to produce new models. It is to find a new way available in the various digital content fields like virtual reality so that it will be used as new landscape design tools and plant libraries can be created. Research Methods analyze LOD when producing models after collecting tree species data and analyze their seasonal characteristics. Research site is the roof garden placed on the top of Graduate School of Environmental Studies(GSES) building, Seoul National University, and Acer palmatum is selected as a species for the modeling. This research will be a baseline in planting libraries and also proposing as a new landscape design tool. However, this research shows the limits of professional techniques in software because of its difficulty and complexity. Nevertheless, it has a provision as a new tool for landscape design when the problem of technological development is solved.

Keywords: VR(Virtual Reality), 3D Planting Library, Seasonable Change, Speed Tree, 3D MAX ;
1. Introduction

Recently, there have been movable and changeable architectural structures adapted to climate and environment such as dynamic façades. Adding ‘movement’ to settled structures or spaces, which is the so-called Movable Architecture, has been proposed in relatively various ways for some time [1]. Likewise, there have been efforts attempting to make dynamic façades by using material and technology in a given set of boundaries and conditions. The landscape architecture, on the other hand, though it is a field dealing with living things, rather than nonliving things, has been limited to a fixed vision. As landscape architecture whose materials are mostly living things, is a field sensitive to the passage of time, its degree of changes as time goes by, is greater than that of sculptures or architectural structures. Thus, the flow of time acts as a great possibility in landscape architecture[2]. Planting, which is more sensitive to seasonal changes than any other material, shows an everyday change in forms, colors, and texture. Yet, a sense of season is lacking when you observe bird’s eye views and perspective drawing in landscape design. It is mainly because the images ignoring a seasonal sense are designed by designers who make a bird’s eye view and perspective drawing with a fixed viewpoint.

2. Case Study

Seoullo 7017 is an elevated, linear park in Seoul, built atop a former highway overpass. The path, which opened in May 2017 and whose length is one kilometer lined with 24,000 plants, is similar to New York City’s High Line. Since Seoullo 7017 promotion image is different from its actual image, people who had a look at the promotion image became confused when they actually made a visit. Though its promotion image includes colorful flowers and flourishing trees, the reality is nothing at all like it. The gorgeous looking flowers, which in fact, look unrealistic in Seoullo 7017 promotion image, were elaborately photoshopped with computer graphics by using a picture taken at the actual spot. It only aimed to attract people to the location and as a result, a seasonal sense was completely neglected. As Seunghwan Oh, a professor of photography at Kyung-Sung University pointed out, the vision with a touch of computer graphics of an actual picture and disharmony of reality and virtual reality will destroy the idea of vegetation colors and season that people have [3]. Accordingly, the difference between the unrealistic image made in order to encourage people to take a walk and the reality has sharply come into view.

Fig. 1. Landscape seasonal change

Fig. 2. Difference between computer graphic and real image of Seoullo
3. Purpose

A major cause to such a problem is the absence of landscape architecture libraries. It is because in the field of landscape, non-geometric landscape elements, such as plants, topography, and water, make it difficult to establish a material library due to the lack of information and technical skills [4]. It is difficult to establish libraries because landscape plant species are diverse in trees, shrubs, herbaceous and groundcovers. Also they look different every season. Therefore, designers make an error related to seasons by using a 3D image of unidentifiable trees when making a bird’s eye view and perspective drawing or they do so in the process of editing and retouching images using Photoshop. To solve the problem of the absence of planting libraries, Speed Tree, a software which enables designers to get realistic models of tree shapes and make changes to them, is a great tool with strong potential to be utilized by landscape architects. Also, a comparative analysis between Speed Tree and Autodesk 3D Max, when making an image of the same tree, Unlike previous 2D images or 3D animations, Speed Tree, which gives a seasonal sense to images by using a compatible game engine (Unreal Engine4), can visualize seasonal change through VR. The purpose of this research is not just producing models. It is to find a new way available in various digital content fields like virtual reality so that it will be used as a new landscape design tool and plant libraries can be created.

4. Methods

This research analyzes LOD when producing models after collecting tree species data and analyzing their seasonal characteristics. Tree models are made in two ways. First, using Speed Tree for Unreal Engine4 version, a suite of 3D-modeling tools that combines the efficiency of procedural modeling with the flexibility of hand modeling, we made a 3D model of a tree considering seasonal and visual characteristics of a real tree. Second, with Autodesk 3D Max, a popular 3D software generally used by many, make a tree modeling of the same tree made by Speed Tree. After the modeling, the tree model will be exported to Unreal Engine4 and blueprinted to express the seasonal change.

5. Site

Research site is the roof garden placed on 4th floor of Graduate School of Environmental Studies(GSES) building, Seoul National University. GSES is located in Seoul where there are clear seasonal change. This site is located in 7b plant hardiness zone which means that the plants can withstand a minimum temperature of -14.9°C to -12.3°C. The latitude and longitude geographical point is Latlng (37.462119,126.954198) in Google maps. 10 species of tree, 20 species of shrub and more than 60 species of herbaceous are planted in roof garden.
6. Selection of Plants

After selecting the tree model, it is planted in the GSES roof garden. Especially, the selected tree should have clear characteristics of seasonal changes, it should be something like the evergreen tree. Acer palmatum is a maple tree that grows in Korea, Japan and China. Acer palmatum is a small deciduous tree or a large shrub with a broadly spreading crown. The plant can be grown as a small single-stemmed tree or a large multiple stemmed shrub. The form of the tree is broad-rounded, with a layered branching structure. Acer palmatum has clear characteristics of seasonal changes. In the spring, new shoots grow up, and slowly, the size of the leaves increases in the summer. Then, the color of the green leaves slowly turns into red in the fall. Finally, in the winter, the leaves fall to the ground.

7. Speed Tree Modeling

7.1. Generation

Speed Tree is based in procedural modeling by controlling the generation. Models are built by creating a hierarchy of objects that create geometry. These objects are called generators. Each generator creates one or more components of the model based on its properties [5]. Procedural modeling allows the creation of the trunk, branches and leaves step by step. It is easy to edit the LOD (Level of Detail) because of its separated layers.

7.2. Trunk

Nodes are what a Generator makes as part of procedural modeling. Every single individual piece of geometry in the tree is a single node [5]. Nodes can be added and deleted for the users to control the trunk form very flexibly.

7.3. Branches

Maple tree forms straightened trunk height to crown base with a broadly spreading crown. Large branches separate into small twigs, and maple leaves start to show in these twigs. Speed Tree provides for the users to make a detail design by controlling the LOD properties.

7.4. Leaves

Meshes are managed in the Mesh Asset Bar. This is where users can import meshes, create new meshes and modify parameters about meshes. Users can model a mesh in any 3D software, such as Autodesk 3D Max. Transforming the mesh makes the images more three dimensionally realistic leaves. Material tools provide for the users to
manage the leave images such as mapping the texture and colors.

7.5. Limitation of Speed Tree

Tree models are available to use in various digital content fields like Unreal Engine 4 by exporting in format of SRT. However, it is difficult to immediately induce seasonable changes. The reasons for the limitation of Speed Tree are as follows:

1. Speed Tree can’t make animation data on its own. The meaning of animation data is the growth of tree and the scale of the leaves which gets bigger or smaller. Unlike Autodesk 3D Max, there is no animation data which induces the tree to go through seasonable changes.

2. Tree models made by Speed Tree can be exported to Autodesk 3D Max. However, there are too many leaves and branches to create new animation data for each. As the leaves and branches are made randomly, it is almost impossible to create their own animation settings for activation.

To improve the solution of these limitations, one can make model and create animation data by using Autodesk 3D Max. Then export the data to Unreal Engine 4 to activate seasonable change.

8. Autodesk 3D Max and Unreal Engine 4

8.1. Autodesk 3D Max - Modeling & mapping

First, modeling needs to be made in Autodesk 3D Max. Making two different structures is to create different animation.

1. Big structure model (trunk and branches)
2. Small structure model (twigs and leaves)

Big structure model can be used from Speed Tree because of its single structure. After the modeling, Maple tree bark will be mapped. Mapping is a method of projecting pictorial information (materials) onto surfaces. On the other hand, small structure must be made only in Autodesk 3D Max because of creating different animation for the movement of the whole twigs and leaves.

8.2. Autodesk 3D MAX - Bones system

A bones system is a jointed, hierarchical linkage of bone objects that can be used to animate other objects. Bones are especially useful for animating tree models that have a continuous skin mesh [6]. Users can animate trees with forward or inverse kinematics. By making bones system in a big structure model, it is easier for users to control the growth direction.

8.3. Autodesk 3D MAX - Animation data

Animation is based on a principle of human sight called persistence of vision. Viewing a series of related still images in quick succession, perceive them as continuous motion [6]. Each individual image is referred to as a frame. Unlike big structure model, small structure model is hard to
animate in bones system because of its large amount twigs and leaves. Small structure model needs different methods of controlling animation data in order to control each twigs and leaves. After creating animation data, small structure models will be placed near the big structure model where the leaves will be grown, by copy and paste. Making different types of small structure can help the tree look more natural and not artificial.

8.4. Autodesk 3D MAX – Key animation mode

Key animation mode can animate the position, rotation, and scale of an object, and almost all other settings and parameters, by adding new tracks [6]. Track is a continuous frame which controls the time. Users can edit the time at some point to make the tree animated. In other words, it is possible to control the tree movement in each frame. Using key animation mode can make Maple tree leaves grow from inside to outside and top to bottom.

8.5. Unreal Engine 4 – Material

Export the model and animation data from Autodesk 3D Max to Unreal Engine4 in fbx format. Before animating the tree, material blueprint must be set in Unreal Engine4 by material and mapping source we made in Autodesk 3D Max. This process can make the color of the leaves color by preparing each material and mapping source.

8.6. Unreal Engine 4 – Key animation

In order to get started with animations, user will need to first add an animation track. After adding an animation track, the timeline will become active and user can begin adding Animation Keys that are associated with values that shift over time[7]. Import the animation track that was made in Autodesk 3D Max and edit to see the tree movement in each frame.

9. Discussion & Conclusion

In this research tree models are made in two ways. First, use Speed Tree, suite of 3D-modeling tools that combines the efficiency of procedural modeling and Autodesk 3D Max, creating modeling and animation data. Autodesk 3D Max was used to export the data to Unreal Engine4 because of the limitation of Speed Tree. By using Unreal Engine4 blueprint, the tree model showed the visualization of interactive seasonal changes that 2D images or 3D animations couldn't express before. This research will be a baseline in planting libraries and also proposing a new landscape design tool. However, this research shows the limits of professional techniques in software because of its difficulty and complexity. Nevertheless, it has a provision as a new tool for landscape design when the problem of technological development is solved.
10. Future Research

This research is on-going, and we aim to establish more planting libraries by adding diverse trees, shrubs, herbaceous and groundcovers. We are trying to add more species to those planted in the GSES roof garden and show the whole realistic landscape scenery that reflects seasonal changes. Furthermore, we are planning and developing UI (User Interface) programs to give seasonable change in the environmental factors such as terrain, water, soil, wind and climate. We are also attempting to find a way for Speed Tree animation data to activate Unreal Engine4 by making new programs. VR has a great potential provision as technical development proceeds, and it will be an innovative landscape design tool to create new ways of representing nature.

Calibration of the Model ENVI-met V4 for Predicting the Microclimate Variation in an Urban Park

Yingnan Li\textsuperscript{a}, Yiwen Han\textsuperscript{a}, Youngkeun Song\textsuperscript{b,}\textsuperscript{*}

\textsuperscript{a}Interdisciplinary Program in Landscape Architecture, Seoul National University, Seoul 08826, Republic of Korea
\textsuperscript{b}Dept. of Landscape Architecture, Graduate School of Environmental Studies, Seoul National University, Seoul 08826, Republic of Korea

Abstract

Urban parks have various spaces that produce an environment with specific microclimatic conditions. The microclimates have impacts on human comfort, thereby affecting the utilization of urban parks. However, it is difficult to measure the microclimatic variations of the holistic parts within a park. ENVI-met offers an opportunity to feign different planning scenarios in order to optimize planning decisions. It has been widely used in the literature and calibrated by field measurements.

This work presents the ENVI-met V4 calibration for predicting the microclimate variation in Deacheong Park, which located at Gangnam district, Seoul, South Korea. Both the fixed and mobile weather station on field campaigns and microclimate measurements were carried out during 12th August 2017 to represent a typical summer day. Our research results show very similar results between measured and simulated data of air temperature showing as root square error (RMSE) 0.76 °C, mean average error (MAE) 0.65 °C, and the index of agreement in 0.74. In addition, 3 nesting grids on each side were suggested for reducing the boundary effects and providing a better performance of the model. Our study indicates that ENVI-met model is capable of simulating the microclimatic variations in urban green spaces. It can be referenced in the practical work of parks design by predicting scenarios for real cases.

Keywords: ENVI-met model; Urban park; Microclimate; Numerical simulation
1. Introduction

Numerical models have been successfully used for understanding and predicting the variations of urban meteorological environment [1,2]. For instance, the development of MUST scheme was able to predict the detailed urban surface temperature distribution for individual buildings [3]; Jeong and Yoon (2012) used Hoyano model to evaluate the interaction between building types and outdoor thermal environment [4]; moreover, ENVI-met model was widely used for analyzing the impacts of landscape elements on microclimates [5,6]. Aforementioned numerical simulations are considered as appropriate ways to obtain the prediction of environmental performance characterizing an urban space and improve the outdoor environment. However, for getting more accurate output, it is necessary to calibrate models by comparing the simulated results to the in-situ measurements.

For this study, we focus on ENVI-met which is a three-dimensional microclimate numerical model. It is able to simulate the interactions between surface, plant and atmosphere in urban environments [7]. It offers an opportunity for research to conduct at the resolution between 0.5 to 10m with a maximum of 240 grid cells in the horizontal direction and a temporal resolution of 10s (http://www.envi-met.com). When using numerical models, the input weather data and parameter setting affect the accuracy of the results [8,9]. Therefore, an urban outdoor environment in fine scale can be examined by ENVI-met.

Although the ENVI-met model has been widely implicated in previous studies, there is limited information on the detailed process of its validation. Therefore, the objective of this research is to calibrate the ENVI-met for an urban park by contrast the simulated data with field campaigns. The calibrated model can be used for further study on setting different scenarios.

2. Methodology

2.1. Study area

Our study was conducted at Daecheong Park which is located in the Gangnam district (37°49′26.4″N, 127°08′26.0″E), Seoul (Figure. 1). It is a neighbourhood park, covering a land area of 14,089 m2. The canopy cover in this park consists of deciduous and coniferous trees, and shrubs of Buxus koreana with ~50cm. We conducted our in-situ measurements on 12th August. The day was rainless and cloudless, which represents a typical hot summer day in Seoul.

There were three principles that followed in selecting the site for our study. First, the park is not connected with the other big green areas, as those may affect the measuring results. Second, there should be a different distribution of tree canopy cover in the park, so that we are able to detect a diverse thermal environment. Third, because the topography is an important factor for the meteorological environment, the park should be flat. Therefore, Daecheong Park is suitable as the subject for this research.
2.2. Validation of ENVI-met

The study combined the fixed and mobile weather station on field campaigns. For the fixed measurement, the data was collected automatically at the 1-minute intervals by Watchdog Mini-stations (Spectrum Technologies USA Inc., USA) on three sampling: Sampling point A was set on the roof of a building of three stories that is located at the northern corner of the park with about 10m in height; Sampling point B was set at the 2 m height at the open space of the park; Sampling point C was mounted on tree trunk at the 1.5m which in the centre of the park (Figure 2). For the mobile measurement, three TR-72wf Thermo Recorders (T & D Corporation, Japan) attached to a metal pole at 0.1, 1.5 and 2 m above the ground was used for recording the air temperature and relative humidity by moving around the study area. The air temperature and relative humidity were collected by TR-72wfs at the 1-second intervals during 4 specified periods across the day: 9:00, 11:00, 13:00,15:00. A GPS (GARMIN GPS 60CS) system was also attached to the pole for recording the geographical coordinates of each sampling point.

The input parameters for setting the ENVI-met model are showed in Table 1. Furthermore, the input parameters of precise locations, heights, trunk heights, trunk diameters and canopy diameters of the trees and the building height surrounding the Deacheong park were defined by field survey. For increasing the stability of the simulation for elements close to the border, nesting grids should be set to each side of the modeled area. However, the amount of nesting grids has an impact on the accuracy of the simulations, thus we tested models with 1 and 3, respectively.

Hourly averaged air, surface, and soil temperatures were retrieved from the fixed micrometeorological stations at the sampling point B. Specific humidity values were obtained at 2500 m for Phoenix from the University of Wyoming (2013) Department of Atmospheric Sciences [10]. Wind speed data at 10 m above ground along with data for the most frequent diurnal wind direction.

2.3. Data analysis

The accuracy of the simulated results was evaluated by root square error (RMSE), mean average error (MAE), mean bias error (MBE) and Willmott’s index of agreement, which is a statistical index of model performance.

3. Result

3.1. Comparison of the observed and modeled air temperature for fixed measurement

The comparison between the observed value of fixed measurement and the modeled temperature at corresponding height was shown in Figure 4. It seems that the ENVI-met tends to over-predict the air temperature for both open space and under canopy. The difference between simulated values and measured values under canopy were higher than that at open space.

We compare the accuracy of simulated results between the model with 3 nesting grids and 1 nesting grid. The result showed that there are little differences between the model with two models, the indexes of agreement were all over 0.7 (Table 2). However, 3 nesting grids were selected for further assessment as the it helps to increase the stability of the simulation for elements close to the boundary of the study area.

Table 2. Quantitative measures of the performance of the ENVI-met model with different nesting grids based on observed and simulated air temperature.

3.2. Comparison of the observed and modeled air temperature for mobile measurement

The vertical observed records of the temperature were compared to the simulated temperature with similar height in the model (Figure 4). Even though ENVI-met overestimated the temperature, it enables to perform a similar vertical gradient when compared to the observed data. In the open space, the temperature is higher when closer to the ground surface. Conversely, the temperature under the canopy was lower when it reached closer to the ground surface.

Finally, the accuracy of simulated results in vertical distribution was also evaluated by using Willmott’s index of agreement. The MBE for all comparisons shows that the model generally over-predicted temperature.
4. Discussion and conclusion

ENVI-met model reasonably approximates the observed data for this study, similar weather conditions were presented throughout the experimental day. However, diurnal predicted air temperature was higher than the recording of in-situ measurement. This contrasts with previous studies that found ENVI-met to underestimate the diurnal air temperature [11,12]. This is likely caused by the added nesting grids, as no objects can be placed inside the nesting area due to solar radiation that can reach the surface undisturbed which often results in an unrealistically high temperature of the ground surface in the nesting area. This is especially true when non-evaporating surface materials have been used [13].

In this study, the 3D urban microclimate model ENVI-met (version 4.0) was used for evaluating the thermal environment at a neighbourhood park during a typical hot summer day. The results show that the ENVI-met model had a good performance by 0.51-2.55 °C (Table 2). MAE ranged from 0.59-2.55°C. The larger error occurred during the afternoon (i.e., 13:00 and 15:00). In general, the simulated air temperature fits well with measurements as the acceptable magnitudes of index of agreement by 0.69-0.88.

Mapping the Equivalent Vertical Sunshine Duration Curve of Outdoor Space beside Buildings for Dynamic Landscape Planting Design

Chuang-Hung Lin, Zheng-Zhe Xie, Chien-Yuan Han, Shao-Wei Lu

Abstract

Dynamic shading behavior between buildings and other objects has been suggested as one way of changing microclimate and the change in microclimate that would in turn reduce the demand for heating and cooling. Understanding the dynamic shading behavior is an important aspect of the correct consideration of the sunshine in a built environment. Clearly, in order to reach the ideal landscape model for planting design, the light environment for plant growth also has to be taken into consideration. This study of dynamic sunshine distribution takes university buildings as a case to discover and discuss the light comfort zone for plant growth in the area adjacent to the buildings. In addition to simulating a shadow map that displays the duration of shadow at ground level a further number of shadow maps are constructed to represent the shadow patterns and durations at different heights above the ground. These are analyzed to gain an understanding of the vertical distribution of sunshine and its duration. Therefore we developed a novel concept, equivalent vertical sunshine hours curve (EVSH Curve), for different seasons and heights to review the required sunshine conditions for greening around a building. At the same time the behavior of the non-symmetrical light environment was observed on both sides of the portico due to the influence of nearby buildings. A more comprehensive deeper investigation of the light environment will indicate a more appropriate planting design for a greening place in a built environment.

Keywords: sunshine duration curve; planting design; vertical light environment;

1. Introduction

Sunlight is one of the essential elements in the ecosystem, and it has been proven that the quality, intensity, and duration of light directly impact plant growth. The quality of sunlight refers to the color or wavelength reaching the plant’s surface, and output peaks of sunlight on the ground should also be in the visible range. The intensity and duration of sunlight varies significantly under different conditions, such as latitude, season, region, and even the geographic location. In response to the above characteristics of sunlight, plants control their internode length, leaf size, count, and the density of their chloroplasts. Plants also determine the optimum timing for flowering and other physiological processes (Levitt, 1980; Boardman, 1977) from those characteristics of sunlight. Therefore proper and effective usage of sunlight always has been an important consideration in horticulture and landscape architecture (Robert, & Gillespie, 1977).

Recent studies of sunlight in the residential environment have been focused on techniques for reducing the intensity of the urban heat island effect and reducing the energy consumption of buildings (Wong, & Chen, 2009; Rosenfeld, Akbari, & Romm, 1998). Simulation models and experiments have indicated that the use of vegetation could be an effective approach for changing the microclimates of outdoor and indoor environments (Burbia, & Bucheriba, 2010; Argiro, & Marialena, 2003). Akbari and Taha conducted a large-scale simulation and reported that increasing the vegetation...
surrounding a city by 30% and the vegetation around houses by 20% would decrease the costs for cooling in the city by 30-100% (Akbari, & Taha, 1992). Small-scale controlled experiments also have demonstrated that trees placed along the wall of a house can reduce cooling costs by 26 - 47% in a region that has a mild climate (Akbari, Kurn, Bretz, & Hanford, 1997). In a region in which the climate is hot and humid, shade trees can provide as much as 80% of the desired cooling effect (Limor, & Hoffman, 2000). Further studies demonstrated that trees planted with different layout in a yard and at different distances from a building could change the indoor environment, e.g., reducing the harvesting of the heat energy in sunlight by the structures, decreasing natural ventilation, and so reducing the use of air-conditioning (Stavrakakis, Zervas, Sarimveis, & Markatos, 2010; Yang, 1997). As we noted above, the relationship between buildings and trees is an important consideration, and most of the earlier investigations were focused on the beneficial influences of trees on the microclimates of buildings.

Conventionally, greenery was often provided around buildings in spaces where sunlight was often obstructed and so the plants encountered environmental stress for their growth. The lack of sufficient sun exposure slows the rate of photosynthesis and the production of chlorophyll in ground plants. Long-term deprivation of sufficient light exposure will result in unhealthy plants and unfavorable conditions for the differentiation of flower buds (Cain, 1971) and the development of fruit (Seeley, Micke, Kammereck, 1980) that influence ornamental quality and the greening effect, but few studies have addressed the location and growth condition of trees subject to the shading effect from nearby buildings. Yezioro and Capeluto et al. (Yezioro, Capeluto, & Shaviv, 2006) evaluated the ratio between the insulated area and the total examined area for a period of a year at an urban square with a specific width, length, and height. The recommended insulated and shaded areas of such a design were presented, and the best locations for deciduous plants and evergreen trees were indicated. Wan and Jun (Hongbing, Jun, Yonghong, & Li, 2010) performed a case study to optimize the planting design between residential buildings and meet good daylighting requirement. The proposed model helps us to determine which trees to plant between buildings and to realize good daylighting in a built environment. Lin et al. (Lin, Ling, & Chang, 2007) calculated the distribution of sunshine duration around buildings on a university’s campus. According to different plant distributions, such as orientation or the distance to the building, the shading impact of nearby buildings on the growth conditions of the trees was demonstrated. The result illustrated the conventional “symmetric” or “row” plant design was usually unable to allow a light environment fit for plant growth. Unlike non-living objects such as statues, street lamps, chairs and ponds, plants grow and alter as time passes. When striving to create a “comfort zone” for human beings, the comfort zones for plants should also be understood and taken into consideration in order to create a mutually beneficial environment for plants and human beings.
In this work, we developed a visual and directly perceivable method, namely the equivalent vertical sunshine hours (EVSH) curve, to demonstrate the sunlight environments at different seasons and heights, and we further analyzed the distribution and duration of sunshine as these are influenced by adjacent buildings. This approach was intended to discover and present the information required to design optimal planting schemes for different seasons and at different ages. If the EVSH curve used for this study can, in fact, be used to predict the growth restriction and condition of the plant and give advice on ex-ante evaluation of planting design, this approach can become a much needed tool for “sunlight prediction first; plant choice second; design last”.

2. Method

The evaluated area of sunshine conditions was the main campus of National United University, Miaoli County, Taiwan (24°N, 120°E). Since the shadow map was highly related to the arrangement of the buildings, partial campus layout including height of the building is illustrated in Figure. 1. The main research area for determining the duration of sunlight that the plants received during different seasons was the greening place in front of the three-story building (building 1), and a detailed map of the investigated area is shown in Figure. 2. There were ten Juniperus chinensis planted in front of the building, and the growth performance characteristics of each plant such as, bend direction and shoot tip displacement are illustrated.

![Figure 1. The partial campus map of the buildings at National United University.](image-url)
2.1. Simulation of a building's shadow at different elevation

For easy comprehension by designers, we drew shadow graphs at different elevations, i.e., ±0 m, +1 m, +3 m, +5 m, and +10 m by using the Reviet software. The setting of four different elevations above the ground level (±0 m) was based mainly on the circumstances that +1 m is the average shrub height; +3 m and +5 m are the average heights of a small arbor, and +10 m is for a mature arbor. The open space on the north side of buildings was delimited and divided into a 1 m x 1 m grid. We decided to determine the number of hours of sunshine in each grid.

2.2. Accumulation of grid sunshine hours

Shadow distributions at five elevations were determined every hour from sunrise to sunset at the vernal/autumnal equinoxes, and at the summer and winter solstices respectively, and then the two-dimensional sunshine hour distribution of each equinox or solstice at different height was obtained by calculating the shadow distribution on the grid. The sunshine hour map with different elevations at winter solstices for example is shown in Figure 3. The two sides of a building’s portico are generally key greening places because that is where people enter the building and form their first impression of the building. So we also conducted further analyses of sunshine hour distributions 1.5 m
away from the right and left sides of the portico.

2.3. Overlapping and transforming the top view into a section view

Through use of overlapping sunshine hour distribution with various height from 0 m to 10 m, sunshine hour distribution near two sides of portico were transformed from top view to section view referred as the EVSH curve, as shown in Figure 4-6. The curves represent the influenced "equivalent" sunshine duration range as modified by the shadow of the buildings.

Figure 3. Sunshine duration maps with different elevation around the building 1. (a) at ground level (b) at an elevation of 1 m (c) elevation of 3 m (d) elevation of 5 m (e) elevation of 10 m. The line on the map is the border between section A and B.

2.4. Ranges of sunshine for plant growth

The average sunshine duration in Miaoli County, Taiwan, at vernal/autumnal equinoxes and the summer and winter solstices are 12, 13.6, and 10.5 hours respectively. In this work, we take three sunshine duration ranges namely 1-4 hr, 4-7 hr, and 7-11hr for sun-shade plant growth under most conditions in winter, vernal/autumn, and summer as points of departure when we discuss optimal locations and arrangement of plants. In turn those findings will be captures into design guidelines.

3. Results and Discussion

To analyze the influence of sunshine duration at equinoxes and solstices, the EVSH curves of two sides of the portico are discussed in the following sections.

3.1. EVSH curves of section A and B at vernal/autumnal equinoxes

As illustrated in the Figure 4(a), the EVSH-4 curve of section A showed that the point which gets four hours of sunlight is located 3 m away from the building, but the
point that also got four hours of sunlight moved inward by 1.5 m at a height of 10 m. The number of hours sunlight that a curve depicts is given by the number following the capital letters EVSH. In the same manner, if a plant requires seven hours of sunshine at the ground level, it must be shifted 6 m outward, reaching 9 m away from the building. In contrast, the points of EVSH-4 and EVSH-7 at the height of 10 m are 1.5 m and 3 m away from the building, respectively, and their relative distance is 1.5 m, which is much shorter than the relative distance at the ground level. In other words, the height of the plant should be more than 10 m to receive 7 hours of sunshine at the distance of 3 m. The distribution of the EVSH-7 curve of section B is approximately the same as in section A, sketched in the Figure 4(b). However, when the elevation is less than 5 m, the EVSH-4 is significantly different from the EVSH-4 curve of the section-A.

### 3.2. EVSH curves of section A and B at the summer Solstice

As illustrated in the Figure 5, the shadow area of the three-story building was narrower than it was at vernal/autumnal equinoxes due to a higher solar elevation angle at the summer solstice. The EVSH-7 curve in section A was revealed in Figure 5(a) and one can observe that the point to get 7 hours of sunshine on the ground was 2 m away from the building, but at a height of 10 m, the distance is reduced to 1 m. Similarly, the point to get 11 hours of sunshine on the ground was 6 m, whereas, at a height of 10 m, the required distance was only 2 m. Therefore, 2 to 6 m away from building is the region that has 7-11 hours of sunshine on the ground at the summer solstice, and there is a 4 m difference between height at ground and 10 m of the EVSH-7 curve. Figure 5(b) indicated the EVSH curve of section B; the distribution of the EVSH-11 curve is approximately the same on both the east and west sides, but the distribution of EVSH-7 curves on the two sides were different.

#### 3.3. Deduction of "light comfort zone" from EVSH curves by comparison of two sections of the overlapping diagrams

In Figure 6(a), one can observe the point of the EVSH-1 curve of section A on the ground was 8 m outward from the building. The points of the EVSH-4 curve on the ground and at a height of 10 m were shown to be 13 m and 3.5 m away from the building, respectively. It means that there is 9.5 m difference in the EVSH-4 curve between ground level and at the height of 10 m. In section B as illustrated in the Figure 6(b), the curve of EVSH-4 is approximately the same as the section A. Due to the influences of the portico and the ten-story building, the distance of EVSH-1 was 1.5 m further away than it was for the section A.
Figure 4. The EVSH curve at the vernal/autumnal equinoxes. (a) section A and (b) section B. The equivalent vertical sunshine hours were 4 and 7 respectively.

Figure 5. The EVSH curve at the summer solstice. (a) section A and (b) section B. The equivalent vertical sunshine hours were 7 and 11 respectively.
3.4. Deduction of "light comfort zone" from EVSH curves by comparison of two sections of the overlapping diagrams

When the sunshine duration maps of the section A and B are overlapped, as shown in Figure 7, one can easily observe the difference between the two. At vernal/autumnal equinoxes, the distributions are obviously dissimilar at the section A and B of the portico. As we can see in Figure 7(a), the sunshine hour distribution near the section A of the portico was influenced by the shade effect of the three-story building itself, but it was rarely affected by the portico itself or the ten-story building. The recommended planting location at equinoxes for a popular shrub, with a growth height of less than 1 m, is 3 m away from the building on the section A. However, if one would like to set the plant on the section B of the building, the location of the plant stand should be set at least 6 m away from the building so that the plant has at least the required four hours of sunlight as also can be observed from Figure 4.

In comparison with the vernal/autumnal equinoxes, at the summer solstice a smaller area was covered by the building's shadow and the variation of the shadow pattern by the portico was less notable at heights less than 5 m, as shown in Figure 7(b). However, shadow patterns at heights greater than 5 m...
were different between the section A and B; this was attributable to the extension of the shadow of the ten-story building at the afternoon. Another intriguing point was the elevation of 1 m at the section B of the portico where the more shaded area was observed. It is counterintuitive that less area would be shielded as the height increased. Actually, the real condition can be obtained only by careful consideration of the buildings located farther afield.

Taiwan is located in a subtropical region, and high temperatures usually persist throughout the summer. It has often been suggested that creating shade by planting trees was a useful approach to change the microclimate of the adjacent buildings. When the proper amount of shade is provided by buildings, it is advantageous for the plants. As shown in Figure 7(b), placing plants 6 m away from the building does not allow the building to provide sufficient shade for the shade plants, so it was preferable to locate shade plants within 6 m away from the buildings.

At the winter solstice, the duration of the sunshine on the north side of the building was insufficient when it was originally determined. Taking 4 hours as the expected value, the distance required was at least 13 m away from building, reaching to the basketball court, as shown in Figure 7(c). Due to the low solar elevation angle in winter, most sunlight is blocked by the building, and a great increment of shadow length was observed; therefore, the shadow created by the portico was minor, and the difference of the sunshine hour distribution at the section A and B was not significant. On the other hand, in order to make better use of sunlight and to save heating energy, generally, it was realized that placing deciduous plants alongside a building would not block the natural lighting of the windows in winter.

Through the analysis of the distribution of sunshine duration from vernal to autumn, we can conclude 5 m away the building was the better location for planting a sun-shade tree. Moreover, shrub should be planted 2-3 m and 4-6 m away from the building at the sides A and B respectively to obtain the same sunshine hours. As noted above, this design approach was a not symmetrical layout. If plants are planted without considering the duration distribution of sunshine, the growth conditions and the ornamental quality of the plants could not achieve the desired effect. This approach helps for the rapid creation of unique and imaginative landscape designs, and decreased costs for maintenance.
In the northern hemisphere, most areas on the north side of buildings are faced with the problem of insufficient sunlight. However, a green and beautiful entrance scene can be constructed successfully so long as ornamental plants with shade tolerance are placed at proper distances from the building.

In this work, we present the EVSH curve as a novel concept to review the required sunshine conditions for greening around a building. The ESVH curve can also be applied in reducing the maintenance cost of the plants in the built environment and for mastering the guidelines of "sustainable landscape design" before the commencing with the construction. In particular involving the concept of the EVSH curve for the layout design of roadside trees, flower beds, and plaza greenery in urban environment, one can determine the relevant conditions in advance as follows:

1. Sun plants or shade plants to be selected
2. The proper planting distances from buildings
3. Plant height and expected growth height
4. Planting seasons and ages of tree.

Figure 7. The overlapped EVSH curve of the section A and B at different seasons. (a) at the vernal/autumnal equinoxes (b) at the summer solstice (c) at the winter solstice. Drawing outlines represent the better location for planting a sun-shade tree or a shrub.

4. Conclusions
Three of the findings from simulation and on-site observation are worth summarizing:

4.1. Visualized quantitative data was beneficial for landscape design in helping to make decisions according to local conditions

Planting design and arrangement in accordance with local conditions are important. Conventionally, the meteorological data in a contained environment such as a greenhouse was monitored on a regular basis in order to know the optimal region for the trees and flowers. However, due to the city's varied topography and building patterns, weather conditions may vary from block to block. It is always laborious and costly work to acquire long-term meteorological data in a built environment to determine the optimal species of plants adapted to the different light conditions. The computer simulation techniques involved in making such an extrapolation can be quite effective and accurate. In the study, the visualized sunshine maps reveal that not only shade effect of the three-story building (building 1) but also the shade effect from building 2 and 3 should be taken into consideration; moreover, sunshine hours at different elevations were also displayed for evaluating their growth conditions. As far as the case is concerned, arbor planting in a symmetrical configuration did not coincide with the symmetrical sunshine condition. At the left side of the portico side B, the sunlight distribution resulted in an adverse situation for the growth of grass and shrubs, and one solution for the situation was to cultivate ornamental plants with shade tolerance.

4.2. Vertical elevation effect on the light environment: arbor-shrub-grass

Generally, the canopy layer of arbor is the main area for photosynthesis, and the direction of plant growth is also modified by the light environment. In this case, the *Juniperus chinensis* lean outward to the EVSH curve; moreover, the sparseness of branches and leaves of *Juniperus chinensis* can be observed in the shaded area, as shown the pictures in Figure. 2. The multi-layer planting approach was a promoted index in the field of green building design. In order to reach the maximum greening effect, the comprehension of the vertical sunshine distribution is an essential task during the design, and the developed EVSH curve could provide an alternative approach to expand the design in scope and depth based on this quantitative analysis in the future.

4.3. Construct a plant “Light Comfort Zone” to promote "the optimal 4-D design"

Since four clearly distinct seasons is the characteristic of the climate of subtropical zones, the impacts of creating shade in sunshine conditions obviously vary with the different seasons. The four dimension (4-D) light environment including space and the seasonal change for plant growth is worthy of detailed analysis. In summer, the overheated period in Taiwan lasts 2-3 months. If one can take the advantage of the shading effect from the buildings, it would be possible to
transform limits to positive potentialities for plant growth. To reveal the facts hidden in the ecosystem by observation is one meaning of the "visual ecology" in a built environment (Robert, Thayer, 1976). It is a powerful method to construct a mutually beneficially environment between nature and design.

Synopsis:
The world is growing fast, especially in the urbanized areas. Urbanization is a complex phenomenon that involves change in multiple dimensions, including a growing number of people who live in urban areas, the expansion of built environments, and changing norms, cultures, and ways of living. It is a complex and connected network in which every decision has far-reaching consequences. It is also a living system in which ecology, economic exchange, policy, and social justice inform and intersect one another. Our environment is reacting to the rapid changes we have made, as a result, the projection and prediction of impact have surprised us more frequently in reality than ever before. None of the major challenges of modern cities facing, whether it is poverty, environmental degradation, social segregation, transportation or inequality, exist in isolation of the others. Globalization not only reflects the interconnected economic and social system, but also changes the scale of the event and of vulnerability. It leads to a re-thinking of the scales of resilience as a chain of network.

Sometimes, the projection in sea level rise and the growing urban phenomenon do not correlate to scale of living in people’s daily life. It has to be geographic sensitive when we talk about the future of resiliency. It is important to think regionally yet with a systematic network in mind. We also need a plan that looks beyond preparation but also mitigation and resiliency in many aspects. The plan will build a consensus and facilitate among different agencies and for the public to have a right channel to understand the complex issues and prepare accordingly. As a result, the messages and delivery for such a comprehensive issues have to be carefully thought through to have a more inclusive dialogue, especially for the group that is most vulnerable when the event arises. A community’s connection to place is at the very heart of resilience.

Although the message should be as simple as it should be, we do need layers of strategies that is interdisciplinary and looking beyond the conventionally defined resiliency in the urbanized areas, to investigate the potential issues that is caused by the climate change or other human factors. The urban resiliency is a transformative concept that requires the new approaches to address both the flexibility and efficiency without compromising. It also should be an integrated concept that pushes the boundaries of understanding in the contextual conditions across social, ecological, economic and systems that allow agencies to adapt and learn. In the lecture, Ming-Jen will share cases in Boston and other global cities who have taken on these unprecedented challenges.

Synopsis:
Gena Wirth, Design Principal at SCAPE, will talk about SCAPE’s work advancing coastal resilience through the design of living infrastructure. She will feature two projects, Living Breakwaters and Public Sediment, that shift the infrastructure planning paradigm toward the design of living and adaptive systems that can respond to uncertainty and environmental change.

SCAPE’s work is inspired by pre-industrial age agriculture, aquaculture, and technology and reinterprets these systems to inform future relationships with the land and water. Living Breakwaters is inspired by the historic oyster reefs of New York City, where subtidal reefs and leased oyster beds once extended across the shallow water flats of Raritan Bay, reducing storm impacts and filtering water. Looking back reminds us that dramatic change in place, environment, and ecosystem is part of understanding current urban ecology, and critical in projecting forward newly modified cohabitats and communities. Living Breakwaters builds on this legacy and is developed for the Rebuild by Design initiative in response to the damage caused by Hurricane Sandy. The project develops a protective necklace of breakwaters designed for risk reduction and habitat regeneration along the South Shore of Staten Island and Raritan Bay in New York, planned to start construction in 2019.

While extreme events shape the dialogue around climate resilience in coastal regions, many large-scale infrastructures designed to protect against these events neglect the experience of the everyday and sever a community’s relationships with water. Public Sediment, a project designed to help the San Francisco Bay area adapt to rising sea levels, plans for community stewardship and ecosystem function within a larger watershed, today, to adapt to threats at the water’s edge. Public Sediment for Alameda creek is a proposal to design with mud, the building block of resilience in the San Francisco Bay area. The baylands require sediment to keep pace with sea level rise, yet sediment is trapped upstream in dams and flood control channels. To bring sediment to the baylands, the project proposes to unlock and redesign Alameda Creek upstream, as the creek is the largest local tributary that feeds the Bay. Public Sediment strategically redesigns this waterbody to create functional systems that sustainably transport sediment, engage people, and provide habitat for anadromous fish. Upstream work boosts sediment flows downstream, and connects the creek to the marsh, creating a resilience and healthy bayland that can better adapt to sea level rise.

Both of these projects represent a paradigm shift in how we plan for climate change – rather than hardening the edge and ignoring the long-term consequences, this work propose to recalibrate our relationship with sediment and water resources and invest today in living systems that grow over time and adapt to a changing climate. While the projects are site and place-specific, the concepts are broadly applicable across multiple scales and geographies.
Designing Resilience In Asia. Designing The Unpredictable, planning with uncertainty.

Professor Oscar Carracedo García-Villalba
Director Designing Resilience in Asia Research Programme
Director Master of Urban Design
National University of Singapore

Synopsis:
In the last decade and beyond, we have witnessed in greater frequency extreme weather events and natural disasters due to the effects of global environmental and climate change. Events such as the 2015 earthquake in Nepal, the 2013 typhoon Haiyan or the 2011 flooding in Thailand evidence how relevant is building resilient Asian cities and communities, specially with the exponential urbanization and population growth.

The Designing Resilience in Asia (DRiA) International Research Programme, hosted by the School of Design and Environment of the National University of Singapore, was initiated in August 2014 with the objective to promote and foster a substantive research and discussion about innovative ideas and propositions towards the resiliency and sustainability of Asian cities in light of the effects of climate change.

In the DRiA, we understand Urban Resilience as a model for anticipating, preventing and preparing for the effects of climate change and global warming that we are experiencing before us such as sea level rise, flooding, coastal erosion, storm surges, typhoons, earthquakes, etc. The programme assumes an active responsibility to return to our cities and urban environments the original environmental qualities. With the objective of promoting this environmental recovery, practical actions and specific solutions are designed and planned to adapt to the impacts of climate change, as well as to mitigate the causes of global warming, protecting cities and communities and reducing their vulnerability.

The DRiA programme aims to fill the gap between research and practical implementation promoting innovative responses to climate change through design. With this objective, the programme integrates research, education and capacity building efforts and translates research into practice in industries, local authorities and their cities globally.

An interdisciplinary network organization of researchers, designers, architects and planners from 14 prominent universities from Asia, Australia, Europe and North America, work on the investigation and proposal of architectural design, building technologies, urban planning and urban design solutions adapted to different contexts in order to prevent, anticipate, prepare for and respond to the environmental effects while simultaneously improve the quality of life of cities.

Last but not least, as a research programme within the National University of Singapore, the DRiA aims to create awareness and inspire students to re-think the role and social responsibilities of architects, urban designers and planners, and stoke the flames of passion within them. Through several projects done in China, the Philippines, Indonesia and Thailand, the lecture will explain how the DRiA understands urban resilience and the method applied to face the challenges that climate change poses to our cities.
[Eco]Logical Urban Placemaking: Connectivity and Climate Change Resilience by Design

Judith Stilgenbauer
University of Hawaii at Manoa School of Architecture, 2410 Campus Road, Honolulu, HI 96822, USA

Abstract

Comprised entirely of islands and surrounded by ocean, the Hawaiian archipelago and its inhabitants are highly vulnerable to the inevitable effects of climate change. The waterfront in Honolulu’s urban core is fragmented and lacks resilience, as well as social and ecological connectivity. Many of the city’s most densely populated areas, and the drivers of the state’s economic development—such as Waikiki—are located in very low-lying areas of the island of Oahu. Soon, these coastal parts of Honolulu will see increasing instances of multi-hazard flooding in near-shore developments through rising sea levels and the effects of storm surges, as well as ground water inundation. The city’s various fast-moving redevelopment and transportation plans currently do not sufficiently acknowledge these coastal vulnerabilities.

This paper highlights the role of landscape architecture in the creation of resilient waterfronts. It advocates for the anticipation of climate-change-related challenges through innovative urban ecological design that embraces dynamic conditions and flooding rather than preventing them. By challenging conventional wisdom and pushing beyond the status quo, the design research presented here—with its focus on tropical Honolulu—furthers and broadens the contemporary global discourse on climate-change-resilient, adaptive urban coastal development.

The outcomes of multiple years of applied research and speculative ecological design studios on topics of coastal resilience and sea level rise adaptation strategies held at the University of Hawaii School of Architecture under the direction of the author have stimulated public awareness and significantly contributed to the local professional discourse on the topic. Forward-looking, conceptual planning and design proposals for parts of the South Shore of Honolulu advocate for resilient, amphibious waterfronts that respond to climate change, flooding and inundation, as well as issues related to the city’s aging conventional infrastructure.

In times of changing climates, near-shore urban ecological design practice must anticipate variable built environment conditions and focus on adaptation strategies that decrease coastal vulnerabilities. Researchers and practitioners of landscape architecture are uniquely positioned to address the urban challenges of our time through water-sensitive ecological design.
Future Resilience concepts. Carefully conceived retreat and abandonment strategies for areas with future amphibious ground conditions need to be combined with intense densification and resource-self-sufficiency in less vulnerable parts of waterfronts. Adaptive multi-purpose ecological infrastructure, hybrid-type public open space systems, and networks of ecological priority zones become essential drivers of urban form in the planning of climate-change-resilient Honolulu coastal areas. They act as soft defense mechanisms against sea level rise and inundation, allow for indeterminacy, increase biodiversity, provide ecosystem services, and, at the same time, create livable urban place amenities for all people.

Varied, locale-specific sea level rise adaptation design strategies for waterfront neighborhoods and their infrastructure have the potential to merge the seemingly conflicting goals of ecological performance and urban placemaking into mutually beneficial, resilient relationships.

**Keywords:** Climate Change Resilience; Urban Waterfronts; Ecological Design; Sea Level Rise Adaptation; Placemaking

**Introduction**

As a result of growing ecological and social design challenges, in recent decades the environmental design professions have focused increasingly on sustainable urban design practices that address variable built environment conditions. This paper explores the role of adaptive, ecological infrastructure as an essential driver of urban form in the planning of resilient Honolulu waterfronts. In the not-so-distant future, climate change, weather variability, sea level rise, and ground water inundation will profoundly affect densely populated high-value areas of this tropical-climate metropolis. Practitioners of landscape architecture are uniquely positioned to address these urban challenges through forward-looking, water-sensitive ecological design concepts that have the potential to further and broaden the contemporary global discourse on resilient urban waterfront development.

**The Reality of Our Cities**

Heavily affected by ongoing urbanization, many metropolitan areas of the world are characterized by a general lack of ecosystem services. Most central city environments suffer from insufficient vegetated areas and the consequences of the urban heat island effect. Cities’ crumbling conventional gray infrastructural systems, engineered streams and copious amounts of impervious surfaces heavily impact the hydrological cycle and contaminate nearby bodies of water. Ongoing climate change will continue to amplify these and other urban ecological concerns and their resulting socio-economic and public health consequences.

The U.S. Global Change Research Program’s recently updated 2017 *Climate Science Special Report* in its “high” scenario predicts a 2-meter sea level rise by 2100 relative to 2000 levels. The six scenarios presented in the research range from low to extreme. [1] Comprised entirely of islands and surrounded by ocean, the Hawaiian archipelago and its inhabitants are highly vulnerable to the unavoidable effects of global warming. Rising sea levels will inundate Honolulu’s low-lying, densely developed waterfront in the foreseeable future. It is only recently that Hawaii
legislators, scientists, planners, and designers have begun to discuss and address the effects of climate change on the state’s built environment.

**Flooding Vulnerabilities and Responses**

Regular instances of saltwater inundation in coastal Honolulu are among the obvious effects of more frequent extreme weather events. The same can be said for the continuing erosion of shorelines, beaches, and wetlands, as well as expected habitat shifts or losses in protective aquatic ecosystems and coastal agricultural areas. Salt intrusion and potable water contamination are of great concern in a densely populated island environment with limited resources. Additionally, due to the higher density of intruding seawater, rising sea levels will result in ground water inundation of low-lying inland urban areas that are already prone to drainage problems and nuisance flooding. Contaminated coastal sites are in danger of releasing their pollutants into the water. Public uses and access to shorelines will be affected, public health impacts are expected, and weak populations might be displaced or left behind.

![Fig. 1. Multi-hazard inundation map illustrating Honolulu impacted by 1-meter sea level rise (blue) plus tsunami (orange) or hurricane surge (red); image: University of Hawaii Sea Grant College Program, 2014.](image)

Vulnerability maps, such as Figure 1 above, clearly illustrate how much of Honolulu's critical urban infrastructure and existing building stock will be in harm's way in the event of a one-meter sea level rise plus storm or tsunami surges: dense urban residential areas and economic centers, wastewater treatment facilities and major sewer lines, energy facilities, as well as transportation systems, including Honolulu's newly planned rail and the international airport. In late 2017 the Hawaii Climate Change Mitigation and Adaptation Commission released its new *Hawaii Sea Level Rise Vulnerability Adaptability Report*, a statewide evaluation of the islands’ susceptibility to sea level rise. Using models that predict a sea level rise increase of 1 meter by 2100 (an intermediate scenario by current standards), the report estimates that flooding due to coastal inundation will cause over $19 billion in land and structure damage, displace around 20,000 people, and affect 26,000 acres of coastal land, 65,000 structures and 38 miles of major coastal roads. [2]

Rather than passively reacting and rebuilding after disasters, cities such as Honolulu that—to date—have been spared major climate-change-related flood events need to anticipate future changes and increased variability in built urban waterfront environments. The common goal must be to embed creative forward-looking solutions in today's urban design plans and regulatory frameworks that anticipate change and address future climate-change-related ecological and socio-economic vulnerabilities in order to enhance and
sustain the quality of life and health for
generations to come.

**Dynamic Processes Over Time**

The landscape architecture profession
throughout history has embraced the
ephemeral and dynamic nature of its
medium and thus the notions of temporal
change and adaptation. In recent years, the
importance of the temporal and
indeterminate component in urban
ecological design has been widely
recognized and ecological processes are
routinely integrated into the planning and
design of urban sites.

Dynamic ecological placemaking that
balances designing for uncertainty with a
more traditional focus on carefully selected
permanent urban armatures and people-
centric places can lead to resilient solutions
that decrease shoreline developments' climate-change-related vulnerabilities.
Currently underutilized sites most
vulnerable to inundation, as well as outdated
structures and mono-functional
infrastructural elements, must be
reprogrammed into adaptive, multi-tasking
public open space systems and dynamic
green infrastructure. Innovative changes in
policy and operational practices will allow
for more spatial and programmatic
flexibility and a greater degree of
uncertainty in the built urban environment.

**Design Strategies for Rising Sea Levels**

By studying recent sea-level-rise-themed
ideas competitions and precedent design and
policy initiatives around the country that
address issues of coastal flooding and
inundation, particularly in the Gulf of
Mexico region following hurricane Katrina
and the New York and New Jersey areas
subsequent to superstorm Sandy, one can
deduce a number of common defense and
accommodation strategies.

Traditional hard defense systems against
coastal flooding include engineered linear
systems such as levees, seawalls, rip-rap,
and other forms of barriers that armor
existing shorelines. These systems have
been known to fail over time, often resulting
in catastrophic damage.

In contrast, networks of soft, green defense
systems—including strategically placed
living breakwaters, oyster or coral reefs,
coastal wetlands, tidal marshes, other green
shoreline buffers, and extensive systems of
park and green infrastructure in coastal
urban areas—rely on ecosystem services to
retain and absorb inundation, slow erosion,
provide habitat, and increase the distance
between water and vulnerable development
(Figure 2).

![Fig. 2. Soft defense and strategic retreat vision for McCully Avenue in the Ala Moana area of Honolulu; image: Duangpon Hanseree, UHM SoA, Spring '15 ARCH 743, instructor: J. Stilgenbauer.](image-url)
Commonly agreed-upon sea level rise accommodation design strategies include the elevation of coastal built structures and infrastructure, for example by raising the elevation of the ground or building on pilings that allow flood water to flow underneath; conceiving of floating buildings, transportation and infrastructural systems that respond to changing water levels; and developing floodable structures and open space systems designed to withstand inundation. Additionally, where feasible from a socio-economic perspective, withdrawal strategies might need to be applied strategically over time in the most vulnerable coastal areas of low-lying cities such as Honolulu. These strategies include designing for disassembly, managed abandonment, and retreat to higher ground or structures. Cities will need to apply locale-specific, complex combinations of the above mentioned and other innovative engineering and design strategies to achieve the goal of more resilient urban waterfronts.

Honolulu’s South Shore

A tropical island state in the middle of the Pacific, Hawaii will be progressively more affected by the dramatic effects of global warming and sea level rise. Many of the most densely populated areas of Honolulu and the drivers of the state's economic development, such as Waikiki, are located in very low-lying areas of the south shore of Oahu, which makes them prone to numerous flooding and inundation vulnerabilities. Soon, these parts of Honolulu’s waterfront will see increasing instances of multi-hazard flooding in near-shore developments through rising sea levels and the effects of hurricane and tsunami surges, as well as storm and ground water inundation.

The city's various fast-moving, existing shoreline redevelopment and transportation plans for Honolulu’s urban core currently do not sufficiently acknowledge these unavoidable coastal flooding vulnerabilities. The outcomes of multiple years of applied research and speculative, academic ecological urbanism studios on topics of sea level rise adaptation strategies held at the University of Hawaii School of Architecture under the direction of the author have stimulated public awareness and significantly contributed to the local professional discourse on the topic. These forward-looking, conceptual urban design proposals for the Waikiki, Ala Moana, and Kakaako neighborhoods of Honolulu advocate for resilient, amphibious waterfronts that respond to climate change, inescapable shoreline changes, flooding and inundation, as well as issues related to the city's aging conventional infrastructure.

Resilient Waterfront Design

In times of uncertain future urban conditions, it seems critically important that current urban design practice for near-shore developments focus on the implementation of hybrid-type performative public open space systems, adaptive green infrastructure, and networks of ecological priority areas that anticipate rising sea levels and amphibious ground conditions. Such an approach allows for the merging of the seemingly conflicting goals of ecological function and urban placemaking into a mutually beneficial, resilient relationship.
Hawaii’s year-round warm, humid, and nutrient-rich conditions provide fertile ground for varied, layered public open space networks, green infrastructure, and responsive, adaptive coastal wetland systems. Our goal must be the creation of sustainable urban place solutions that are problem solving, multifunctional, and dynamic, yet livable, beautiful, and memorable. Innovative urban design needs to allow for indeterminacy and, at the same time, appeal to humans’ desire for stability in their built environments.

Policy, regulation, development, and urban design decisions should be based on the spatial identification of vulnerable elements of coastal areas through mapping over time and careful risk assessment that, in addition to physical, ecological, cultural, and social factors, also takes into consideration questions of ownership and real estate value. Carefully conceived managed withdrawal strategies need to be combined with intense densification in higher areas. The design of these future dense, self-sustained and off-the-grid neighborhoods should apply varied sea level rise adaptation strategies through elevation of buildings and critical infrastructure, interspersed with floodable, performative open space-dominated public places. Locations most prone to damages from flooding and inundation should be set aside for programmatically indeterminate open spaces and ecological priority areas; more expensive, permanent development should occur in less vulnerable areas.

Critical (infra)structural systems and new transportation elements, gradually elevated off the ground over time, facilitate access to areas designed for flooding and connect future densely developed areas with decentralized systems of water, energy, food, and waste.

Recent design research conducted by the author with graduate students at the University of Hawaii School of Architecture has resulted in a number of additional findings and recurring themes. Urban ecological design proposals that anticipate and embrace change and flooding rather than attempting to prevent it seem more promising in addressing climate-change-related challenges. A carefully designed hierarchy of water-based and elevated, innovative transportation systems can serve as a resilient alternative to Honolulu’s current automobile-centric circulation system. As water levels rise, walkways and critical infrastructural elements need to be elevated off the ground. Streets become canals; underutilized spaces that are prone to flooding are turned into productive or ecologically performative urban landscapes. Elevated public transit, bicycle networks, and covered walkways facilitate pedestrian and material flows and become conduits for future adaptable, resilient urban infrastructure (Figure 3).

Fig. 3. New elevated urban infrastructural systems; image: Ronald Ribao, UHM SoA, Spring ’14 ARCH 543, instructor: J. Stilgenbauer.
Conventional gray infrastructure is reprogrammed into green infrastructure and ecosystems. A system of canals, wetlands, public open spaces, and elevated walkways drives urban form. Hard edges are softened, begin to perform, and provide habitat and storm surge protection. Coastal highways become waterways and floodable pedestrian corridors. These multi-purpose public waterfront promenades reflect both sea level rise adaptation and urban placemaking strategies (Figure 4).

Fig. 4. New pedestrian-oriented waterfront promenades and coastal defense systems; image: Ronald Ribao, UHM SoA, Spring ’14 ARCH 543, instructor: J. Stilgenbauer.

Self-sufficient, walkable eco blocks replace conventional city blocks and gray infrastructural systems. Areas that are subject to inundation undergo a scenario of managed retreat and possible future abandonment through elevation of critical infrastructure, retrofit of existing structures, and eventual disassembly. New ecological priority areas and biodiverse park-hybrid urban agricultural landscapes provide ecosystem services, create urban place amenities, and serve as soft defense mechanisms against sea level rise (Figure 5).

Such academic, speculative design work, by its nature, questions numerous current land management and ownership systems, regulatory frameworks, and ongoing development plans. However, as tragically demonstrated in places such as New York after superstorm Sandy, drastic changes in the way we regulate, plan and develop our waterfronts are necessary in order to prepare for the inevitable changes ahead. It is the role of the academy to challenge conventional wisdom and push beyond the status quo through furthering and broadening the contemporary discourse on resilient shoreline development and long-term planning and ecological urban placemaking for a sustainable urban Hawaii.

All urban waterfront planning and design work must anticipate uncertainty and focus on adaptation strategies that decrease shoreline vulnerabilities. We need to highlight the significance of green public corridors and other types of multi-purpose infrastructure that have the potential to adapt to changing environmental conditions and perform as soft shoreline defense systems.
and, at the same time, open space amenities and places for people.

Abstract

Internationally a growing body of literature has interrogated the vulnerability, risk, resilience, and adaptation of Indigenous peoples to climate change. Key traits in this literature synthesis point to the impacts of climate change on sovereignty, culture, health, and economies that are currently being experienced by Indigenous (First Nations) communities globally. While knowledge and science of how climate change impacts are affecting Indigenous peoples can contribute to the formulation of policies, plans, designs and programs for climate change adaptation, settlement resilience planning and greenhouse gas emission reductions, little research has validated this knowledge as well as its potential. In Australia, climate change is expected to have social, economic and environmental impacts on urban Indigenous communities inhabiting coastal areas throughout south-eastern Australia. These impacts include a loss of community and environmental assets, cultural heritage sites, significant impacts on the quality of life of populations, and the establishment of favourable conditions for the spread of plant diseases, weeds and pests. Over most of south-eastern Australia, including southern Victoria and the Brisbane region, climate change is expected to lead to increased risk of heatwaves, longer drought periods, increased bushfire risk, increased risks of flood events and more frequent coastal inundation and associated impacts such as coastal erosion.

This paper defines and describes the key frameworks that inform Australian Aboriginal (and Torres Strait Islander) understandings of climate change impacts and pathways for adaptation and mitigation, including, sovereignty and self-determination, culture and cultural identity, and Aboriginal communities health indicators, with an emphasis upon Geelong and Brisbane urban areas. It also provides a synthesis of climate knowledge, science, and strategies that Aboriginal communities are exploring, and their understanding of the gaps in research on these issues. A review of the literature examining the impacts of climate change on urban Aboriginal people found that there is limited research on the topic in Australia and globally. The review identified that lower socio-economic members of this group are more vulnerable to climate change compared to the general Australian population. Their adaptive capacity is low as a result of the same systemic issues confronting Aboriginal people that have led to disadvantage. As such, research on climate change adaptation positions climate change as one
of the many issues facing Aboriginal people and needs to be addressed collaboratively and not in isolation. Research from other more remote regions in Australia and abroad indicate collaborative community-based approaches are needed for effective climate change vulnerability assessments and the building of individual and collective adaptive capacity.

The evidence emerging from this research clearly demonstrates that Aboriginal people’s consideration of the future, even with the overlay of climate change and the requirements for serious considerations of adaptation, are significantly influenced and dominated by economic aspirations which are seen as fundamental survival strategies for their communities.

**Keywords:** Australia; Indigenous knowledge systems; Aboriginal knowledge systems; First Nations; Climate change; Wadawurrung; Quandamooka; Kaurna; Wathaurong; Boon Wurrung; Bunerong; Jagera; Landscape architecture

1. Cultural Acknowledgement

We wish to acknowledge the Elders, families and forebears of the Kaurna people of the Adelaide Plains region, the Wadawurrung and Boon Wurrung peoples of the Kulin Nation surrounding the Port Phillip Bay region, the Jagera people of the Ipswich and Brisbane region, and the Quandamooka people of Moreton Bay and North Stradbroke Island, past present and future, who were and are the custodians of the land and water for many centuries.

2. Introduction

For some of our Indigenous co-authors on this paper, they are not certain what all the relatively sudden interest in ‘climate change’ is all about.

Our Wadawurrung human ancestors have witnessed and orally recorded histories of sea level rises, loss of land bridges and the formation of new bays and barrier reef complexes, seen volcanoes exploding and their lava cover our favoured grasslands, and the vegetation of our Country change from a mixed wet sclerophyll to a dry sclerophyll open forest and expansive grassland in synergy with major increasing changes in temperature and declines in seasonal rainfalls [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11].

For the last 50 years we have witnessed academics and politicians debate, research, discuss and put forward arguments and thoughts about the last 200-500 years of human residency and impacts upon this planet.

The question we ask is,

Why are we not asking the Indigenous peoples of their regions who have generationally witnessed often 60,000 years of climate change transformation, and whom offer remarkable lessons in resilience and adaptation, what has been occurring and how have they managed this change and how to go forward?

We all know that the Earth is changing, is continually changing, has never stopped changing its environmental fabric and biological residents since Pangaea evolved in the late Paleozoic and early Mesozoic eras, and humans have certainly aided the pace and perceived impact of this change in the last 12,000 years since the Agricultural Revolution by their ‘acts of progress’ and the digital accessibility revolution that we are experiencing. It is more a question of time, shortness and longevity of time that
offers different insights as to this ‘climate change’ of which Western knowledge appears to be temporally short in its ‘reading’ of time, whereas Indigenous peoples interpret time in both temporal short and long but also future time dimensions.

Climate change is affecting the sovereignty, culture, health, economies, and life of Indigenous or First Nations peoples across the World [12, 13, 14, 15, 16, 17, 18, 19]. The level of recognition of impacts upon First Nations peoples and their Country’s or lands/waters however is very mixed according to political jurisdiction and that First Nations’ standing and political legitimacy within the boundaries of the present ‘nation’ in which they reside today. In particular in Australia [12], New Zealand, the United States and Canada [13, 14, 15, 20, 21], there are very different understandings and recognitions of First Nation sovereignty and scientific acceptance of their Knowledge Systems as holding valuable longitudinal environment.

Colonisation has resulted in dispossession and transference of residency and knowledge, but not the cultural obligation and will to care for Country and to take a larger custodial role within the ‘temporary’ Western rules/laws that have only often 200 years of existence [22, 17, 23, 24, 25]. Thus, for Aboriginal Australia, the passion and commitment to continue custodial obligations and relationships with Country, with each Aboriginal nation’s or community’s lands and waters [27], is still there despite social, economic, demographic and educative attempts to assimilate and colonize both people and land.

Country refers to Australian Aboriginal and Torres Strait Islander people’s traditional affiliation and responsibility for lands and waters which they collectively refer to as their Country, of which they are a systemic part of this Country [28, 29, 30, 31]. The analogy, is an ecological system whereby their culture positions humans both as an equal actor but also as an environmental quality performance monitor in anticipation of the return of their Ancestors whom vested these obligations and responsibilities upon them. Responsibility to look after or ‘care for country’ is a key part of these Aboriginal societies together with their family groups, clans and as individuals.

Anthropologist Rose (1996) has explained Country as:

People talk about country in the same way that they would talk about a person: they speak to country, sing to country, visit country, worry about country, feel sorry for country and long for country ... country knows, hears, smells, takes notice, takes care, is sorry or happy ... Because of this richness, country is home, and peace; nourishment for body, mind and spirit; heart’s ease [28].

In this paper, we use the terms ‘First Nation’ and ‘Aboriginal (and Torres Strait Islander)’ and ‘Indigenous’ interchangeably unless referencing a specific group or specific recognition status.
3. International obligations

The right to Indigenous self-governance and self-determination has been acknowledged by the majority of nations around the world as signatories to the United Nations’ Declaration on the Rights of Indigenous Peoples [43]. Appendix A summarises the key Articles that need to be heeded.

In October 2016 UNESCO led a workshop on “Mainstreaming Traditional Knowledge to support Climate Change Adaptation Policies” focussed on the valuable role that Traditional Ecological Knowledge (TEK) plays in its ‘adaptation to climate change variations that concluded the need to contend with environmental changes, as recorded in points 1-5 in Appendix B, and that

These knowledge systems are transmitted and renewed by each succeeding generation, and ensure the well-being of people around the globe by providing food security from hunting, fishing, gathering, pastoralism or small-scale agriculture, as well as healthcare, clothing, shelter and strategies for coping with environmental fluctuations and external forces of change [13].

4. What the literature is starting to conclude

Increasingly academic literature has been examining the vulnerability, risk, resilience, and adaptive capacity of First Nations, Indigenous and Aboriginal peoples to climate change. There is however little Aboriginal voice in this literature and to a lesser degree Aboriginal authorship of this ‘research’ and discussion.

This larger body of literature is increasingly pointing to climate change impacts upon Aboriginal sovereignty, culture, health, livelihoods, and economies that are currently being experienced by Aboriginal communities internationally. This literature is increasingly concluding that each and all Aboriginal communities are already experiencing the impacts of climate change [14, 32]. While such impacts differ accordingly to region [33, 34, 35], there are commonalities in how climate change is experienced by these communities and how they are perceiving it is affecting their lifestyle, Country or customary obligations, and culture in the shadow of colonisation, dispossession and questionable sovereignty legitimacy over their ‘nation’.

Thus, coastal communities are witnessing erosion and sea-level rise threatening community infrastructure Country health further and are leading to forced displacement and relocation; some inland or freshwater communities are witnessing changes in streamflow and water temperature negatively affecting the succession and harvesting of fish, shellfish, eels and other culturally important species; for inland or saltwater communities rainfall frequency decline and increased propensity of prolonged drought is affecting soil quality and agricultural practices [36]. Such is evident affecting in reductions in access to culturally important habitats and species; such as making it more difficult for hunters
to access traditional hunting grounds, changes in animal migration patterns and plant flowering and fruiting patterns, changes in water temperature and flow increasing stresses upon fish and shellfish populations that are often vital to the economic, spiritual, and cultural health of communities; or, the increasingly influx or transmigration of noxious or exotic invasive animal and plant species mixed with prolonged drought disrupting agricultural and food harvesting practices. These changes threaten traditional knowledges, food security, water availability, the essence of Country and Aboriginal cultural obligations to Country, further undermine Aboriginal ways of life and the environmental quality and ‘health’ of lands and waters (Country) that have adapted for thousands of years.

The vulnerability of Aboriginal communities and their respective Country to climate change can be thematically observed through their cultural, social, and economic dependence on local species, habitats, and ecosystems, as well as legal, social, and political contexts of colonialism, institutionalized racism, and forced relocation [17, 23, 24, 25, 26]. Vulnerability is a product of systems of inequality and is not characteristic of a community Marino [24]. Communities and their respective Country differ in their vulnerability to climate change based on their distinct cultural practices and economies, and the vulnerability of Aboriginal socio-political, economic, and ecocultural systems may differ by geography and climate regime [37]. Climate-change ‘adaptation’ refers to preparing for, responding to, and coping with the effects of (contemporary) climate change. While ‘adaptation’ is not new for Aboriginal peoples, climate change impacts for Aboriginal peoples are increasingly threatening that what Whyte [26] calls their “collective continuance” or a “community’s capacity to be adaptive in ways sufficient for the livelihoods of its members to flourish into the future.”

Aboriginal vulnerability and resilience to climate change cannot be separated from colonialism 23, 24, 26, 38]. The latter created the contemporary economic conditions for anthropogenic climate change and the legal and social constraints that limit Aboriginal resistance and resilience capacity to ‘normal’ development change to their Country as well as climate change itself.

Thus,

Climate change itself ... is thoroughly tied to colonial practices, both historically and in the present, insofar as greenhouse gas production over the last two centuries hinged on the dispossession of indigenous lands and resources [38].

As a result of colonialism, many of the traditional adaptation practices that allowed Aboriginal communities to endure environmental changes are no longer possible. Thus, climate-change adaptation is not only about responding to observable impacts of climate change, it is also about understanding the politically-informed context and the often Western process that structures the way Aboriginal communities are exposed to the impacts of climate change.
The Intergovernmental Panel on Climate Change (IPCC) defined resilience as “the ability of a social, ecological, or socio-ecological system and its components to anticipate, reduce, accommodate, or recover from the effects of a hazardous event or trend in a timely and efficient” [20, 21, 39].

Although Aboriginal resilience does not eliminate the consequences of colonialism or climate-change impacts, it does demonstrate the capacity of Indigenous populations to monitor impacts and to develop strategies for adapting to and mediating climate change in short to long term visions. This resilience is embedded in Traditional Ecological Knowledges, livelihood diversity, Country-specific cultural values, and new social and cross-Country networks towards sharing strategies and information about adaptive capacity [13, 40].

5. Indigenous Communities in Australia

To better understand these Aboriginal peoples’ strategies to climate change, a deep investigation was undertaken with key representatives from Aboriginal organisations in five coastal locations in three states of south-eastern Australia [13, 41, 42]. The research thematically unravelled social, economic and environmental impacts on these Aboriginal communities including a loss of community and environmental assets, such as cultural heritage sites, with significant impacts on their quality of life and the establishment of potential favourable conditions for the spread of plant diseases, weeds and pests. The research also found that opportunities did not readily exist for engagement with climate change adaptation policy and initiatives and this was further exacerbated by acute shortages of qualified/experienced Aboriginal members that could represent their communities’ interests in climate change adaptation forums. The research conclusions clearly demonstrates that Aboriginal people’s consideration of the future, even with the overlay of climate change and the requirements for serious considerations of adaptation, are significantly influenced and dominated by economic aspirations which are seen as fundamental survival strategies for their communities.

A number of specific climate change induced issues to emerge from the research included: the potential for Aboriginal involvement in the ‘bush tucker’ industry utilising wild plant species will potentially suffer from changes in species availability; concern was expressed about changes associated with peri-urban and urban development which appears to be escalating micro-environmental changes; peri-urbanisation is a major environmental change which threatens cultural assets including Aboriginal sites; Aboriginal communities need representation in climate change adaptation forums and to be more directly involved in land and sea care projects. The chapter concludes with recommendations to better position Aboriginal engagement and knowledge systems in the wider climate change adaptation policy discourse.
Whilst conventional Australian climate change-related Aboriginal research has tended to focus on traditional Aboriginal communities of remote and central and northern Australia, these residential facts highlight the importance of understanding the majority of Aboriginal people, i.e. those residing in urban and peri-urban locations. Of note is a key difference between coastal urban and peri-urban Aboriginal people and those residing in semi-arid, arid and tropical communities in northern Western Australia (WA), Queensland (Qld) and the Northern Territory (NT). In essence, the former do not live in discrete Aboriginal communities and tend to be generally integrated into the wider urban and peri-urban community, i.e. the majority of urban and peri-urban Aboriginal people live ‘off-country’. This fact had important methodological implications for the research engagement with the case study organisations [12].

The participating Aboriginal organisations included:
- Boon Wurrung Foundation Limited – Boon Wurrung Country.
- Quandamooka Lands Council Aboriginal Corporation – Quandamooka Country.

The location of these communities are depicted on Figure 1. A summary of the generic characteristics of each of the five case studies and their respective organisation is provided in Appendices B and C..

Figure 1: Location of participating Aboriginal organisations. Source: [12].

6. Key Issues

The research employed a mixed method methodological process reliant upon a series of workshops with each community group. This resulted in the emergence of a number of consistent themes, namely: (i) Aboriginal representation; (ii) housing; (iii) employment; (iv) environmental and cultural assets; and (v) wild food network together with Aboriginal communities’ perceptions as to climate change variable risk and impact [12, 41].

Aboriginal Representation (or sovereignty) refers to the opportunities for, and capacity of, Aboriginal people to represent their interests and concerns in climate change meetings, decision-making forums and policy documents that are largely controlled by various tiers of government. This also relates to the availability of individuals who are capable
of representing their community’s interests in such forums and discussions.

Housing clearly was a key theme. It includes a category of issues related to the ability of Aboriginal people to either move or modify their existing housing to mitigate the effects of climate change. It also concerns the degree to which Aboriginal people can engage in energy and water saving schemes for climate change adaptation. All participants noted the large numbers of Aboriginal people from their communities who were reliant on public housing.

Employment concerns the negative aspects of job loss due to changing employment prospects through climate change and also included the positive aspects of job creation in industries involved in climate change adaptation and mitigation, such as carbon-trading and sequestering schemes and revegetation programs.

Environmental and Cultural Assets includes those connected to land managed by Aboriginal people as well as on-Country not directly accessible to Aboriginal people. It includes cultural sites containing burials and archaeological materials, as well as native title areas, Aboriginal-run farms, areas connected to fishing and hunting licences and national parks for which there are joint management agreements.

The Wild Food Network includes those concerned with the cultural and economic importance of Aboriginal people being engaged in the native bush food industry, particularly with wild harvesting, growing, processing, value adding, catering and spin-off guiding/talking businesses.

The evidence emerging from this research clearly demonstrates that Aboriginal people’s consideration of the future, even with the overlay of climate change and the requirements for serious considerations of adaptation, are significantly influenced and dominated by social and economic aspirations which are seen as fundamental survival strategies for their communities. This is largely because many other initiatives can be linked and/or run in parallel with climate change adaptation initiatives which can start to address some long standing issues of a socio-economic and human capacity nature.

Such strategies need to involve a high degree of inclusive participation and youth engagement to empower greater youth Aboriginal connection to Country, thus improving the chances of enhancing the climate change adaptive capacity of individual and collective Aboriginal peoples.

In summary, there was universal recognition that climate change was placing a disproportionate burden upon Aboriginal people. Circumstances contributing to this unsatisfactory situation included:

- the lack of specific climate change adaptation policy to support Aboriginal people and communities;
- a lack of awareness and understanding of climate change and adaptation options by Aboriginal urban and peri-urban people; and
• their dispossession and absence of direct access to their Country.

There was an overwhelming position that to adapt to climate change, access to land was important, change had to be seen, and there was a need to understand it.

7. Conclusions, Barriers and Limitations

Aboriginal peoples’ values and perspectives are absent in most Australian (Commonwealth, state and local) government climate-change programs and initiatives. Aboriginal community involvement is also lacking on government climate-change committees, working groups, and initiatives, leaving Country-specific perspectives and values absent from this discourse. This disvalues the significance of Aboriginal peoples’ knowledges in informing government climate-change research and policy towards the formulation of effective climate-change solutions.

The majority of Australian research relies upon peer-reviewed literature and does not take into account Aboriginal traditional knowledges and oral traditions. This further marginalises Aboriginal organisations, their voices and those of their communities and members whom are already delimited by limited access and vulnerability to political and economic contexts. Even with existing funding sources, communities often lack equitable access to financial, technical, and other resources needed to adapt and mitigate climate impacts and support renewable energy, energy efficiency, and green jobs programs.

While there is an increasing Australian government policy shift towards joint management of lands and waters particularly vested as ‘national parks’, the complexity of land and water ‘ownership’, native title, jurisdictional ‘management’ is resulting in unclear impacts upon native title and reserved lands, ancestral Country’s generally, as well as sacred sites and places therein.

Increasing Aboriginal participation and empowerment in climate-change initiatives is a key solution for increasing the resilience of Aboriginal communities in Australia.

There is a need to ‘listen’, ‘listen’, ‘listen’ and ‘ask first’ before writing conclusions, ‘answers’ and policies. Aboriginal perspectives and traditional knowledges must inform and guide climate-change assessment and adaptation to develop culturally appropriate strategies.

Because climate-change vulnerability is a product of historical and ongoing social inequality [24], it is important that Aboriginal communities facing relocation have access to lands of their choosing that allow them to continue traditional practices. The perspective and knowledges of Aboriginal communities serve as an invaluable source of knowledge for climate-change adaptation and mitigation strategies nationwide because of Aboriginal communities’ demonstrated capacity for adaptation [13].

However, with the limited number and diversity of Aboriginal communities covered
and the limitation in chapter length, the report captured only a snapshot of the breadth of climate-change impacts and solutions.

The lack of published knowledge about climate-change impacts on Australian Aboriginal (and Torres Strait Islander) peoples disadvantages these communities. Thus, research is needed to address these knowledge gaps to comprehensively and sensitively describe Country-specific Aboriginal (and Torres Strait Islander) values and ‘histories’.

Finally, we can be inclusive and comprehensive through the:

- Inclusion and integration of Aboriginal values within climate change understandings, policies and initiatives;
- Creation of Country-specific chapters on Aboriginal (and Torres Strait Islander) values in all climate change understandings, policies and initiatives;
- Publication of special reports on Aboriginal (and Torres Strait Islander) issues.

These changes would provide opportunities for the inclusion of more Aboriginal perspectives and voices [12].

So, if the contemporary policy and decision makers really want to appreciate climate change adaptation, resilience strategies, and a long perspective of environmental change ‘Why are they not asking the Aboriginal (and Torres Strait Islander) peoples of their regions?’

### Acknowledgments

The authors wish to acknowledge the kind involvement and support of the Quandamooka Lands Council Aboriginal Corporation Ltd, the Jagera Ganay-Magil Aboriginal Corporation Ltd, the Boon Wurrung Foundation Ltd, the Wathaurong Aboriginal Co-Operative Ltd and the Kaurna Nation Cultural Heritage Association Inc in consenting to participate in this research project and enabling staff and Elder involvement in the project.

The Landscape Carbon Calculator:
A Tool to Understand and Improve our Carbon Footprint

Pamela Conrad, RLA, LEED AP, Senior Associate
CMG Landscape Architecture, 444 Bryant Street, San Francisco, CA 94107

Abstract

Landscape architects are uniquely qualified to process and synthesize complex challenges that yield sustainable, world-changing solutions. We have a significant role to play in climate change – both in adapting landscapes from the effects of global warming and by mitigating, or designing against, the causes of global warming.

‘Landscape’ is what sets us apart from architecture and this distinction makes all the difference in what we are trying to accomplish. Landscapes are traditionally planted in one form or another so they possess the power to sequester carbon where architecture cannot. That said, landscape architects can do better than carbon neutral. We can strive beyond neutrality by providing Climate Positive solutions. In order to join this global initiative, we must measure the contribution of the profession.

To improve the impact of our projects on the planet, we must understand their Landscape Carbon Footprints. To enable this initiative, I have created a carbon calculator for landscape architecture that can track the carbon footprints of our projects and help set collective goals for the profession. This tool uses a 3-part structure that takes into account Sources, Sinks, and Costs – arriving at a Landscape Carbon Footprint.

After developing a beta version of this tool and running several CMG projects through it, directly applicable insights are observed. By making a few design or material changes, we can see drastic reductions in the overall carbon footprint of a project and the time needed to offset the carbon emitted during construction. On a park project, a few simple moves could have eliminated 200 metric tons of carbon from the atmosphere. And on a plaza site, by increasing the planting area from 5% to 10%, the time it takes to offset its emitted carbon is reduced by over 100 years.

This exercise confirmed that landscape architects impact the environment beyond the sensory experience. Through the development of this tool and ongoing carbon tracking through the life
of a project, we can greatly improve the carbon footprint of our projects. We can both decrease the amount of carbon emitted through our work and sequester additional greenhouse gases from the atmosphere, contributing to the reversal of global warming. It is through advancements like this that our profession has the chance to ensure future resilience of our planet.

Keywords: mitigate climate change

1. Introduction

As landscape architects, we are uniquely qualified to process and synthesize complex challenges that yield sustainable, world-changing solutions. We have a significant role to play in the fight against climate change – both in adaptation but also by mitigating the causes of global warming. But what is holding us back, and what are the tools that we need to step up to this challenge?

According to the Intergovernmental Panel on Climate Change (IPCC) we are on track to hit a two degree (Celsius) increase in global temperatures by the year 2050 [1] — at which point in time the scientific community tells us we “lock in the climate” to a constant state of change. Beyond this point, reversing global warming is no longer possible and we understand now that we have thirty years or less to prevent this catastrophic tipping point. Considering not all countries have signed the Paris Agreement, which targets preventing the two-degree increase, we need to take it upon ourselves as a profession to contribute to this goal.

The World Green Building Council reports that the built environment contributes to nearly half of the annual global greenhouse emissions [2]. Because landscape projects are typically grouped into the “built” environment with architecture and infrastructure, it is difficult to distinguish the landscape architectural contributions to the global carbon dilemma.

To put the impact of profession of landscape architecture into the global carbon context, according to the International Federation of Landscape Architects (IFLA), there are approximately 75,000 landscape architects [3] in the world. Conservatively, if the average size of our projects is an acre and each team (of 2 landscape architects) builds a one acre project per year, with an average emission of 25 lbs of carbon per square foot, the carbon footprint as a profession is 20 million metric tons per year – equivalent to the volume of 7,000 Olympic size swimming pools. At that rate, by the year 2030 the emissions exceeds 70,000 swimming pools, and by 2050 – the year we are expected to reach the 2-degree tipping point – it reaches over 200,000 pools (apprx. 500 million metric tons). Again, that is an extremely conservative estimation, but highlights the fact that our work does have a direct measurable impact to the environment.

The good news is there is something that we can do about it right now, without requiring global treaties or government mandates, or reducing the quality of our work – just the willingness to design for change.

Paul Hawken’s book, “Drawdown” describes eighty solutions that when implemented together over the next thirty years will reverse global warming. Fifteen
of the solutions are land-based. All of which can be implemented in the work of landscape architecture and add up to 20% of the total drawdown needed. They equal 200 out of 1,050 gigatons (GT) required to reach drawdown— the point at which atmospheric greenhouse gases begins to decline on an annual basis [4]. Those solutions cover a wide range from designing walkable cities to afforestation.

To address the positive contributions of site design specifically, as landscape projects contain trees and plants, they possess the power to sequester carbon. So, if each 2-person team of the 75,000 landscape architects builds a one-acre project per year for the next thirty years, we will sequester over 800 million metric tons of carbon (.84 GT) in our projects as typically designed with a 60% softscape to 40% hardscape ratio. After subtracting out our carbon footprints, the delta of our positive contribution is .28 GT of sequestration. If we can increase our contribution slightly through modifying our designs and increasing our sequestration above .32 GT, we will make it into the top 75 solutions for reversing global warming from “Drawdown”, achieving a greater impact than implementing ridesharing globally.

Landscape architects can do better than carbon neutral. We can instead strive beyond neutrality to be Climate Positive and contribute to the fight against global warming. To do this, we need the tools for change.

2. Objectives

2.1. Measuring Landscape Carbon Footprints

To improve the impact of our projects on the planet, we need a better understanding of Landscape Carbon Footprints. Carbon calculators exist for architecture, such as Athena or GaBi but none are publicly available for landscape architecture. Our work is distinct enough that we need a specific and custom carbon calculator for our profession in order to track carbon footprints and set collective goals. Without being able to measure the carbon footprint of a site, it is extremely difficult, if not impossible, to contribute to the 2030 Challenge [5] that the IFLA and the American Society of Landscape Architects (ASLA) have adopted, which targets that all projects be carbon neutral by 2030.

2.2. Goal Setting for the Profession of Landscape Architecture

We also need to understand Landscape Carbon Footprints to define terminology and appropriate goals specific to our profession.

The 2030 Architecture Challenge is an excellent and ambitious target for our colleagues, but is just that – an architecture challenge. “Carbon Neutral” being defined by Architecture 2030/The 2030 Challenge states that “All new buildings, developments, and major renovations shall be carbon-neutral by 2030”, and defines “Carbon Neutral” as “using no fossil fuel greenhouse gas (GHG)-emitting energy to operate” by the year 2030. Although the embodied carbon is understandably a fraction of the energy uses of a building over time, not targeting design elements that we
can easily change through the process is a missed opportunity.

More importantly for landscape architecture, because landscapes typically consume very little GHG-emitting energy to operate, as a profession, we should be more concerned about the GHG’s emitted in the production/construction of our sites. Being “Carbon Neutral” for landscape architecture is better defined as the point at which the emitted carbon from the project is offset by the site itself. The most significant goal for landscapes should be to minimize the initial carbon footprint of the project, offset that footprint through sequestration as soon as possible, striving to reach the point where we pull additional carbon out of the atmosphere. It is an instead a more proactive goal of being “Climate Positive”.

The thickening layer of greenhouse gases in the atmosphere is the cause of rising temperatures and the cause of climate change. Drawing it down is the most significant contribution that we can make as a profession to reverse global warming.

3. Methods

Without finding the tool needed to understand the carbon footprint of our projects at CMG, I created a simple carbon calculator. It uses a 3-part structure that takes into account Sources (embodied carbon of materials/construction – carbon emitted for the project), Sinks (such as trees, plants and wetlands – where the carbon is stored), and the Costs (carbon emitted through grading, ongoing maintenance, etc.). Then by adding the Sources and Costs together and subtracting the Sinks you arrive at the Landscape Carbon Footprint of a project.

\[ \text{Sources} - \text{Sinks} + \text{Costs} = \text{Landscape Carbon Footprint} \]

The Inventory of Carbon & Energy (ICE) Version 2.0 [6] from the University of Bath, funded by the Carbon Vision Buildings, the Carbon Trust and the UK Energy Research Council establishes the material embodied carbon quantities referenced in the calculator.

Similar to a typical project cost estimate format, the calculator lists building materials with their associated embodied carbon quantities. Separately the landscape Sink data includes annual sequestration rates (comparable to the US Forest Service tool called iTree [7]) which are subtracted from the total year one footprint. Similarly, the Costs, or additional emissions over the life of the project, are identified and added into the overall footprint.

A carbon footprint quantity represents the day one/year one impact, but in reality, that number changes over time. If the site has greater carbon Sinks than Costs, the initial carbon footprint is offset more quickly. The total emissions from the construction of the project are then tracked over time to identify the carbon neutral point and the transition into having a Climate Positive impact.

To gain a broad level understanding of Landscape Carbon Footprints, a wide range of projects were run through the calculator as originally designed – a garden, a park, a plaza, and a streetscape. Then modifications were made to the site without reducing the quality of the design to see if the overall footprint could be reduced.
In a separate exercise, the projects were scaled-up in size to better understand the emissions, sequestration opportunities, and offset time for larger scale projects.

4. Results

4.1. Measuring Landscape Carbon Footprints

By making a few design or material changes, we can see drastic reductions in the overall carbon footprint of a project and the time needed to offset the carbon emitted during construction.

The first case study was a half-acre garden project that was 60% pervious and included seventy trees. If our design replaced some lawn for shrubs, used a locally sourced wood versus tropical hardwood, and minimized the aggregate base, we could have reduced the footprint by 25 metric tons and lessened the carbon neutral milestone by five years.

The second case study is a six-acre park, also 60% permeable and with closer to one hundred trees. This project as currently designed has a conservative footprint estimate of 1,000 metric tons of carbon, which will take at least thirty years to offset. By changing some asphalt to stabilized crushed stone paving, minimizing paving quantity by consolidating the vehicular access areas, reducing the depth of aggregate base, adding in fifty trees and swapping some lawn for shrubs, we could have reduced the carbon footprint by 20% and knocked ten years off the carbon neutral milestone.

Perhaps most significant is the half-acre plaza case study site, with only thirteen trees and 5% permeable surfaces. Just by increasing the planting area from 5% to 10%, we could have reduced the time it takes to offset its emitted carbon by over 100 years. Not only was sequestration increased, but also with the increase in planting area, hardscape was eliminated and less drainage infrastructure was required. The streetscape study found similar and comparable impacts and reduction strategies as the plaza.

One element that all case studies shared was the ability to decrease the time to get to carbon neutral by 50% without making significant design changes or quality reductions.

Another notable observation is that when scaling a project up in size, if the ratio of hardscape to softscape remains the same, the offset time remains similar to the small project. However, the overall carbon emissions of a large project significantly increases, so we should be mindful of trying to increase the softscape ratio on larger projects, ensuring to minimize the overall carbon emissions.

In addition to the case studies, through examination of the Inventory of Carbon & Energy and literature review, the following high-level strategies can be deduced:

1. High carbon outputs are from highly processed materials – plastics, steel, concrete
2. Natural elements have less embodied carbon – if wood, use reclaimed, or sustainably harvested
3. Use recycled materials where possible like steel or aluminum
4. Plant as many trees and plants as you can – incorporate forests at any scale, even tiny ones can have a great impact
5. Create other carbon sinks
   5.1. Coastal wetlands, such as mangroves, tidal marshes, and seagrasses can sequester up to five times the amount than tropical rain forests. [4]
6. Consider bamboo- because it is a grass, the plant can store carbon in the soil for thousands of years. [4]
7. Green roofs can sequester carbon and also reduce the energy needs in the floor below by 50% [4]
8. Use the maximum amount of cementitious substitutions (slag, flyash, silica fume) in concrete
9. Get creative to reduce materials in a attempt to “do more with less” – limit piping by using natural swales and permeable paving
10. Overgrading leads to an excessive release of CO2. Keep your site’s carbon in the soil. More information is available through understanding regenerative farming practices.
11. On urban projects, “greening” is a challenge. Consider vertical vines/gardens or rooftops.
12. Product manufacturers need to provide the carbon footprint of their products so we can incorporate this into the overall project carbon footprint. The preferred standard is the Environmental Product Declaration (EPD), a standardized report that uses the technique of life-cycle assessment (LCA) to quantitatively measure the environmental impacts of materials or products.

4.2. Goal Setting for the Profession

With the information from the beta version of the Landscape Carbon Calculator, we know at a high level that we can make changes immediately to our projects without reducing the quality of our work. With the case study knowledge, we could set a goal as a profession to reduce the emissions offset time of our projects by 50%.

The case study examples also highlight that there is a significant importance in the ratio of hardscape vs. softscape. With that knowledge, we could target a 60% permeable to 40% hardscape ratio from the outset of our designs. By employing that ratio, we can set professional or practiced-based goals of, for example, “All projects have a targeted goal of offsetting their footprint within 10 years” so we can more quickly contribute to drawing down additional carbon from the atmosphere.

With a better understanding of the profession’s impact, we can further define our role in global solutions, and set goals for ourselves. None of which was possible or at least was not publicly available to date.

5. Conclusions

5.1. Measuring Landscape Carbon Footprints

This exercise made it clear that landscape architects impact the environment beyond the sensory experience. With a more refined tool and ongoing carbon tracking through the life of a project, just like a cost estimate, we can greatly reduce the carbon footprint of our projects. Not only can we decrease
the amount of carbon emitted through our work, but the sooner we offset their carbon footprints, the sooner our projects can begin sequestering additional greenhouse gases from the atmosphere and contribute to reversing global warming.

The Landscape Architecture Foundation (LAF) has selected the advancement of the Landscape Carbon Calculator as a 2018 Fellowship recipient. This national platform, combined with the support and testing through CMG, will allow the calculator to be publically available and distributed for use in 2019.

Refinements to the beta version of the Landscape Carbon Calculator are scheduled to be shared at the ASLA Annual Conference in Philadelphia, Pennsylvania, USA in October 2018.

Once complete, this tool can become a resource for existing sustainability rating systems such as LEED or SITES to adopt.

5.2. Goal Setting for the Profession

Because we are a global profession, we must set goals at the global level. To date there is no guidance or measure of success for improving our contribution to this environmental crisis. Now is the time for us to step up in support of the Paris Agreement.

With the knowledge gleaned from the Landscape Carbon Calculator, our leading organizations can establish Climate Action Goals. These goals can targets for our contribution to the 2030 Challenge specific to our profession.

Because global temperatures and seas are already rising, our profession has a significant role to play in adaptation and designing for resiliency as well as mitigation. These goals should span all aspects of our professional contributions to climate change.

Climate Change is the most significant environmental challenge of the century and our contribution is now more important than ever. Through the development of the Landscape Carbon Calculator, which can inform a series of goals to support the 2030 Challenge and the Paris Agreement, landscape architects will join other leaders as Climate Positive advocates for the world.

Abstract

Discourses about urban heat island effects has pointed to two positive conclusions that firstly inserting greenery into the city fabric will ameliorate the impacts and that secondly the existing fabric already is serving in some capacity in ameliorating the effects. Both are conclusions positioned in static temporality and do not respect the dynamic nature of landscapes and in particular tree species. In these discourses little attention has been given to nurturing existing vegetative resources, sustaining these resources and how best to holistically address temporal change or the senescence of these resources. This paper considers case study’s the internationally iconic town planning template of the ‘City of Adelaide Plan’, elevated to prominence by Ebenezer Howard in his garden city arguments, but focuses upon the Park Land ring that has historically characterised Adelaide as being unique and of international cultural significance.

Trees are not static elements like buildings. They grow, mature and die, and their mature-phase profuse oxygenation cools the city environment and psychologically enriches its terrestrial and aquatic residents’ (human and animal alike) environmental behaviour. But tree loss is change. Loss does have a deterioration upon the urban heat island. It represents damage to the integrity of the urban forest, and is dynamic and multifaceted in its characteristics due to age, drought, species, longevity, clustering, water-draw, and density. The latter are exceedingly difficult variables and attributes to model especially when dealing with a plant palette of Indigenous, native and exotic species with a paucity of historical knowledge about their growth performance and health compounded by the short less than 200 year post-colonial invasion history of Australia’s plant and landscape architecture knowledge.

This paper examines vegetation geodesign modelling for the Adelaide Park Lands landscape to consider the consequences of species growth and senescence upon its urban heat island.

The evidence emerging from this research clearly demonstrates that Aboriginal people’s consideration of the future, even with the overlay of climate change and the requirements for serious considerations of adaptation, are significantly influenced and dominated by economic aspirations which are seen as fundamental survival strategies for their communities.

Keywords: Adelaide Park Lands; Tree succession planning; geoplanning modelling; Landscape architecture
1. Introduction

Contemporary academic and scientific discussions about urban heat island effects has pointed to two positive conclusions. The first is that by the insertion of greenery into a city’s fabric amelioration of heat island and climate change impacts will occur. Secondly, the existing vegetative fabric of the city is already serving in some capacity in ameliorating the effects [1, 2, 3]. Both are conclusions reflect the static temporality of data pertaining to trees and vegetation in their calculations and modelling. Both conclusions do not respect the dynamic nature of landscapes and in particular tree species type and growth patterns. Additionally, these discussions have paid little attention to nurturing existing vegetative resources, sustaining these resources and how best to holistically address temporal change or the senescence of these resources [4, 5].

This paper investigates the internationally iconic town planning template of the ‘City of Adelaide Plan’ [6, 7, 8, 9, 10, 11], elevated to prominence by Ebenezer Howard [12, 13, 14] in his Garden City arguments. The core focus of the investigation is upon the Park Land ‘ring’ that has historically characterised and encircled Adelaide resulting in its design, urban planning and environmental uniqueness and of international cultural significance [15, 16, 17].

Trees are not static elements like buildings. They grow, mature and die, and their mature-phase profuse oxygenation cools the city environment and psychologically enriches its terrestrial and aquatic residents’ (human and animal alike) environmental behaviour. Tree loss, tree limb fall, tree foliage shedding, pests and disease can affect the tree, natural and human tree structure or root damage is or results in change to the individual tree species as well as the tree family in its immediate location, and possibly the species only across a wider landscape [18, 19].

Tree loss has a deteriorating impact upon the urban heat island. It constitutes damage to the integrity of the ‘urban forest’, whether a formal or informal forest, whether a set of vegetated corridors or roadscapes, whether a sequence of exotic or indigenous grasslands, and thus this ‘urban forest’ is dynamic and multifaceted in its characteristics due to age, drought, species [18, 20], longevity, clustering, water-draw [17, 21], and density [19].

The latter factors are exceedingly difficult variables and attributes to model. Such modelling is especially more difficult when dealing with a mixed plant palette of Indigenous, native and exotic species with a paucity of historical knowledge about their growth performance and health compounded by the short less than 200 year post-colonial invasion history of Australia’s plant and landscape architecture knowledge.

Thus, vegetation in a city is the green infrastructure that enlivens the spirit and character of the place, psychologically and physically enriches the well-being of humans and animals, and mediates many of the negative effects of a city.
This paper examines vegetation geodesign modelling for the Adelaide Park Lands landscape towards understanding the consequences of species growth and senescence upon its urban heat island [2, 3].

The evidence emerging from this research clearly demonstrates that Aboriginal people’s consideration of the future, even with the overlay of climate change and the requirements for serious considerations of adaptation, are significantly influenced and dominated by economic aspirations which are seen as fundamental survival strategies for their communities [22, 23, 24].

### 2. Urban Ecology

Urban ecology evolved internationally in the 20th century as being a potential solution for improving sustainability and liveability in cities [25]. Authors like Steiner [26] and Ndubisi [27] have asserted that ecologically motivated landscape architecture and site design, such as the Sustainable Sites Initiative [28], is good practice.

With an increasing urban population globally and the challenges of incremental depletion of the Earth’s resources and increasing pollution, more academic and policy attention is being given to investigating, analysing and proposing actions to improve the quality of our urban environments. The conservation and enhancement of nature and natural processes in cities is increasingly perceived and documented as one key solution to some of these global and local challenges. The two-way relationship between city and nature, or
the ecology of the city, is instrumental in this policy discussion, whether in Singapore, Melbourne or Adelaide.

Niemelä [29] has investigated the emergence and history of the discipline of urban ecology and studied different aspects of urban ecology science. His examination of the ecological patterns, processes and applications in urban environments and accompanying discussion about the ecology of urban settings and their relationship with urban land use planning, points to the immediacy of taking a solid appraisal of existing and proposed green infrastructure and the need to take a dynamic vision to manage this resource. What is also clear from contemporary research is that the bigger picture of ecological land use and smart growth planning and proposed strategies and criteria for planning and designing multi-functional green infrastructure need to scaffold and promote ecological services in the city.

We argue that urban ecological studies must include multi-functionality, connectivity, integration, communicative and social-inclusive processes, and a long-term strategy thinking, and recommend that these approaches be applied to improve our cities. But such investigations must be dynamic in their perspective, not be impeded by ‘now’ information, but toned to incorporate the modelling of vegetation growth and succession so to better manage the current and future urban heat island effects that are increasingly encircling our cities. In formulating this argument, we recognise that a major goal of urban ecology is to understand the relationship between the spatiotemporal patterns of urbanisation and ecological processes. Such research needs to identify and discuss urban ecological patterns and processes in a dynamic not time static model, and in particular examine it having regard urban infrastructure planning and design.

Urban ecology principles have evolved since the 1970s, and there is increasing interest among scholars to investigate ‘urban ecology as science of cities’ [30]. Urban ecology principles currently embrace a wide range of variables, values and attributes in habitats, biodiversity, plants and vegetation, animals/wildlife, soil, chemicals, air, water and organisms, greenspaces, and residential, commercial and industrial areas in cities and rings around the city [31].

Pickett et al. [32] have recently concluded that ecology in, of and for the city are valid approaches to advancing the knowledge of urban ecology. In this research, ecology in the city focuses on natural features within cities, whereas ecology of the city involves entire urban mosaics as social-ecological systems of biological, social and built components. Ecology for the city helps urban sustainability goals and encourages ecologists to engage with other disciplines to shape sustainable urban environments. These perspectives—especially Pickett et al’s [32]—are helpful in landscape ecological methods and their applications in the study of urban infrastructure as it relates to broader urban environments.

3. Adelaide Park Lands and National Heritage

The ‘Adelaide Park Lands and City Layout’ was included in the National Heritage List as fulfilling criteria a, b, d, f, g, and h as quoted in Appendix 1.

Minister Garrett concluded that the place fulfilled 6 of the 9 values for Listing evaluation under section 324JJ of the Environment Protection and Biodiversity Conservation Act 1999 [34], and that the ‘significance threshold’ was successfully fulfilled.

The Adelaide Park Lands is a ‘cultural landscape’ comprising approximately 900ha. It is a multi-layered tract of land possessing Indigenous and post-contact associations, meanings and physical expressions both tangible and intangible [35, 36].
Cultural landscapes falls within the definitions of cultural heritage used by the former *Australian Heritage Commission Act 1975* [37], the present *Australian Heritage Council Act 2003* [38], the ‘Burra Charter’ as authored by Australia ICOMOS [39, 40], and the meaning under the *Operational Guidelines for the Implementation of the World Heritage Convention* [41, 42]. The latter definition is provided in Appendix C.

As a definition, and given the nature of the recent National Heritage listing, the listing is for the ‘Adelaide Park Lands and City Layout’. Thus, the listing includes the ‘park lands’ but also the squares within the ‘layout’ as well as all roadways and several tracts of state government administered land including the Adelaide Botanic Garden. It is important to note that most published literature separates the ‘park lands’ from the ‘squares’ in their narratives and definitions, but that under the Listing both tracts of land are included and that this spatial definition is used in this article. Further, most published literature also interchangeable uses ‘park lands’ or ‘parklands’ as a descriptor for the tract.

The place was deemed as possessing ‘outstanding heritage value to the nation’ in influencing the ‘course [and] … pattern’ of the nation’s ‘cultural history’, as per criterion (a) [9, 10, 15, 43, 44, 45, 46, 47].

In particular, it contained a physical expression of the Plan draped over the Adelaide Plain and continued to maintain high integrity in its authenticity and had suffered minimal compromise in amendments and changes to the overall configuration and road circulation system.

Second, the Plan was concluded a being a precedent of settlement planning in the Australian colonies, that embodies an aesthetically embellished ‘city plan’ possessing wide boulevards, generous open spaces reminiscent of London’s town squares.

Third, the overall ‘Plan’ had been and continues to be guided by a single co-ordinated management regime and this longevity of curatorial role, deemed valuable as part of the criteria applicability, was equally matched by a citizen or community-based action group – the Adelaide Parklands Preservation Association.

Fourth, it was concluded that the Plan exists as an international town planning precedent possessing the essential characteristics of the influential Garden City planning philosophy and movement, and continues to hold an international precedent role today in planning and landscape architecture literature.
4. Tree Longevity

Trees are both the longest-lived and largest organisms on Earth. These are distinguishing factors within the plant kingdom. Trees have been described by Shigo [48, 49] as being ‘A perennial, woody, compartmented, shedding plant; may be short or very tall, single or many-stemmed, sometimes massive, and long-lived’. Cobham [50], due to tree longevity, has observed that these plants can ‘provide long-term structure’ to the landscape. Additionally, Fakes [51] has observed that in order for a tree to provide this structure and therefore make this significant contribution to the landscape, it must ‘live long enough’. If they do live long enough however, old trees may become ‘important points of reference’ in the landscape, and may assist to ‘determine the character of an area’, according to Russell et al [52].

As ‘integral parts of cities around the world’, and within a planning context, trees in urban landscapes have been considered to be features almost as important as buildings themselves, noted Russell et al. [52], and ‘have a higher priority in our towns and cities now than at any time previously’. The importance of trees in the landscape has resulted in a need for appropriate levels of understanding of these living organisms.

Definitions of both ‘senescence’ and ‘aging’ within the plant kingdom were examined in studies by Leopold [53], and Noodén [54, 55]. Leopold [53] has defined senescence as ‘the deteriorative processes that are natural causes of death’, and aging as the ‘processes of accruing maturity with the passage of time’.

Thus, aging was perceived as incorporating ‘... a much wider span of physiological changes, some of which may lead to the weakening of the organism while others may be quite neutral with respect to the capability of the biological organism to survive’. Examples of aging provided by Leopold [53] include the ‘physiological changes in a plant’, such as those causing ‘its conversion from a seedling to a juvenile...
plant, from a juvenile plant to a mature plant’ or in the ‘gradual decline’ in vigorous growth as age increases. Salisbury and Ross [56] defined senescence as ‘The processes of deterioration that accompany aging and that lead to the death of an organ or organism’. Leopold [53] characterises senescence changes as including changes leading to the colouring and eventual death of leaves on deciduous trees in autumn, and the death of annual and biennial plant species following their fruiting period.

Noodén’s [54] definition mirrors Leopold’s, with senescence described as ‘a decline in physiological functions leading to death’, with the following concise explanation:

During the course of their lives, all multicellular organisms and their organs or tissues reach a peak in terms of their physiological function, and then they decline until they die. This process of decline leading to death has been termed senescence, and a distinction has been made between degenerative changes that lead to death (senescence), and those that do not necessarily cause death even though they accumulate with age (aging) [55].

An important aspect of a study into tree longevity is an examination of the various factors that influence the lifespan of trees. The purpose of this is to identify the factors that cause tree death, and therefore potential limitations to tree life spans. The misconception within the wider community of trees being bestowed with ‘eternal’ life and not requiring replacement due to senescence was observed by Pescott [56] as having a detrimental effect in landscapes, as authorities can be influenced by these community-based attitudes.14

Patrick [57] established ‘that amenity tree plantings have a finite life’ and will eventually succumb to senescence. Shigo [49] also observed that ‘Trees, like all living things, grow old and die’. Hannah and Yau [58] stated that ‘Trees have a finite lifespan’. Building upon this Hannah and Yau [58] reasoned that beyond their optimal age, trees ‘will start to decline, reach senescence and ultimately die’. Crucially within this context of the inevitable nature of tree death, Clark and Matheny [59] observed that at some point in the lifespan of the tree, the amount of energy produced cannot meet the demands for continued ‘growth and survival’, resulting in tree decline and death. Shigo [49] had also noted this through the observation that ‘No living system can grow beyond the limits of energy available to operate the system’, and that ‘no matter what you do, all living things will eventually die’. If tree senescence exists and tree death can be substantiated, there must also exist upper limits to tree longevity.

5. Methodology

In this research, the development of models predicting possible future tree senescence patterns required a review of various fields of research in order to establish appropriate models for use, and to assign confidence levels based upon the knowledge of tree growth, longevity, and senescence in predicted landscapes. Various tree growth parameters were collected from the field and combined with assigned tree ages to create matrix models that represented expected tree
growth trends. Through the incorporation of curves fitted to these matrix models, tree ages could be assigned to tree specimens of unknown age, to determine dates of establishment based upon key growth parameters [60].

Tree longevity figures for each taxon were sourced from an expert horticulturally-qualified and applied practice experienced peer reference group survey conducted specifically for this purpose.

Through the combination of calculated tree age and predicted tree longevity, senescence patterns for a region of the Adelaide Park Lands were modelled. Interactive structured query-based GIS software was incorporated to display these senescence patterns visually, and to provide interpretations of future landscape scenarios.

Results obtained from the peer reference group survey provided a range of valuable figures representing expected tree longevities for 131 taxa from within the Adelaide Park Lands environment. An extract of the detailed results is set out in Appendix D.

These longevity figures, combined with matrix models and GIS simulations, were test trialled in Tuttangga/Park 17 of the Adelaide Parklands in 2009 [19], and revealed that considerable populations of established trees within Tuttangga/Park 17 in the Adelaide Park Lands are at a high risk of reaching senescence within the near future.

The data was then in 2018 applied against the whole of the Adelaide Parkland tree vegetation inventory, and similar concerning results and patterns as to tree senescence were realised.

The geospatial modelling part of the methodology employed to produce the various maps consisted of utilising a series of spatial overlays. Each overlay consisted of an aerial base map image of the City of Adelaide which was then over layered with GIS spatial data [60].

The City of Adelaide Tree file [60] represented the street trees in the CBD and North Adelaide region and are illustrated as red dots in Figure 7.

The Public Service Mapping Authority [61] Adelaide tree imagery file was used to illustrate the trees located in the Adelaide parklands area which surrounds the Adelaide CBD.

The PSMA raster file was converted from raster image to ESRI polygon shape file. The conversion process allowed the file to be thematically represented highlighting the number and type of tree.

A key finding from this modelling is the ‘scary’ end results of both the volume and spatial locations of tree senescence that will occurring in the next 20 years across the Parklands and city landscape.

Contextually, this is ‘scary’ because:
- the City is ill-prepared for this volume of tree senescence,
- the City does not have an adequate tree succession plan in place nor mature replacement trees going in plant nurseries ready to be used,
the City lacks a policy understanding as to how this will affect the city’s built environment character and fabric, and least of all the major urban heat island impact that will dramatically increase the city’s surface and reflection temperatures in the absence of this volume of species senescence as well as the locations where this senescence will occur.

Figure 7: Tree data assessment inventory locations of trees in the City of Adelaide.
Figure 8: Tree data assessment inventory locations of trees in the City of Adelaide, identifying patterns of projected tree senescence.
5. Directions

Tree longevity and senescence modelling is little used internationally as a tool to better understand the environmental changes faced by a city and its governance entity in dealing with climate change impacts, the implications of the urban heat island effect, and specifically tree succession planning.

In this research, it is:
- very clear that the City of Adelaide is ill-prepared for this volume of tree senescence;
- that the City of Adelaide does not have a robust tree succession plan in place nor mature replacement trees going in plant nurseries ready to be used, as used to occur under previous horticultural administrations of the Council in the 1860s-1940s period when extensive tree plantings occurred, and a very conscious tree-species specific tree planting program and vision were employed;
- that the City of Adelaide lacks a policy understanding as to how this will affect the city’s built environment character and fabric, and that such will dramatically affect the quality and intent of the National heritage Listing citation of the place as well as the Council’s adopted urban forest, greening, city strategy, and sustainability policies; and
- least of all the City of Adelaide council has little appreciated the role of extant vegetation and prospective tree senescence in managing existing and prospective the major urban heat island impact that will dramatically increase the city’s surface and reflection temperatures in the absence of this volume of species senescence as well as the locations where this senescence will occur.

Such findings, and conclusions, we venture, could easily be realised across the world.

In cities across the world, we need to mindful of these findings because of the way that are traditional tree succession planning has and is occurring being informed by static information lacking a dynamic context and the construction of an expect-informed reference group that has first experience in tree longevity and senescence pertaining to a specific piece of landscape.

Acknowledgments

The authors wish to acknowledge the GIS resources of the City of Adelaide Council in undertaking this investigation.

Future Resilience

(ACHM) 2005 Cultural Heritage Survey of the Adelaide Parklands.

[34] Australia, Environment Protection and Biodiversity Conservation Act 1999.

[57] R.T.M. Pescott, Life Expectancy and Planned Replacement, Proceedings of the Symposium on Street Trees, conducted by the Victorian Division, Australian Institute of Parks and Recreation, at La Trobe University, Bundooora, Saturday, 8th June, 1968, A.E. Wilkie (Ed.), Australian Institute of Parks and Recreation, Victoria Division, Melbourne, 196.

The National Heritage criteria against which the heritage values of a place are assessed are:

a. the place has outstanding heritage value to the nation because of the place's importance in the course, or pattern, of Australia's natural or cultural history
b. the place has outstanding heritage value to the nation because of the place's possession of uncommon, rare or endangered aspects of Australia's natural or cultural history
d. the place has outstanding heritage value to the nation because of the place's importance in demonstrating the principal characteristics of:
   i. a class of Australia's natural or cultural places; or
   ii. a class of Australia's natural or cultural environments;
f. the place has outstanding heritage value to the nation because of the place's importance in demonstrating a high degree of creative or technical achievement at a particular period
g. the place has outstanding heritage value to the nation because of the place's strong or special association with a particular community or cultural group for social, cultural or spiritual reasons
h. the place has outstanding heritage value to the nation because of the place's special association with the life or works of a person, or group of persons, of importance in Australia's natural or cultural history

Appendix B

The national significance of the Adelaide Park Lands and City Layout lies in its design excellence. The Adelaide Plan is regarded as a masterwork of urban design, a grand example of colonial urban planning. The city grid and defining park lands were laid over the shallow river valley with its gentle undulations, described by Light as the Adelaide Plains. The city layout is designed to take full advantage of the topography, an important innovation for the time. The streets were sited and planned to maximise views and vistas through the city and Park Lands and from some locations to the Adelaide Hills. A hierarchy of road widths with a wide dimension to principal routes and terraces and alternating narrow and wide streets in the east-west direction were featured on the historic plan. Features within the Park Lands area included a hospital, Government House, a school, barracks, a store house, a market and a botanic garden and roads.
Appendix C

37. The term ‘cultural landscape’ embraces a diversity of manifestations of the interaction between humankind and its natural environment.

38. Cultural landscapes often reflect specific techniques of sustainable land-use, considering the characteristics and limits of the natural environment that are established in, and a specific spiritual relation to nature. Protection of cultural landscapes can contribute to modern techniques of sustainable land-use and can maintain or enhance natural values in the landscape. The continued existence of traditional forms of land-use supports biological diversity in many regions of the world. The protection of traditional cultural landscapes is therefore helpful in maintaining biological diversity.

39. Cultural landscapes fall into three main categories, namely:

(i) The most easily identifiable is the clearly defined landscape designed and created intentionally by man. This embraces garden and parkland landscapes constricted for aesthetic reasons which are often (but not always) associated with religious or other monumental buildings and ensembles. ...

(iii) The final category is the associative cultural landscape. The inclusion of such landscapes on the World Heritage List is justifiable by virtue of the powerful religious, artistic or cultural associations of the natural element rather than material cultural evidence, which may be insignificant or even absent.

Abstract

In 2011 Thailand was hit by flood catastrophe which cost 14 trillion baht in damage. It was the wakeup call for Thai people to relook of what cause and what shall we develop our territory in the future.

For many decades we have developed our solid territory impose on the fluid territory. Fluid territory where we are living in is the Chaophaya River Floodplain which people in the past learnt how to adapt their way of life with flood phenomena. Since modern time we have applied the idea of man overcoming nature by building the solid territory. This solid territory is blocking the water way, replacing permeable surface, contaminating fertilized soil. We also applied modern agricultural method in order to be able to cultivate rice for 3 – 4 times per year which leave no rooms for flood water to contain. We also built the flood wall along the river bank to prevent city area from flooding .This flood wall has worsen the flood situation by escalating the water level in the river to be higher. This flood wall also damage ecology along the river at the same time. Solid city has applied solid solution to tackle the water by separating water from people and natural way of life. Solid territory has no rooms for water.

The flood situation will be worsen in the future due to the climate change which cause more rain fall and sea water rise while we still continue to build our solid territory to accommodate growing population. We shall relook at how the future territory should be developed in order to live with ongoing water challenges.

Hybrid city is the idea of how can we learn from the local wisdom in living with water in order to transform the solid territory to be more resilience with water and transform city to be more livable for all at the same time. Landscape can be a tool as green infrastructure in transforming the city toward hybrid city where solid and fluid territory can be coexist sustainably.

The strategy is to create more rooms for water within the solid territory by

1. Transforming agricultural land into water detention network
2. Safeguarding the existing permeable surface.
3. Reclaiming more permeable surface from the solid territory
4. Creating more water detention area and permeable surface with the new development.
5. Re-connecting all the water detention area of both private and public to work as one system
6. Forming a guideline to ensure the continuation of the water resilience strategy.
7. Empowering people to be part of the process

This strategy can be applied both in private and public development, new and existing development, as well as unutilized city infrastructure and abandon land. These developments include condominium, Community Park, street scape and district revitalization. With this strategy it will help city and citizen to relook in adapting our solid city to be more resilience with water challenge in the near future.

1. Introduction

With the growing of urbanization which create much problems to the environment especially at the flood prone city in the Asian metropolis where it is located in the river floodplain. The more we built or expand the city the more flood and environmental problems will occur due to city blocks the water way and it remove the permeable area for water. As the United Nation has predicted that by 2050, 70% of world population will live in the urban area. We have to transform the existing city not only to take care the growing population but also finding the way to resilience with water and environmental challenges at the same time.

This study looks into how the territory in the floodplain area has developed and evolved from the past until today by looking at Bangkok city as the case study. This study has led us to understand what cause the problems and importantly what are solutions from the local wisdom in living with water. This study also have led us to apply those wisdom into some of our ongoing landscape intervention projects which help transforming city to be more resilience with water which we can then conclude into strategies that can be applied to other flood probe area. We called the “Hybrid solution” which focusing on how we can make the existing city to be more resilience with water and environmental challenges while maintaining the city growth and lifestyle of the people at the same time.

2. Agenda

2.1 River as sources of life: Fluid Territory
Bangkok situated in the Chaopraya River floodplain. This floodplain was formed 6000 years ago by formation of the natural silt that Chaopraya River brought. Floodplain is where rivers meet and where the land is form. During the rainy season, water from the mountains in the north together with water from its own zone rainfall flow into the river and overflow into the flood plain area. With its property of floodplain which almost flat, it makes the water not to drain properly. In consequence, the area is flooded in the rainy season with an average height of 0.5 -1 meter. The water stays for a certain period of time around 3-4 months before slowly flow into gulf of Thailand. This natural phenomena brings natural silt which
contain a lot of natural fertilizer that help to shape the land.

Fig 1. Chaopraya River Floodplain

Fig 2 Section of Chaopraya River Floodplain

People who lives around Chaophraya river floodplain do aware of this water phenomena and natural asset that the river brings, people utilize this asset by settle their villages and cities near the river and within floodplain area so that they can benefit from this natural asset of water and fertilize soil. People then cultivated rice and orchard. People also use river for accommodating their daily life.

River becomes sources of life and culture in many ways. Thai people learn how to live with water not against it. It is the “fluid perception” in people mind that lead people to form “fluid territory” in adapting their way and space of living with water phenomena.

We still can see some evident of “fluid territory” in people settlements along the river and within Chaopraya River floodplain. Some of settlements along the river people adapted their boats to be their living area or constructed their house on floating pontoon. Some communities constructed their house on the tall stilt where living quarter located above flood level on second floor, while on the ground floor is used for storage. In some case people tide their house with the pole and let it float when the flood came during rainy season.

Fig 3 Settlement of People in Chaopraya River Floodplain

For agricultural activity, most of the floodplain area was used for cultivating rice. People creates the ditch and dike system around their farm lands to detain water which benefit of growing rice. People also do aware that rice is the planting species which consume a lot of water. One of the native rice specie that people in the past used can even tolerate with high water level up to 3 meters. In some areas along the
Chaopraya River, people strengthen the existing canal system to bring water from the river into their orchard plantation which formed by ditch and dike system.

For city planning along the river, canal system is the main intervention tool in helping city manage flood. Bangkok is one of the example, city has benefited from the orchard area and rice field around the city which acted as the sponge in absorbing water during rainy season. The city core itself also strengthened the canal system to serve as defensive barrier as well as the water way to channelling water from the north to the sea quickly.

Those adaptability concept in architecture, agriculture, city planning and way of living with water has progressively been changed when Thailand entered to the modern era.

2.2 Modern Era: Fluid Territory VS Solid Territory
During the modern era, Bangkok city area has expanded to respond with the growing population. However the way we develop the city in the modern day is no longer has “fluid perception “in living with water in mind like what people in the past had. We adopt the western way of urbanization in using technology and engineering approach to overcome natural phenomena. In consequence, we imposed the “solid territory” into the existing “fluid territory” which full of dynamic ecosystem of people and nature.

Fig 4 Evolution of the Settlement along Chaopraya River from Fluid to Solid Territory, Past to Present

The “solid territory “that we built has replaced orchard, rice field as well as natural area with concrete city and industrial estate. This solid territory is completely removed these productive
landscape area which also acts as water detention area for the city. Canal system in Bangkok city were also destroyed by replacing many of canals with roads. We used to have almost 2000 canals in the city in compare to 1600 canals at the moment. Bangkok city nowadays has lost its ability in dealing with flood.

Bangkok city and also other cities in Chaopraya River floodplain has grown in the way that block ed the water way .The agricultural land also been modernized .Nowadays we cultivate rice for export which focus more on the productivity which require irrigation infrastructure, technology and fertilizer. Native rice species was modified, rice field can no longer hold amount of flood water during rainy season since farmers require space to cultivate rice throughout the year.

![Fig 5 Settlement Block the Waterway in Chaopraya River Floodplain](image)

It becomes clear that the way we developed our city by imposing the “solid territory” into the “fluid territory” without carefully taking water phenomena into the consideration has led to the flood catastrophe in 2012 which cost 1.4 Trillion bath in economic damage and lost many life.

2.3 Solid Territory and its consequence.

Bangkok city is one of the city that illustrate how the city has evolved from” fluid territory “where people can live with water in harmony to the “solid Territory” where water become a threat .Nowadays almost 50%of the Bangkok city has already been transformed into concrete surface .The city surface has only 2% of green space while the 18% of agricultural and 8% of abandon area around and within city are undertreated due to urban sprawl. Many canals has already been replaced with road while Chapraya River also been narrowed down due to the encroaching settlements along the river which left only 24% of the city surface in channelling water.

As the result city is becoming more solid and losing its own capacity in absorbing water and ability in channelling water during the rainy season. Bangkok city has applied engineering approach in solving flood problem by constructing floodwall along the river and around the city. We are now living inside the floodwall .This flood wall has been constructed after flood catastrophe in 2012 in order to protect city from flooding. Flood gate and mechanical pump has been applied at all canals and river throughout the city to manage the water during rainy season.
Fig 6 Floodwall along Chaopraya River

The floodwall is as tall as 2.85 m from mean sea level which at some location it is high as one story building. It was built in the river just in front of the riparian area. This wall blocked the water flow which essential to the survival of riparian ecology. Those riparian ecology slowly died and soon was replaced with land reclamation. There are some evident show that by replacing those riparian area, it caused in reducing number of fresh water fish in the Chaopraya River.

The floodwall also built just in front of the river community which suffer the way of life of the people living along the river since they cannot connect to the river like what they used to be. The wall also prevent the rain water to flow to the river naturally, city need to apply mechanical pump to pump the water out to the river.

Fig 7 Construction of Floodwall along Chaopraya River

Floodwall not only replaced the riparian ecology along the river but also replaced the relationship between people and the river which is the unique way of life of people living along the Chaopraya River. River is becoming the drainage channel since there is no natural and people life.

2.4 Territory's Future Challenges

By the year 2050, Bangkok population will be increased by 11 million people which will cause city to be expanded. If we continue to develop the city by continuing in replacing the “fluid territory” with “solid territory” we may face more natural catastrophe in the future. Fluid territory is play an important role in keeping the urban ecology in balance.

We need to increase city ability in dealing with flood by increase water detention area rather than removing them. At the moment Bangkok has water detention area which has the capacity of 13 million cubic meters, however city still require at least another 6
million cubic meters to be able to cope with the ongoing and future water challenges. These engineering approach in managing water with floodwall and mechanical pump does not seem to be the sustainable solution since it depends on mechanical and it effects natural system and people way of life. With the increasing impact of climate change, BKK is going to be effected by higher rainfall and seawater rise at 3 mm a year. It’s going to pose the big challenge to the city which subsided at 5 cm a year. There is a prediction that by 2030 Bangkok city will be permanently flood.

2.5 Adaptability Approach.
It becomes clear that we cannot continue in fighting with water or continue in developing the territory in the direction that against the natural phenomena. We also realized that we cannot give up our territory to the challenges we are facing since territory has already been well developed for many generations. The best approach is to adapt our territory and also our way of life to the ongoing environmental challenges. Adaptability is the fundamental concept in which people in the past and even today learn how to live with water in harmony. Here are some examples;

Architecture; people built their house on the tall stilt to locate their living area above the flood level and some people still live in the boat or floating pontoon until today.

Agriculture; farmers applied ditch and dike system to manage water to benefit their rice and orchard plantation. In some case they reinvent floating pontoon which made of bamboo or plastic material to do farming. These floating pontoons allow farmers to continue their agricultural activity during the flood season.

Adaptive Way of life; People who live in Sena community which located on Chaopraya Rive bank in Ayudhaya province has to modify the entire district to respond with the rising water during the flood season every year. They installed the temporary

Fig 8 Floating House and Agricultural Farm

Fig 9 Floating Rice Field
platform made of timber planks in the street and also in their house and shops above flood level. These temporary timber platform enable people to continue their daily life during the flood season for 3 months.

Fig 10 Elevated Platform during flood at Sena Community in Ayhdhaya Province

Transportation; this case study shows how people innovate their everyday elements to live with flood. They combined two difference things together which are motorcycle and boat in order to create the “amphibious vehicle” that enable them to navigate to anywhere during flood.

Fig 11 Amphibious Vehicle during flood

Those examples in adaptation with flood have shown the common characteristic as follow:

1. Territory need to be adapted for the survival of people.
2. We must look at flood or water as the natural resources that can benefit our way of live and can also increase economic value.
3. We must adapt our lifestyle to live with water instead of changing the environment to fit ours

2.6 Hybrid City

Since we cannot change our city to be completely “fluid “since it might not be relevant to today people behaviour. We also cannot continue in developing the city to be more” solid” since it will create more problems. “Hybrid city” is the idea in transforming “solid territory” to be more resilience with water by applying the ideas of” fluid territory “which people in the past use to adapt their territory to live with water in harmony.

The strategy is to increase city capacity in dealing with flood by making rooms for water out of the solid territory .Creating more water permeable areas and water detention areas in the city will help city absorb and detain more water during rainy season. This would help not to put so much pressure in term of water volume into the river and canal systems. The river and canal system then be able to channel water from the north and other part of the city to the sea quickly.

We also need to revitalize river, canal system and linear park to connect all the
water detention areas in the city as part of green infrastructure.

The objective is not only to make city be able to survive out of the water challenges but also to use this opportunity to revitalize the city for a better living condition for the people and create economic value at the same time. Importantly, it must include people to be part of the transformation process in order to create the city where everyone is belong.

2.7 Transforming Grey to blue and green network for resilience Bangkok

Even Bangkok has already been developed for solid environment for 48% of the city surface, there are still remaining resources in term of canal network, parks, abandon areas and agricultural area that can be revitalized to create the water resilience city.

There are 7 Intervention tools to be applied

Bangkok situated in the Chaopraya River floodplain. It is surrounded by agricultural land. However during the past decades these agricultural land was replaced by industrial and urban area due to urban sprawl. As the result it also replaced the water detention area which help to absorb flood water before overflowing into Bangkok city. We shall look into the possibility in safeguarding the remaining agricultural land around the city and redeveloping them for water detention purpose by improving ditch and dike system around the agricultural land to increase water detention capacity, improving canal and irrigation system to better channelling the flood water to and from these agricultural areas in order to work as the water detention network. We also need to promote water agriculture activity during this 3 month of detention period so that farmers can get economically benefit from the water at the same time.
2.7.2 Safeguarding existing natural area in the city
There are remaining untouched area in the city center and around city peripheral area owned by government and private for 8%. The government should find the policy in purchasing or renting those land from private or creating tax incentive policy to encourage land owner to safeguard them from urbanization. There is a possibility in developing them to be an ecological park for people to recreate and learn about natural ecology. Importantly it can combined with the water detention facilities within the park to help city mitigating with flood water.

2.7.3 Reclaiming water permeable surface and water detention area from built Environment

2.7.4 Creating new permeable surface and water detention area with the new developments.

With the current approach in creating the new development, we tend to replace the existing green which is the natural water permeable area as well as water detention area with the solid surface. We should find the way in maintaining the same water capacity of the land in absorbing and detaining water while allow the developments to take place to respond with the growing population and urbanization. The new development should look into the possibility in make building to become green provider and water collecting element by applying green roof and vertical green. The ground floor should provide sufficient amount of permeable surface and on ground or underground water detention area.
2.7.5 Reconnecting all the water detention area.

In order to manage the water volume efficiently, we need a network in connecting those existing and new scattered green areas to work as one system. We shall look into the possibility in revitalizing the existing canals network and also abandon liner space in the city like footpath, space underneath the expressway to work as Liner Park in collecting and channelling water runoff in the city. In additional, this linear space can help in cleansing this water runoff though a combination of planting and mechanical filtration.

2.7.6 Empowering people to be part of the process

For many decades we have been developing the city for the purpose of accommodating growing population and generating economic growth without understanding what are the purpose of the city. City is for people life. Without understanding the people behavior, we will continue to develop the city that no one use and belong to. We must change the process in developing the city from top down to co-create where people is part of the process from the beginning. With this co-creation process, it is not only creating the specific outcome that respond well to the ongoing and emerging people behaviour but it is also empowering citizenship of the people to create the city that everyone is belong. We should use this opportunity in transforming the city to be more resilient with water and also resilience with people need and behaviour as well.
2.7.7 Forming policies and guidelines

To ensure the transformation of city from solid to hybrid city where it resilience with water will take place in the future, we need the appropriate incentive policies and guidelines. There are possible policies such as providing tax reduction for those who safeguarding the land for water detention, providing subsidized fund for private development to improve water detention capability, providing FAR bonus for private development who provide extra water permeable surface and water detention area. We also need to come out with the framework in guiding the process and physical space in transforming the city. This framework include the principle in city planning to provide sufficient amount of green space as part of green infrastructure to help city mitigating with water and others environmental challenge. It also include how the building and open space should be formed in order not to block the water way and creating the water resilience environment.

2.8 Conclusion

Landscape architecture will play an important role in helping solid city to transform into “hybrid city” where territory is more resilience with water. However each territory has its own context and evolution which we must learn from so that we can choose the suitable tool to be applied appropriately. These tools include planning of the agricultural land to increase capability in detain water. It also include the planning at the city area in finding more rooms for water from safeguarding the existing natural and abandon area ,reclaiming more permeable and water detention area from the solid territory , integrating water detention and permeable surface with the new development and forming the incentive policies and guideline to stimulate the transformation and ensure the proper result. Lastly as the city is for people life, we need to make sure that people will play a central role in co-creating the Hybrid City.

Fig 17 Design Guideline in integrating water detention area and network into the development

Green open space and the impact of tsunami-induced damage in Banda Aceh City

Desy F. Makhmud, a Ray M. Syahadat, a Daisy Radnawati, a Priambudi T. Putra a
National Institute of Science and Technology (ISTN), Jl. Moh. Kahfi II Kampus Bhumi Srengseng Indah, South Jakarta 12640

Abstract

On 26 December 2004 the coast of Aceh, Indonesia had experienced 9.1 RS earthquake followed by tsunami wave about 30 m. One of the worst affected cities is Banda Aceh. This disaster causes hundreds of thousands of victims lost their lives, destruction of public facilities and infrastructures, and the paralysis of economy and community activities for several months. This disaster also made some disturbance and remnant patches that can be used as data to calculated the extent of damage. Some areas that have green open space on the coastal areas are allegedly able to minimize the damage caused by the tsunami. The distribution of green open space in Banda Aceh City before the tsunami was in an uneven condition, especially in the coastal ecosystem areas. According to tsunami researchers from Amalgamated Solutions and Research (ASR), the region of Aceh still has the potential of another tsunami even though they already facing tsunami before. But during this development they not really concern to that threat. After 13 years post tsunami, there’s no mitigation program from the viewpoint of landscape architecture. The mitigation program is more directed at rescue activities during and after the disaster but does not think about saving the physical environment from a region. This study aims to examine the relationship between the number of green open space in Banda Aceh City before the tsunami with the damage caused after the tsunami. The method used was multiple linear regression. The results obtained from this study indicate a linkage of the number of green open space to the magnitude of damage caused by the tsunami. So that development of the city in the coastal area should concern the existence of the green open space area.

Keywords: Coastal; disturbance patch; landscape architecture; mitigation; remnant patch.

1. Introduction

Indonesia has a high disaster threat, namely tsunami waves. Tsunami is a series of wave of ocean waves in large size due to the shift in the seabed due to earthquakes.

One of the coastal areas of Indonesia that had experienced a tsunami that is quite
severe is the coastal region of Aceh. On December 26, 2004 Aceh Province was hit by a tectonic earthquake of 9.1 RS followed by a tsunami wave as high as 30 m. Many impacts caused by this disaster among other damage to public facilities, and infrastructure, until the economic paralysis and community activities. Information obtained from some government agencies (Bakornas, PBP, Depkes, Depsos, and Media Center National Institute), the highest number of casualties in Aceh Province with numbers reaching 400,000 people (died and displaced). Based on the data also shows that the largest area affected by this disaster is the coastal area of Banda Aceh [1].

After more than a decade after the tsunami, the government and people began to rebuild the city of Banda Aceh. This activity deserves appreciation of its speed, but its reconstruction does not fundamentally change the community's perspective to build a more resilient city to face the possibility of a similar disaster. The rapid decision to complete spatial planning entirely restores the description of the city of Banda Aceh prior to the tsunami. Yet according to tsunami researchers from Amalgamated Solutions and Research (ASR), Aceh is still a potential tsunami even though the tsunami was hit by a big tsunami [2].

Recognizing this, the United Nations governments began to think about the disaster aspects and to think about how the city should be designed to deal with various types of disasters independently. One is the concept of resilient city. This concept focuses on the city's development system in order to adapt to the coming of the disaster so that when a disaster occurs a city will not experience too much damage and have the ability to return to its original condition when faced with challenges or in a downturned condition.

The presence of green open space will also affect how much impact caused by tsunami waves. To realize Banda Aceh City that is resistant to future disasters it will be calculated impact through regression analysis comparing the amount of vegetation to the impact caused by tsunami waves, after the analysis results obtained then will be done coastal environmental engineering strategy with the concept of coastal layered coastal system (defensive structure), this environmental engineering can be either artificial structures or natural structures.

2. Methods

This research was conducted in Kota Banda Aceh, Aceh Province. The study was conducted for 4 months starting from September to December 2017.

The study was conducted by calculating the amount of vegetation before the tsunami and the magnitude of the damage caused after the tsunami through the image map obtained in Google Earth Pro, then processed through the application AutoCAD2007 and Microsoft Excel. Map of number of vegetation taken is map on 23 June 2004 and map after tsunami on 28 January 2005 as many as 16 images with same size. Locations are randomly selected and dominant in areas with the greatest damage.
After calculating the amount of vegetation and the damage caused, then the data is processed for multiple linear regression analysis to see the relationship between the parameters that yield the equation $y = a + bx$ and the correlation value ($R$).

To strengthen the analysis, the interview was conducted with an expert of landscape planning that have focused in tsunami case, especially in Indonesia. After the results obtained it will be made a design recommendation in the form of environmental engineering done to realize the city of Banda Aceh as a resilience city. This mitigation effort is obtained from expert interviews and literature studies.

3. Results and Discussions

Of the 16 images of the downloaded image map, calculating the amount of vegetation before the tsunami and the magnitude of damage caused after the tsunami, the results are obtained:

a. Total vegetation (2014) is 844,740 m$^2$
b. Total damage (2015) is 1,240,726 m$^2$
c. Total of lost land (2015) is 241,879 m$^2$

Correlation test using multiple linear regression analysis shows the relationship between the proportion of green open space to the impact of damage caused by tsunami waves in Banda Aceh City. With X variable 1 which is the total damage, and X variable 2 which is the missing plain. The result is that every 1% of the vegetation will reduce 0.08 m$^2$ of damage and 0.59 m$^2$ of land lost due to tsunami waves.

Based on interview with Qodarian Pramukanto on coastal spatial planning, the concept of a layered defense system (defensive structure) should be applied. Starting from the front liner structure to the back of the structure is important to consider in the preparation of environmental engineering guidelines and construction of coastal areas. Environmental engineering in coastal defense systems against splashing can be either artificial structures or natural structures.

In the coastal environment built, can be built artificial structure in the form of breakwater (offshore breakwater). The construction of wave breakwater walls along these coastal areas is built on the face of the waters of the bay or port. The coastal defense line is reinforced with a protective wall structure on the shoreline combined with evacuation paths on the rear. Material for the manufacture of retaining walls can be made of stone or concrete. In planning
should be studied in more detail in the form of structure must be strong and economical. However, the application of artificial coastal protection structures built in coastal waters or on shorelines should be through careful planning, otherwise there will be considerable impacts such as disruption of current patterns.

Another model is to plant along the coastline to the rear as far as 100 meters as the tsunami control forest (tsunamic control forest). Furthermore, this protective green line is combined with a protective structure built in the rear layer, and it’s equipped with an evacuation path.

Vegetation has an important role in reducing the speed and strength of the waves. With layered and multi strata compositions, vegetation can damp the waves that come in several altitudes. In addition, the vegetation plays a role as a run-off filter before it is dragged back to the sea, holding on to the mass of vegetation so that it will be easy to carry out evacuation actions. The effectiveness of muffling the waves of the coastal green line depends on the composition of the vegetation and the thickness of the green line. The type of empowered coastline vegetation is highly dependent on local ecological characteristics.

Coastal forests are planned to be 500-1000 m wide adapted to the existing shapes and conditions of the coast [3]. The coastal forest as a barrier has a vegetation density between 40-60 trees per 100 m2 depend on the shape and character of the planted tree. The location of this coastal environmental engineering planning recommendation is one of them located at Ulee Lheue Beach, Meuraksa Sub-district, Banda Aceh City. It is the most heavily affected area of the tsunami waves, as it is a land facing the Malacca Strait. This location became an early fortress for the city of Banda Aceh in the south.

1. Erosion Retaining Structure
2. Evacuation Path
3. Tsunami Control Forest (tsunamic control forest).
4. Evacuation Path
5. Breakwaters (offshore breakwater)
Vegetation is a blend of various types of plants that grow in a particular area. Differences in the environment in which plants live will give different vegetation patterns [4]. The beaches of Banda Aceh are dominated by sandy beaches. The presence of the dominant sand in the coastal area causes the plant species that can live are plants that resist drought, high temperatures, strong winds, full sun and high salt levels [5]. These plants can survive, especially in the dry season with minimal moisture or dew at night. In choosing the type of coastal vegetation should be very careful to achieve the function of the plant that can reduce the impact of tsunami waves, abrasion dampers, reducing wind and animal habitats. Generally, coastal forest in Indonesia consists of various ecosystems with barringtonia formation dominated by tree species, pes-caprae formation is dominated by vines, while mangrove forest formation is dominated by mangrove species [6].

Physically mangrove forest is an ecosystem that serves as a wave dismantle absorbers. The root system can act as a breakwater and sediment trap. This would be more effective if supported by mangrove forest formations whose condition is still natural. The density of mangrove forest that tends to decrease will result in its function as a wave damper will also tend to decrease [7]. As a coastal stability protection system, the preservation of mangrove forests should be maintained so that the coastline is not abrasion so that it will support the ecological process in it.

Based on the results of data acquisition, since the 1980s mangrove forests in Aceh have experienced the peak over the function of a pond. This happens because the outbreak of shrimp business in Indonesia at that time. After the tsunami, the extent of...
mangrove forest here is declining. Mangrove forests before being affected by waves in 2004, generally grow naturally scattered along the coastline so it is still preserved ecosystem sustainability. After more than a decade, now the existence of mangrove forest in Banda Aceh city is still a focus for the government. The results showed that mangrove forest that grows naturally or intentionally planted (silvofishery).

Table 1. The types of mangroves found in Banda Aceh before the 2004 tsunami and after the 2015 tsunami

From Table 1 above shows the distribution of mangrove contained in Banda Aceh City in 2004 there are 8 types of mangroves that grow naturally before the tsunami. Post-tsunami re-planting of mangrove vegetation while maintaining the existing species, so that in 2015 there are 18 mangrove species that have grown up in several coastal areas in the city of Banda Aceh.

4. Conclusion

The city of Banda Aceh that had been hit by the earthquake and tsunami waves almost more than 1 decade ago gives us the learning to be more responsive to the possibility of disasters that will come. The process of disaster mitigation not only takes place as a form of community action in its daily life, but also leads to the physical mitigation of an area. This is called a concept of resilient city, a city can adapt and recover quickly from future disaster attacks. The presence of green open space in Banda Aceh City has a substantial share in reducing the impact of the tsunami. Each 1% of the vegetation will reduce 0.08 m² of damage and 0.59 m² of land lost due to tsunami waves. The form of environmental engineering that can be done is by artificial structures in the form of breakwaters (offshore breakwater) and tsunami control forest (tsunamic control forest) equipped with evacuation path at the back.

The selection of appropriate coastal vegetation is also important in reducing the impact of the tsunami disaster. The existence of coastal forest with the formation of the ecosystem of barringtonia, pes-caprae, and mangrove forest into a single unit that can reduce the occurrence of coastal erosion, erosion control, muffle the wave as well as a habitat for the flora and fauna. With this concept, Kota Banda Aceh is expected to adapt to the possibility of future disasters.

Banda Aceh still has the potential to experience another tsunami. The City Government of Banda Aceh should be able
to analyze the physical condition of its area before undertaking post-tsunami reconstruction so that development can be sustainable in the future. Green open space planning is one of the mitigation way to improve the quality of resilient city.

Reconstruction Processes and support activities since the Great East Japan Earthquake

Mayumi Hayashi*

*University of Hyogo, 954-2 Nojimatokiwa Awaji City Hyogo Japan, postal code 656-1726 Japan

Abstract

The Great East Japan Earthquake, which occurred in March 2011, caused serious damage and was followed by a large tsunami and an accident at a nuclear power plant. In this report, I describe the reconstruction process and continuing support activities in Miyagi Prefecture, which is cooperating extensively with Hyogo Prefecture where I reside.

The number of dead and missing people for this whole disaster is totally about 24,600. Miyagi Prefecture had no nuclear power plants, so there was no direct damage from that, but it had about 18,000 dead and missing people, the highest number of any prefecture.

As of November 2017, about 70% of the roads and 100% of the railroads had been reconstructed. However, 9750 people were still residing in temporary housing that was built just after the disaster. This is a decrease of 8% from the peak. The number of residences is 4,658, which is a decrease of 10% from the peak. Municipal public housing project construction has also advanced, with 14,886 residences (92.5% progress rate) completed in 21 municipalities. The progress rate for rebuilding community development projects is 100%, with 229 districts having completed disaster relief group relocation promotion projects and land division adjustment projects. In addition, publicly-funded community facilities, such as new public halls and “Everyone’s House,” have been newly established in various places. The recovery process is going smoothly, but large numbers of people are still in temporary housing, have been left behind by reconstruction, or need mental care.

At the beginning of the process, we provided support from Hyogo Prefecture with environmental improvements in temporary housing, providing horticultural therapy programs as a form of mental care. In addition, we carried out various other support activities, such as making plans for parks for new town planning, proposing plans for resettlement locations at higher elevations, and proposing biotope districts utilizing new natural resources.

We offered projects for the elementary school site where 74 children and teachers were taken by the tsunami, providing revegetation support efforts around the school and a horticulture...
therapy program for the families of the children. Recently, we supported planting around an “Everyone’s House,” which had been built as a new community facility. We also continued planting support activities at welfare facilities and the planning of a biotope district in cooperation with the Agency for Cultural Affairs.

While doing various support activities like this, we have also been focusing on holding forums and networking aimed at collaboration and exchange with groups that are engaged in green community development activities in Miyagi Prefecture. From disaster restoration and reconstruction, a network for community-building that utilizes new greenery is starting to spread.

Key Words: Great East japan Earthquake, reconstruction processes, support activities

1. Introduction

The Great East Japan Earthquake, which occurred in March 2011, caused serious damage and was followed by a large tsunami and an accident at a nuclear power plant. In this report, I describe the reconstruction process and continuing support activities in Miyagi Prefecture, which is cooperating extensively with Hyogo Prefecture where I reside.

The number of dead and missing people for this whole disaster totalled about 24,600. Miyagi Prefecture had no nuclear power plants, so there was no direct damage from that, but it had about 18,000 dead and missing people, the highest number of any prefecture.

As of November 2017, about 70% of the roads and 100% of the railroads had been reconstructed. However, 9750 people were still residing in temporary housing that was built just after the disaster. This is a decrease of 8% from the peak. The number of residences is 4,658, which is a decrease of 10% from the peak. Municipal public housing project construction has also advanced, with 14,886 residences (92.5% progress rate) completed in 21 municipalities. The progress rate for rebuilding community development projects is 100%, with 229 districts having completed disaster relief group relocation promotion projects and land division adjustment projects. In addition, publicly-funded community facilities, such as new public halls and “Everyone’s House,” have been newly established in various places. The recovery process is going smoothly, but large numbers of people are still in temporary housing, have been left behind by reconstruction, or need mental care.

At the beginning of the process, we provided support from Hyogo Prefecture with environmental improvements in temporary housing, providing horticultural therapy programs as a form of mental care. In addition, we carried out various other support activities, such as making plans for parks for new town planning, proposing plans for resettlement locations at higher elevations, and proposing biotope districts utilizing new natural resources.

We offered projects for the elementary school site where 74 children and teachers were taken by the tsunami, providing revegetation support efforts around the school and a horticulture therapy program for the families of the children.

Recently, we supported planting around an “Everyone’s House,” which had been built as a new community facility. We also
continued planting support activities at welfare facilities and the planning of a biotope district in cooperation with the Agency for Cultural Affairs. While doing various support activities like this, we have also been focusing on holding forums and networking aimed at collaboration and exchange with groups that are engaged in green community development activities in Miyagi Prefecture. From disaster restoration and reconstruction, a network for community-building that utilizes new greenery is starting to spread.

2. Method

Below we examine our activities and their results both chronologically and by field of activity. Our activities can be roughly categorized as follows. Later, I will elaborate on my ideas following these categories.

1. Investigations at initial stage
2. Support for temporary housing
3. Proposals for community design
4. Support activities for reconstructed housing and permanent facilities
5. Networking

3. Results

3-1. Investigations at initial stage

Hyogo Prefecture, which is where I live, has broad regional collaboration with Miyagi Prefecture, so there is cooperation among administrative municipalities to carry out various activities. As a result, our activities also mainly focus on Miyagi Prefecture. As an initial investigation, we surveyed the damage from the north of Miyagi Prefecture, mainly from the towns of Minami Sanriku, Onagawa, Higashi Matsushima and Matsushima (Emergency Research Report on Reconstruction Support of the Japanese Landscape Architecture Academic Society). Based on the results of the investigation, we sought “soft reconstruction.” This is not to deny the influence of the terrain and the large tsunami that also changed the soil, but, as related to livelihoods and the reconstruction of homes, we considered community planning that takes natural activity into account. At the same time, we also sought cooperation with government
agencies, experts, local residents, NPOs and others. Now that 7 years have passed, what was and was not accomplished should be verifiable at present as a passing marker in time.

3-2. Support for temporary housing

3-2-1 Horticulture Therapy Program

For temporary housing, we have been consistently providing horticulture therapy programs and support for vegetation planting since the beginning of the initial period. The main places include large-scale and small-scale temporary residences in Minami-Sanriku Town, temporary residences in Miyatojima (including Tsukihama, Ohama, Murohama, and Satohama), Higashi-Matsushima City, around Okawa Elementary school in Ishinomaki City, Ogatsu, Nagatsuraura, Miyagi University in Sendai City, and citizen centers.

Horticulture therapy programs frequently used “flower bento boxes,” “terra cotta pot planting,” “hanging baskets” and the like.

In the initial stage, “flower bento boxes” were easy to use because they can be provided inexpensively and easily. The method used is as follows.

1. Prepare a hundred-yen plastic bento box, planting base, flower materials, scissors, etc.
2. While showing a sample, cut the flower stems short and insert them into the planting base.
3. Have participants put names on their completed boxes, such as “Bento full of love” and “Spring bento,” and show them to each other.

![Fig. 2,3 Flower bento making horticultural therapy program](image1)

![Fig.4 Flower terra cotta pot making horticultural therapy program](image2)
④ Afterwards, have herb tea and snacks, and relax with hand baths in warm water with floating herbs.
⑤ Inform participants that flower and plant activities stimulate the mind and promote positive brain activity and recommend continuing hands-on interactions with vegetation.

To some extent, after time, we began to use terra cotta pots and hanging baskets in which flowers can actually grow rather than bento boxes. An overview of these efforts follows. We made a pamphlet called, “Let’s participate in activities using flowers and plants!” We made a container garden for residents of temporary housing. Even after over five years since the Great East Japan Earthquake, there were still many residents living in temporary homes, and programs utilizing flowers and plants were effective. In Higashi Matsushima City and Ishinomaki City, for example, we have been conducting a continuous horticulture therapy program. In addition, we held tea times with herb tea and other refreshments so that these flower and plant activities also play a role in building spiritual stability in rebuilding the lives of the participants.

Flower arrangement programs have been found to not only provide healing and refreshment to refugees, but also to help activate the brain. Therefore, we tried to provide the refugees with this knowledge as well. We call this "dropping anchors." We tried "dropping anchors" and encouraged them to continue this activity so that the effect of the program would not end with just one experience.
3-2-2. Support for vegetation planting

The summary of vegetation planting support activities is as follows.

In September 2011, we made planters for the residents of temporary houses newly built in Minami-Sanriku Town. We also advised the launch of a "Flower Association," and suggested creating a community group with flowers and plants for the 240 residents. In addition, we provided planter support even for small-scale temporary houses.

On Miyatojima in Higashi-Matsushima City, in addition to making planters, we also made flowerbeds, including small-scale ones and a large-scale one of about 400 square meters. These functioned as temporary vegetation flower beds and encouraged local community interaction. We also provided similar vegetation planting support for temporary housing in the city such as at the Hibiki Industrial Park.

In order to encourage the participation of men, we also produced a large wooden kit for vegetable growing and provided a program for this. Men participated less often in flower programs, but it was easier for them to participate in vegetable cultivation, and this induced their activity in the temporary housing.

In the Ogatsu district, around the Okawa Elementary School area and in the Nagatsuraura district of Ishinomaki City, we supported the creation of a large-scale botanical garden in collaboration with local residents and the "3.11 Miyagi Association for Supporting Reconstruction with Flowers and Plants" NPO. We also conducted the above-mentioned horticultural therapy program at the same place. The tsunami...
destroyed nearly all of the Ogatsu district and took the original residents of this large-scale garden. The surviving daughter and her husband maintain the garden with local residents. In addition, this son-in-law, who was a teacher at an elementary school, is conducting "earthquake disaster education" at a temporary office. He shares information about the situation at the time of the earthquake and knowledge about future disasters. Many visitors come to the place now widely known as the "Ogatsu Rose Garden." Support and cooperation never ceases from people all over the country.

School children from around Okawa Elementary School were in a state of waiting inside the school. As a result, over 70 people were killed by the tsunami. Many survivors have lost children or grandchildren. As a vegetation planting support activity, we plant flowering trees around the elementary school. In addition, when doing vegetation planting activities, we also offer horticultural therapy programs.

The Nagatsuraura district is a fishing town with oyster farming. A local leader who lost his grandson built a new lodge for fishermen. The local community also manages restaurants and other businesses and is trying to rebuild it. Here we also continue to plant trees around the lodge and offer gardening therapy programs.

3-3 Proposals for community design

In the Miyatojima district of Higashi-Matsushima City, we made a town development proposal in response to the request of a citizen center for a disaster area that had been completely washed away. In that process, we held workshops with the citizens, professionals, government officials and others from May 2012 to confirm the wishes of local residents while making a proposal for a green space.

We asked the people in Tsukihama area of the Miyatojima district what kind of town they expected, what they wanted to have, and what they wanted to do, for example. After summarizing these expectations, we created a greenery plan.
While checking every proposal written on sticky notes with the participants, we put the plan together. In the Tsukiyama district, they wanted to keep the Isuzu Shrine that had originally been there, preserve the crossroads, which connects to the shrine, as an important place for the town, make a temporary garden with flower beds and continue the custom of utilizing a rock cave “bora” formed from sandstone as storage. They also wished to maintain a walking path, preserve *Rhaphiolepis indica* var. *umbellata*, which is at its northern limit here, plant palm trees along the coast, restore a safe seashore, and emphasize the view from the observation deck. We submitted a plan that included these ideas.

In addition, among community planning proposals for Ohama in the Miyatojima district of Higashi-Matsushima City, there was one to conserve as wetland a valley area where rice paddies could no longer be used as agricultural land because of sea water infiltration. Ultimately, as a region of special scenic value designated by the Agency for Cultural Affairs, the city purchased it from the private sector, and provided support to conserve these wetlands.

3-4. Support activities for reconstructed housing and permanent facilities

Even though seven years have passed since the earthquake, about 73,000 refugees are still living in temporary housing. However, a lot of people have moved to higher elevations and are able to with donations. Planting trees to create green spaces around these facilities and in areas swept away by the tsunami has also increased. In response to requests from such places, we have also been providing vegetation planting support activities throughout the region.

In September 2017 and March 2018, we carried out vegetation planting support activities together with a gardening therapy program at a “Connection house” in Shichigahama Town. We planted a lawn, trees and herbs with local residents, our
Fig. 15 planting herbs in community garden students, horticultural therapists and volunteers. New community facilities were created, and the people doing vegetation planting activities seemed so alive, appearing to be full of hope beginning new lives there.

3-5. Networking

The population along the coast of Miyagi Prefecture is scattered. Various volunteer activities are performed, but there are few networks connecting the organizations. We visit Miyagi Prefecture for reconstruction aid from Hyogo Prefecture several times a year, and often we do it in collaboration with various organizations. We proposed creating a network to connect them and held a first gathering forum in 2014, inviting a woman who had formed a green “garden island” network in Hokkaido Prefecture.

In 2015, for a second forum, we organized workshops by grouping tables for each theme, including vegetation planting, horticultural therapy, open gardens, environmental education, networking, and village forest preservation. In 2016, we launched a network called the “Green Exchange Forum” and linked it to social networking services. In 2018, we decided to collaborate with Tohoku Gakuin University's volunteer stations.

4. Discussion

As mentioned above, the Awaji Landscape Planning & Horticultural Academy (University of Hyogo) has conducted ongoing support activities, starting from field investigations and proposals made

Fig. 16 Keynote speaker for the forum to make networking

Fig.17 "Exchange forum on using greenery to invigorate the region" in 2014
immediately after the disaster (conducted as the Kansai Branch of the Japan Institute of Landscape Architecture).

In the early stage, we supported horticulture therapy programs with the goal of mental care at temporary residences, combining community building with vegetation planting. Those programs are continuing where temporary housing still exists.

After the earthquake, we began providing vegetation planting support at community welfare facilities that had been restored, and we have since carried out such activities in various areas. Starting with temporary green spaces, recently, there has also been permanent landscaping. In particular, vegetation planting activities at elevated relocation sites and rebuilt community facilities, combined with the enthusiastic motivation of local residents, creates a sense of achievement.

Miyagi Prefecture also has a long shoreline called the Sanriku Coast where the population is sparse and the role of women in community activities had been modest. Many women there are now participating as individuals in active organizations. Creating networks for them has been one of our goals. Currently, about 70 people have been able to connect though social networking services and participate in the forum. Furthermore, we plan to hold meetings in the fall of 2018 to coordinate with students. Such activities can be continued because Hyogo Prefecture provides sources of funding, including various subsidies and funds for consulting activities. Students, NPOs, and university faculty members are able to continue their activities because of these funds, and we would like to express our appreciation to Hyogo Prefecture.

How to minimize the design of a place damaged by the disaster

Case study of Great East Japan Earthquake

Noriko Akita*

Assoc.Prof. Graduate School of Horticulture, Department of Environment Science and Landscape Architecture, Chiba University
648 Matsudo, Matsudo City, 271-8510, Chiba, Japan

Abstract

In Japan, we met a serious disaster seven years ago. Currently, most of the reconstruction projects are coming to an end. However, the part where we are calling "low-lying area" is left behind from reconstruction. It is a place directly attacked by the tsunami, and it is also the place of home for the affected people. The area is designated as a disaster risk area, the construction of houses is prohibited, and the land use demand is extremely low. From such a situation, it is difficult to draw a future image for this area. In this paper, I proposed a new landscape design method for such kinds of damaged place based on the experience and knowledge that I have been making the garden with the residents in this place for 5 years.

Keywords; Great East Japan Earthquake, reconstruction, low-lying area, consensus building, minimumu design

1. Introduction

For the Japanese, March 11, 2011 is a day that can't be forgotten. The magnitude 9.0 Great East Japan Earthquake was one of the most powerful earthquake in world history, and the huge tsunami that followed caused massive damage to coastal areas in the Tohoku region in particular. More than 15,000 people passed away, more than 400,000 homes were lost, 561 square kilometers of coastal area land was damaged by flooding. We have lost more than we imagined.
declared to the affected residents and to the world that we will finish the rehabilitation projects within 10 years from the disaster.

Approximately seven years have already passed from an earthquake disaster, and most of the reconstruction projects are in the final stage. However, many areas left from the reconstruction projects exist. Especially the area where were attacked by the tsunami directly which we called "low-lying areas" have few future plans and projects. Many lands affected by such disasters were isolated from the reconstruction project and abandoned.

For reconstruction projects, low-lying areas are dangerous and unusable land. As a result, the areas were abandoned and devastated. However, it is a place where the affected residents were engaged in their daily life before the disaster, and it is also unforgettable hometown for all. It was painful for them to see the areas were ignored, and the reconstruction project was progressing in new residential areas that are not familiar to them. I thought that planning future in this area is necessary because the revitalization of this area will be a power to promote the motivation for the reconstruction of local residents.
2. 2. A garden for mourning a mother

2.1. It started from planting a flower

Just after the earthquake, for the low-lying areas, there were no schedule of reconstruction projects and no budgets. So nobody was able to maintain it and only rubble was abandoned.

Under such circumstances, a very small personal activity began around the summer of 2011. A resident who lost her mother by the tsunami was tried to plant flowers to mourn her mother. Her mother's house was at a low-lying area.

Fig.4. Just draw grass and pick up rubbles in 2011

When she was planting flowers in the place where the mother house was, members of the university, including professor and students who came to support the temporary housing in the area, encountered her and helped plant the flowers. They belonged to the faculty of horticulture and the specialty field of the professor was land use and landscape. During in 2011, it was a time that many missing people were still not found, so they could only draw grass and pick up rubble. However, in March 2012, one year after the earthquake, a change in feeling occurred to her. With the cooperation of family members, volunteers, local landscape company and the university members, she transformed the land where the mother's house was located into a large flower garden.

Fig.5. Large flower garden was born at the low-lying area

2.2. Changes in characteristics of the garden

Because the damage of the Great East Japan Earthquake was extremely large, even one year after the earthquake, most of low-lying were completely untouched. For this reason, affected people were pleased that a large garden was born. Around March 2012, there were few places where the flowers bloomed in affected areas. The garden was located along the main road, local residents, workers of the reconstruction project, many passers-by, enjoyed seeing the garden flowers.
As time passed, people gathered gradually in the garden. People who have been hurt their mind by the earthquake looked at the flowers and healed, and people who experienced similar painful experiences talked to each other at the place. At that time, new residential areas were under construction and low-lying areas were abandoned, so there was no place for people to gather and talk each other. Although it was not a place to construct for the reconstruction project with subsidies, it gradually changed to a public space for the people.

The garden also gradually developed, such as building a garden house and introducing a toilet, and changed it into a space where many people can welcome. All these work was done by handmade by residents and volunteers. A concert was also held in October 2013 when two and a half had passed since the earthquake disaster. This place healed and cheered the hurted people.

3. Reconstruction project and the garden

3.1. New road reconstruction project

This garden was located in Ogatsu Town, the peninsula part of Ishinomaki City, Miyagi prefecture. Ogatsu Town was merged into Ishinomaki City in 2005. The population of Ogatsu Town has drastically decreased from about 4,000 to 1,000 due to the earthquake disaster. The center of the town attacked directly by the tsunami, the whole area was designated as a disaster risk area, and to build of a house was prohibited. The population reduction rate in Ogatsu Town was the highest among the affected local communities.

Since the center of Ogatsu Town was designated as a disaster risk area, there are few residents who could remain there and it is difficult to form consensus among local residents. The plan of the reconstruction project of Ogatsu Town was delayed. Some residents went out of this place due to the fear of the tsunami. Some residents wanted to remain in the area, but the town which lost everything by the tsunami was inconvenient and difficult to continue living. There were few safe lands, and only a very few number of temporary houses could be built.

Under circumstances in which reconstruction projects are hardly decided, it became clear that the location of the garden was included in the new road constructed as a reconstruction project even though there were nothing in the surroundings. At that
time local governments did not consider the gardens made by the residents and their activities.

3.2. future plans for the entire center area

The garden was forced to relocate. At first, the members of the garden strongly opposed this reconstruction plan. However, because it was a garden that started with personal motives, new issues have arisen since diversified people began to visit the garden. For example, it was not enough to respond to elderly people and wheelchair users who are difficult to walk. So they finally decided to relocate the garden and create a universal space and true public place for all. We, the members of the university who helped her garden since 2011, also helped to make the relocate plan of the garden.

Toward the relocation of the garden, we held workshops many times by gathering local residents, stakeholders of the garden and local residents who had lived the center area of Ogatsu Town. In the process of repeated discussions, participants noticed that it is necessary to formulate future plans for the entire center area of Ogatsu Town to exam the functions required for the new garden. The garden was growing no longer the space for the landowners but the public space for the entire center of Ogatsu Town. Garden stakeholders wanted the garden to play a role to supplement what is necessary to reconstruction the center area of Ogatsu Town. They began thinking seriously about the future plan of the whole town and the division of roles that the garden should play.

Fig.8. Workshop with local residents

Fig.9. Discussion with residents using models

Through these process, we began to examine the landscape design of the entire area where damaged by the tsunami, that is low-lying area and disaster risk area in Ogatsu Town.

4. Changes in requirements on landscape design

4.1. The situation of the triple disadvantage

The center area of Ogatsu Town was very difficult to consider future land use. This area
was in a situation of having triple disadvantage.

First, the demand for the land use was extremely low. There is no public transportation. It is also far from the highway. Therefore, it is very difficult to access there. There used to be a residential area, so the site size is small. Basis of many houses remained, but since there are no plans for the future, expenditure of subsidies to remove this was not planned.

Second, because the whole center area of Ogatsu Town is designated as a disaster hazard zone, construction of residential buildings and houses are prohibited. Without local residents, it is also difficult to use land as a commercial. On the other hand, there is not enough space as an industrial site.

Third, human resources in the area were extremely limited. Because the whole center area of Ogatsu Town was designated as a disaster risk area, there are no residents. Only some elderly residents remain in the temporary houses, and the rest of the people lived outside the area to find a job because the town was completely destroyed. There were only dozens of reconstruction houses were planned to build in the center area where about a thousand people lived before the earthquake. Therefore, even if many people visit here, there are few people able to respond and there is no place for new people to live.

However, Ogatsu Town is a blessed place with abundant natural resources. Seafood such as scallops and salmon, stone mined from the mountain, river of beautiful water, starry sky, all were wonderful charms.

4.2. Consensus building and budget issue

In the Ogatsu Town, some local residents and local governments could not form consensus regarding reconstruction projects fully at that time. Several local key persons strongly opposed the reconstruction project. Reconstruction projects were delayed greatly, some residents raised distrust of local governments. Under such circumstances, it was impossible to draw landscape design with top-down style at the whole low-lying area. Moreover, the control type landscape design of the conventional expanding urban space did not fit in such a shrinking area. We had to create a new landscape design method in order to design this kinds of low-lying areas.

Initially local government have decided industrial land use for this area. However, local residents also understood the harsh reality that companies would not come here. On the other hand, even in the case of planning public facilities, the population of Japan has declined sharply, so for the place that visitors can’t expect, the reconstruction agency did not allow budget expenditure. The era of people gathering as long as we create a nice and beautiful landscape design space is over. Even if it is a facility that the residents are requesting, due to lack of maintenance budget, local governments have abandoned construction of new facilities. Under such circumstances, how should we consider landscape design for low-lying areas?
5. Changes in requirements on landscape design

5.1. Examine a new landscape design method

We have examined a new landscape design method for places where land use demand is low and damaged by the disaster, based on knowledge and experience on the development and maintenance of the garden over the past five years.

It consists of the following four steps. 1) Based on the intention of residents' future land use activities in the area, 2) Formulation of land use plan by 2 step zoning based on consensus of local residents, 3) The future land use plan and landscape design should be connect past and present and to the future. This is a new bottom-up, resource-based landscape design method. I would like to explain the details below.

5.2. Based on the residents' intention

Even a place with rich attractive natural resources, it can’t make use of resources unless there is a person who uses and manages it. In order to realize the future plan, people who are in charge of that are indispenable. So we focused on the capacity of residents who are interested in the area, intend to engage in the area, and decided to live in the area. At the same time, we have encouraged residents to draw out their potential capabilities of land use through opportunities such as workshops and hearings.

In areas with limited resources, the intention of future residents' activities are the most important factor to realize future plans. We tied the land use with the intention of residents. Even if it is apparently a vacant lot, there are various potentials, and designing the future inconsistent with it will lower the motivation of the residents' activities.

It is very important to discover local potentials that are not visible at the moment, and to draw the future plan including them. It will also foster their possibilities.

5.3. 2 step zoning based on the consensus

Based on the consensus building of the residents, we have formulated a land use plan using two stage. It is impossible and undesirable to decide all the land use at once. Generally, in the case of reconstruction projects, the budget is not expended unless all the future plans are first formulated. However, in this area, it was impossible to do so because demand for land use is too low and regulation was too strong. So we roughly divided the entire low-lying area into 8 zones, and determined only the direction of each zone. It was difficult to obtain the consensus of residents of the detailed plan, but residents were able to agree on rough zoning based on previous land use. The point of rough zoning was to set up zones that are consistent with the resources of the remaining shrines and shops, etc. and previous land use. That is, we drew a plan for the future connecting the past and present points.
5.4. Detailed design stage

Even if drawing a dreamlike future land use plan or beautiful landscape design, if there is no person who realizes or uses it, it will only become a rice cake drawn in a picture. So future land use plan should be drawn on the current extension line. It is also the plan that local residents could managed and understand. Of the eight zones, we have formulated a detailed future plan and landscape design only for the zone where garden activities are actually being conducted. It is not an irresponsible groundless desire, but it depicts the future based on activities in the area where each person can do. We minimized the design for the future. But landscape design is important for residents to imagine the future of the area and to share with all relations. Landscape design has the power to drive residents' motivation and make hope embrace the future. After that, our proposed landscape design was approved as an official plan of Ishinomaki City. This became the first comprehensive plan and landscape design for the low-lying area where attacked by the tsunami.

6. Conclusion

At first glance, there seems to be nothing in the land that was deeply hurt by the disaster. However, there is a potential existence of residents' intention to stand up from a sad experience. We should not ignore it. "Connect the time" is also an important role of designers in places where past and present were disconnected by the disaster. In such a place, the current state is very fragile, so if we design the landscape strongly, there is a danger of erasing the future as well. Drawing a beautiful landscape design that all people concerned share and hope for in the future with minimizing the design, encourages the resident activities and opens the way for revitalization.

Acknowledgments

I deeply appreciate everyone concerned with the garden, Ishinomaki city officials, and other concerned.

Disaster Management Through The Use Of

Animated Physical Model

Kenya Endo
Ramboll Studio Dreiseitl, 115 King George’s Ave, #06-02, 208561 Singapore

Abstract

4 dimensional model (4D model for short) is a representation method that combines physical model with an overlay of projected animation. It allows landscape architects to illustrate anticipated changes in the future, as well as to share his/her ideas with broader audience. This paper examines the usefulness of 4D model, specifically in the context of community engagement process for disaster and risk mitigation. Community workshop was conducted in Nagashizu as a case study, one of the heavily devastated communities along Tohoku Coastline from the unprecedented tsunami followed by Great East Japan Earthquake on March 11th, 2011.

Feedback during the workshop, regarding the usefulness of 4D model as a tool to help visualize, understand and imagine schemes for future resilience, was generally positive. For example, risk mitigation measures were discussed using the animation that explicitly illustrated the most catastrophic scenario born by the natural disaster in Nagashizu. It successfully allowed residents to realize the innate threat to their lives, which was not thoroughly recognized before the tsunami in 2011. Community-wide awareness could have mitigated the losses, by guiding all residents to take prompt evacuation actions. Participant’s suggestion on incorporating tsunami wave speed, people’s evacuation paces into the 4D model is one of the constructive solutions that will help refine the method for future application.

Likewise, compared to conventional community engagement procedure using 2 dimensional drawings, 4D model demonstrated its greater ability to showcase future outlook of Nagashizu both spatially and seasonally in detail. Series of rendered graphics have served to broaden participant’s imagination in the course of brainstorming potential activities that can take place in Nagashizu, not only what, but also where and when. 4D model has smoothen the process in a way that both residents and non-residents have come together as one, and exchanged ideas that interrelate with Nagashizu’s unique natural and cultural features.

In terms of future prospect, the workshop outcome has suggested that 4D model can be utilized in various purposes and phases in the process of disaster management, by customizing its content. In addition, resident’s feedback has also reminded the significance of landscape architect’s involvement in such process – as a narrative developer and a communicator. Unlike
engineering approach, landscape architects have the ability to synthesize indigenous natural and cultural resources into the argument of resilience planning. This Nagashizu 4D model workshop served as a first successful attempt of its kind, and demonstrated the potential for scaling-up the methodology into other sites in the world, or even in our daily practice.

**Keywords:** Disaster Management; Community Engagement; Representation Method; Four Dimensional Model

---

1. Introduction

In response to climate change and intensifying natural disasters, landscape and ecological systems have increasingly become a featured topic in the conversation of future resilience. Policy makers are slowly acknowledging the impossible-ness of shielding cities from nature’s powerful forces, but instead to explore measures that are inspired by adaptability and inclusive planning [1][2]. In such context, landscape architects’ role has grown ever so important due to our inherited ability to synthesize dynamic natural systems, and envision short-term, long-term narratives that are rooted to the site. Since disaster management is a highly inter-disciplinary process, our communication skills have become vital as well, to lead, agitate and settle conversations with a diverse group of expertise.

As a landscape architect, I have witnessed tsunami recovery process along Sanriku Coastline in Japan, from the earliest time when basic lifeline was still not in operation. Through the personal experience, there were a couple of lessons come to light with regards to communication technique in situations specifically to community engagement - firstly, we, landscape architects, are not fully equipped with tools to represent changes and multi-spatial conditions. Particularly in disaster mitigation and planning process, spatial proposals must address, for instance, changes in water levels, various scenarios for evacuation measures, as well as dual functionality of spaces during normal times. Secondly, we must learn how to share our design proposals with broader audience. Planning for future resilience entails participation and understanding from the general public, who are not all planners nor engineers. The methodology of sharing ideas must be tangible and straightforward.

1.1. Concept of 4 Dimensional Model

The 4 dimensional model (4D model for short) is a representation method that combines physical model with an overlay of projected animation (Fig 1).

---

Fig. 1. Snapshot of 4D modeling concept using test models. People’s movement, rain event and water level fluctuation were incorporated in the animation.
It can represent various spatial conditions over time, such as, water fluctuation, weather change, seasonal cycle, patina and people’s movement. Strictly speaking, projecting digital graphics or simulation onto object(s) is not necessarily an innovative approach. A couple of successful applications are demonstrated in the field of research, participatory design and exhibition display [3][4][5]. However, there are little studies conducted, which couples digital display methodology with disaster management, despite its high visual communication capability [6]. Bearing that in mind, the objective of this paper is to clarify the usability of 4D model in the context of community engagement, specific to disaster and risk management. Identified potentials and challenges were further digested to discuss ways in which enhance the role of landscape architects in the conversation of future resilience.

2. Site Context

2.1. Great East Japan Earthquake

On March 11th 2011, a magnitude of 9.0 earthquake hit the north-eastern coast of Japan, followed by an unprecedented tsunami exceeding 15m in height, recording 38m in wave run-up. Extensive areas along Tohoku coastline got heavily attacked by recurring tsunamis, washing away all sorts of standing objects - coast protection infrastructures, buildings, cars, forest, and killing over
15,000 people in total [7]. Also known as the Great East Japan Earthquake (3.11 for short), it was both one of the most powerful ever recorded as well as the most costly natural disasters in Japanese history (Fig 2).

2.2. Small Fishing Community: Nagashizu

Nagashizu, is a small fishing community along ria-shoreline, located at the southern tip of Minami Sanriku Cho (MSC for short), a coastal town located in Miyagi Prefecture (Fig 3). Before 3.11, there were 39 households, 172 residents dwelling at low-flatlands, nestled within a hilly topography. This terrain amplified the impact of tsunami by constricting the way and funneling the wave 800 meters into the valley, inundating 16.9Ha of land [8]. The epi-center was located 140km away, so tsunami waves

Fig. 5. Construction of Route398/seawall (Dec, 2017)

Fig. 6. Overview of Nagashizu in relation to landform, inundation and infrastructural works.
Base data source: Miyagi Prefecture and Town of Minami Sanriku
arrived 30-40 minutes after the shake. As a typical coastal community, Nagashizu was well-equipped with sea protection infrastructures, such as wave-off blocks, sea-gates along shoreline. In addition, tsunami evacuation drills were conducted typically once a year and a number of sign boards for evacuation routes were provided by MSC. 7 years have passed. Currently, reconstruction works in Nagashizu are halfway through, including uplifting Route 398 – a 7.3m high elevated driveway above sea level, a structure that co-functions as sea wall. Similarly, 350m-long concrete embankment along Nagashizu river has been developed with more than 6m higher than water level (Fig 4-6). Most of the residents have migrated to higher grounds, approximately 600m away from the original settlement location. As many residents rely on fishing industry, ports and docking facilities are proposed for the open-spaces (disaster hazardous area) which are mostly left unplanned. Since most of the reconstruction works are going to be completed soon, Nagashizu stands at a milestone to plan for the future - how to revitalize the community once again with a resilient foundation.

2.3. Definition of Social and Community Resilience

The term “resilience” is a context-sensitive concept, and it entails both structural and non-structural interpretation in disaster risk management [9][10]. In this paper, emphasis is placed on the latter, and referring to Bruneau et al. (2003) [11], resilience is defined as “the ability of the community to mitigate hazards, contain the effects of disasters when they occur, and carry out recovery activities in ways that minimize social disruption and mitigate the effects of future adversity”. Furthermore, the paper gives sub-category of social and community resilience, which key contributors differ as following; in Nagashizu, aspects that enhance social resilience are identified as communication, risk awareness, risk preparedness, and sharing of information. Likewise, community resilience is measured by long-term population wellness, quality of life, and post-disaster community functioning [12]. Particularly, community resilience is a critical concern for Nagashizu and other neighboring communities, where sustainable communal operation is in danger due to population decrease.

3. Methodology

In order to capture the sufficient extent of the coast and inundated area, an A0 size (840mm x 1194mm) physical model was created in 1:400 scale, with white foam board, cutting out every 1m contour lines. Base plans were collected through town and prefecture websites [13][14][15], and onsite survey and interview was conducted in December 2017 for clarifications. In addition to the physical model, total 4 minutes animation was created using Adobe AfterEffect, Rhinoceros 4.0 in conjunction with algorithmic modelling tool Grasshopper. Featured attributes in the animation were water level, micro-climate, movement of vehicles and fauna & flora. These materials were used to evaluate and discuss the following 3 points:

1: Evaluation on its usefulness for infrastructural planning - In Nagashizu, infrastructural planning was led by MSC.
town officials back in 2013. The intent was to understand the actual briefing procedure with Nagashizu residents, and compare the effectiveness of visual communication between conventional 2 dimensional plans versus 4D modeling.

2. Evaluation on its usefulness in planning for social resilience – The animation depicted the changes in water level and land conditions, in order to illustrate imminent threat of tsunami, flooding and land-slides. It is a translated version of the town’s hazard map with motion, supplemented by author’s slope analysis (color coding based on slope angle) and simple water flow simulation. The target was to rediscover resident’s pre-3.11 awareness level towards risks, and to collect ideas to upgrade social resilience for the future.

3. Evaluation on its usefulness in planning for community resilience – The animation illustrated an outlook of Nagashizu’s in the year 2030, and rendered various community phenomena unique to Nagashizu within the animation (including spring folk festival, indigenous marine fog during summer time and rare migratory birds in Autumn), for the sake of addressing participant’s prospects on sustainable community redevelopment.

4. Results

4.1. Community Workshop in Nagashizu, MSC

The workshop was conducted on March 24th 2018, at Nagashizu-Inn. There were total of 19 participants: 4 local residents from Nagashizu, all in their mid-30s, 10 University students from Tokyo (2 students in landscape related field, 8 students in non-landscape related fields), and 3 facilitators including the author. The workshop was conducted in a relaxed setting, in order to address frank feedback from the local residents (Fig 7-9).
4.2. Discussion Summary of Infrastructural Planning

It was clearly expressed by all participants that 4D model is absolutely superior to 2 dimensional plans in visualizing proposed infrastructural works. Unlike vector-based information with technical dimensions and annotations, 4D model successfully conveyed the perception of post-construction state – how they will be experienced from human eye-level. In fact, when construction works began to materialize in later years, residents were astonished by the massiveness of the 7.3m high seawall. It was often the case throughout MSC that residents expressing their concerns of being blind to the sea, which ironically amplified the un-secureness to tsunami disasters.

During the reconstruction planning phase in 2013, the frustration from the residents seemed to be borne in the long process of scrutinizing ideas. Resident’s proposals tended to travel a long one-way passageway, just to find out that they come to a dead-end due to budgetary or legal reasons. Therefore, their collective suggestion was to embed a function within 4D model that allows immediate modification of the animation so as to speed up the process of idea development and refinement.

4.3. Discussion Summary of Planning for Social Resilience

“If this visual were shared before the 3.11 tsunami, we could've avoid such a big loss” – this is one of the most influential comments received from the residents, which also proves the effectiveness of 4D model as a tool to raise awareness of disaster risks. The appreciation was directed to the effort for enabling all participants to realize and discover the possible hazardous scenarios. In other words, the accuracy of tsunami inundation extent in the animation, for instance, seemed not necessarily important, but more on the realization of risk was point of their interest.

Residents expressed that, now they know...
that climbing up the nearest high grounds makes sense, but it was not the case immediately after the earthquake. Some residents ran in the opposite direction from shoreline for security, which while it seemed logical, was actually not appropriate from a geographic viewpoint. Some residents remained at home watching TV, wishing to gain information, or drove close up to shoreline to observe the sea level. All residents could have made prompt actions for evacuation if only they were aware of the catastrophic scenario.

In addition, the information on vulnerable terrain and potential risk of landslide was accepted with surprise by residents. They mentioned that they were not familiar with town’s hazard map, and especially elderly people will not have easy access to online information.

With regards to 4D model in the context of social resilience, core of the discussion was for the evacuation scheme. One of the most constructive feedbacks was to incorporate tsunami wave speed and people’s walking speed into the animation. For example, elderly people will have slower walking pace, and it will be even slower at sloped terrain or unpaved pathways. In this way, 4D model can support community members in deciding best evacuation center location and its routes, as well as establish a community-wide consensus.

4.4. Discussion Summary of Planning for Community Resilience

It was agreed that a series of rendered graphics enhanced the imagination on potential activities that can take place in Nagashizu, not only what, but also where and when. From a non-planners point of view, it seemed a challenge to imagine the full-picture after completion of all infrastructural works, let alone, tap ideas on top of it. Therefore, resident’s remarks emphasized the importance of knowing the spatial organization in detail at earlier stage, which will allow them to prepare ideas to revitalize community as soon as possible.

However, it became clear in the end, that there was a strong need of specialists to help guide the spatial planning process, especially for public amenities. Residents explained that so called “public spaces” where children can play, for example, were spontaneous and ubiquitous in Nagashizu’s surrounding forests, thus they did not require any planning efforts. Likewise, seasonal folk festivals used to be held at shrine owner’s front yard. Considering these backgrounds, large area of disaster hazardous area requires external inputs to plan its full usage for community wellness.

Having said that, it was interesting to brain-storm ideas with non-local students as well, which helped outline the uniqueness of Nagazhizu. Outdoor theater, Tarzan play (adventure zip-line made out of vines), and Instagram-perfect monuments with ocean view, were some of the ideas raised and discussed. 4D model successfully brought all participants to one table, and drew diverse ideas that interrelated to local resources. One of these ideas could become the seed to boost local tourism or eco-educational programs in the future.

5. Discussion

During the workshop, there were a number of profound insights for 4D model, as a tool to assist the process of disaster management.
Following remarks summarize other potential ways to further expand its usage.

5.1. For Other Areas in Japan or Beyond

There was a suggestion by participants that similar type of workshop should be conducted at other waterfront communities in Japan, or elsewhere in disaster prone countries in the world. Large number of communities that sit above Japan’s Nankai Trough, for example, must be ready for a huge magnitude earthquake expected to occur within next 30 years in 70-80% percentile [16]. How will such communities foster a robust foundation for social and community resilience? Who will be able to facilitate discussion among community members, to properly plan for a resilient future?

4D model workshop in Nagashizu was the first attempt to answer these questions by offering a basic methodology for landscape architects to demonstrate not only the threats but also the potentials of any given site, and share the findings with broader audience. Hence, participant’s aforementioned suggestion implied the scalability of the methodology, and at the same time, the latent significance of landscape architects in the process of resilience planning. This is because, it is only possible through the lens of landscape architects that to thoroughly comprehend local context in multi-scales and multi-moments. Creating an animation took a similar process as unfolding a number of dynamic layers (cultural, ecological and hydrological) that make up the physical landscape we see today, and reassembling them into a story. Nagahsizu in particular, there were a number of indigenous natural and cultural factors that were incorporated into the narrative. Similar steps can be applied to other parts of the world - unlocking unique features of the site, reinterpreting, and finally incorporating them into the materials for community dialogue sessions.

5.2. For Our Daily Practice

There are also potentials for 4D model to be adapted in our daily landscape practice. Projects that deal with climate adaptation, and/or waterfront environments are some the territories for exploration. Natural systems and materials that landscape architects deal with are, needless to say, never in a static state. It is our challenge to anticipate changes over time, and to weave compelling design scenarios that maximize environmental and economical returns in the long run. In occasions of interfacing clients, 4D model will well-adapt to support practitioners to elaborate changing landscapes in their design proposals.

In order to examine its potential in our daily practice, the idea of 4D model was shared and discussed with 10 young professional landscape architects in Singapore. Feedbacks received were mostly positive and some ideas for improvement were:

- Add sound effects to enhance the overall ambience
- Projector should be placed right above the model so that participants can interact with the model freely
- Use diagrams and infographics to incorporate site’s non-visible information
- Overlay results of various simulations (hydraulic, sunlight, wind modeling)

Pointed out difficulties were in the technical aspect, namely, in terms of software and time. To answer such concerns, animated
materials can be recycled through templates to shorten the production process. Similarly, depending on the focus, subject matter for animation can be selective and reduced to minimum.

As digital technologies rapidly make progress, so should our digital literacy. At the end of the day, digital representation shall diversify our design languages and strengthen our commitment to clients.

6. Conclusion and Prospects

4D model was well-appreciated by community members from Nagashizu in MSC, to help them visualize, understand and imagine schemes for future resilience. The workshop clarified that 4D model can be utilized in multi-purposes by customizing its content - for infrastructural planning, for social and community resilience planning. Simultaneously, 4D model revealed the limitations of conventional procedures of community engagement. Unlike engineering approach, landscape architects have the ability to synthesize indigenous natural and cultural resources into the argument. Nagashizu 4D model workshop served as a first successful attempt to seek opportunities to scale-up its methodology to other sites in the world, or even in our daily practice. However, a number of technical refinements were highlighted, in order to make the argument more effective and robust. Next 4D model workshop to be conducted in the world, should address the suggestions raised.

Lastly, Nagashizu residents stressed their hope of never to repeat the tragedy again. There were tremendous losses from 3.11, but lots to learn as well. Landscape architect’s perspective and our design thinking are essential to further worldwide discourse of disaster preparedness schemes.

Acknowledgments

I would like to express deep appreciation to the local residents who took the effort to participate the workshop in Nagashizu. Especially, the discussion went fruitful, thanks to Mr. Masanori Sato, Mr. Takeshi Endo, who shared their struggles and insights during their long journey of disaster recovery. In addition, special thanks to Mr. Taiga Fukushima, Ms. Hiromi Koyama, who helped address frank opinions from the participants, and crystalize the argument. My thanks go as well to colleagues from Ramboll Studio Dreiseitl Singapore for your kind suggestions. Thank you very much.

Singapore’s ABC Waters Programme: Integrating Blue-Green Designs in Urban Landscapes

Setting the context

Tan Nguan Sen
Chief Sustainability Officer
Public Utilities Board
Singapore

Synopsis:
The ABC Waters Programme was launched in 2006. After over a decade since its inception, there are lessons learnt, obstacles surmounted and future challenges to overcome. Intensive development of our City-State has resulted in rapid urbanisation, with direct impact to our hydrological regime. 2/3 of mainland Singapore functions as catchment area that contributes to our water supply.

At its core, Blue-Green Integration has been the backbone of the ABC Waters Programme. Multidisciplinary in nature, the Programme has required the knowledge and expertise of Planners, Designers and Engineers; the trust and support of inter-agency collaboration and active participation and appreciation from the general public. Sustainability through the support of society and stewards of the Blue-Green movement are essential to the longevity of the Programme and the completed projects.

The presentation is framed upon the context of:
1. Urbanisation and its impact on the hydrological regime
2. Blue-Green Integration: ABC Waters design features integrated with the Urban Landscape
3. Sustainability through stakeholders, 3P Partnership and life of the project after conception

Urbanisation and the impact on surface water & hydrology

Singapore’s integrated water management strategy, with a closed loop system is one that relies upon effective harvesting of surface run-off to our reservoirs, the largest of which is Marina Reservoir with a highly urbanised catchment. Urbanisation’s impact on the quantity and quality of stormwater runoff and increased peak flows in the public drainage system is a challenge that needs to be addressed. The ABC Waters management strategy differs from traditional stormwater management; it advocates a distributed system to detain and treat stormwater runoff, and to do this upstream, at source.
Blue-Green Integration: ABC Waters design features integrated with the Urban Landscape

3 Projects are selected to showcase a set of inherent challenges and integration at different scales. ABC Waters design features perform different functions such as conveyance, treatment and detention. These are expressed and integrated uniquely to each project.

1. Kallang River Bishan-Ang Mo Kio Park is the flagship project of the ABC Waters Programme. The project showcases integrated blue-green planning and government inter-agency collaboration at its best. At its core, this river restoration project is a well-loved regional park that is unique, for it is distinctly urban and adjacent to housing developments.

2. Downstream of Bishan Ang-Mo Kio Park, a subsidiary drain of Kallang River at Toa Payoh Lor 8, is an example of a retrofit blue-green project that solved a recurring flooding issue within the estate. A simple ABC Waters design feature - a rain garden, turning a liability into an asset.

3. Waterway Ridges – a collaboration with HDB and a pilot project to integrate ABC Waters Design Features with the landscape at a precinct level. Rain gardens are designed for the first time with active multi-functional spaces such as bioretention lawn basins, that can used as active open space during dry days. Rainwater is expressed in a water feature after being conveyed and cleansed – a celebration of the effectiveness of bioretention systems in a designed architectural feature.

Sustainability through stakeholders and 3P Partnership

With knowledge, and the understanding that education is key, initiatives like the ABC Waters Learning Trail are targeted at secondary school students, to educate about water related issues, encourage a conservation mind set, keep our waterways clean and adopt water safety habits. The Rain Gardens in Schools project built rain gardens in 8 schools, (primary to tertiary level) to reinforce these values and to enhance opportunities to learn about water, e.g. hands-on testing of water quality within the educational site and permeate application of ABC Waters design features within the water catchment.

Life of the project and its longevity is heavily dependent upon its care post-construction. Outreach via stakeholder consultation for the buy-in of the project pre-implementation is as important as the buy-in required by the stakeholders for the project’s maintenance post-implementation. Sustainability of the ABC Waters Programme at its core is in its improvement of the urban landscape and its inherent added value to society. Continued support from stakeholders and the public can only strengthen the cause for well-designed and fully integrated Blue-Green Urban Landscapes.
Biodiversity For Strengthening Resilience To Climate Change: The Singapore Experience

Dr. Lena Chan
Senior Director,
National Parks Board,
Singapore

Synopsis:
Many areas are facing the effects of climate change and coastal cities experience the consequences most severely. Solutions and preparations for climate change are most effectively if carried out in phases and ahead of time. While biodiversity will be affected by climate change, it can also contribute to the adaptation, mitigation and resilience.

Singapore by virtue of its physical location in the Malesian region is rich in flora and fauna, hence, Singapore’s native biodiversity can form the cornerstone of nature-based solutions to climate change. Singapore already has a head start when it evolved from a Garden City to a green and blue biophilic City in A Garden.

The National Parks Board (NParks) of Singapore plays a major role in positive actions for climate change through several policies, strategies and action plans that form the thrusts of NParks' Nature Conservation Masterplan. These include the conservation of 4 Nature Reserves, increasing greater variety of plant species, ecologically connecting important natural ecosystems, promoting skyline greenery, enhancing and enriching habitats in the Nature Reserves and parks, and carrying out species recovery programmes. The application of sound science and modern technology is crucial for the rational basis of these activities.

To ensure the sustainability of these actions, the participation has to be all-inclusive. This is only possible with the partnership of the public, private and public sectors working hand-in-hand. The young must be engaged from the earliest possible stage, hence education at all levels from pre-school to tertiary is essential. Public awareness and citizen science would further augment and drive people’s efforts to meet the climate change challenges.
Prepared Communities – participatory resilience planning in vulnerable communities

Lubaina Rangwala
Managing Associate
WRI India’s Sustainable Cities Centre
India

Synopsis:
With climate change, cities are increasingly exposed to a range of hazards such as severe and prolonged droughts, intense rains, and increased temperatures. “The number of deaths attributed to natural disasters continues to rise, despite progress in implementing disaster risk reduction strategies. From 1990 to 2015, more than 1.6 million people died in internationally reported natural disasters” (SDG 13, Sustainable Development Knowledge Platform). The loss of livelihoods and the impact on social and economic assets, public health, and physical infrastructure that may continue to challenge the lives of vulnerable people, are seldom accounted for. As the world continues to urbanize, climate change is expected to increase the intensity and frequency of existing hazards, as well as usher in new climate risks.

Globally, experiences of the disaster management community suggest that there is a need to link top-down, institutionally driven disaster management approaches with community-based bottom-up approaches, to ensure that the city resilience strategy in fact enhances community resilience initiatives (IPCC 2012) rather than deepening infrastructure gaps. Moreover, since city resilience strategies largely focus on engineered or ecological solutions to manage risks (Vale 2014), they fail to focus on social assets – building back social networks and ensuring psychological recovery after an extreme climate event – systematically eroding a city’s social resilience capacity. In this context, planning and design play a critical role in shaping a city’s urban agenda towards climate sensitive and resilient pathways, while enhancing social cohesion.

Local communities are constantly shaping their built environment to improve their quality of life, reduce impending risks, and enhance their resilience capacities. To this end, the World Resources Institute has developed a participatory resilience planning process that helps cities and communities leverage their social assets in shaping resilient neighbourhoods and preparing for extreme events. This process involves collecting primary and secondary data in low-income communities living in at-risk areas in the city, assessing their resilience capacities, and co-developing resilience actions in gender and age segregated workshops. This process was conceived as a counter-approach to most top-down city resilience strategies and plans that tend to retain departmental silos, and largely focus on engineered solutions to reducing vulnerability in cities.

For this presentation, I will share findings from our projects in Surat (India) and Semarang (Indonesia), of working in low-income vulnerable communities, assessing their resilience needs and capacities, and co-developing resilience actions through a participatory planning process. Resilience actions ranged from climate risk management, improving urban infrastructure and services, and enhancing safety and social cohesion in low-income communities living in at-risk areas. Through these examples the presentation will address the following questions: How can cities assess, leverage and enhance the social assets available in vulnerable communities to design community-based resilient infrastructure that is locally relevant, gender sensitive, innovative and scalable? Moreover, how can this learning influence a city’s resilience plan, to enhance community initiatives and mainstream bottom-up planning processes?
Synopsis:

By 2030 60% of the world’s population are living in cities, a proportion that will continue to rise as the 21st century unfolds. Cities will absorb—in less than 40 years—almost the entire increase in population in all recorded human history up to 1960. Cities are not just bricks and mortar. They are made to work not just by governments but also by the collective action of individuals, businesses, and institutions that collectively define it. From here on, we refer to cities, we refer to everyone that plays a part in shaping their city. This is also the century where we will see globalization forces bringing rapid change to our cities. On one hand, there will considerable economic development opportunities; on the other hand, industries may also decline at a rapid pace.

Cities have always faced risks. Historically, many of the world’s greatest cities have demonstrated their resilience in the face of resource shortages, natural hazards, or conflict. In the 21st century, the number of people living in cities and global pressures that play out at a city scale—such as climate change, disease pandemics, economic fluctuations, and terrorism—poses new challenges and uncertainty.

Our cities need better infrastructure and much of it will be conceived, designed, and built in the next 20 years. The annual cost of infrastructure that is resilient to climate change is around $1.2 -1.5 trillion. The world cities will require estimated $57 Trillion in global infrastructure investment in 21st Century. In ASEAN itself the major cities will require approx. 2.5 Trillion USD worth of infrastructure by 2030 & will house close to 350 Million Citizens. This is an unprecedented phenomenon of urbanization that needs a new outlook towards our cities & helping them in creating its required infrastructure & built environments.

100RC has recognized resilience as a critical urban agenda, and an opportunity for cities—particularly rapidly growing cities—to ensure that their development can enhance rather than undermine their resilience. Resilience doesn’t just involve a better understanding of hazards, risk assessments and acting to reduce losses. It also includes tackling underlying vulnerability and strengthening the city’s ability to withstand, recover from, and adapt to whatever shocks and stresses the future holds.

This is demonstrated by the decline of the US City of Detroit, Michigan, which was overly reliant on a single industry as its economic base. The city’s failure to diversify its economic base meant that alternative options were not available to employers and employees when one industry began to decline. Like Detroit, many large cities such as Mumbai and Barcelona were once major centers of manufacturing. Both cities have evolved over time to absorb the decline of their manufacturing base with new industries such as tourism, culture, media, finance and information technology to continue to thrive today.

A city’s wealth is not necessarily a defining factor of its resilience as relatively poor cities can also make choices that build resilience, create a thriving & liveable place for its citizens to live, adapt & grow.
Biodiversity For Strengthening Resilience To Climate Change: The Singapore Experience

Dr. Lena Chan
Senior Director, National Parks Board, Singapore

Synopsis:
Many areas are facing the effects of climate change and coastal cities experience the consequences most severely. Solutions and preparations for climate change are most effectively if carried out in phases and ahead of time. While biodiversity will be affected by climate change, it can also contribute to the adaptation, mitigation and resilience.

Singapore by virtue of its physical location in the Malesian region is rich in flora and fauna, hence, Singapore’s native biodiversity can form the cornerstone of nature-based solutions to climate change. Singapore already has a head start when it evolved from a Garden City to a green and blue biophilic City in A Garden.

The National Parks Board (NParks) of Singapore plays a major role in positive actions for climate change through several policies, strategies and action plans that form the thrusts of NParks’ Nature Conservation Masterplan. These include the conservation of 4 Nature Reserves, increasing greater variety of plant species, ecologically connecting important natural ecosystems, promoting skyrise greenery, enhancing and enriching habitats in the Nature Reserves and parks, and carrying out species recovery programmes. The application of sound science and modern technology is crucial for the rational basis of these activities.

To ensure the sustainability of these actions, the participation has to be all-inclusive. This is only possible with the partnership of the public, private and public sectors working hand-in-hand. The young must be engaged from the earliest possible stage, hence education at all levels from pre-school to tertiary is essential. Public awareness and citizen science would further augment and drive people’s efforts to meet the climate change challenges.
Synopsis:
Rapidly increasing demand for food and agricultural non-food products to meet the demands of rising populations with new consumption patterns have worrying implications for sustainability of many ecosystems globally. Our aspirations towards global sustainable development and future resilience are dependent on how the world's ecosystems and their components are managed predominantly at the landscape level. Challenges of global food supply, welfare and livelihoods for billions of people, carbon sequestration, conservation of biodiversity and provisions of renewable energy, water and soil fertility all need to be addressed at the landscape level. Numerous studies indicate that sustainable use of many of our renewable resources is being exceeded on a global scale and that we should approach future use with great care. Production landscapes, if managed appropriately, yield a wide range of goods and services vital to humanity, including food, wood and other raw materials, as well as life support processes (e.g. climate regulation, water purification), life fulfilling conditions (e.g. educational, aesthetic and recreation opportunities) and conservation options (e.g. genetic diversity for future use).

However, the provision of ecosystem goods and services at landscape scale can vary considerably depending on land use and land cover, and management choices. For example, landscapes dedicated mostly to agricultural production have limited capacity to produce the range of ecosystem services required for human health and well-being, while landscapes with a mosaic of land uses can produce a wide range of services, although these are often subject to trade-offs between multiple ecosystem goods and services. This talk will briefly introduce the landscape research in CIFOR, ecosystem services under different landscape management scenarios and the potential for planning and reconfiguring landscapes toward achieving future resilience.

BETWEEN A ROCK AND HARD PLACE: Building Resilience in an Uncertain World

Jonathan Rigg
Director of the Asia Research Institute and Department of Geography
National University of Singapore
Singapore

Synopsis:
This presentation will seek to do four things. It will open by discussing the theme of ‘resilience’: what it means, how it is used, and its shortcomings. Second the paper will reflect on inherited vulnerabilities and how they have been addressed, or not, by processes of development-as-modernisation. Third, the paper will show, drawing on fieldwork in Nepal, Laos, Thailand and Vietnam, how increasing prosperity and declining vulnerability have also been accompanied, not infrequently, by rising ‘precarity’ – the precariousness of modern life. This will then illuminate the puzzle of how we see growing wealth and material prosperity across Asia on the one hand, accompanied by a growing precariousness of life on the other. This raises questions about the achievement of resilience through neoliberal policies of wealth and growth generation. Finally the presentation will return to high level debates and reflect on the ‘reductionisms’ inherent in much climate change science.
Urban Wilds as a Resource of Resilient Cities

Yun Hye Hwang
Assistant Professor, Department of Architecture
National University of Singapore
Singapore

Synopsis:
The intensive and exponential growth of human activities in cities is a key driver of the significant loss of habitats. Given the competing land use for economic-driven human development, urban wilds could become a compelling natural resource to achieve ecological resilience in cities. Urban wilds are a bottom-up approach that starts with the simple act of reducing human interruption while allowing the spontaneous growth of landscapes. It is geared towards enhancing urban biodiversity and increasing the structural complexity and heterogeneity of urban landscapes, which, in turn, supports various local habitats that strengthen the ecosystem’s capacity to deliver important ecological services. Inspired by Alberti’s (2016) planning principles under uncertainty (maintaining the diversity of urban patterns, increasing adaptation capacity, actively reconfiguring policy actions, and expanding time scale of decision-making), the talk begins a discourse on the extent to which urban wilds can enable resilience in urban ecosystems by discussing three ongoing research projects.

1. Wild landscapes in a tidy city, Singapore: Manicured urban greenery is the norm in Singapore, but this approach obstructs the accommodation of ecosystem dynamics and misses an opportunity to socio-ecological benefit from the region’s tropicality. The two pilot projects have generated design and management strategies promote the use of spontaneous growth of urban greenery and suggest steps that can be taken at a policy level. A hybrid of natural growth and selective human management offers an approach to negotiating social demands in a compact city and provides a strong ecological incentive that works in harmony with the region’s characteristics.

2. More greenery for the poor, Mumbai and Jakarta: Many studies on disparities in the distribution of urban green spaces (UGS) focus on accessibility of public green spaces. Yet when all types of UGS, including unmanaged greenery, are accounted for, claims of green space distributive injustice become more complicated. Using the case studies of Mumbai and Jakarta where the inequality issue has grown, this project questions the common assumption that the poor have less green space by analysing green space distribution patterns, vegetation densities, and patch sizes. The project’s findings have practical consequences for policy and planning towards ecologically inclusive communities.

3. Kabalikat Mangrove Project, Manila: Situated in the mouth of the Pasig River, off Manila Bay, Baseco has been reclaimed. The coastlines were left bare and became a dumping site between two stone breakwaters extending out of the river and South Harbour, with a third of the settlement area marked as flood-prone. Spontaneous mangrove planting along the coastlines of Baseco to mitigate the impact of typhoons was started in 2012 by local NGOs in partnership with the resident group, Kabalikat; they used leftover funds from disaster relief donations to start a disaster risk reduction project. Despite numerous setbacks and a low mangrove survival rate, gradual improvement can be observed over three years, with constant improvisation by residents adding to the success.
Infinitely adaptive socialized housing development for urban regeneration and resiliency

Jouykovi Ignacia Cruel

*Rizal Environment and Natural Resources Office, Rizal Provincial Capitol Bldg., Antipolo City 1870, Philippines

Abstract

Living in a fast-paced world requires one’s ability to adapt. Rigid cities planned with minimal, or worse, no foresight and without room for any possible changes and for problem mitigation, expose people living in them to extreme vulnerability. With more than half of the world’s population currently living in cities, urbanization continues to expand, and with it the increase in urban poor communities, social alienation, and environmental pollution intensifies, especially in developing countries like the Philippines. Every month, approximately five million people migrate to cities all over the world. In Metro Manila, eleven percent of its residents live in slum areas.

The urban poor face multiple threats to their lives—pushed to places of least favorable circumstances and detached from various basic services. One of their weapons for survival is establishing informal settlements, though usually at areas in high risk areas (e.g. near waterways) —a product of survival and adaptation to the urban environment. Despite the living conditions of the urban poor, they have proven to have great capacity to improve and invest in their communities. These informal settlements should be seen as potential growth areas; these settlements are the answer to the incessant problem of growing slums.

The paper aims to strengthen the urban poor safety net by developing a design framework for self-sustainable, climate change-adaptive, and low-cost housing developments along waterways, where residents benefit from the surrounding areas to create an osmosis effect. Nearby linear parks serve as recreation area, flood-buffer zone, and bioretention basins with park bridges connecting them, for improved mobility and utilization of areas. Along with it is the implementation of an infinitely adaptive system that is not repetitive in nature, and, in turn, will help reduce the urban poor’s vulnerability and will enable to cope up with the city’s progress.

This design framework also aims to dispel the stigma and isolation of socialized housing from their surrounding developments by integrating and intermixing them with the community, thus, creating better access to basic services and giving the urban poor a sense of ownership and the sense of responsibility of taking care of their property and their surroundings as well.
In the Philippine setting, usual relocations sites are located at areas away from the town proper of nearby rural towns, with row houses haphazardly built. It is no news that many, some up to sixty percent, return to the city. Rather than uprooting and displacing established urban poor communities into disconnected pockets lying at the fringe of development, their current location along waterways is retained and is optimally utilized. From being areas of high risk and low value, the development becomes the city’s first line of defense in mitigating the impacts of climate change, while, at the same time, provides better quality of life to the urban poor through sustainable landscape design and planning principles that promote urban regeneration and resiliency, among many others.

Keywords: Socialized Housing; Urban Regeneration; Urban Resiliency; Mitigate Impacts of Climate Change; Landscape Urbanism

1. Introduction

Urban populations have skyrocketed globally, where in more than half of the world’s population live in cities. UN Habitat reports that current urban trends indicate that an additional three billion people will be living in urban areas by 2050, increasing the urban share of the world’s population by two-thirds.[1]

As urbanization continues to rapidly expand, the increase in urban poor communities, social alienation, and environmental pollution intensifies, especially in the developing world where current responses are having difficulty keeping up. Rigid cities planned with minimal, or worse, no foresight and room for changes and/or problem mitigation, expose people living in them to extreme vulnerability. But these did not stop the estimated five million people who migrated to cities every month last 2016[2], and will not stop. Rather, it is projected to increase in the next coming years while rural population will decrease, with Asia and a number of its subregions on a more extreme level than that of the world as indicated in Table 1[3].

2. Urban Slum Formation and Slums of Hope

Aside from being a need and right, provision of ‘decent shelter’ is an essential precondition for social stability, as stressed upon Costa Rican President and Nobel Peace Prize recipient Oscar Arias. Global initiatives, such as City Alliance’s Cities Without Slums and UN’s Millennium Development Agenda, were started with the general goal of achieving significant improvement in the quality of life of people, especially of slum dwellers, including equal accessibility to basic needs and services, such as adequate and secure shelter.

But as governments of developing countries continue to focus on economic growth rather than providing linkage between expected
urban growth and housing provision, the quintessential problem on lack of ample and secure shelter, especially for the poor, will continue to plague the developing world\textsuperscript{[3]}. In the Philippines alone, the backlog on socialized housing was estimated to have reached 5.7 million units in 2016. An estimate of 2,600 housing units are needed to be built daily over the six-year period to resolve the said backlog\textsuperscript{[4]}. As government fail to effectively link economic growth to projected urban development and socialized housing provision, the competitive demand for land intensifies. As a result, the urban poor, usually large proportions are of rural migrants, are displaced into blighted informal settlements and are increasingly marginalized—pushed to settle at the fringes of development with the least favorable circumstances and are detached from various basic services. As the struggle of finding adequate and secure shelter persist and worsen, informal settlements in urban cities will remain in the same areas but intensely become denser. Asian cities such as Karachi, Dhaka Mumbai, Kabul and Metro Manila have some of the largest slums\textsuperscript{[5]}, with Manila having eleven percent of its residents living in blighted communities\textsuperscript{[6]}.

Establishing informal settlements, usually at areas of high risk (e.g. near waterways) that no one has interest in, serves as one of the weapons of the weak [Figure 1] to ensure survival and adapt to the urban environment. It is estimated that one out of seven persons in the world, or roughly one billion people, live in slums\textsuperscript{[7]}.

Figure 1. Informal settlement as answer and weapon of the poor against threats, reinforced by creation of a safety net.

“Slum” lack consistent terminology and is used interchangeably with “squatter settlement” and “informal settlement”. United Nation – Habitat \textsuperscript{[8]} construes slum household as any household lacking access to improved water, improved sanitation, sufficient living area, durable housing, and secure tenure. On top of concerns for their daily grind, slum dwellers are also threatened by environmental problems (air pollution, water pollution, flooding, and congestion) brought about by urbanization and economic development. These problems affect majority, if not all, of city inhabitants but “the levels of exposure and impact are highest in slums due to their location, limited infrastructure, and coping strategies.”\textsuperscript{[9]} (Ballesteros, 2011)
Despite the living conditions of the urban poor, they have proven to have great capacity to improve and invest in their communities. These informal settlements are starting to be seen as potential growth areas – as ‘slums of hope’ and the possible answer to the incessant problem of growing slums.

In the developing world, slums are in fact the dwelling places of much of the labor force and informal employees that drive the economy of cities. They are melting pots for different racial groups and culture, serving as breeding grounds for iconic political, and cultural movements. Through innovative solutions, the poor are able to improve their own living environments, and paved way to the “gradual consolidation of informal settlements.” [10]

3. Strengthening the urban poor safety net through in-city and in-filling relocation

Close-knit communities of slum are one of the safety nets of the urban poor [Figure 1], as well as relying on nature, and employers. These are the few things they depend on during times of difficulty - nature for food and livelihood, their family and neighbors for financial and emotional support, and employers for income and loans. But through repressive policies such as forced evictions and resettlement, which sadly are still implemented in some cities, this safety net is weakened, if not entirely destroyed.

Off-city relocation model of resettlement often fail to support the social welfare of the urban poor. Usual relocation sites are located at areas of great distance from livelihood sources, and with row houses haphazardly built by developers that limit participation of affected community/ies in the settlement development phase. It is no news that many return to the city. In the Philippines, up to sixty percent of relocatees return. [11][12] (Galuzka, 2013 & Shahani, 2016)

Also, off-city relocation hasten depletion of land, a finite and scarce resource, and promote irresponsible sprawl. Instead of opening a ‘new land’, which may be utilized for a more critical and vital need such as forest conservation, in-filling and upgrading of blighted, underutilized, and vacant spaces in the city is a more sustainable option. In-city resettlement and in-situ upgrading maximize scarce available resources and consecutively reasonably lower socialized housing’s production and development cost so that beneficiaries may afford them. This type of managed densification integrates and intermixes the community and secures their tenure, reinforcing their safety net and recognizing every individual’s right to the city. Some degree of harmony, order and discipline encompass the city and augment its resiliency and ability to regenerate.

4. Infinitely adaptive socialized housing development

However, on-site and in-city relocation proves to be a great challenge for the government of developing countries as space becomes premium and limited in the cities, amplified by rigid master plans that fail to respond to people’s need and
anticipate changing circumstances. Applying
the concept of infinite flexibility/adaptability
to in-situ socialized housing development
may then be a great response to improve
urban resiliency and urban regeneration. The
concept views a city to be system of
flexibility, made up of modular core and
parts governed by the occupants; a matrix of
incomplete objects and forms, wherein
customers complete what the designer
started.

Main roads, high-end commercial areas,
affordable commercial areas, waterways,
green spaces, and transit stations are to be
used as indicators on where to place the
development and how they are to be formed.
Close proximity to low-end commercial
areas and transit hubs and access to main
roads were factors prioritized to augment
their linkage to the city, promote soft modes
of mobility within, to and from the
development, and create an osmosis effect
wherein residents have access to affordable
basic services and can benefit from
surrounding areas.

4.1. Cyclical Housing Towers

The housing itself shall comprise of a
structural frame and utility core that includes
the stairs, elevators, mechanical-electrical
lines, and plumbing lines, much like a
skeletal frame. Modular, prefabricated units
can be purchased or rented, adding more as
the need for expansion arises. Affordability,
then, is certain without compromising ample
living space as cyclical housing [Figure 2] is
accommodated – from living alone, to
having a partner and children until the
children build their own family and the
cycle continues.

By providing the frame and basic utilities,
the occupants themselves finish what was
given – an infinitely adaptable system yet
not repetitive in nature. As change of rate in
slum and depressed are the highest in the
city, the housing tower/structure is perfect in
containing the constant changing of the
residents’ homes. Mixing pockets of green
communal spaces, such as vertical edible
gardens, and commercial units into the
housing structure will help induce more
growth into the development and eventually
to the city. [Figure 3]
4.2. Public space for social, economic, and ecological development

Aside from preventing sprawl, redevelopment of informal settlements along waterways and vertical expansion of the housing structure also frees up the space on the ground level for other uses [Figure 4]. It can then address the issue of poor and scarce public space and provide democratic access to the river. Well-designed public space should not be seen as a luxury amenity but as vital to the well-being of the poor and the development of their community. They boost their social and economic quality of life. Depending on the needs of the community, they may be parks for recreation, public gathering, or marketplace – better yet a harmony of all.

Space is also optimized to mitigate effects of climate change and undesirable ecological impact like flooding, water pollution, and air pollution. Parks will also serve as transitory flooding parks and bioretention basins. Proper easement along waterways should be strictly implemented to provide for planting strips of rain gardens, sidewalks, and bikelanes. [Figure 5] Creeksides and riverbanks are rehabilitated in order to fortify the development’s defense against flooding brought about by torrential rains. Various sustainable bio-engineering solutions may be applied depending on the situation and budget like vegetated geogrids for bank stabilization and proliferation of site-appropriate aquatic plants for rain water filtration and slowing down of river current. Developing pedestrian park bridges help reinforce connection between the development and the city.

The optimal aim of the development, aside from ample housing provision, is to give the urban poor something worth taking ownership of to restore their self-respect. By providing them something that they can be proud of and can call their own will awaken their innate concern to protect it. Hand-in-hand with ecologically sound habitable place-making, from being areas of high risk and low value, the development then becomes the city’s first line of defense in mitigating the impacts of climate change, while, at the same time, provides better quality of life to the urban poor through sustainable landscape design and planning.
principles that promote urban regeneration and resiliency, among many others.

Re-enrooting Food and People to the Place and Re-exploring Landscape Locality for Future Resilience: A Case Study for the New Approaches Used in a Landscape Project in Yilan, Taiwan

Kuang-Yu Wang

Department of Landscape Architecture, Chung Yuan Christian University, Taoyuan City, Taiwan

Abstract

Present day societies are highly connected to, and driven by, the global flows of resources and subject to influences from far beyond their geographic locations. Efficient and productive functioning requires the division of labor, production, and land uses, etc. to be strongly emphasized and implemented. As the development and functioning of places become more and more connected to the global and interregional contexts, and their physical existence mainly supported by professionally-provided services and production, the substantial socioeconomic networks for the functioning of a place, such as food, people, and communities, are, therefore, divided from each other at the local level and disconnected from the local contexts. The seemingly prosperous, globally attached but locally dis-embedded modern societies are often dependent upon the efficiency of division and accurately functioning systems beyond their location. While detached from the integration of a strong socioeconomic infrastructure and the local contexts, they can be vulnerable to environmental changes and poor prospects for future resilience.

Motivated by concerns that a new tourist center will open shortly providing, on the one hand, new sources of local development; but on the other hand, making significant changes to the local landscape due to tourism development and capital investment, a landscape project in Yilan County, Taiwan, in 2017 has responded to these challenges by using “food” as a medium of landscape intervention. The study examined this project which aimed to be a pilot project of using “food of the local table” to guide the local development and landscape changes into an inclusive, sustainable, and resilient future scenario. It explored and presented the multiple aspects of the value and characteristics of the local landscape; introduced the idea of embedment through the food on the local table at mealtimes; and demonstrated a new eating experience which could highlight the added value of the local landscape for the promoting of sustainable, inclusive local development grounded on local resources.

“Enjoying food of the local table, savoring the character of the local landscape” was the slogan of the project. The local table project created a local network of farmers, chefs, small business owners, and residents, and using “food” as a medium to initiate new actions and relations in order to revitalize the local socioeconomic chains. By re-enrooting food, its production, and the people involved to the place, the integration of landscape contexts aims to
strengthen the viable local socioeconomic infrastructure and to re-explore landscape locality as a valuable asset for the sustainable development and future resilience of the local communities.

The project shows new possibilities for the role of landscape architecture and new approaches for intervention within the landscape. The new strategies for the resilient future development could also focus on the re-exploring of landscape locality and the re-enrooting of food, people, and communities to the places while, at the same time, enjoying the diverse opportunities offered by global collaborations and exchanges.

Keywords: Embedment, Food, Landscape locality, Inclusive development, Socioeconomic infrastructure

1. Introduction

The food system, according to Malassis (1994), is the manner in which mankind organizes itself in time and space to obtain and consume its food and has been passed on through history and societies. In the early stages there was a unity of the location of production and consumption, commodity chains were relatively short, and food was not only for feeding but also the basis of creating strong bonds of human development and social cohesion in a locality.

The growing emphasis on the global and interregional division of production, especially since the first half of the twentieth century, lead to the delocalization of site-specific activities whereas the food-induced local social, cultural, and economic chains were broken down and replaced by the agro-industrial model characterized by specialization and intensification which has found a good match with the notions of globalization and urbanization familiar to contemporary society.

The present-day societies are becoming highly connected to, and driven by, the global flows of resources and subject to influences from far beyond their geographic locations. To secure efficient and productive functioning requires the division of labor, production, and land uses, etc. to be strongly emphasized and implemented. As the development and functioning of places become more and more connected to the global and interregional contexts, and their physical existence mainly supported by professionally-provided services and production, the substantial socioeconomic networks for the functioning of a place, such as food, people, and communities, are, therefore, divided from each other at the local level and disconnected from the local contexts.

The seemingly prosperous, globally attached, but locally dis-embedded, modern societies are often dependent upon the efficiency of divided and accurately functioning systems beyond their locations. While detached from the integration of a strong socioeconomic infrastructure and the local context, such societies can be vulnerable to environmental changes and poor prospects for future resilience.

In rural areas for example, rather than embedded in the local environmental and socioeconomic conditions, agriculture is now characterized by socio-technical regimes shaped by schemes of prescription, control and sanctioning by state and private agents (Van der Ploeg, 2006). This has led to homogenization of agriculture and landscape in which national and international pressures such as speculative price-setting and subsidized technological investments have caused a “dis-embedding” of the agricultural landscape from its local and regional social,
environmental, and economic context. Through the ongoing process of regionally embedded regimes being replaced by the new ‘socio-technical regimes’, it is the logic of ‘un-embedded’ finance capital that influences rural landscape and development, rather than the aspects of embeddedness (Lyson, 2006).

The declining capacity of the agriculture landscape to contribute to the local economy could be understood as a consequence of large scale, intensive agriculture failing to bring economic benefits to the immediate local economy because of its dependence on long supply chains and economies of scale (Gallent et al. 2015). This situation does not offer attractive employment opportunities or invest its value added to the local economy when it depends on, and connects mainly to, exogenous systems instead of local socio-economic networks and resources.

An alternative local development model, stressed by Slee (1994), could come from endogenous factors whose value is determined by the variables within the regional system. Moreover, the benefits of development based on such factors tend to be retained in the local economy and local values are respected. In a modern context, how can food and eating be a bridge to re-connect to development that is embedded in the locality? How can an area employing endogenous factors grounded on local resources become a driving force for sustainable local development and landscape?

The study examined a landscape project in Yilan County, Taiwan, in 2017 which has responded to these questions by using “food” as a medium of landscape intervention. The project demonstrated that local landscape characteristics can be well represented in a “local table” (a locally embedded meal), thereby creating added value to the eating experience. It showed that territorial resources can be important assets to the local communities for an inclusive, sustainable, and resilient future landscape scenario.

Based upon interviews with the project organizers, participants, guests, and the analysis of documents, the study examined the notion and representation of landscape, the locally embedded creation of food and the eating experience, the meaning of locality for future development, and the new approaches of landscape intervention.

2. The “local table” project

2.1. The project and the area

The local table project was held in Juangwei Township, Yilan County, Taiwan between February and June 2017. The project area is located on the coastal region of Yilan County facing east to the Pacific Ocean. The geographic features of the landscape consist of a low, fertile, alluvial plain, the coast and sand dunes, and small communities aligned north-south fitted into the edge of the sand dunes and the plain. Like many present-day rural areas, agriculture used to be the major driving force of the local landscape but now it cannot sufficiently support the local economy and jobs.

Motivated by concerns that a new tourist center will open in the area in 2018, on the one hand, tourism could provide new sources of local development; but on the other hand, the local landscape is expected to face significant changes due to tourism development and capital investment. The project aimed as a pilot project for using “the food of the local table” to guide the local
development and landscape changes. “Enjoying food of the local table, savoring the character of the local landscape” was the slogan of the project. It explored and presented the multiple aspects of the value and characteristics of the local landscape; introduced the idea of embedment through the food of the local table meal; and demonstrated a new eating experience which could highlight the added value of the local landscape for the promotion of sustainable, inclusive, local development grounded on local resources.

2.2. The participants

a. Two teachers as project organizers from the landscape architecture department of Chung Yuan Christian University (CYCU).

b. Seven master students in the CYCU landscape architecture department who helped to produce field records and to create the “meal of the local table”.

c. Two local young people who ran a bed and breakfast and provided a venue for the project with the kitchen and dining space for the local table meal. They were also the major local contacts working closely with the organizers and helping to gain access to local chefs, farmers, artisans, and residents.

d. A film director who helped the students to produce field record films.

e. A local photographer doing photo records of the project.

f. A Chef and two assistants from the local area who helped to create the recipes, menus and who lead the cooking of the “meal of the local table”.

g. Three young local farmers who practised environmentally friendly farming and provided food ingredients and materials for the meal.

h. A young artisan who helped to create tableware items.

i. Three local residents who helped to provide food materials.

2.3. The main activities

a. Creating one meal for a dinner as a demonstration of the embedded idea of food, people, and locality. The process for creating the meal included:

   a). Field studies of the project areas to find local resources related to the creation of the meal and a good eating experience.

   b). Discussion of the major ingredients and materials that are most representative of the local landscape.

   c). Discussion of the menu (Table 1) and eating as a holistic experience.

   d). Discussion of each course in the menu regarding the concept, name, expression, ingredients, and presentation.

   e). Creating a local network of people regarding the produce used for the meal.

   f). Several rounds of test cooking.

b. Invited guests from public and private sectors of tourism, commerce, agriculture, culture, and the design and planning department to come to the dinner and share ideas for follow-up actions.

c. Field recording of the landscape, seasons, people, and the production. The field records were made into short films, photographs and drawings, and presented in an exhibition combined with the meal, thus providing a multi-sensorial eating experience.

3. Landscape on the table: The characteristic of the local landscape
manifested through food and the eating experience

The idea of landscape has multiple dimensions combining physical, symbolic, and relational aspects. According to Wang (2015), landscape does not exist merely as objective facts, but also a creation out of human perception and imagination. While the physical and symbolic notions stress the visual and the already-made representations of landscape; nonetheless, the relational aspects emphasize landscape not so much as an entity in itself but as the assembled outcome of networks and embodied functioning relations (Wang and Chou, 2016).

Landscape is, therefore, not the still, scenic images and physical existence as commonly understood, but as something dynamic and having multiple aspects. Taking such notions, the project demonstrated that the multi-aspects of the local landscape could be expressed through food and the eating experience; and such embedment could highlight the eating experience that created added values and turned local resources into place-specific assets for sustainable local development.

3.1. The representation of local landscape through the menu and food ingredients

The food ingredients for creating the menu and the meal were the first question addressed in the project. Through the discussions among the chef, the local farmers, the CYCU teachers and students, the bed & breakfast owners, and some local residents, different ingredients were nominated. Discussions then proceeded through debates and communications which resulted in a list of categories and ingredients as most representative for the local landscape including six categories and a total of sixteen ingredients.

The categories and the ingredients showed the local people’s awareness of the geographic traits of the area. They also showed that the collective memories and local living played an important part in interpreting the local landscape. The creation of the meal and recipes were based on the list in Table 2.

According to one participant:
“I’ve never thought about this before, that the ingredients of food could represent our landscape. I’m impressed to realize that this landscape supported us with a complete meal on the table from seafood to pork, rice and vegetables.”

The meal did not only deliver the characteristics of the local landscape, but it also highlighted the diverse capacity of the landscape to produce food. In many places within contemporary society, the agri-industrial model of global and interregional division has deprived areas of the capacity to support a full meal on their local tables.

3.2. The eating experience connected to local materials and landscape images

The second question was the local materials (Table 3) and environmental characteristics that can be used in the meal and through the eating experience (Figure 1). The field study has recorded the local environmental contexts related to the creation of the meal and expressed through drawings, film, and photography in an exhibition at the venue as an accompaniment to the serving and eating of the meal. The landscape
contexts (the land, seasons, people, sunrise-sunsets, rainy-sunny, insects, birds…) of the locality were therefore connected to the people having the meal, highlighted the eating experience, and increased the added value of food and the locality (Figure 2, 3).

The design of the meal and eating experience were incorporated in the project through using representative local ingredients, the name of dishes, the exhibition of field records, and the presentation, tableware and decoration with local materials. The eating and enjoyment of food were highlighted as multi-sensorial activities combining gustatory, olfactory, visual, tactile, audio, and perceptual contacts. In the model of global division, the eating of food can be independent from any indication of specific locations, but, as stressed in the project, it can also have close connections to a location. According to interviews with the guests, the multi-sensorial eating experience highlighted the value and appreciation of the local landscape and has a good potential as an asset for local development.

3.3. The local reciprocal social network induced by the creation of the meal

The creation of the meal has not only created a chain of local ingredients and materials, but also created a social network of people (Table 4). In this case, the global and interregional division model shifted to the endogenous reciprocal network grounded on local resources and engaging local collaborators. The connections of the social networks could help to build up the social capital of the local communities in which reciprocity arises from such connections (Putnam, 2000). According to the chef:

“Using mainly local resources to create a full meal, I felt restricted at the beginning but then I found it challenging and rewarding as new resources and links to people started to emerge. It gave me new inspiration and meaning for cooking.”

4. Conclusion

The ‘place-less’ discourse of division and globalization are significant forces for change in the present-day landscape. In this case, the development of a location was strongly subject to the exogenous factors that are externally determined by variables outside the causal system of the local region. In the discourse of global and interregional division, the exogenous factors can be transplanted into local regions or localities, and the benefits of local development can be exported despite local values and identities tending to be trampled (Slee, 1994). As the development of a location is subject mainly to the exogenous factors, it could lead to vulnerability in future resilience and also cause an identity problem for a location.

In response to this problem, as Marsden (2017) stressed, the place-specific assets and place-based approaches should be developed for sustainable territorial development which embodies the construction of locational identities, brands, and images around new and redefined goods and services embedded in the locality. The effective social management of environmental resources should combine natural, social, economic, and territorial capital as ways to enhance the local and regional specific assets rather than disrupting and disregarding them. The viable social and economic activities that utilize the varied and differentiated forms of
environmental resources in sustainable ways could provide net benefits and add value to the local environment and community (Kitchen and Marsden, 2009).

The project showed new approaches for intervention within the landscape and stressed a shift from the place-less discourse of division to the emphasis of place-specific assets for locally-embedded territorial development. The strategies for the resilient future development could come from the creation of added value through re-exploring the local landscape and re-enrooting food, people, and communities to the places while, at the same time, enjoying the diverse opportunities offered by global collaborations and exchanges.

Sydney’s Olympic Peninsula:

Growing the Green Games Legacy - a Showcase for Urban Resilience

David Martin,

Sydney Olympic Park Authority,

Sydney Olympic Park, New South Wales, 2127 Australia

Abstract

Sydney’s Olympic Peninsula extends over more than 700 hectares and provides an opportunity for developing a showcase for sustainable and resilient communities building on the legacies of the 1988 Australian bicentenary, 2000 Olympic ‘Green Games’ [7], highly integrated blue, grey and green infrastructure systems unified by world significant landscape architecture. With nature at its heart, the Olympic peninsula is envisaged to become a focal part of the Greater Sydney Commission’s (GSC): ‘Greater Sydney 2056: a metropolis of three cities’. [1]. The GSC vision also includes a new Sydney ‘Central City’ District [2]:

“A city in its landscape valuing green spaces and landscape, an efficient city using resources wisely and a resilient city adapting to a changing world.”

Within this district lies the Greater Parramatta Olympic Peninsula (GPOP) [3] and inside this; a new ‘Super Lifestyle Precinct’ providing opportunities to develop an exemplar resilient and ‘biophilic’ city.

The Sydney Olympic Park MASTERPLAN 2030 (2017 review) [4] (Figure 1) adopts the Green Building Council of Australia (GBCA) ‘Green Star Communities’ [5] sustainability framework supported by a ‘honeycomb’ of New South Wales (NSW) Government planning policies.

Annually over 10 million visitors attend sporting, entertainment and cultural events, 3 million people visit parklands, more than 50,000 residents live in neighbourhoods around the park and each week; thousands of students come to the park for sporting and education programs.
The Olympic Peninsula continues to attract growing global interest as an exemplar for major event legacy and education for sustainable development; particularly from Asia. Sustainability researcher Aziz says [6] (Figure 2)

“Data analysis of the (Sydney Olympic Park Authority) global mapping on Technical Insights Tours (2007-2017), 304 international and domestic visits with 11,844 visitors recorded throughout the period with no less than 25 formal visits per year. A steady number of visitors each year showed that Sydney Olympic Park is recognised as an ‘outdoor classroom’ for experts, students and public to benefit from the Olympic venues and parklands. The reliance is not just on sports and events for Olympic Legacy, but also in providing a liveable landscape for the public”.

This paper includes several ‘early adaptation’ case studies as pilot projects toward urban resilience by improving thermal comfort in a hotter/drier climate, a response to wildfire and use of controlled burning as a landscape management tool and finally; steps toward future-proofing wetlands and estuarine infrastructure from tidal inundation. Together these projects seek to improve the resilience of vulnerable landscapes and liveability for a diverse set of Olympic Peninsula communities.

New opportunities and challenges for landscape architects require trans-disciplinary collaboration to further develop and adapt the Olympic Peninsula to a complex set of urban growth factors such as new public transport networks and the need to future-proof growing communities against natural hazards.

Learnings from pilot projects build on the bicentennial and Olympic legacies and highlight possibilities for the Olympic Peninsula to evolve as a showcase resilient city with nature at heart; in the centre of Sydney.

**Keywords:** resilience; adaptation; green infrastructure, liveability; community; Olympic legacy
1.0 INTRODUCTION: Building on green legacies and a hot spot for Landscape Architecture

1.1 BICENTENNIAL PARK 1988: Innovation, celebration and education

Landscape architecture on the Olympic Peninsula commenced by playing a leading role in the planning vision, design and construction overview for the 102 ha Bicentennial Park, one of Sydney’s most popular urban parks. Encompassing both passive recreation areas and nature reserves this was one of the first innovative and contemporary Australian urban parks to be constructed on broad-scale municipal landfill and fully integrated with protected estuarine wetlands. Since the park’s inception it has been delivering environmental and nature based education programs annually to over 25,000 primary, secondary and tertiary students and professional workshops in urban wetland and bio-diversity management.

1.2 OLYMPIC SUMMER GAMES 2000

‘big bang’ park and Green Games legacy

The motto adopted for Sydney 2000 Summer Olympics/Paralympics has been the ‘Green Games’ [7]. Sydney’s 1993 bid to the International Olympic Committee (IOC) to host the 2000 Summer Olympics included ‘Environmental Guidelines for the Summer Olympic Games’ [8]. This document provided a sustainable development framework to guide the planning, design, material selection and waste avoidance for the 2000 Olympic and Paralympic games. These guidelines had major significant impacts on all sporting venues, the Athletes Village and major event operations. Sydney Olympic Park’s rapid planning, design and delivery over a 7 year period has led it to be described as a ‘big-bang’ park.

1.3 Emerging World ‘Hot Spot’ for Landscape Architecture

In landscape architectural terms; Sydney’s Olympic Peninsula has been evolving into a global ‘hot-spot’ with over three decades of continuous professional practice, Australian and international peer recognition through design excellence awards, extensive journal publications, case studies. Annually the parks is used as an ‘outdoor classroom’ by thousands of students from landscape architecture and other built environment disciplines.

The precinct has been shaped by design-led processes including expert Design Review Panels, design competitions, best practice design policies and guidelines. This has led to a richly layered body of built work including many innovative built projects ranging from intimate spaces such as the 2006 ‘Shipwreck Viewing Site’ published in...
the International journal ‘TOPOS’ (Germany) [9] to regional play spaces such as the 2015 Blaxland Riverside Park; as the first Australian cover feature for the ‘Landscape Architecture Magazine’ (USA) [10].

2.0 COMMUNITIES OF THE OLYMPIC PENINSULA

The Olympic peninsula is comprised of a complex and evolving set of ‘communities of place’ including:

- Visitors – to major events, recreation from a regional catchment, tourists
- Residential – emerging high density precincts inside and adjoining Olympic Park
- Professional Workers – defence, banking, IT, government services and retail;
- Students – primary, secondary and university including significant international cohorts; and
- e-communities – connected by various social media platforms

Communities also exist at both local and global scales and within a ‘virtual’ context as shaped by social media. The issue of engaging people with parklands through social media and virtual visitation was explored by Ferris and Martin in their 2013 Landscape Architecture Australia journal article ‘Going Glocal : Connecting People and Parks’[11]

2.1. EDUCATION COMMUNITIES: Local learning with global leverage

The Authority’s local/global education events such as an annual Youth Eco Summit (YES) connect thousands of primary and secondary schools to a range of nature based learning and urban sustainability challenges. Digital technologies and Smart communication platforms are deployed to link peer to peer learning groups from regions in Asia, the Pacific and North America. The Authority is also a member of the United Nations Regional Centre of Excellence (RCE) Greater Western Sydney (GWS) for Education for Sustainable Development. This includes a strong track record in partnering to educate students in line with sustainable development goals such as SDG 4 – Quality Education and links to the Climate Protection Programs (CPP) working with the City of Parramatta.

2.2 SOCIAL SUSTAINABILITY RESEARCH: Key Findings

Brazilian landscape planner Eveline Mussi [12] conducted research into the emergence of social sustainability in the development of Sydney Olympic Park and neighbouring areas of Wentworth Point, Rhodes and Newington (Figure 3). Mussi identified ‘regional and internal’ communities and four phases of growth since the 1993 bid for the 2000 Games categorised as:
Mussi’s fourth phase of dwelling explores differing community attitudes to the environment, ‘Green Games’ legacy, liveability, social inclusion, a desire for parklands volunteerism and the needs of specific residential communities.

As a more recent phenomenon starting in 2012; ‘pioneer residents’ first arrived to live within the park boundaries. Adjoining the park’s boundaries are more established residential communities within the former Athletes Village at Newington, Rhodes and Wentworth Point falling under the jurisdiction of adjoining municipalities of Parramatta and Canada Bay. Census data reveals that residents in the districts around the park are typically well educated, middle income, culturally diverse (with major overseas born cohorts from China, Korea, India, Iran) with a significant proportion of young families.

The projected district population of the Olympic peninsula will exceed 100,000 with some residential precincts such as the Olympic Park town centre having over 20,000 residents/km2 forming some of the most dense residential neighbourhoods in urban Australia. Together with ‘major event’ visitors, Sydney Olympic Park has high densities and growing ‘communities’ of residents, students, and professional workers potentially exposed to increasing natural hazards and climate risks.

With such culturally diversity, communications and engagement with these communities to develop resiliency provides opportunities to use smart technologies to provide information on extreme weather events, potential risks and suggest alternative locations and activities.

3.0 RESILIENCE: Future-proofing, Shocks & Stresses

GSC Environment Commissioner Rod Simpson defines urban resilience [13] as:

“The capacity of individuals, communities, institutions, businesses and systems within a city to survive, adapt, and thrive no matter what kinds of chronic stresses and acute shocks they experience”.

Key principles of urban resiliency:

- Strong coordination – complex problems require collaboration and risk sharing;
- Modelling and analysis – understand vulnerabilities ahead of planning stage;
- Having a plan – be strategic, not reactive before building or undertaking improvements;
- Building back better - after a damaging or shock event take the opportunity to upgrade; and
- Capacity Building – planners, built environment designers, asset managers, place managers
City of Sydney’s Chief Resiliency Officer; Beck Dawson approaches climate risks and resiliency through the dual lenses of ‘shocks’ and ‘stresses’. [13]

**Shock** events are typically catastrophic and are sudden or ‘big hit’ events. These include wildfires, extreme heat events, storm surges, flash flooding and wind storms generated by East Coast Lows (ECLs).

**Stresses** are chronic, incremental and longer term. These include changes in ocean and soil temperatures, declining or shifting patterns of seasonal rainfall and trending changes in maximum and minimum air temperatures.

### 3.1 UNDERSTANDING VULNERABILITIES: Olympic Peninsula

Scenario modelling undertaken by federal agencies OZCOASTS [14], NSW Office of Environment & Heritage AdaptNSW [15] and more site specific investigations undertaken by the Authority show the Olympic Peninsula has a complex set of vulnerabilities to changing climate and natural hazards due to combinations of the following factors;

- A local geography of low lying estuarine landscapes at the confluence of the Parramatta River with freshwater riparian streams (including Haslam’s, Boundary and Powell’s Creeks), constructed water bodies, wetland habitats and tidal waterways means that the Olympic Peninsula is vulnerable to tidal inundation, flash flooding and long term sea-level rise;

- A mosaic of built landscapes and remnant habitats (including threatened flora and fauna);

- Extensive areas of clay-capped landfills which are prone to drying out, saturation and runoff after intense rainfall resulting in vegetation cover becoming more easily stressed;

- **Shocks or ”Big Hits”** from natural hazards such as wildfire, East Coast Lows (ECLs) such as flash flooding events are occurring more frequently with more intensity. Exposure to extreme urban heat events in western Sydney [16] mean that air temperatures can often be 5-10 degrees hotter than coastal areas of Sydney; and

- **Stresses** - King Tides/tidal inundation, salt water intrusion into fresh water bodies, hotter/drier conditions/decreasing soil moisture/increasing rates of evapotranspiration, elevated plant stress, loss of bio-diversity/habitat , increasing population/demand , ageing assets and critical infrastructure such as irrigation systems, path networks, bridges etc
4.0 ADAPTATION: Understanding scales, horizons & triggers

Under AS 5334-2013 [17], the Australian Standard for Climate Change Adaptation of settlements and Infrastructure, adaptation is defined as

*Changes made in response to the likely threats and opportunities arising from climate variability and climate change. Adaptation can be spontaneous or planned, and can be carried out in response to or in anticipation of changes in climatic conditions.*

**Scales** - the Olympic Peninsula requires adaptation planning and resilience strategies at project, precinct and district levels. Land shared with neighbouring municipalities such as the Parramatta River Catchment require working groups to jointly manage risks. The Authority is an active member of the Upper Parramatta Catchment Working Group who’s members also include Parramatta City Council. The Authority is also a member of NSW Government Sustainability Advantage program which facilitates public and private organisations to build organisational capacity in adaptation and resiliency.

**Horizons** – the Authority’s MASTERPLAN [4] is projected toward 2030. Modelling of climate futures by other NSW, federal agencies and research bodies variously adopt horizon years of 2040, 2050, 2070 and 2100. The GSC strategy for metropolitan Sydney runs to 2056. In any case adaptation and resiliency projects must have a clearly identified horizon.

**Triggers** to adapt include:

- Public safety from risks from tidal inundations of low lying pedestrian/cycle paths;
- Asset replacement of essential grey infrastructure such as bridges, roads and paths; and
- Adoption of GreenStar ‘Communities’ [5] sustainability framework. The Authority is now compiling a detailed Sydney Olympic Park Climate Risk Register, and Sydney Olympic Park Adaptation Plan based on AS 5334 - 2013 [17]. This will be followed by the preparation of a Sydney Olympic Park Resilience Plan.
- Potential legal provisions and insurance benefits.
5.0 RESILIENCY/ADAPTATIVE RESPONSE CASE STUDIES

5.1 CASE STUDY 1 (Stress)
Tidal inundation, Badu Mangroves, Bicentennial Park

For an extended period the Manly Hydraulics Lab, a NSW Government agency which monitors change in coastlines and waterways, has been recording local tidal movements in several locations at Sydney Olympic Park. Tidal inundations over popular shared paths in parklands are also recorded by wetland managers and rangers who have noted that the inundation is occurring more frequently and for longer periods.

The results and observations identified that an ageing (30 year old) bridge was being impacted by rising water levels in a highly saline estuarine environment. The following adaptive responses have now occurred:

- Replacement of the vehicle bridge with new salt resistant composite materials
- Installation of hazard signage and pedestrian/cycle gates to restrict public access during inundation periods over pathways for safety reasons;
- Engaging with NSW Geography and Science curriculum through site-based classes using this location as an outdoor demonstration site to educate students on adaptation to changing sea-levels;
- Planning for longer term drainage channel works to increase mangrove outflows;
- Floating boardwalk and outdoor classroom upgrades adopted new composite materials; and
- Installation of a remote controlled ‘Smart Gate’ to improve tidal flushing of the adjoining Waterbird Refuge, part of the East Asian Australasian Flyway (EAAF) [18] for migratory birds.

5.2 CASE STUDY 2 (Shock)
Spring Wildfire, Aquatic Centre Carpark

An uncontrolled or ‘wild-fire’ event occurred in a major venue carpark in the spring of 2013 during an unseasonally hot and windy day.

Fire Authorities were unable to conclusively establish the cause of the fire which led to the destruction of 40 parked vehicles. Prior to this event, there had been a very dry winter and extensive areas of native grasses in the carpark had been ‘winter-pruned’ - a common practice to encourage spring regrowth. Under these dryer than normal conditions grass clippings were left for mulch and possibly acted as a fuel source spreading the fire onto the tyres of parked vehicles. With gusting wind conditions, many adjoining vehicles were also impacted before emergency services extinguished burning vehicles and vegetation.
Other potential contributing factors include the car park being constructed over clay-capped landfill, with non-irrigated native plantings which under dry conditions, result in very low soil and moisture levels increasing vulnerability to fire. Due to emergency evacuation procedures there were no major injuries or loss of life.

Adaptive responses:

- Review of the Authority’s Site Wide Planting Strategy [19] and replanting with alternative fire resistant low-water demand resilient exotic species;
- Installation of automatic irrigation systems to maintain higher soil moisture levels; and
- Changes in timing and approach to native grassland pruning practices.

In the parklands ‘controlled burning’ is now being trialled to promote ecological diversity, weed management and fuel load reduction to reduce risks of wild-fire.

5.3 CASE STUDY 3 (Stress)

Extreme heat and thermal comfort in Blaxland Riverside Park

The key concept for the 2005 Hargreaves Associates master plan for Blaxland Riverside Park included grassed terracing and an elevated ‘Fig Grove’ to connect the people with the Parramatta River - denied to them when the site was used for uncontrolled waste dumping over many decades.

With the number of extreme heat days (40 degrees Celsius+) in western Sydney now increasing [16]; this is impacting on outdoor recreation usage patterns in the parklands. Adaptive Responses:

- As part of a stage 2 new regional playspace in 2012 JMD Landscape Architects [10] skilfully layered new ‘play hill’ landform layers onto Hargreave’s stage 1 upper terrace and provided slots to funnel cooling river breezes from the summer prevailing wind direction.
- Rows of wind-socks were aligned to highlight cooling air flows through the play space.

On extreme heat event (EHE) days, now reaching up to 47 degrees Celsius, [20] play is largely restricted to pockets of shade near established trees, fixed shade umbrellas and the water plaza.

More broadly the Authority, as part of an Adaptation and Resiliency Strategy will be investigating:

- An urban greening/tree canopy strategy to protect, enhance and potentially provide offsets as development bonuses to provide compensatory forms of green infrastructure such as green roofs;
- An extreme heat policy to address visitors coming for outdoor play.
major sporting events, and health & wellbeing of staff;

- Misting jets in future ‘cool zones’ and public places to offer outdoor respite; and
- Potential use of temperature sensors and smart phone Apps to notify local people of extreme heat events (EHE), live temperatures in specific locations and suggest alternative recreation options as part of a Super Lifestyle liveability App.

6.0 OLYMPIC PENINSULA :

Reshaping landscapes and the making of resilient communities

Revisiting the ‘Bicentennial Park Proposal’ document [21] prepared for the Park’s Management Committee and submitted to the NSW Government in 1985; this original concept plan included a bold vision for a new super-size metropolitan park located in western Sydney supported by the following key principles;

**Bicentennial Park 1988-2088** [Figure 4]:

- **major open space focus in the geographic centre of the metropolitan area**;

- **over 700 hectares of coordinated development of residential, industrial and recreational parkland based on sound land-use planning principles.**

- **A strong visionary concept appropriate to the significance of the area, the historical relevance of the Parramatta River Valley and the celebration of Australia’s bicentenary**

When opened in 1988; Bicentennial Park, was reduced to a smaller 102 hectare park however; it embraced many of the original principles of serving regional residential communities through recreation, preserving water bird habitat and wetlands and environmental education programs - a first for a contemporary urban park in Australia.

A decade later this original vision of a larger metropolitan park found new expression as the 430 hectare ‘Millennium Parklands’ in response to the transformative opportunities presented by the 2000 Summer Olympic Games; incentivised by a major event deadline and completed by a dedicated whole of government delivery agency – the Olympic Coordination Authority (OCA).

Fast forward thirty years and arguably there is now a return to this original and bolder scale of green infrastructure thinking from the GSC to integrate Greater Parramatta (Sydney’s second CBD) with the Olympic Peninsula into ‘GPOP’ [3] as a green resilient heart within Sydney’s metropolitan expanse.
7.0 CONCLUSION :

With growing evidence that the Olympic Peninsula is internationally recognised as a ‘hot-spot’ for Olympic legacy, Landscape architecture and as an exemplar for sustainable development; new opportunities exist to evolve into a national and global showcase for adaptive planning, design excellence and resilient communities.

In Roger Johnson’s compendium for the greening of cities ‘The Green City’[22], the urban designer reminds us that time and scale are key parts of city building when he quoted landscape architect Richard Clough from his time developing Australia’s federal capital Canberra and shaping its centrepiece, Lake Burley Griffin while working for the National Capital Development Commission;

“by quiet perseverance that good results in the design of the environment demand continuing decisions at every point and at every scale”.

It is also said that among the design disciplines, Landscape architecture is the only one that involves the fourth dimension of time. Leading Australian soil scientist Simon Leake (who developed the ‘facsimile soil’ profiles over the vast remediated Olympic era land-fill system) reminds us that as professional time travellers;

“these landscapes were never intended to be set and forget” [23].

As part of the Australian Institute of Landscape Architects (AILA) 50th celebrations held in 2016, Sydney Olympic Park was one of fourteen precincts invited to participate in an exhibition titled ‘Parks Changing Australia’ held at the National Museum of Australia, Canberra.

In AILA’s words this event provided a showcase for how

“Landscape architects: reimagining and transforming the outside world and how contemporary parks are re-shaping Australian cities, increasing people’s health and wellbeing and building more ecologically sustainable urban environments”. [24]

Landscape Architects will continue to re-imagine and transform urban places working as green infrastructure facilitators by adding and remaking many layers of built work.

Landscape Architects will continue to play a key ‘pivot’ role in trans-disciplinary coordination informed by lessons learnt from the 1988 bicentenary and 2000 ‘Green Games’ to achieve the broader GPOP vision of a liveable and resilient city. Looking further over the horizon; future generations of landscape architects may have the opportunity to fully realize the super-park ‘1988-2088’ as originally conceived by their visionary predecessors working for the NSW Government in the early 1980’s.

Figure 4. A Bicentennial Event, Bicentennial Park Proposal
Bicentennial Park Management Committee (1984)

- a visionary generous reservation of open space for the people of Sydney within their living area — over 1000 hectares
- a public park established as one of the most "lovely and favourable suburbs in the City of Sydney" — a celebration of Australia’s centenary

- a vital major open space and ‘green lung’ for Sydney
- a social focus for Sydney’s inner suburbs
- 84 hectares in area of which 53 are mangroves
- a park which reflects 1980s trends of recycling and environmental preservation
- too small to function as a major open space or ‘green lung’ needed for Sydney’s western suburbs
- unworthy of the title Bicentennial Park in the grand tradition set by Centennial Park

- over 700 hectares of co-ordinated development of residential, industrial and recreational parkland based on sound landuse planning principles
- a major open space focus in the geographic centre of the metropolitan area
- a strong, visionary concept appropriate to the significance and historical relevance of the Parramatta River Valley and the celebration of Australia’s bicentenary

a bicentennial event
Abstract

Bangkok was originated as the water base city on the Chao Phraya River bank, but nowadays, people progressively separate themselves from the unrelated environment. It is partly due to the shifting of people attitude after the flood catastrophe which hit Bangkok, in 2012. From then Bangkok becomes the solid city and people loose ownership and sense of belonging with the river. Moreover, as the city has been changed, there are city problems and future challenges.

Chao Phraya River Promenade is the government initiative project in revitalising the river by providing 10 m width and 14 km long promenade inside the river. This mega infrastructure aims to create public space and bring people back to the river, but it also changing the way city interact or settles with the river from water base to the solid city. It’s going to create many negative impacts environmentally, socially, and economically. Importantly it’s the top-down approach which is going to end up in building the infrastructure that destroys not only the river but also separate people from the river. This project is the wake-up call to Bangkok people to relook of what are the relationship between the city and the river in the future.

Inclusive River is the territory which use human-centred approach to understand human behaviours, needs, insights throughout the design process to improve the lives of people living the ongoing and future city challenges. These creative and interactive approach requires not only collaborative platform to pull all the resources and tools from different stakeholders, shareholders, organisations and multidisciplinary to implement the territory. Also, it broadens perspectives to identify the appropriate strategies.

Friends of the river (FOR) - the river platform founded in 2015 to reflect people opinions and concerns toward river development and try to find the solution in revitalising the river and area along the river with an inclusive approach.

After applying this creative approach through two case studies; the Co-create Charoenkrung project and Bann Poon community, which the former is one of the revitalising
river districts to become the next creative district of Thailand, and the latter is the pilot project of revitalising river community, it came out with the alternative designs.

These projects had shown the possibility of transforming city to be the inclusive territory to change the perception of the city which not focus only physical space, to create new values out of the existing assets, and especially, create ‘Resilience landscape’ more effectively.

Keywords: Landscape Resilience; Human-centered approach; River Revitalization

1. Introduction

Chao Phraya River has always been and will still be the bloodline of Thai people. For the hundreds of years, it had proven and driven for locals to settle along the river. Canals natural or humanmade began to innervate the city and contributed significantly to the cityscape and the inhabitants’ lifestyle. Bangkok soon earned the epithet ‘Venice of the East’. Chao Phraya River becomes sources of life and culture which Thai people has adapted and learnt how to live well and to create the space of living with water phenomena.

Resembling all thriving metropolitan, Bangkok has been transformed much since its birth. The city has expanded far beyond the river’s banks. However, locals still live, work, and play along the Chao Phraya River. The banks’ landscape and the way of life have also grown vertically. The Sprawling uncontrollably urbanisation appears as a major issue which had occurred the complexities and varieties problems and challenges. Nowadays, Bangkok becomes more and more the solid city which separately city from the unrelated environment after the flood catastrophe in 2012. Similar to all urban rivers, the destiny of the Chao Phraya is intertwined with the town through which it flows.

Government Perspective

There are many approaches to developing the river which comes from a different perspective. The government idea is to bring people back to the river by creating the 10 m. width promenade inside the river for 57 km. which run along both sides of Chao Phraya River. This project is to ensure that the river can be accessible by everyone though the promenade which acts as the new public space for cycling and recreation. The promenade project will help in organising the untidy settlement and landscape along the river.

This policy has come from the top-down perspective without understanding the context and way of life of the people. As, Bangkok is the water-based city where our settlement has always been settle and evolve on both sides of the river. Our culture, ritual and way of life are being created and grown with the river. Constructing the promenade on both sides of the river, it will change the relationship between the city and the river.

The promenade might bring the people to the river for certain extent, but it will also disconnect river community from the river stream since it will prevent them from carrying on the way of life like it used to be. Some of the communities including boathouses who settle inside the river for many generations has to be relocated near the promenade. The tangible and intangible
value which attached to these communities will be gone. The reference point to confirm that Bangkok is the water-based city will be eliminated.

The uniqueness of the Chao Phraya River landscape is the various settlements of the palace, temple, river communities and the way of life of the people which evolving along the river. By constructing the promenade on both sides of the river, it will make the river landscape look all the same.

The promenade will block the visual linkage from the river to the river bank. We will no longer see the temple, palace and importantly the way of life of the people along the river since the gigantic concrete structure of the promenade is going to be the eyesore element which will be seen from the river.

The promenade will make the river narrower. The Chao Phraya River width is around 200m. By creating the 10m. width promenade inside the river on both sides, it will significantly reduce the water body by 10 %. This narrowing of the water will cause water current to be even stronger and might create problems for water taxi and water logistic in the river. Importantly these concrete structures inside the river are going to block the river flow especially during the rainy season where the city is facing high rainfall and receiving a significant amount of water from the north. This promenade structure will create more flood risk by escalating water level to be higher and slower the flow of the water inside the river.

Chao Phraya ecology is in the decaying stage due to it has received much of polluted water from the city and factory along the river; moreover, the riparian area along the river has already been removed due to the construction of the concrete embankment along the river. By constructing the promenade inside the river, it will worsen the situation by preventing natural light from penetrating through the river and the structure itself is going to collect much garbage.

The development of the river seems to create much impact to the livelihood of the people not only one who live along the river but also at the larger group of people who live inside the city and nearby provinces as well. However, the process of carrying out this promenade project has done in a short period without having the public engagement. Importantly, the government has never asked people the right question of how shall we develop the river? Why? It is because the government had already decided that they want to have the promenade as the key answer.

**Developer Perspective**

During the past five years, the land along the river has been the focus of the private developer, since the most property in the city centre has been developed while the area along the river is stilling empty and
waiting to be filled in with the new programs and attractions. Once the government proceed with the underground mass transit system along the river, it also helps to push those empty lands to be developed in recent years.

However, the developer perspective of views is entirely different from the government. The promenade projects seem to devalue the land price because of the disconnecting those land to the river. The developers’ attitude and approach, they want to increase value by invest in shopping malls, condominium and attractions. These developments create value but also creates problems to the river and also community along the river at the same time by bringing an outsider, traffic, pollution and changing the way of life of the people in the area. It seems that the new development did not take the existing value or asset of the community and river into account in developing the project. These developments are not able to fit or blend in and seem to be another commercial area which we can find anywhere else.

**Time to rethink**

Looking and analysing at the macro scale of the city, the policy which involved together with the foresight analysis of what the challenges city is facing right now and shortly. We will understand that there are many issues need to address. Moreover, we necessary to prepare our territory to respond such as Climate changes which caused the city to be permanently flooded, decaying of river community, rising of the ageing population and new generation, Decaying of river ecology, conflicting of commercial and Tourism development with the river value. It is time we need to Rethink and relook holistically from social, economic and environmental aspects to develop the river more sustainably and inclusively.

**Right Question to the Society**

For the past three years since the promenade project was initiated and seeing many commercial developments is rising along the river, it has raised the concerns to all Thai in term of; who has the right to develop the river? How do we want the river to be developed? And what are the challenges which the river, as well as our city, is facing? Since what we are going to do with the river it’s going to affect the entire city and the nearby area as well.

We have to put the right question to ask the society to think it through to come out with the collective vision which everyone does share. It’s time to rethink and relook in developing the river for all with an inclusive approach, not the top-down process and from the one-sided perspective.

**FOR as the platform**

Friends of the River group founded in 2015, as a platform to raise public awareness toward river developments by asking right questions, sharing ideas and knowledge, advocates change through dialogue and discussion with stakeholders.

This platform makes it happen through pilot projects and voice people opinions &ideas to the governments and also to the society to find the common value which all stakeholders share in developing the river. We believe that river belongs to everyone
where all walks of life can be benefitted from the river. Public engagement is the process of finding the common value that everyone shares. Having the promenade is not the solution to respond to needs and aspiration of everyone. Also, it is not the right answer to tackle the ongoing and future challenges in social, economic and environment.

**Inclusive process**

The process is changing the way we carry out the project in conventional approach where the government set the policy then assign designer or specialist to find the answer and let the people use once the project completed. With this top-down or exclusive approach it has to cause the result to be undesirable or in acceptable by the public since it is unable to understand and answer the real need and aspiration of the people. The process did not take people to be part of the process from the beginning which also makes people not belong to the project.

The inclusive approach is the process bring all stakeholders to be part of the process from the beginning to identify problems, set visions and frameworks, find strategies, participate in the design process, and monitor the implementation. Being involved in the process of constructing and managing the project are essential. This inclusive process allows us to understand problems and assets of each territory better which help us to identify the strategy for solving the ongoing and future challenges better. Having all shareholders and stakeholders to be part of the process, it also allows them to realise each other constraints and aspiration. This exchanging dialogue and collaboration will enable them to find common ground in developing the territory and create the active citizen who will help in taking care the community and our society in the future.

2. **Case studies**

2.1 *Co-create Chareonkung Model*

ChareOnkrung is one of the old districts situate in the Chao Praya River bank. It is the melting-pot where many nationalities are living side by side in harmony for generations. It has a unique way of life and beautiful architecture. In recent years, as the district is continually decaying, the growth of residence who abandon shophouses are more rising which caused more the high number of abandon the buildings in the area. There are also phenomena whereby many artists and people who work in the creative industry have moved in to settle their studio and residence in the area. The shift came in 2015 when Thailand Creative and Design Center(TCDC) has decided to move headquarter to the old Thailand Post office building. It will be the central incubator place to groom Creative industry. However, to groom the Creative citizen, we need not only one building, but also space or the district to create the proper ecology, to share, to exchange and do business with the high quality of life.

We apply the inclusive approach and process to transform this decaying district to be the creative district. Our aims do target not only the designer but everyone. We strongly believe that design should be part of everyday life in better living condition and
Everyone has the creativity in them. It took us nine months for the whole process in creating a platform to bring all stakeholders which ranging from governments officer, landlords, developer, shop owners, community, teacher, students, to talk with each other to identify problems and asset the district has. Then we work together to come out with the strategies we want to apply in solving the district problems and creating the creative district.

We found out that the district has many abandon land and buildings which has many potentials to be developed because of lacking the better connectivity from the outside and even within.

There are three strategies to be applied from Rebrand; by revitalise one of the old historical building in the Chaopraya river bank to become a new landmark by infill with a public function such as art museum.

**Relink:** this is the strategy in providing the better linkage and signage to make sure that pedestrian traffic will be able to navigate to and within the district efficiently. Create to create a network between the public and the environment to foster more interactions between local residents and their district.

**Revival:** to regenerate forgotten urban spaces, vacant historical sites back to use as we saw the opportunities to infill with the new program that enable people to exchange and perform their ideas such as workshop building, pocket park, outdoor library, Waterfront Park.

**Rebrand:** to create a newfound awareness for the district, in order to keep the general public well informed and updated about their district and its surroundings.

The beauty of this process is that we let people vote, choose and design the outcome. In the end, we carried out the one to one mockups of all the three strategies to show the stakeholders the future possibility and also to test the idea with the actual people to see the respond and feedback of how community and stakeholders want to look at the creative district.
Co-create Chareunkrung has changed the way we carry out the masterplan in revitalising the district from the conventional method of top-down to be more inclusive with the people and having the actual space for people to test the future scenario.

2.2 BaanPoon Community Model

BaanPoon is the old community situated on the Chaopraya river bank which is going to be affected by the government’s promenade project. The community view that this promenade will disconnect them from the river. It will be unutilized and undermaintained which cause the promenade to be neglected and create crimes in the area. FOR had been working with the community in helping them identify community” value” which comprise of tangible value such as a traditional Thai timber pavilion, Old Chinese shrine, warehouse, old palace boundary wall. The community also has the intangible value in term of people way of life. Once we have identified these value, the community also proposes to revitalise them to be more attractive and accessible by the public by introducing pedestrian and bicycle route to invite more tourist to visit those hidden cultural value. They also propose to turn one of the warehouses to be a community museum to archives community artefact and stories. We also invite a well-known-Thai artist to create their graffiti inside the community space to attract young generation and urban dweller to visit this community.

This Baan Poon Model is showed the government that there is another approach in developing the river by not constructing the promenade but by revitalising these old decaying communities along the river which has a lot of cultural value to be more attractive, accessible and relevant to the society. This approach is the collaborative effort to developing the community based on the asset or the value they have without imposing the new thing that might dilute or destroy the uniqueness of the community.

2.3 River Platform

The Chao Praya promenade project seems to be the wake-up call for Thai to learn from other society of how the past Model in developing the territory has caused problems economically, environmentally and socially if we continue to improve the area by using the old approach in excluding people from the process. To designing sustainably, we need to collaborate with locals, the government, shareholders and stakeholders. Moreover, people do realise their aspiration and ability; they want to contribute and be part of the making process of the territory. This “platform” can bridge the gap between the resources and all participants to work together from the beginning to create the smart “policy”, participatory “process” and sensible “product”.

Refining road networks as ecological corridors in India

Abstract

Over 3.3 million kilometres of road and highway corridors traverse India [1], forming the single largest contiguous network of open space available in the country today. The transit network with 96,000 km of national highways alone, is set to increase exponentially to 200,000 km over the next few years. Expressways, state highways, major district and rural roadways are also expanding rapidly. Yet, development is limited to the carriageway, obscuring the potential of comprehensive ‘landscape corridor’ development.

Designing roads for speed and efficiency, the consequent deforestation, barriers to ecological migration, wildlife fragmentation, loss of habitat and adverse impact to water and soils changes the regional landscape ecology. Attempts to mitigate the effects of particulate emissions, noise pollution and heat and glare too are lost when landscape development is addressed belatedly. To address landscape ecology at a vast scale, create and integrate contiguous ecological open space networks and provide tangible social, cultural, economic, ecological and aesthetic benefits in parallel, is the way forward.

This paper charts out an ‘ecological corridor’ approach to road infrastructure development outlining the opportunities of place, people and context to delineate and define open space conservancies and strategies at a national, regional, state or local level.

As signatories to the Paris Accord and UN Sustainable Development Goals (SDGs) there is a keen focus on road safety, energy efficiency, climate concerns as well as important social indices of health, safety and welfare in India. Landscape architects can play a pivotal role in traversing engineering, contextual and logistical concerns with timely inputs, equitable access for its citizens and due ecological consideration. This can be done through comprehensive documentation of cultural and ecological values, addressing regional landscape planning strategies, site specific design interventions for user engagement, and capacity building and raising awareness through a comprehensive multidisciplinary framework. The impact of this approach, currently in a conceptual stage, on the second largest road network in the world would be far reaching and timely.
Keywords: Ecological framework; road networks; infrastructure development; landscape corridors; comprehensive approach

Historic road networks through India predate the current impetus of road infrastructure development for greater connectivity. In the past historic routes, such as the silk road and spice route created important connects across Asia and the world, with local towns and cities along the way integrating cultural influences of travelers and trade and flourishing. These routes have over time provided scenic interludes and places of rest for the traveler, equitable commons for the local area residents and encampments for recreation and refuge. Today, they are significant historic markers of place, people and unique cultural and heritage values.

1. Current Scenario

Over 3.3 million kilometers of road and highway corridors traverse India [1], forming the single largest contiguous network of open space available to the country. A road infrastructure development impetus by the Government of India will expand 96,000km of national highways exponentially to 200,000km in the next few years. Expressways, state highways, major district and rural roadways are also expanding rapidly.

In 2017 the government allocated over $100 billion towards 83,000km of roads. 34,800km will be built by 2022, including the 24,800km ambitious Bharat Mala route [2]. 1,627km of roads have been added this past year alone [1].

This aggressive focus on land acquisition, road engineering and construction is primarily limited to the road carriageway design and construction, obscuring the potential of comprehensive ‘landscape corridor’ development.

2. Need for this Approach

Designing roads for speed and efficiency, the consequent deforestation, barriers to wildlife migration, ecological fragmentation, loss of habitat, and, adverse impacts to water and soils changes the regional landscape ecology. Attempts to mitigate the effects of particulate emissions, noise pollution and heat and glare too are lost when the landscape is addressed belatedly [3]. A large scale ecosystem services approach will address critical ecological, social and cultural values before they are subsumed by development at a national, regional, state and/ or local level.

Figure 1. Existing road network across the country
This paper charts out a landscape approach with an emphasis on the role of landscape architects, outlining critical issues and opportunities of place, people and context to delineate and define open space conservancies and strategies.

3. Infrastructure and Landscape Works

Roads as ‘Ecological’ or ‘Landscape Corridors’ can provide equitable access to open spaces. Creation of scenic tourism corridors and consolidation of open space resources will include residents, visitors and passerbys in commons so far limited to fragmented parks and pockets in urban areas.

For example, a compilation of data by sixteen National Highways Authority of India (NHAI) regional offices identifies a range of 0-62m [4] widths of land available on both side of roads for plantation and other roadside facilities, based on land acquired. This varies by stretch according to area, land ownership and other conditions. For the 50,000km of roadways envisioned by 2022, using a conservative average metric of 0.5km available width, a minimum area of 25,000sq.km can be used for landscape development. For 3.3 million kilometers, this could be as high as 1,650,000km, at a minimum.

Yet, planting and horticulture work for highway projects is carried out after the road is complete or nearing completion. As a result, planting is accommodated in the space available, and not ideal. Planting is typically done by horticultural contractors, based on minimal specifications and limited planting palettes provided.

Further the project implementation process is decentralized, with delineated roles ascribed to different professionals and agencies. The primary stakeholders are government agencies, transport planners, road engineers and contractors. Government is represented through national, state and
local bodies, highway authorities and local governments.

Despite a growing awareness of the need for sustainable infrastructure and energy conservation, the approach to infrastructure development has not changed in recent years.

4. Landscape Architects as Stakeholders

Typically, the role of the landscape architect, if any, is in the final stages of planting and special conditions or aesthetic projects. Where landscape architects are involved, the lack of engagement before or after the design and tender phase limits the continuous engagement required to address issues that crop up.

Where landscape architects have more successfully completed streetscape projects and infrastructure works has been in private projects and in some cities, where aesthetics, aware clients, and the value of ‘place-making’ is understood. Yet the translation into the public domain and larger regional landscape is limited to a large extent by a few factors -

- Lack of a holistic approach and multiplicity of agencies involved
- No consideration or understanding of landscape requirements during land acquisition
- Lack of understanding of the role of landscape architects and their expertise in synthesizing place-based values
- Lack of insight into place, people, nature, culture, climate and economies
- Low numbers of landscape architects and outreach
- Lack of exposure to large scale planning due to smaller scale project experience of the nascent profession
- Role of academia, research and practice based expertise is fragmented

As signatories to the Paris Accord and UN Sustainable Development Goals (SDGs) there is a keen focus on road safety, energy efficiency, climate concerns as well as important social indices of health, safety and welfare in India, evident in campaigns, schemes and advocacy in force. Landscape architects can play a pivotal role in traversing engineering, contextual and logistical concerns in this scenario.

5. Unique Landscape Perspective

While the domains of economics, sociology, horticulture, forestry, water management and public health are important as well, the role of landscape architects as amalgamators or synthesizers of all these, and more, is crucial and yet, lacking.

Landscape architects can address the capacity of land- soils, topography, water management; people and cultural use of place, design, aesthetics, local crafts and traditions; biodiversity- vegetation, flora, fauna and their interconnectivity; urban and rural lands; land ethic; visuals and aesthetics; and, the technical aspects of materiality, construction, planting and maintenance.
6. Regional Landscape Planning

6.1. Urban growth impacts

India’s forest cover has halved over the last 50 years, with 21.35% mapped in 2015, as opposed to a stated goal of 33% (Forest Policy 1988). Rapid urbanization, deforestation and poor farm practices have resulted in large scale land degradation, depletion of soil nutrients, pollution of land, water and air and poor natural resource management. Loss of top soil of 35% of the global sediment load into oceans, from five percent of the world’s rivers is one resultant [5]. Natural disasters including droughts, flash floods, cyclones, avalanches, landslides brought on by torrential rains, and snowstorms are aggravated by further land degradation.

The role of landscape architects towards reframing road networks as ecological corridors is at two levels-

- Regional Landscape Planning
- Site-specific Landscape Design
In spite of adequate surface water resources and an average annual precipitation of nearly 4000 billion cubic meter, the average flow in the river system is estimated to be 1869 cubic km [5].

While a great deal of development is disconnected and concentrated in urban areas (31% as per 2011 census, but based on the classification of urban as 5,000 inhabitants, minimum density of 400 people per sq. km or more, and at least 75% of male working population engaged in non-farm activities, closer to 47% of 1.3 billion) the contiguous connected network can help mitigate growth impacts.

6.2. Ecological Mapping

Fragmentation adversely impacts regional management of natural resources and continuity of open spaces. The opportunity to develop comprehensively not only the road infrastructure itself, but mold the entire regional landscape is available only if the topography and traditional drainage patterns, natural vegetation, critical biodiversity hotspots, forests – classified and unclassified, significant natural features, cultivation and agrarian economy, cultural and traditional practices related to the land are mapped and documented comprehensively. Maintaining the integrity of four of the world’s 34 biodiversity hotspots- in the Himalaya, the Western Ghats, the North-east, and the Nicobar Islands is in line with commitments made towards sustainable development [5]. As is the potential for open space conservancies that are not limited to designated National Forests.
6.3. Forest Fragmentation

Felling of trees bifurcates corridors. This reduces the core area of the forest with tree fatalities 250% higher along roads in forest interior [7]. The forests from large green networks fragments into patches, limiting both the natural forests and habitation for wildlife.

![Figure 6. (a) Forest Core Fragmentation (b) Conservation](image)

Core area reduction also compromised wildlife migration. Wildlife die from predation and/or greater competition and lesser resources due to shrinking forests. A study from Mudumalai Tiger Reserve, found road mortality of 40 animal species, including amphibians, reptiles, birds, and mammals [6] along interior forest roads.

Other impacts include water and drainage patterns and topography changes that compromise the interdependency of trees, shrubs, ground covers and other natural planting systems.

India has about 100,000 sacred forests, a classification based on spiritual association which has been instrumental in forest protection by locals. Traditional customs are interwoven with the ecology of place, through religion, medicine and food supplies, building supplies and livelihood. The perpetual conflict between foresters, tribal populations and ecologists on the one hand, and developers on the other however, remain contentious.

6.4. Scenic Values

With 103 National Parks and many more state ones, an extensive coastline, mountains, hills, grasslands, deserts, tropical forests and plains, the Indian countryside has vast landscapes of breathtaking yet undocumented scenic value. Taking a cue from the US National Scenic Highway System of 1973 [8], identification, designation and enhancement of distinctive landscape character and aesthetics can be undertaken with development of infrastructure for tourism and transit. China now uses GIS mapping to integrate landscape ecology through visualization techniques, interagency collaborations and inclusion of landscape architects in implementing highway projects.

![Figure 7. Roads bifurcation forest core compromises wildlife crossings (unknown)](image)

![Figure 8. Designed Scenic Routes to highlight natural features](image)
6.5. Road Safety and Disaster Preparedness

A Road Safety Campaign is currently underway to highlight the 400,000 deaths in road crashes annually, 50% of which are preventable [9]. Low pedestrian access leads to exacerbated concerns for safety, resulting in more vehicular usage, more roads and faster speeds. The role of design to resolve these conflicts has been explored cursorily.

Figure 9. Scenic Highway
(http://images.jagran.com/images/16_07_2017-trip-p-160717.jpg)

6.6. Lacunae in Green Highway Policy

Commitments to the Climate Change Accord in Paris (CoP21 Summit) to reduce emissions by 35% till 2030, and the additional carbon sink of 2.5-3 billion tonness through forest cover requires planting of 5000 million seedlings [11]. The Green Highways Policy 2015 encourages sustainable green corridor development, but the focus is limited to planting new trees and transplantation. It is flawed in its approach. Especially in the planting of “open forest” regions (30million hectares) and converting them into “Moderately Dense Forests” [12]. These and other such goals must be assessed for its appropriateness and sustainability.

6.7. Planting

Planting to screen, enhance views, staging; for comfort, commerce, conservation, preservation; and for development and tourism, should determine spatial planning priorities early on. Minor modifications during road planning- roads along the edges of habitation and transition areas instead of through forests, navigating more stable, accessible slopes in steep forested areas, planting native plants can be made.

The role of open space planning for emergency assess and staging during disasters was highlighted during the 2015 Nepal earthquake due to the high mobilization capacities and connectivity of highways [10]. With their proximity to dense settlements and cities, outlying open spaces can act as staging areas.

Figure 10. (a) Typical Urban Growth (b) Protecting Natural Resources, creating scenic views and areas for staging

Planting of new trees requires diversity in terms of region- species planting, landscape massing to develop interdependent viable ecosystems, consideration of supporting insect, reptilian, amphibian, animal and avian fauna native to the place, and use of native plantation. Yet, a lack of understanding of
species diversity required results in a common palette of 30-40 trees planted across the country irrespective of appropriateness. Consequently, the widespread planting of non-native, exotic species will be, and has been, invasive and damaging to local landscapes, e.g. Prosopis juliflora and its debilitating effect on native plants, birds and water resources. Based on the road hierarchy and region, the preparation of diverse native and naturalized plant lists is required. Planting of shrubs, grasses, groundcovers and climbers need to be diversified to bind the soil, reduce soil erosion, water run-off and create buffers to and from the road.

7. Site Specific Landscape Design

7.1. Transactional Capacities of Place

Transactional capacities [13] of place involves the negotiation of place and people, nature and culture, ecology and infrastructure. Without addressing the larger needs of different constituencies and their sense of ownership of land, their freedoms and rights, the street/road will negate a great deal of place based tradition and unique cultural landscapes.

For example, in the northeast states, development has been limited because of lack of access. As a result, the integrity of the ecology, biodiversity and local culture has sustained, but, at a great cost to resource access for its people. With increased connectivity planned, this will change. The rapidity at which it will, and under what constraints, will determine the remaining value of the place and its integrity, not only to its residents, but visitors, tourists and generations to come.

Highlighting the transactional capacities of place, empowering local communities and traditions and avoiding standardization of place needs to be done by engaging and identifying opportunities and threats to cohesive development.

Figure 11. (a) Spontaneous Growth (b) Scenic Conservancy

7.2. Edges and Thresholds

In India, there is a very distinct condition visible along the carriageway. Where the road ends, there is typically an area of ambiguity, with no paving or planting, no transition of any kind to the neighboring or encroached development, settlement or open space. This ambiguous space, the edge, is outside the scope of the road engineer and ‘public space’ and that of the property owner, yet it creates disconnect and is an impediment to seamless access and engagement.

These amorphous edges, includes areas available for landscape development mentioned earlier, are the opportunity to define the right of ways, of carriageways and their locales and for engagement through negotiation. The potential to consolidate development, integrate zones of built and others of unbuilt, define and conserve view sheds to borrowed landscapes in these zones requires definition and dialogue.
7.3. Spatial Perceptions and Place-Making

Minimizing vast contradictions and distinctions of class, caste, religion, language, economic, regional and educational diversity inherent in India can reduce a sense of alienation and isolation. Designed streets and roads are equitable and provide the psychological benefits of inclusion and inculcate a sense of ownership and belonging for its diverse users.

![Figure 12. Planting for seasonality and appreciation](image1)

India’s vast population requires an approach to design that is universal in approach. Simplicity, flexibility, coherence and accessibility along with endurance, sustainability and replicability. Aesthetics and regional specificity will avoid a one size fits all approach. The monotony of an engineering-centric construction robs places of its unique character. Composition of landscape for appreciation and interpretation that uses the seasonality of place adds value and increases associations of place and memory.

7.4. Progressive vs Defensive Design

Engaging with people who live and work along road corridors can engage and benefit from the connectivity and visibility through employment, transit facilities and access.

A lack of understanding of the users, site specific design requirements, communication, need for maintenance and enforcement is responsible for defensive design in public places. Dominated by boundary walls, fences, and other defensive design elements to defend against abuse of place and encroachments is inevitable but exclusionary. Engagement with the public, to understand and plan for the multiple variables inherent in place, to create coherence from the chaos of numbers and diversity is needed.

8. Comprehensive Landscape Approach

The unique opportunity to address landscape ecology at a vast scale, create and integrate contiguous ecological open space networks and provide tangible social, cultural, economic, ecological and aesthetic

![Figure 13. Place making through planting in Pune, India](image2)
benefits in parallel to the infrastructure development is unprecedented in India.

At a regional landscape planning level, landscape architects can-
- Identify opportunities of place, people and context
- Define parameters of development for different considerations
- Evaluate framework for application and engage with the local networks to assess applicability
- Collaborate with allied disciplines
- Reassess and document for further applicability

At a local level, they can-
- Map critical regional and local contextual conditions
- Assess impact of development on ecological, economic, social and heritage of place
- Include landscape considerations during land acquisition and planning
- Making adjustments to the road infrastructure based on contextual conditions
- Help address and moderate impacts of development
- Treat identifiable stretches, intersections/ nodes, edges/ boundaries and landmarks as determinants of this framework
- Involve community and use local expertise

9. Landscape Codes and Guidelines

The Indian Road Congress (IRC), is the apex technical body of road engineers that prepares and disseminates standards and guidelines for road development in India. In 2017, for the first time a Manual for Planting and Landscaping of Urban Roads was prepared to comprehensively address the role of planting and landscape through
- critical considerations of all hierarchies of urban roads
- integrated design with landscape and planting
- implementation details and specifications for horticulture practice
- maintenance requirements [14]

This highlighted in a paradigm shift in thinking to address issues of air pollution, heat island effect and their mitigation, water scarcity and progressive irrigation techniques (drip irrigation, recycled water, xeriscaping), protection of existing trees and green cover, and erosion control – roads in water-logged areas, and bio-diversity zones. It includes an interactive matrix for tree selection based on three climatic zones, to be supplemented by extensive place based plant selections options later.

While this manual was specifically for urban roads, it has introduced a landscape approach to the relevant stakeholders and paves the way for a larger role for landscape architects to reframe road corridors as ecological corridors.

10. Conclusion

Wherein a slower rate of growth, limited opportunities and a nascent community of professionals were limitations of the past, rapid expansion of infrastructure, have highlighted the urgency for landscape
architects to play a key role in this developing this approach.

For the nascent landscape profession, the objectives must be to-

- Build capacity within the profession to address this scale of planning intervention
- Create synergies and collaborations with allied disciplines
- Create a role for engagement and outreach with government agencies and the public
- Develop and support guidelines and best management practices for road landscapes
- Create structural setup to evaluate, audit and provide expertise across domain
- Play a role in decision making, design and implementation, technical oversight and operations and management.

While this paper emphasizes road infrastructure development, rail and metros—both underground and overland and waterway connectivity too are rapidly developing and require an integrated landscape approach.

Abstract

Aguanambi Avenue is located in Fortaleza – CE, Brazil and it is susceptible to flooding on rainy season. The site has been undergoing reforms to improve urban mobility. With the main goal to promote an adaptive intervention on the avenue and its surroundings, this research discusses how Best Management Practices (BMP) can integrate the local grey infrastructure with the aim to complement the drainage, consolidating the urban resilience and providing environmental services in the Aguanambi Canal. This exploratory research promoted a case study area in order to characterize possible causes of the problem detected. An adaptive intervention study has proposed the design and distribution of BMPs on the perpendicular streets to the Aguanambi Canal. The catchment area treated the canal and its surroundings. The research has calculated from this area the rainfall volume received in rainfall precipitation of 65.2mm / h, by 10-year time return. The curbs extension dimensioning has considered a width of existing local streets. The total extension of Aguanambi Avenue is 1250m, on the Coronel Pergentino Avenue is 264m, and finally, on the local streets is 5019m. The result obtained shows the Bioretention of 17.14% of the rainfall volume precipitated with the intervention in just 4.52% of the total area. Considering the positive results, the study has developed guidelines to the constitution of Greenways through the implementation of BMPs in the road system of Fortaleza – Ce. The guidelines proposed about BMP application on the streets allow the consolidation of Greenways in multiple scales, from the local streets of a small housing complex to extensive avenues that cross the city. Through these corridors, important green areas could be connect, in order to consolidate a Green Infrastructure in the city. The connectivity between parks, squares and lagoons promoted by mobility corridors adapted to the Best Management Practices is essential to constitute a resilient city and to achieve ecological services.

Keywords: Green infrastructure; Urban Resilience; Best Management Practices; Greenways; Fortaleza.
1. Introduction

Natural landscapes has been supported the most intense cities growth since last century. Fortaleza, like many Brazilian metropolis, had its urban expansion through the degradation of several natural resources, such as rivers, lagoons, dunes and mangroves [1].

The gray infrastructure, defined as built systems in the cities to enable water and energy supply, rainwater catchment, sanitation, the road system and everything that supports human settlements [2], has led to segregation of natural areas and has caused several environmental problems for cities, such as pollution of water resources, landslides, floods and generation of heat islands.

Fortaleza’s public policies have been adopting overpast solutions to solve infrastructure problems for many years. The Fortaleza’s City Hall is building stations above the Água Nambi stream to get the BRT (Bus Rapid Transit) transportation system. Therefore, another water resource in this city will disappear from the landscape.

The intervention in Aguanambi Avenue shows that the application of the gray infrastructure was the main solution of the project admitted to enable the implementation of the BRT corridor (Figure 1).

Overflows on the Aguanambi Avenue proves the impact of inefficient planning in the last decades that did not consider the natural characteristics of the site such as topography, water resources and floodplains. On January 8, 2017, a 55.6mm stormwater precipitation occurred in the morning and caused the Aguanambi Canal overflow [3], as shown in Figure 2. It seems little, but in vulnerable regions such Aguanambi Avenue, the consequences of this level of storm are disastrous.

Therefore, according to this information, interventions that have been promoting in Aguanambi Avenue over the years, to improve urban mobility, has intensified soil waterproofing around the Canal and has aggravated its vulnerability during the storms.

The end of green spaces in wetland areas contributes to their susceptibility to natural events, which are increasingly common in large cities: intensification of storms, rising levels of the oceans and islands of heat caused mainly due to the emission of greenhouse gases [5]. Therefore, cities are seeking to consolidate an urban resilience to
resist to disturbances and tensions while maintaining their properties [6]. According to 2030 Agenda, one of its Sustainable Development Goals mentions the importance of "Building resilient infrastructures, promoting inclusive and sustainable industrialization and fostering innovation" [7].

Considering the current project for Aguanambi Avenue, this paper will discuss alternatives proposals based in Low Impact Development (LID) in order to show how green spaces can improve flood catchment and turn Aguanambi Avenue a resilient place.

2. Theoretical Basis

The implementation of Green Infrastructure can begin in one building sit, through a rainwater catchment system, for example, and expand to the county scale, like Sponge City in China [8]. According to Benedict and Macmahon [9], greenways or links are critical to consolidate Green Infrastructure in multiple scales and to ensure ecosystems linkages.

These greenways are fundamental for urban planning; the dissemination of this solution represents a great potential for natural resources recovery in cities, states or countries. These corridors may have different widths and behave like a connected, directional network, such as streets, avenues, or roads.

Adaptive interventions applied in cities, based on ecology, are essential for urban resilience [10]. As defined in Bennedict and Macmahon [9], Green Infrastructure is an interconnected network of green areas that promotes several environmental benefits such as climate regulation and biodiversity preservation. The Low impact development (LID) through the Best Management Practices (BMP) of rainwater has been offering the main alternatives for create Green Infrastructure in public and private spaces in the last years. According to Gehrels et al [11], the Green Infrastructure on streets and avenues can offer numerous ecological services that contribute for urban resilience. The main BMP adopted for this research are bioswales, rain gardens, rain flowerbeds, curbs extension and pervious paving, as shown in Figure 3.

According to Hubber et al [12], bioswales are usually located along roads, wide streets and parking lots. These solutions require support devices to direct the water flow and manage overplus rainwater volume. A rain garden is a vegetated depression to infiltrate, but does not retain the runoff, is also known as a biorretention system. According to Bonzi [2], the sinuosity of the curbs extension interferes positively in the road system, creating the traffic calming in addition to catch rainwater. Rain flowerbeds...
are like compact rain gardens, suitable for reduced urban spaces, this BMP do not necessarily have the infiltration function like rain gardens, but perform water cleaning [13]. Pervious paving reduces and distributes the rainwater volume promoting the pollutants removal and encouraging the underground layers supply [12].

This research has introduced some typologies of interventions for urban resilience considering the successive changes and the new project on the Aguanambi Avenue. It has discussed the availability of applying these different approaches in the study area in order to corroborate the developed proposal. Chelleri and Olazabal [14] classify three categories of interventions aimed at promoting resilience:

- Recovery defined as an immediate action for the system to re-establish itself; consolidated by a grey infrastructure for example;
- Adaptation, based on ecology to promote a relaxation of the existing system and prevent possible disturbances. The Green Infrastructure enable this prevention.
- Transformation, intervention based on deeper changes, through the renaturation of the system.

Therefore, this study has proposed BMP to Aguanambi Avenue in order to complement the existing drainage system and to constitute a new landscape with implantation of BMPs and application of pervious paving that could contribute to the natural surface formation and to the rainwater catchment, as well as landscape quality and beauty. Then, adaptive intervention through Best Management Practices could promote important ecological services that contributes to urban resilience [12].

Aguanambi Avenue expanded in the last four decades within the Fortaleza’s urban network. Before its inauguration in 1972, the place was inhabited and housed a stream called Agua Nambi, an natural area for hunting, fishing and transporting canoes, according to Andrade [15].

The Aguanambi Avenue drainage system is not able to withstand intense stormwater because the lack of maintenance and undersized underground galleries. The accumulation of trash and sediments in the pipes can cause their silting [16] and thereby contribute to the reduction of their capacity. The inefficient rainwater's drainage causes floods in the main avenues of the neighborhood, harming the citizens who circulate in these corridors. Much people have already had their vehicles damaged.

The data introduced below can help to find out the rainwater volume, to size and distribute the Best Management Practices and to define its total bioretention rainwater volume capacity:

- 10-year storm event [17]
- 10- year peak flow - 65,2mm/h (mm per hour) [18]
- Runoff coefficient - 0,9 [19];
- BMP dimensions;
- BMP’s rainwater bioretention volume - 0,487m³/m² [16]
- Roads’ extension (Figure 4)
- Total area - 791,901m², as shown in Figure 4 (Appendix A).
In order to distribute and dimension BMP in total area, this research simulated in a local street, Artur Timóteo Street, the distribution of curbs extension because the undersized sidewalks. In addition, it was not possible put green gardens on the sidewalk. The curbs’ extension distribution on Artur Timóteo Street happened according to the location of buildings access, according to Figure 5 (Appendix B).

The proposed curbs extension were with 8m², 35m² and 70m², according to their extension. Thereby, in 120m extension of Artur Timoteo Street there would be 180m² of BMP. From this result, in 1.00m it could be possible to implant 1.50m² of curb extension. In addition, for the sidewalks there would be 3,60m² of pervious paving per 1.00m street extension (Table 1).

<table>
<thead>

Table 1. BMP area and capacity

Below is the information about the precipitation volume that covers the total area of 791,901 m² around Aguanambi Canal:

\[ V = A \times \Delta p \times \text{Runoff} \]

\[ A = 791.901 \text{m}^2 \text{ (area),} \]

\[ \Delta p = 65.2 \text{mm/h (10-year peak flow)} \]

\[ \text{Runoff} = 0.9 \]

\[ V= 46.468.75\text{m}^3 \text{ (rainwater precipitation volume)} \]

4. Results

For the expected volume of 46,468.75m³ with a 10 – year storm event, the BMP system would hold 7,965.22m³ with the transformation in 35,798.9m² of the total area in Bioretention area through Best Management Practices, as shown in Table 2 (Appendix C).

The proposed system would retention 17.14% modifying 4.52% of the total area, as shown in Graphic 1 (Appendix D).

The proposed solution does not correspond to a 100% efficacy, but a minimum bioretention area, less than 5% of total, can contribute to catch a representative part of rainwater volume, acting together with the existing grey infrastructure. In addition to the rainwater retention, the rain gardens, bioswales and curbs extension can promote various environmental services, such as the pollutants reduction in water [21] and the environmental comfort improvement for recreational activities [9].

5. Greenways implementation Guidelines in the Fortaleza’s road system.

Considering the case study carried out at Aguanambi Canal surrounding area, it was possible to understand that Greenways could complement grey infrastructure. BMPs in the road system could promote the connection between ecological hubs by setting up green infrastructure that plays an important role in the accomplishment of environmental services like provision, support and purification [12].

The main contribution of this research is to develop guidelines to suggest the
Greenways formation through Fortaleza’s mobility corridors, purposing BMP in order to distribute stormwater management techniques from a local scale until the Municipal scale. These guidelines complement the urban qualification proposals suggested by Fortaleza’s development Planning and they are in line with parameters established by the new Land’s Use and Occupation Law [22] for the Fortaleza road system.

According to the Law, Fortaleza’s basic road system consists in two Systems: I - Basic Structural Road System; and II - Basic Complementary Road System [22]. The structural system consists in Express and Arterial I pathways, responsible for the regional and municipal articulation road system. The complementary system consists in Arterial II, Collectors, Local pathways, which collect and distribute car traffic from neighbourhoods to Express and Arterial I pathways. Table 3 shows road system properties.

Table 3. Fortaleza’s road system properties

This research has proposed a pattern of BMP distribution based on dimensions determined by Land’s Use and Occupation Law [22] for different street categories from Fortaleza’s road system. The proposition is according to the available space, without harming pedestrians or vehicles movement.

Therefore, this study has done a comparative analysis about BMP bioretention capacity in four kind of pathways: Express, Arterial, Collector and Local. Table 4 presents BMP dimensioning according to roads.

Table 4. BMP dimensioning according to roads.

Bioswales: match with generous central beds on Express roads, where its performance is better. The research has established three meters for the minimum bioswale width. It has restricted bioswale just for Express and Arterial roads.
Rain gardens: the study has designed it with at least 14m² (2m maximum width and 7m minimum length) on the Express, Arterial and Collector road’s sidewalks. So, rain gardens do not get into local streets where the sidewalk has at least 2 or 2.50 meters [22]. This BMP provides free access for vehicles and pedestrians inside buildings.

Rain flowerbeds: it is a rain garden with reduced size, its dimensioning is 6m² (6m length and 1m maximum width). This model provides access spaces for vehicles and pedestrians inside buildings and match with Collector and Local roads.

Curbs extension have 10 m² and match with Collector and Local roads. Express and Arterial roads are not allowed to have speed control through traffic calm. Curbs extension provide access spaces for vehicles and pedestrians inside buildings.

Pervious paving matches with all kind of roads.

This research has calculated rainwater volume considering the BMP areas above presented. This analysis has considered the worst situation, adopting 100% for runoff. Below is the information about adopted data:

- Runoff Coefficient - 1.
- 10-year peak flow - 65.2 mm / h (Δp)
- Corridor extension – 100 m

If the roads have different widths, obviously the rainwater volume (V) changes according to each road typology (Table 5).

Considering the chart above, the BMP’s performance is according to different Fortaleza’s roads. Table 6 presents the bioretention results in Express, Arterial, Collector and Local roads.

### Table 6. BMP capacity bioretention

The results demonstrate that the BMP performance changes according to roads types. Four among the five BMP present better performance in smaller corridors, Collectors and Local streets, according to Graph 2 (Appendix E).
In order to classify the best combinations between BMP and roads for bioretention rainwater, this study has suggested three evaluation levels: Regular, Regular - Satisfactory and Satisfactory – Excellent, as shown in Table 7.

</tr>
</tbody>
</table>

Considering the presented recommendations, it is possible propose some guidelines:

- Rain flowerbeds and curb extensions match with smaller roads, because they fit in the narrower sidewalks and streets, playing a satisfactory role about runoff retention and contributing to the traffic control in residential local roads.
- Rain gardens match with collector and arterial roads, this BMP composes commercial streets landscape projects, encompassing a larger influence area and playing an important role controlling flooding points that damaging mobility in these avenues.
- Bioswales should contribute to the capture and transport of runoff on express roads, characterized by wide sidewalks and central beds, where have space for this type of BMP. Bioswales application can promote the increase of green areas, creating a permeable corridor that integrates distant neighbourhoods.
- Pervious paving are an important complement to increase the runoff bioretention, especially in densely built areas where it is necessary to apply solutions in order to increase the permeability rate.

The guidelines proposed above for BMP application in the road system allow the consolidation of Greenways in multiple scales, from the local streets of a small housing complex until an extensive avenue that crosses the city. Green Infrastructure
consolidation through these greenways in Fortaleza city could connect important green spaces. The connectivity between parks, squares and lagoons, promoted by mobility corridors adapted to the Best Management Practices, is important for a resilient city construction.

6. Conclusion

Proposing an adaptive intervention in the Aguanambi Canal surrounding was important to show that BMP application could complement grey infrastructure in vulnerable areas in order avoid flood. It allows the resilient spaces consolidation in the City.

Different kinds of roads influence the BMP distribution and performance in local streets or large avenues. The first investigation at Artur Timóteo Street has contributed for the following studies carried out in order to construct the Greenways implementation guidelines.

These guidelines could be part of development Fortaleza City Planning. The BMP network could create green areas on streets and avenues forming Greenways in order to integrate squares and parks in the city. Implementing rain gardens on the streets could increase the public policies about appreciation of green spaces. In addition, stakeholders could take care of squares, streets or a little garden.

Finally, Green Infrastructure is able to prevent, through its regulatory properties, the negative impacts on natural resources because urban growth and grey infrastructure. Consolidating Green Infrastructure in Fortaleza through the Greenways could ensure environmental and urban quality, improving rainwater drainage and enabling a resilient city for Fortaleza’s citizens.

Study On Effectiveness Of Strategies To Re-Establish Landscape Connectivity Of Expressways; With Reference To Southern Expressway Sri Lanka.

Aroshana.N.G.I,a Suresh, E.A.T.b*

aUniversity of Moratuwa, Moratuwa, 10400, Sri Lanka
bUniversity of Moratuwa, Moratuwa, 10400, Sri Lanka

Abstract

Construction of highway is the most emerging massive development tendency in Sri Lanka. With these development activities, there are a lot of environmental and social issues started. Land and subsequent Landscape fragmentation is one of the main issues that highly effect to the environment by the construction of expressways. This paper designates, post construction landscape study on the effectiveness of the landscape connectivity structures to restore connectivity. Geographic Information Systems (GIS), least cost path tool has been used within the selected two plots; 25km alone the expressway to identify animal crossing paths. Animal accident data use as the measure for determining the most contributed plot for landscape connectivity. The number of patches, Mean patch size, Class area use as a parameter to determine the most effective land use class to reestablish the landscape connectivity.

The scrub, grass and marsh were the most positively affected land use typologies for increase the landscape connectivity. It represents the growth increased by 8% within the 12 years of time. From the least cost analysis within the plot one, 28.5% of total animal crossing structures are within the high resistance land use classes. Southern expressway used reinforced compressed earth technologies and It has been controlled the growth of the climax community. According to all findings, it could assume that involvement of the landscape crossing structures contributes to re-establish connectivity, but it is not enough to restore the majority of disturbance performed by the expressway. Connectivity measures used within the study can use as a tool for re-evaluate future involvement of highway crossing structures. Proper placement of the highway crossing structures leads to increase the rate of connectivity. The study recommends that monitoring the all stages (preconstruction, construction and post-construction) of the project and preliminary design, and the involvement of the research applied connectivity assessment strategies help to overcome the complication regarding the re-establishment of landscape connectivity; using the highway crossing structures that facilitate the growth of flora and fauna.

Keywords: Landscape fragmentation; Habitat Lost; Least Cost Path; Migration corridors
1. Introduction

Land-use and land-cover changes are so pervasive that, when aggregated globally, they significantly affect key aspects of Earth System functioning. They directly impact biotic diversity worldwide [1]. Which leads to many environmental concerns. In this decade construction of the highways takes priority in the developing Sri Lankan context.

In developing Sri Lanka the road network at present is deemed insufficient to support the growing traffic load. Therefore the latest trend in Expressways to facilitate fast land based transportation. This include, the Colombo-Katunayake Expressway (E 03), which is fully functional, the Southern Expressway (E 01) that operates up to Matara and planned to be extended up to Hambanthota, the Outer Circular Highway (OCH) that has been completed from Kadawatha to Kottawa and the Northern and Central Expressways which are still at the final design stages.

On the other hand it obviously disturbs the environmental and leads to many issues within the future. Roads precipitate fragmentation by dissecting previously large patches into smaller ones” and by creating a barrier to movement and dispersal between adjacent habitat patches [2]. Massive amount of land modifications has to be done in order to initiate and construction of highways. Fragmentation of the landscape is the one of the main issues that cause by the highway.

Road and highway construction affects wildlife through the direct loss and fragmentation of its habitat by introducing a source of additive mortality for wildlife populations, and by disrupting animal movement and dispersal [3]. Most of the countries have several methods to mitigate landscape fragmentation the highways. Highway crossing structures have been constructed in many parts of the world in an effort to mitigate negative effects of exclusion fencing on wildlife populations [3].

The main focus of the research is to identify the degree of contribution of highway crossing structures in Sri Lanka whether enough to mitigate the landscape fragmentation. According to the selected study dimensions. Geographic information system (GIS) / Land use maps and Least-cost modelling use as theoretical approaches for determining the level of landscape connectivity.

This study will help to identify the issues and strategies that helps for future highway projects to enhance landscape fragmentation mitigation techniques and to explain about the importance of landscape architectural involvement of highway crossing structures to mitigate landscape fragmentation. It expresses the importance of proper placement of crossing structures. Further it will provide evidence for the need of the involvement of professional Landscape Architects to address the landscape issues during the all stages of the project.

2. Landscape Fragmentation and Mitigation Strategies

2.1 Landscape fragmentation

“Landscape fragmentation is mainly defined as the breaking of habitat ecosystem or landscape into smaller pieces which is usually caused by human activities” [4].

“The concept of fragmentation refers to the transformation of the landscape, often driven
By disturbances, from a uniform to a more heterogeneous and patchy situation” [5]. Following image shows the schematic representation of the fragmentation process and its different stages. In gray it represents the original land cover, and in white the anthropogenic or new land cover.

2.2 Causes of Landscape fragmentation

There are many factors that induce fragmentation. Anthropogenic activities and new expansions of the lifestyles highly disturb the natural setting of the environment and it’s highly effects on landscape fragmentation. Landscape fragmentation due to roads, urbanization, and other human development has major impacts on wildlife, including many species of concern [6].

Transportation corridors, Farmlands, Transmission lines, Industrial zones, urban expansions and man-made reservoirs highly promote landscape fragmentation in different ways.

2.3 Landscape fragmentation due to expressway construction

Landscape fragmentation caused by transportation infrastructure has a number of detrimental effects like reduction in size and persistence of wildlife populations, changes of local climate, and increases in pollution and noise from traffic. Therefore, data on the degree of landscape fragmentation are needed for assessing the sustainability of human land uses.

As early as 1970, wildlife biologists began publishing research on the effect of roads on wildlife populations as barriers to movement [7].

Following figure shows the degree of landscape fragmentation changes referring the degree of human impact.

2.4 Mitigation of landscape fragmentation in southern expressway

During the project processing period of the Southern Expressway that started in 1996,
environmental assessments were prepared by authorized institutions and authorities. “The expressway route is located, as much as possible, along the foot of the hill slopes to minimize the loss of farmland and the relocation of residential building.” [9]. Committee of the Southern Expressway development project includes various monitoring teams and a cluster of responsible professionals to measure the effects on the existing mechanisms. The completion report presents the process and mitigation measures they have given for the success this project. According to the Southern Expressway reports they were concerned about avoiding wetlands and existing flood plains, ensuring the aesthetic value of the area by tree plantation, minimize the tree removal during the construction and proposing over passes and under passes to increase permeability. They had considered mitigation measures for noise and visual intrusion caused by the expressway.

3. Landscape connectivity and transit corridors

3.1 Connectivity

‘Connectivity’ can be broken down into ‘structural connectivity’ and ‘functional connectivity.’ Structural connectivity refers to the physical relationship between landscape elements whereas functional connectivity describes the degree to which landscapes actually facilitate or impede the movement of organisms and processes. Functional connectivity is a product of both landscape structure and the response of organisms and processes to this structure. Thus, functional connectivity is both species- and landscape-specific [10].

Their’re having three main types of connectivity

- Habitat connectivity
- Landscape connectivity
- Ecological connectivity

1. Habitat connectivity

Habitat connectivity is the connectedness between patches of suitable habitat for a given individual species. It may be defined at the patch scale or at the landscape scale [11]. The term is chosen to include the word ‘habitat’ to emphasize its species-specific nature.

2. Landscape connectivity

Landscape connectivity is a human perspective of the connectedness of native vegetation cover in a given landscape. It may be expressed using various buffer- or distance-based metrics that can be calculated from maps of human-defined land cover. The term is chosen to include the word ‘landscape’ to emphasize its anthropocentric nature the concept of a landscape is a human construct [12].

3. Ecological connectivity

Ecological connectivity is the connectedness of ecological processes across multiple scales, including trophic relationships, disturbance processes and hydro ecological flows. The measurement of ecological connectivity is not straightforward and depends on which aspect of ecological connectivity is to be estimated. Despite this difficulty, ecological connectivity is an important concept that is not adequately
captured by existing definitions of connectivity [10].

3.2 Landscape transit corridors

1. Habitat corridor
   Habitat corridors is the capacity to facilitate movement, which occurs in different patterns and processes, and at different scales depending on the species or ecological process of interest. Thus, habitat corridors need not be linear or narrow and must be defined from the perspective of the organism or process being targeted for conservation [13].

2. Migration corridor
   Migration corridors are used by wildlife for annual migratory movements between source areas [13].

3. Dispersal corridor
   Dispersal corridors are used for one-way movements of individuals or populations from one resource area to another. Dispersal is critical to the maintenance of genetic diversity within populations of species and to the persistence of fragmented populations which may require regular immigration to avoid local extinction [13].

4. Commuting corridor
   Commuting corridors link resource elements of species’ home ranges to support daily movements including breeding, resting and foraging. As such, commuting corridors facilitate localized movements throughout the landscape important to daily survival and reproduction [13].

3.3 Types of Highway Crossing Structures

Following highway crossing structures used within most parts of the world to increase landscape connectivity.

1. Landscape Bridge
2. Wildlife Overpass
3. Multiuse Overpass
4. Canopy Crossing
5. Viaduct or Flyover
6. Large Mammal Underpass
7. Multiuse Underpass
8. Underpass with Water Flow
9. Small- to Medium-Sized Mammal Underpass
10. Modified Culvert
11. Amphibian and Reptile Tunnels

4. Data collection Methodology

Research Objectives

![Research Objectives]

1. Identify the degree of landscape connectivity after construction of southern expressway.
2. Identify the involvement of the highway crossing structures to establish landscape connectivity.

Structural connectivity
- Time relative land use GIS map analysis.
- Cost theory based species flow analysis.
- Highway crossing structure analysis

Functional connectivity
- Animal accident data analysis
- Questioner survey

Figure 3: Research objectives and Data collection method
Source: Author

1. Identify the degree of landscape connectivity after construction of the
southern expressway from the construction stage to the present situation.

2. Identify the involvement of the highway crossing structures to establish landscape connectivity.

5. Case study selection criteria

Southern expressway (E01) is the first and the oldest expressway in the country. The project started in the year 2002 and by 2011, it was open to the general public. The southern expressway selected as the main case study. The case study selection criteria differ from each other according to the study dimensions. Following diagram briefly shows the case study selection criteria.

Figure 4: Case study selection
Source: Author

5.1 Structural connectivity study plot selection

This is focused to comprehend the landscape structure and land use pattern to identify how they affect ecological corridors, circulation pattern and continuity of that area. Selected a specific plot consisting of a maximum variety of vegetation (including forest patches), an interchange environment, and drains to study the fragmentation and degradation of the landscape structure. And also availability of GIS and Highway crossing structure data have been used to select the appropriate plots. This is a comparative study of the landscape transformation within the period of pre-construction, under-construction and post-construction stages of the Southern Expressway.

5.2 Functional connectivity study plot selection

This focuses to find the degree of functional connectivity by analyzing animal accident data and questionnaire survey. “Habitat fragmentation occurs when changes in habitat configuration occur as a result of the breaking apart of habitat, independent of habitat loss.”[14]. Increased number of collisions between vehicles and animals become the main reason for habitat fragmentation.

The people living since the year 2000 within the village were selected as the participants for the questionnaire survey. As they have experienced all the stages pre-construction, under-construction and post-
construction stages of the Southern Expressway. And also availability and variety of animal accident data have been used to select the appropriate plots.

5.3 Case studies

Time relative land use GIS map analysis, Highway crossing structure analysis and Animal accident data analysis use 2 plots within the southern expressway. Each plot contains 25 km along the southern expressway, which starts from the Kottawa highway interchange. One plot contains 24000 ha area of land beside the expressway. The frequent animal crossings and accidents were identified using the accident data records of the expressway. A five-year time frame from the opening year of the Southern Expressway was selected to analyze the accident data. One plot used for the Cost theory based species flow analysis, which has most of the landscape connectivity structures according to the ‘Highway crossing structure analyses.’ Questionnaire survey is conducted from a rural village called “Keebiya” which has higher number of landscape connectivity structures intersect.

6. Theoretical approach

Landscape ecology focuses structure, function and change of the landscape.

Structure: The spatial relationship among the distinctive ecosystems or elements.

Function: The interactions among the spatial features.

Change: The alteration in the structure and function of the ecological mosaic over time [15].

6.1 Landscape structure

“Landscape structure expresses the spatial pattern of landscape elements and the connections between the different ecosystems or landscape elements. Landscape structure assesses relationship between ecosystems as measure, number, size and shape” [16].

6.2 Landscape metrics

“Landscape metrics help us to understand changes in landscape from different Perspective (Visual, ecological, cultural). Landscape metrics have greatly contributed to the landscape ecology studies” [16]. Landscape metrics could be calculated under Patch, Class and Landscape levels.

6.3 Least-cost modelling

Least-cost modelling is one of the GIS-based techniques used to create regional-scale wildlife movement models in a manner that makes it possible to identify potential linkage areas across highways [17]. Identification of least cost path and least cost distance is achieved by using raster landscape resistance map. Cells represent the estimate the resistance to species movement [18]. The least-cost path is the route that offers an organism the greatest probability of survival in traversing the entire distance between source and target patch [19]. Least – cost path modeling use resistance layer to define the level of hardness of movement by using different land cover types.

</tbody>
</table>

CA: Class Area, NUMP: Patch Number, MPS: Mean Patch Size, ha: hectare, % percentage

Table 2: Landscape connectivity level analysis, plot one and two
Source: Author

According to the table, plantation paddy and other (scrubs, grass, and marsh) shows a slight enhancement of connectivity. The increment of the plantation and paddy lands are mostly caused by anthropogenic activities. It can’t be considered as a measuring factor for connectivity reestablishment. Especially the increment of the land cover types which is categorized under other (scrubs, grass, and marsh) can be seen under both plot one and plot two. These Land Use classes mostly provide the facilities to animal habitats and it also naturally creates features with the minimal anthropogenic involvement.

By comparing plot one and plot two, a higher increment can be seen within plot two. In the connectivity structure analysis there are lot more connecting structure within the plot one
rather than plot two. This expresses the idea that the number of crossing structures do not define the level or frequency of connectivity reestablishment within southern expressway.

7.3 Cost theory based species flow Analysis

Cost modeling illustrates the most appropriate landscape corridors by using land use pattern and resistance values. Figure 6 shows the least cost path generated from the ArcGIS program and existing locations of highway crossing structures that mostly cater for landscape connectivity. Gray colour horizontal lines indicate the existing structures. Black colour lines indicate the least cost path.

Black colored rectangles indicate the places that are not suitable for landscape connectivity structure according to the land use pattern. The areas marked by the black rectangles are having a higher resistance value than other areas.

In southern expressway there are quite a number of structures that tend to support the landscape connectivity. 28.5% of total animal crossing structures are within the high resistance land use classes, which partially suitable as landscape connectivity corridor. Proper placement of the highway crossing structure should be considered within the early planning stage of the project. The cost theory base analysis with the updated and well detailed land use maps and contour maps leads to do proper analysis relate with the placement of the landscape crossing structures.

7.4 Animal accident analysis

Analysis shows animal accidents frequency of two plots which are not affected by number of connectivity structures. It may be affected by other factors such as climate change and other natural phenomena. But it expresses the idea that a number of landscape crossing...
structures are not the only factor for reestablishing landscape connectivity. It’s also affected by the suitability of highway crossing structures to the individual place itself by considering the specific characteristics, animal behaviors and suitable types of crossing structures.

7.5 Questionnaire survey

Questionnaire survey is used to identify the functional connectivity of the landscape in the ground scale. Analysis express, behavioral changes of animals can be experience after construction of the expressway. It shows landscape fragmentation effects on animals within the context. Participants mentioned population enhancement of the peacocks and pigs, animal accidents can be experienced within the context. Which means they were having environmentally unbalancing occurrences due to the construction of the expressway. This analyze express the idea that they are having functional evidences of landscape connectivity structures within southern expressway and the animals were using the landscape connectivity structures rarely.

8. Conclusion

The research outcomes express the main idea that the landscape crossing structures used within the southern expressway (E01) partially contribute as expected to restore the connectivity within the context which was fragmented by the construction of southern expressway, but they are having evidences identified by the research, the mitigation measures done by the southern expressway project to re-establish landscape connectivity is not adequate to restore the damage.

Analysis of the evolution of the landscape pattern by using data from the land use maps helps to determine the degree of connectivity over time and crossing structure analyze shows the degree of involvement of the landscape crossing structure to reestablish connectivity. Cost analysis helps to determine the suitability of existing locations of the landscape crossing structures by using least cost modeling. Functional connectivity of the landscape is decided by the analysis of animal accident data and the questionnaire surveys.

Animal crossings were used frequently within the southern expressway. The disruption of free movement of wildlife has resulted in frequent vehicle collisions with wildlife as they attempt to cross the expressway. Some of the modulation techniques used in expressway construction has to be improved with the proper understanding of the context. The analysis shows the existing placement partially considers the landscape pattern, animal movement corridors and the vegetation distribution. Proper placement reduces the number of animal accidents and keep the ecological connectivity between patches.

More reliable and context generated design is essential to provide better solutions to reduce the negative impact towards natural processes due to construction of expressways. It needs the knowledge of expertise and should do proper research within the planning and pre construction stages of the project. When compared it is comprehensible that the facilities provided for landscape connectivity is less than the facilities provided for human infrastructure.
connectivity. Strategies used for re-establishing the landscape connectivity may not be equal as the strategies used for human infrastructure connectivity, but it should be adequate to manage the balance of the natural system.

Special features such as track devices, inferred camera systems and sand bed tracking to determine landscape connectivity are used in developed countries. Researches with those mentioned advance technologies will help to identify more accurate species movement paths and can lead to proper placement of species transit corridors.

The preliminary stage of a project for the design and location of the connecting structures highly need the contribution of professionals like ecologists and landscape architects. Their contribution within the planning stage, construction stage and the functional stage also impacts the final outcome.

This is the time to direct these transportation development strategies towards the creation of sustainable transportation system. The future expressway projects such like the Kandy north expressway, southern expressway extension and immersing road development projects across the national parks like ‘wilpattu’ need special attention. With the proper consideration of the socially, economically and environmentally sustainable enrichment within the all stages of the projects help to attain the maximum benefit for the country. The involvement of well experienced and skillful professionals, especially within the fields of ecology, planning and landscape architecture are also a crucial factor for above mentioned achievements.

Abstract

In an era of globalisation and environmental instability, the ‘landscape’ is often perceived merely as the physical context rather than as the core element to establish a vision for a whole region, create values, share memories and play a key role addressing the global challenges we face. The focus of this paper is to enhance and emphasise the impact that spatial strategies have in sustainable design and how landscape practice can be instrumental in future-proofing and protecting our cities. The paper forms part of a wider research project examining innovative landscape strategies across Europe, assessing the extent to which low carbon, sustainability and spatial quality can be delivered effectively at the urban and strategic scales. We argue that a sophisticated process needs to be put in place in order to be able to deliver landscape schemes that appropriately identify and address current environmental and social challenges.

This paper discusses the outcomes of two major pioneer landscape infrastructure projects in the Netherlands (the ‘Room for the River’ and the ‘New Dutch Waterline’) that have demonstrated new ways of engaging with both climate and aesthetic elements during the conceptual and implementation phase of a strategic scheme. The Room for the River is a landscape adaptation programme addressing water level management, while the New Dutch Waterline aims to regenerate inundation sites by introducing cultural and social activities while preserving the landscape infrastructure. Exploration of the impact that policy and legislation have on the landscape demonstrates that governance plays an important role in ensuring the success of a strategic landscape project. An investigation of urban and rural projects dealing with climate adaptation through these two projects shows that a multidisciplinary focus is a significant factor in the development of an effective project framework.

We conclude that the establishment of a project framework, clearly supported by legislation and policy, will make a real difference in the way that professional practice and politics deal with landscape infrastructure. The integration of environmental and quality concepts from the early stages of the project process, and the attention to the importance of design, can ensure effective implementation and smooth communication during the development of a landscape scheme, leading to future resilience.
Keywords: landscape design; sustainability; climate adaptation; project framework; flooding

1. Introduction

Research observing and evaluating strategic landscape schemes across Europe that have developed pioneer ways of envisioning, processing, managing and delivering large-scale projects has resulted in the identification of best practices that enhance sustainability and spatial quality in regional landscape-based schemes. As Stephenson [1] states, ‘presenting landscape as “space” has a long pedigree in assessment practice, but conveying its rich and messy place-values is still a rarity in practice’. The interpretation of low carbon is often challenged, with practitioners, researchers and others questioning whether it is based on activities, lifestyles and voluntary behaviour change or in policy frameworks influenced by regulatory forces [2].

The significance of this paper comes from the examination of two case studies in the Netherlands, the Room for the River (Ruimte voor der Rivier) and the New Dutch Waterline (Nieuwe Hollandse Waterlinie), which demonstrate how water safety, hydrological efficiency and sense of place contribute to low carbon and design quality. Through identifying the lessons learned, the real benefits of a well-thought-out and sustainable design as well as the importance of the governance in decision making, we explore how the two schemes have generated an innovative way of dealing with the strategic scale and how this affects the landscape infrastructure and the environmental scene in the Netherlands. We identify a series of innovative steps that these strategic projects have followed from establishing the vision, integrating design at an early stage, to the interaction of governance and public participation and the successful delivery with further outcomes to the regional or national planning process. The whole project process is conceptualised as an alternative to the common current project frameworks, resulting in large-scale schemes that effectively address environmental challenges, behavioural change and quality of space.

2. The vision for sustainable strategic spatial schemes

Introducing a powerful vision for a sustainable landscape project that deals with environmental challenges while, at the same time, enhancing social and cultural characteristics and delivering economic benefits is not an easy thing. Nevertheless, we suggest that it should be one of the fundamental steps in order to bring landscape design to the forefront of sustainable development. The ‘design concept’ for landscape, as it also might be called, can describe the story of a place, make it inspiring, attractive and appealing to visitors and locals.

The Room for the River and the New Dutch Waterline are two pioneer national landscape programmes dealing with climate change, water level rise and quality of space. Their focus lies in the effective delivery of large-scale developments that address environmental challenges and educate people about the landscape.

2.1. Room for the River

The Room for the River is a climate adaptation programme that was introduced as an alternative to traditional planning approaches and was intended to form a more sustainable way of dealing with increased rainfall and rising sea levels. The serious
flooding that affected the Netherlands in 1993 and 1995 was the trigger for a change in the planning and management of the river catchment areas (Fig. 1, Appendix), resulting in the development of this programme. It is a national-scale design strategy, ensuring a high level of protection against rising water levels in 34 locations across the Netherlands, while introducing a vision for a carbon-neutral life. Aiming to improve the overall environmental quality in the river region and having developed a method for the assessment of the designs proposed, this scheme is also a good example of how the low-carbon concept can be covered in spatial strategies.

2.2. New Dutch Waterline

The ‘New Dutch Waterline’ is also a national landscape programme consisting of approximately 60 different fortifications across the Netherlands (Fig. 2, Appendix), focusing on the preservation and revitalisation of the landscape infrastructure and aiming for enhanced sustainability and quality of space. The fortification network was originally designed in the 19th century as a military defence system to enable controlled inundation through sophisticated landscape engineering, but was never used, leaving a historic and cultural landscape now in need of revitalisation.

The vision of this scheme was to create new values for the fortifications, aiming to preserve and regenerate the existing structures while improving their visibility and accessibility to the existing landscape. The successful implementation of the programme, together with the emphasis on sustainability and landscape quality, has resulted in improvement of the existing historical landscape, creation of valuable public space and a unique identity to the landscape; and has led to nomination as a tentative UNESCO site.

The two Dutch case studies are successful examples of a visionary narrative, introduced by landscape design and expressed through drawings and text, a process that allowed the vision to be developed and transformed over time. Designs embedded into the project process have created beneficial outcomes for public engagement and delivery, by improving communication and visualisation of the landscape ideas. The two schemes demonstrate the significance of a landscape concept presented visually, and the need for the landscape project process to be perceived in a different way than is commonly the case today, blending ideas with drawings and text following a vision for sustainable future.

3. Project process framework

The examination of the two case studies presented here reveals an innovative project process that builds upon the proposed vision. The structure followed by both Dutch schemes introduces an alternative way of working, compared with the common landscape infrastructure project frameworks. The establishment of a vision has secured environmental uncertainties, and embedded key ideas such as low carbon and spatial quality in project delivery. On examining the frameworks evolved by the pioneer studies, we suggest that the schemes were not only planned to deliver a piece (or pieces) of infrastructure, but to create sustainable places and cover environmental and societal needs, paying respect to the cultural aspects. Looking and evaluating the landscape, the area and the society, a series of concepts and ideas have been identified resulting in a new
combination and effective use of methods and techniques (eg. legislation, continuous evaluation, timing) that follow an overall alternative project framework.

A sophisticated process focusing on spatial understanding, a different way of ‘conceptualising and shaping the project’, the integration of key ideas into policies and politics and the importance of early planning at the implementation and delivery of a large-scale scheme, are all important elements for the regional design project and have played major roles in both the Room for the River and the New Dutch Waterline. In particular, a framework focusing on the conceptualisation and the actions shaping the scheme’s vision has the potential to affect governmental values as well as decision making, with consequent impacts on project delivery and outcomes.

Regional- and strategic-scale schemes are often conceptualised, established and delivered by the project management or administration process, controlled by governmental institutions. They often follow a ‘common’ and ‘conventional’ process of management and delivery, and it seems to be only when there is multidisciplinary interest and a pressure for a low-carbon vision, as happened at the two case studies, that an alternative project process is likely to emerge.

We suggest that a sequence of processes referred here as ‘shaping the project/alternative project framework’ needs to be established and introduced for all major infrastructure schemes. Such administrative frameworks can develop on a strategic scale (as with the example projects discussed here) and can form a significant part of decision making, securing the way in which quality elements can be spatially implemented. Van den Broeck [3], discussing administrative processes and policies, has suggested that “it is a challenge to develop a new kind of “frames” and a new way to use them for judgement and decision making aiming at spatial quality, however these frames [are meant to] to ensure legal certainty’. As shown by the successful outcomes of the Dutch projects examined here, such frameworks are likely to secure the effective delivery of a sustainable scheme and become a powerful example of large-scale implementation.

3.1. Key points of these project frameworks

Specific elements integrated to their project frameworks have impacted positively on the delivery of the programmes of the two innovative strategic schemes presented here. We suggest that the elements identified play a major role in the way in which a vision is communicated and understood during the project development. The key practices identified are: vision, early integration of important messages, communication, continuous evaluation of the project process, policy and legislation, governmental support, education and awareness, active and continuous public engagement and use of design as a driver for business regeneration and economic outputs.

One of the main outcomes of the study is that concepts such as spatial quality and low carbon, that may be challenging owing to their elastic and variable definitions, can be effectively delivered when they are properly planned and integrated in the earliest stages of a landscape project. The importance of ‘timing’ for key messages in a landscape design secures their integration within the overall vision and highlights the importance and benefits of their delivery. For example, the Room for the River demonstrates a variety of key actions based on a strategic
project framework. This framework focuses on key concepts such as hydrological efficiency and spatial quality, the way in which they have been carried through from the beginning (concept) to the implementation phase and the actions of the stakeholders involved.

Another vital element in the project framework, but one that is often introduced at a later stage, is strong communication. A less effective communication strategy within the project management can cause implementation delays and result in a diversion of its environmental scope. In strategic schemes, the diverse stakeholders need to be clear about the vision and then use tools, communication channels, drawings and vocabulary, introduced through the project framework, that will help them transition from the conceptual to the implementation phase.

Early integration of important ideas, a solid project framework and legislation have significant impacts on decisions made during the landscape process and result in new ways of project delivery. Successful integration of these elements in the ‘routine framework’ of a landscape scheme would enhance landscape identity, delivering a scheme with strong environmental messages and producing enhanced landscape quality in the perceptions of its users.

4. Different approaches in the Dutch projects

Individual methods, such as those described above, have probably been used in previous landscape schemes, however it is their combination in addition to the creation of a strong policy framework guarded by external expert teams and governmental institutions that has resulted in the successful implementation of the pioneer schemes Room for the River and New Dutch Waterline. Their landscape process demonstrates how design can change public opinion on sustainable landscapes and the way in which policy and legislation secure project delivery.

Policy

The Dutch system appears to be quite progressive in the integration of such concepts, but for this to be implemented, policies need to be in place to support the management of the process [4]. The legislation introduced and facilitated the schemes, settled design at the core of the process and helped in the creation of a unique team to evaluate the projects’ progress regarding spatial quality. The fast pace with which the project framework is often established makes it challenging for such concepts to be properly introduced, therefore the innovative method of a dedicated team has offered significant outcomes to this point. The European Climate Adaptation Platform explains that ‘the old policy [in the Netherlands] was based on discharging surplus water to the sea as quickly as possible, the new policy became to first retain water, then store the water and finally discharge the excess water. The new water policy was later linked to nature development and implementation of the EU Water Framework Directive’ [5]. Similarly, the two projects examined here fulfil legal requirements with key elements of water safety, secured their integration within the process and their implementation in the landscape scheme.

Stakeholder Collaboration

The programme framework developed for the Room for the River illustrates how
the different stakeholders communicated and collaborated in securing the goals set by the administration. It deals with the integration of conceptual ideas being developed across the different projects and the way in which they can be secured during the landscape process. The main bodies involved at a strategic scale are illustrated in Fig. 3 (Appendix) and are the ‘Programme Office’, the ‘Landscape architecture team embedded in the Programme Office’, the ‘Water management team’, the ‘Spatial Quality team’, and ‘Deltares’, the external quality and sustainability team [4]. Additional institutions, organisations and individuals have also taken part in various stages of the programme.

The Programme Office and the individual project teams are responsible for the final decisions; however the other bodies participating in the programme, such as Deltares, the external Quality team, evaluate specific quality elements such as water efficiency, landscape quality, environmental elements and more. The Landscape team has a continuous communication role between the Programme Office and the Quality team, supporting the project development. The Water Management team is embedded in the main structure of the scheme and it is responsible for the evaluation of water safety, sustainability and low carbon elements. Deltares is responsible for a second evaluation of the environmental aspect, and also secures the water management process.

Addressing all scales

The focus of processes has followed a sequence from the broad scale, through various intermediate stages, down to the very detailed characteristics of a specific location.

Demonstrating the close involvement of governmental institutions not only in strategic but also in local scale for the Room for the River, it was found that the Ministry of Infrastructure and the Environment established an administrative collaboration that was set as a partnership agreement with the Ministry of Economic Affairs, Agriculture and Innovation, Werkendam City Council (near Noordwaard - one of the 34 project locations), Rivieranland Water Board, Province of North Brabant (province of Noordwaard) and the Department of Public Works South Holland [4].

Design as a major communication tool

Design needs to be established as a requirement of the project framework for the scheme to be able to respond appropriately to the setting and the social and cultural needs of the area. Drawings have a significant role in this strategy, communicating ideas and engaging stakeholders throughout the process. Both national schemes had a close relationship with designers and a Quality team, aiming to secure not only function but also sense of place and public engagement. More specifically, the concepts of spatial quality, low carbon and design had not been used in the same holistic way in such large-scale projects before [4], which makes it an innovative conceptual framework in landscape strategies. Given the success of the two projects, this has a major potential impact for the future spatial planning and design policy of the Dutch government.

5. Why they are successful
We suggest that the delivery of the landscape schemes is an outcome of their success in creating a holistic plan and project framework embedding all the different elements presented above in a way that all play a key role in the landscape design process. We argue that the political dimension facilitates the landscape project, and impacts on political actions related to the landscape design and the whole region. A series of important steps (clarification, shaping the project, politics, policies, institutional involvement, and timing) are necessary in order to secure the delivery of the key qualities and elements. The development of alternative project frameworks by the national programmes in the Netherlands would not have been achieved without strong support from the government and the creation of new legislation, securing a smooth delivery of the landscape projects. Whether dealing with historic landscapes and sensitising the society or having the desire to create a landmark project, addressing climate change, while the same time enhancing economic and social values, these strategic developments clearly had the effective support of the government before and during the project process.

Highlighting the importance of procurement processes in the implementation of landscape design, Moore [6] has stated that ‘to have any real chance of providing a sustainable and lasting blueprint for the landscape, this way of working needs to become wholeheartedly absorbed into all of the decision making institutions and organisations responsible for policy, strategic or regional planning at a national or international level’. The projects discussed here have illustrated that legislation and politics in relation to landscape design can be an effective way to engage with the land and the region and guide the development of a new way of thinking, as well as acting both in public and private sectors. Spatial quality, water safety, hydrological efficiency, community engagement and landscape preservation are addressed in the policies and legislation of these national programmes, helping to ensure their integration within the narrative and therefore their successful delivery within the scheme [4]. Increasingly it is recognised that ‘there is no alternative for countries but to incorporate low carbon measures in their development policies. The reality of climate change demands it, and there are also clear benefits in pursuing such for policies’ [7]. Both the Room for the River and the New Dutch Waterline have made significant progress in the interrelation of politics and the landscape, changing public opinion and establishing specific laws for the landscape scale in relation to climate challenges.

6. Conclusion

Successful delivery of sustainable strategic schemes is not a one-way process, and requires the engagement of various actions. We suggest that policies, legislation and the establishment of a project framework all have significant impact on the extent to which key ideas are being delivered at the strategic scale, and secondly that design plays a significant communication and interpretation role for those concepts, allowing better integration in large-scale strategies.

The establishment of an alternative project framework that addresses the needs of each project individually is considered necessary, but it requires support from policy and governmental legislation,
especially on a broader scale. The suggestion for such a framework focuses on recognition of the increasing importance of concepts such as low carbon, climate change, spatial quality and visual representation for improved communication. Therefore a process that will successfully provide integration of all these individual elements to a large-scale scheme will be a step towards long-term and real sustainable implementation and a formula to more clearly address climate challenges through landscape architecture.

Acknowledgments

The authors want to thank EIT Climate-KIC, which has supported this research throughout, as well as all the stakeholders at the Room for the River and the New Dutch Waterline.

Appendix

How we are making room for the river

**Deepening summer bed**
The river bed is deepened by excavating the surface layer of the river bed. The deepened river bed provides more room for the river.

**Water storage**
The Volkerak-Zoommeer lake provides for temporary water storage when exceptional conditions result in the combination of a closed storm surge barrier and high river discharges to the sea.

**Dyke relocation**
Relocating a dyke land inwards increases the width of the floodplains and provides more room for the river.

**Strengthening dykes**
Dykes are strengthened in areas in which creating more room for the river is not an option.

**High-water channel**
A high-water channel is a dyked area that branches off from the main river to discharge some of the water via a separate route.

**Lowering of floodplains**
Lowering (excavating) an area of the floodplain increases the room for the river during high water levels.

**Lowering groynes**
Groynes stabilise the location of the river and ensure that the river remains at the correct depth. However, at high water levels groynes can form an obstruction to the flow of water in the river. Lowering groynes increases the flow rate of the water in the river.

**Depoldering**
The dyke on the river side of a polder is relocated land inwards and water can flow into the polder at high water levels.

**Removing obstacles**
Removing or modifying obstacles in the river bed where possible, or modifying them, increases the flow rate of the water in the river.

A study of the planning and design process of
Green infrastructure focusing on green street approach:
Guidance to successful implementation

Joowon Im
University of Texas at Arlington, CAPPA Building Suite 203, 601 West Nedderman Dr., Arlington, TX 76019-0108, USA

Abstract

Green infrastructure pursues sustainable and affordable development approaches to promote resilient urban environments. It is becoming more useful for being able to prevent the destruction of limited natural resources and amending the degraded environment of urban areas as providing multiple (environmental, social, and economic) benefits to a community rather than pursuing a single-purpose approach (e.g. stormwater management). Regardless all the potential benefits, one of the challenges in promoting the application of green infrastructure is the “uncertainty” about what it can provide and how it is implemented. One way of promoting successful application of green infrastructure with emphasis on multiple benefits will be understanding the implementation process because it can help to provide consistency in decision making and understanding what is required for overcoming uncertainty. To have specified investigation, the study looks into different processes of implementing green street (one of 11 elements of green infrastructure recommended by the US EPA) for a better understanding of multi-step protocols of the implementation processes. It brings into focus on what needs to be considered regarding procedures, resources, disciplines, stakeholders, and others throughout different steps of the implementation processes. The study aims to provide an overview of an established green street oriented implementation process and promote its effective application by investigating different processes and empirical insights of city officials who worked on green street projects. Primary data collection was a semi-organized interview with city experts who worked on green street projects from selected six cities. The list of target cities are not exhaustive but the criteria for the study was 1) cities with strong history of implementing green street and with projects completed more than one year ago, 2) cities allowing convenient access to rich documentation on the projects, and 3) cities with available experts who had worked on green street projects in their respective municipal departments (which could include Parks and Recreation, Environmental Protection, or Planning and Development, for example). There was an additional round of interviews with other city experts who worked on green street projects (nominated successful projects by city experts from the first round of interviews) to obtain more detailed data regarding the implementation processes. The data was primarily analyzed using content analysis based on
cultural psychology, which includes multi-step qualitative analysis followed by flowcharts/diagrams and a member check method. The analysis presents the implementation of green street projects involves a breadth of important considerations, such as Setting Priorities, Funding Sources, Involvement of Multiple Parties, Planning & Design Protocol, Public Outreach, Operation & Maintenance, and Challenges. Various resources, techniques, and procedures are therefore required for the implementation process. As taking them into account, the author suggests a suitable framework to guide the process for successful implementation for planners and designers, especially who are in the early part of adapting a green street. It also aims to provide more understanding of green street and the implementation process for the promotion of its installation and acceptance by planners and designers and even by the public for the future of the urban resiliency.

**Keywords:** green street; green infrastructure; design process; sustainability; urban resiliency

### 1. Introduction

Green infrastructure pursues sustainable and affordable development approaches to promote resilient urban environments. Although it is useful to prevent destruction of natural resources and to provide the urban areas with environmental, social and economic benefits, one of the reasons promoting the application of green infrastructure can be challenging is the “uncertainty” of its intangible benefits and lack of general knowledge among the public and planners [1]. Therefore, understanding the implementation process of the infrastructure is important and may help promoting successful application of green infrastructure. It will help to provide consistency in decision making and understanding what is required. The study looks into different processes of implementing green street (one of 11 elements of green infrastructure recommended by the US EPA) for a better understanding of multi-step protocols of the implementation processes. It brings into focus on what needs to be considered regarding procedures, resources, disciplines, stakeholders, and others throughout different steps of the implementation processes. The study aims to provide an overview of an established green street oriented implementation process and promote its effective application by investigating different processes and empirical insights of city officials who worked on green street projects.

#### 1.1. Importance of Green Street

Green streets are designed to deal with stormwater runoff at the source by closely mimicking natural processes in urbanized watersheds. They are primarily implemented on a public right of way. They are often more environmentally and economically effective than conventional storm or combined sewer systems. As an element of green infrastructure, an ideal green street projects are designed using a complex strategy for pursuing urban resiliency and sustainability. It can, like green infrastructure, “act as a synthesis of a number of other areas of planning (greenways, green spaces, high-density planning) to promote a coherent discipline for future development” [2]. The multiple benefits of sustainable development are the ultimate goal for green streets considering site contexts. This means that green streets need to emphasize the network system approach that can successfully integrate multifunctional disciplines to
promote their influence throughout the site. The green street approach is now being adopted by many localities, the projects are widely recognized as providing effective and “affordable solutions that meet many objectives at once” [3].

2. Methodology

The primary methods chosen for the study is a semi-structured interview with experts from different municipalities who worked on green street projects to obtain their insights. It is to evaluate the processes in detail based on their specific experiences and opinions in the field [4][5] regarding how decisions were made and what procedural actions were taken.

The six-sample cities, which performed rigorous green street approaches have chosen through purposeful sampling [6] and the criteria of the selection are: 1) Cities with a relatively long history of implementing green streets with those projects completed more than a year previously, 2) cities allowing convenient access to rich documentation (municipal reports, articles (news, journals), websites) on the projects, and 3) cities with available experts who had worked on green street projects in their respective municipal departments. The sample cities are Seattle, WA, Portland, OR, New York, NY, Philadelphia, PA, Washington D.C., and Arlington, VA. In addition, another round of interviews with city experts were conducted for the four case projects selected from the list of successful green street projects nominated by the experts from the interviews including case projects frequently mentioned through websites of design firms or municipalities allowing a variety of sample projects and data. Selected projects are Broadview Green Grid (Seattle, WA), Holman Pocket Park and Green Street Bike Boulevard Project (Portland, OR), Maynard Avenue Green street Project (Seattle, WA), and College Avenue Promenade, (Blacksburg, VA).

The collected first interview data was analyzed with a content analysis of psychological phenomenology developed by Ratner [7] to study aspects of green street implementation, with a focus on how green streets were planned and constructed (attributes of considerations regarding the implementation of green street). Interview contents were analyzed and relevant statements were grouped and summarized as ‘central theme’, then central themes were grouped and categorized as ‘general theme (upper level of the central theme)’ [7]. The method was chosen to effectively analyze the contents of interviews as a whole rather than focusing on interview questions to categorize the contents. The next analysis focused on developing a model process of green street implementation involving three phased analyses: The interview responses only regarding typical implementation processes in the six sample cities were analyzed. These data are categorized following the simplified four-staged landscape planning protocol: project initiation, design, construction, and operation & maintenance (See Figure 1) with a deductive approach. The four-staged model made the comparison of different processes in the sample cities more effective and convenient. In addition, the second-round interview focused on specific performances (actions in the decision-making process) that have been conducted for four successful green street cases were analyzed. The results were also categorized and added corresponding to each stage (See Figure 2).

A member check analysis was adopted in the process of creating a green street oriented model process not only to increase validity [8], but also to develop a green street oriented model process. The created preliminary model process was presented back to the expert participants for their review and, feedback and the model
process was modified and finalized accordingly.

First, Improving Stormwater Quality and Quantity (CT.1); Inclusion of Additional Benefits (CT.2); and Change in Priorities (CT.3) were identified as sub-attributes (central theme) to be considered in the green street implementation process. They were grouped under Setting Priorities (GT.1, general theme). Stormwater management was a common priority for all of the six sample cities. Additional benefits were also mentioned as priorities in building green streets in three cities. The most considered benefits were neighborhood improvement, traffic calming, traffic functionality, environmental improvement, and cost effectiveness. Some of the sample cities changed the priorities of their green street projects over time depending on city’s needs.

Second, Fund/Grant from Local Municipality (CT.4) and Federal Fund/Grant (CT.5) were identified and grouped under Funding Sources (GT.2). Experts identified two primary funding/grant sources from municipalities and federal agencies. All sample cities received funds/grants from their municipalities regarding city development plans (capital improvement and neighborhood development), which were not strictly limited to stormwater projects. Funding for the projects also tend to be a mix of funds/grants from different agencies, often offered communities expertise and resources.

Third, City Initiated Projects (CT.6), Public (online/resident) Initiated Projects (CT.7), Private Developer Initiated Projects (CT.8), and Projects Involving Multiple Departments (CT.9) were identified as sub-attributes and grouped under Involvement of Multiple Parties (GT.3). For all of the sample cities, municipalities were the main agents initiating green street projects. This is understandable considering its primary location in the public right of way, but some of projects were also initiated by

3. Analysis

3.1. Attributes of Planning and Design of Green Street

The first analysis presented a breadth of important attributes of considerations (7 general themes and 31 central themes) in the planning and design of a green street (See Figure 3).
communities or private developers. In general, green street projects involve multiple departments during the implementation process. In the sample cities, the interdisciplinary approach meant that various departments were involved, particularly environmental departments (mainly with a stormwater management focus) and transportation departments (mainly with a city improvement focus), followed by parks and utilities. An interdisciplinary approach to projects allowed for new ideas and professional collaborations, but it also often caused conflicts of interests or confusion.

Fourth, Available Space for Implementation (CT.10), Consideration of Site Contexts (CT.11), Consideration of Pedestrian Safety (CT.12), Improvement to Life (CT.13), Improvement from Previous Design (CT.14), Effective Stormwater Treatment Performance & Implementation (CT.15) were grouped under Planning & Design Protocol (GT.4). Experts mentioned design protocols that focused on efforts to include additional benefits, such as improving pedestrian safety or promoting better living. Green streets also can simply provide effective stormwater management by rigorously utilizing available space in the right of way. Though the sample cities had design standards and manuals, experts tried to consider various aspects beyond the manuals and standards by considering site contexts.

Fifth, Public/Community Meeting (CT.16), Phased Public Outreach (CT.17), Public Education (CT.18), Individual Conversation (CT.19), Sending out Flyers (CT.20), and Plant Palette Selection (CT.21) were grouped under Public Outreach (GT.5). Public outreach was an important process of obtaining insights from the public as well as informing the public regarding what would happen so that they could prepare for the construction in their neighborhood. Moreover, it was an opportunity to get consent from the public for the project. The public outreach could take the form of public meetings with communities or local community groups regarding design decisions, collecting opinions, informing about construction schedules, and/or visiting individual homes to hear opinions. Other forms of communication include flyers, postcards, and emails for people who live and work adjacent to green street projects.

Sixth, Municipal Involvement (CT.22), Public Involvement (CT.23), Private Contractor (CT.24), and Inclusion of Monitoring (CT.25) were grouped under Operation & Maintenance (GT.6). Maintenance was mainly conducted with municipal involvement, though no significant responsibilities were given to particular parties. Also, in some cases only ‘light maintenance’ was used. Some programs made an attempt to include public involvement, in their maintenance programs, but this mostly entailed simple tasks such as weeding and collecting trash. Some cities have considered or hired private contractors, for maintenance. And some of the programs made use of inclusion of monitoring to test how green streets were functioning in relation to current use and future improvement.

Lastly, Challenges in Setting Priorities (CT.26), Site Constraints (CT.27), Economic Considerations (CT.28), Technical Challenges in Design and Construction (CT.29), Community Resistance/Concerns (CT.30), and Difficulties in Public Outreach (CT.31) were grouped under Challenges in Green street Implementation (GT.7). Challenges in setting priorities arose from disagreement between municipalities and the public in the decision-making process. Much of this disagreement arose from the different goals and priorities of the parties involved. Because green street facilities typically need to contain a certain amount of water and underground installations, especially concerning underground conditions,
difficulties may arise. Green street projects often depended upon obtaining the needed funds and pursuing affordable construction. Since green streets were a relatively new approach, technical challenges in design and construction, also came into play. Some of the projects met with community resistance or concerns, regarding having green streets in their neighborhoods and enduring the disruptions of construction. Lastly, difficulties in public outreach concerning community education was discussed.

3.2. Green Street Oriented Planning and Design Process

In this section, each sample city’s process and distinctive procedural performances of selected case projects were examined and a green street oriented planning and design process for successful implementation was derived. The overall performances in each city were categorized into a four-stage process: project initiation, design, construction, and operation & maintenance.

When developing the preliminary model process, for project initiation stages, the experts’ discussion centered on how the sample cities prioritize site selection, seek project opportunities, and work with other departments (interdisciplinary approach). In the discussion of design stages, public outreach was discussed as an important means of receiving feedback from the public and getting users involved in the design procedure. In the discussion of construction stages, bidding procedure was described and maintenance stage has not shown any particular discussion but light maintenance throughout the year.

During the member check process to finalize the model process, all the experts approved of the division into four stages of the model process, but there were various opinions on the sub-stages included in each stage. The first item the experts noted was that public outreach could take place more than once and fulfilled different purposes at different stages in the process. The second point raised was that the site analysis could be done in two stages: project initiation and design. Lastly, public outreach was to obtain public support for the project, design development was to provide actual benefits to the community, and the construction substage was to ensure the design was built as intended. The feedback was reflected and a green street oriented process for successful implementation was presented diagrammatically in Figure 4.
4. Conclusion & Recommendations

4.1. Accommodate Multiple Visions and Designate a Champion for the Project

The presence of stakeholders or interested parties whose strong vision and clear objectives guide the green street project can help to ensure that all those involved remain on track as they progress through the different stages of green street implementation. So then, green street projects are also likely to provide the additional benefits to the community.

4.2. Maintain Good Communication Among Related Departments for Effective Interdisciplinary Collaboration

Although a clear vision of the desired endpoint is important, having a champion (either an individual or an agency) who takes responsibility throughout the process is critical for the success of a project since “goodwill [to continue the project] seems to be most effectively garnered by influential individuals within the implementing organization acting as program advocates or ‘champions’” [9].

The research process that green street projects were truly interdisciplinary in nature due to the fact that they are implemented in a public right of way and deal with stormwater runoff. The departments related to Transportation and

---

Figure 4. Green street oriented planning and design process: Final
Environmental Services are likely to be the most heavily involved. Planning and Parks Departments come in a close second, and other departments, such as Utilities, Maintenance, and Fire Departments, may also be included. The funds, plans, and priorities of green street projects inevitably differ from one project to another. Each department can play its part in successful communication by remaining constantly aware of the potential for conflicting objectives and misunderstandings, and conflicts can be resolved by regular meetings or forming formal interdisciplinary green street teams.

4.3. Understand and Respond to Needs of the Public and Stakeholders

In this research, the public was one of the critical components for implementing successful green street projects. Local people are the ones who will be utilizing the street and interacting with the design elements. It is therefore critical to study what the public's needs and expectations from a given project. It is also hard to satisfy every agency and individual who might be affected by green street projects, thus, as concluded in the previous chapter, public outreach should be considered during all of the stages of a green street implementation process. Public outreach also provides a means of collecting opinions from users and explaining the rationale behind the selection of a project site. A phased outreach approach that syncs with different design completion stages appears to have particular success. At the construction stage, public outreach can be used to inform residents about the construction schedule and available amenities to keep local businesses operating. In the operation & maintenance stage, public involvement in maintenance can be promoted as part of a stewardship program.

4.4. Consider the Whole Street Envelope When Planning and Designing Green Street

In order to maximize the potential benefits of green street practices, a project should be considered together with the street envelope as a whole rather than simply as an isolated system (See Figure 4). This is the case because green streets are located adjacent to where people live, work, and play. However, in the current manuals and design standards, drawings seldom include site contexts such as buildings and street furniture or dimensions of the sidewalk/roadway, along with other factors that consists a street as a whole. Moreover, stormwater treatment facilities need to perform infiltration, provide planting beds, and incorporate underdrain pipes if necessary. Consequently, especially for green street practices, underground conditions need to be investigated through on-site inspections because they can differ from existing documents. Thus, not only the surface areas of a site, but also its underground conditions must be taken into account to ensure the success of a green street project. Figure 5 shows an example of a green street application that considers the site contexts as a whole. Various applications of a green street approach are presented in Figure 6.

Figure 5. An example of a street envelope: design considerations in a green street practice including land use, sidewalks, planting areas, roadways, and underground conditions.
4.5. Integrate Green Street Practice with Primary Municipal Plans and Other City Development Plans to Secure Funds and Address Multiple Benefits

To promote the multiple benefits that can be achieved with the implementation of green streets, integration with larger development plans can be an effective strategy. Adding the green street approach to municipal plans can provide useful opportunities to obtain stormwater management-related funds, freeing up municipal funds to pay for other streetscape improvements. It can also be useful solution for any communities with stormwater related issues but not enough budget. Also, if a funding shortage is experienced, designers and planners may seek for a partnership with other agencies, such as the U.S. Environmental Protection Agency (EPA), U.S. Department of Transportation (DOT), U.S. Department of Housing and Urban Development (HUD), U.S. Department of Agriculture (USDA), U.S. Department of the Interior (DOI), and more (Environmental Protection Agency, 2014).

4.6. Integrate Maintenance Plans into Green Street Master Plans

Once the construction stage is complete, maintenance becomes the most important aspect of green street projects because they all require a certain level of maintenance. Despite its importance, maintenance represented a surprisingly low priority for those implementing green street projects. This low interest in maintenance can also affect public acceptance of a green street. Drainage and infiltration systems require constant care to deal with the public’s concerns and keep green street facilities running smoothly. A clearly needed change is to incorporate a maintenance plan into the design and construction stages for easier operation and improved public acceptance. Low maintenance strategies can also be incorporated and deciding on a principal agency for the maintenance could be helpful. Another approach, which has proved successful, is creating a plant palette that allows users to select the plants they would prefer to have near their homes. Public participation in maintenance has the benefit of securing residents’ interests in and

Figure 6. Examples of green street practice: 0. Green street on slope with planter type cascades; 1. Green street with wider sidewalk and seat wall; 2. Green street with wider sidewalk and landing space for street parking; 3. Green street with outdoor activity area in conjunction with sidewalk; 4. Green street with wider and leveled stormwater planter, access to the building, and diagonal parking space; 5. Green street with extended stormwater planter for traffic calming; 6. Green street with stormwater planter in median for safe crossing.
engagement with the projects in their neighborhoods.

4.7. Archive and Share Related Research and Knowledge by Conducting Post-Construction/Occupancy Evaluation and Monitoring

Green street is a relatively new strategy, with the oldest project in the United States (the SEA Street in Seattle) going back about seventeen years. Since green street practices typically include living plant materials, the techniques adopted need to consider the suitability of plant species and drainage systems in a given facility with particular living environment, site conditions, types of practices implemented, target pollutants, and users’ preferences. Thus, the techniques and knowledge are still in the development stage and it takes time for the system to fully function and be evaluated. Post-construction evaluation or monitoring was seldom mentioned by the experts throughout the interview responses. Post-construction monitoring and evaluations can contribute to the development of more advanced techniques and minimize the potential for mistakes and bad practices in future projects.

4.8. Develop and Provide an Appropriate Green Street-Oriented Process for Each Municipality based on the Derived Model Process in This Research

Planners and designers can use the model process (Figure 4) developed in this research as a checklist to ensure that the necessary protocols and resources are in place to maximize the additional benefits for successful green street implementation. The sub-stages that are listed under the four main stages in the model are collective elements, and planners and designers should choose the sub-stages that most closely match their local conditions and available resources at both the municipal and site levels. The provision of a process that has been tailored to suit the needs of a particular municipality and local community will contribute to the achievement of a successful green street project.

Green streets need to be considered as a complex strategy rather than a simple stormwater treatment solution. Green street oriented planning and design process can have the plan to include social and cultural contexts along with required design elements and site conditions for future resiliency of urban communities.

Abstract

The Three Bridges Square in Feixianguan Town of Lushan County is an important livelihood project in the “4.20 reconstruction after strong earthquake in Lushan”. Because of its special natural and cultural environment background, it bears the role as the door to “gateway” and it records the nature and humanities history of Lushan County. It has witnessed the responsibility in Lushan for someone who has supported the entire construction process after the disaster.

The project follows the important instructions of the country’s post-disaster reconstruction and the guiding principles of regional planning. It responds to the complex environmental issues like some bases covered by earthquake-hit areas, as well as to protect the ancient Tea Horse Road, the entrance to Tibet, the Red Army’s ancient bridges and 318 national highways in terms of four aspects: the planning and positioning, traffic organization, layout of function, and coordination of characteristics.

Through using of cantilevered platforms and expanding the use of beach land by reasonably using of terrain heights to ease the tense condition of land use. The design start with the actual needs of local people with considering local traditional activities and the materials and construction techniques to effectively resolve problems in local self-building.

Keywords: Earthquake aid construction; Post disaster planning; Square design; Local construction

Fund Items: National Natural Science Foundation of China (No. 51578173); National Natural Science Foundation of China (No. 51678180)

1. Introduction

On April 20, 2013, an earthquake with a surface wave magnitude of 7.0 occurred at the junction of Longmen Town, Baosheng Town and Taiping Town in Lushan County, Ya’an City, Sichuan Province (30.3°N latitude and 103.0°E longitude). The
maximum intensity of it was 9 degrees and the area affected by the disaster was about 18,682 square kilometers. There were 4045 aftershocks in the earthquake area and 1.52 million people were affected. The 4•20 Lushan M7.0 earthquake had caused huge losses to social economy and people’s property, immediately, the nation launched an emergency response plan after the disaster and spared no effort in emergency rescue and transitional resettlement, and quickly started the recovery and reconstruction of the area.

In order to meet requirements of the Party Central Committee of CPC, State Council and Sichuan Provincial Party Committee and Provincial Government's decision-making for post-earthquake recovery and reconstruction of the “4·20” Lushan earthquake, and in accordance with important instructions of Secretary Xi’s on May 2 in “Report of the CPC Sichuan Provincial Committee on the earthquake relief work of the "4.20" Lushan strong earthquake that are "Comprehensive and accurate assessment of disaster losses, obeying rule of the people-oriented, showing respect for nature, overall consideration, being based on the current, meeting long-term scientific reconstruction requirements, and starting the disaster recovery and reconstruction work as soon as possible", it should guarantee the restoration of post-disaster reconstruction in Lushan to be carried out scientifically, efficiently, and in an orderly manner. Making it sure to actively and steadily restores the normal life, production, study, and working conditions of the people in the disaster-stricken areas, and promotes the recovery and development of economic and social disasters in the disaster-stricken areas. The Three Bridges Square project is a key project for reconstruction work. The design follows the macro control of the entire disaster area and the overall control of the regional planning. "The construction of the post-disaster area is a process of reconstruction. In this process, Foresight and historicity in planning is equally important."

As an ancient city with a history of more than 2300 years, Lushan county is the only way for the ancient Sichuan Tibet tea horse road and the important node of the red culture in Sichuan Province. Feixian guan is the South Gate of Lushan, also, the first pass of Sichuan-Tibet. It has always been one of the goods and distribution center of the four major counties all around. Now, there is still a historical trace of prosperity.

The national highway 318, which was built after the reform and opening up, is known as China's most beautiful road. This road is still the main road to Tibet at present. Countless backpackers and cycling Team entering the Tibetan area through Feixianguan, Three Bridges Square is precisely built in this juncture, which is called "the first throat" on the Sichuan Tibet line.

The site is triangular shape (Figure 1). One side is facing the Xing Jing River and the Baoxing River, and the other two borders are connected Tianquan and Lushan country by the National Road and the provincial road, which occupy the place of the intersection of the traffic, and form the first stop for the relief and reconstruction.

Therefore, the environment in which the project is located is relatively complex and the design is faced with multiple challenges. Its concept is to integrate the expressive themes of the 4-20 earthquake disaster, in the meantime, it also needs to follow the macro
Future Resilience

ideas of the superior planning. In the implementation, the comprehensive consideration includes that the base is located in the ancient Tea Horse Road, the location of the road, the value of transportation to Tibet, the importance of the entrance of Feixianguan Town and other natural environmental issues, and the geographical characteristics of residential areas in northern Sichuan, historical values of the Red Army Bridge and the bridgehead, and other cultural and environmental issues like the use for the surrounding people and future tourists, and the specific response to regional planning guidelines and national instructions are also should be included.

2. Planning and positioning

As the leading unit in the post-disaster reconstruction, the China Regulation Institute was commissioned by the State Council to resident and design. In the master plan of Feixianguan Town, it proposed to integrate tourism development with sustainable development of the local economy and integrate urban and rural development and new rural construction. Through the effective allocation of space resources, the orderly arrangement of construction projects to deal well with the relationships among tourism development, urban construction, resettlement, environmental protection, tourist markets, community interests, cultural heritage, industry interaction, regional development, etc. Regarding 4A scenic spot as a standard, to conduct construction of a high-quality tourism area and to complete tourism infrastructure and improve adaptability, feasibility and persistence of supporting service facilities to lay a good foundation for the dynamic cycle of planning, construction, operation and management of Feixianyi area.

As an important spatial node leading the area, Three Bridges Square also occupies the largest flat open space in the planned field, and its opportunities and challenges coexist. It is necessary to "seek common ground" and follow the guidance and control of planning. It is also necessary to "reserve difference" to explore the way in which it balances the contradictions between multiple site elements and thus shoulder the value and mission of leading the region.
The commemorative nature of the plaza determines the image landmark and the particularity of the design. The Three Bridges Square is also an important junction for the planning of three important tourist routes: the regional cultural line, the traditional commercial leisure line and the sports ecological line, and strives to achieve "Livable, suitable for business, suitable for travel", closely follow the regional orientation of people's livelihood (Figure 2).

It will become an important part of the disaster area's revitalization of tourism development, business operations, and tourism service systems. Relying on the unique natural landscape environment and profound historical and cultural heritage to provide a good venue for the development of the district and it will be the main celebration platform for the festival in Lushan County. It will fully consider the actual situation of the disaster area and the needs of the people and effectively improve the urban and rural living environment. We must take into consideration the actual situation of the construction of the disaster area, the damage situation and the direction of development after the earthquake, and reasonably adjust the distribution of cities, towns, townships, villages, and infrastructure and productivity in the disaster area so as to make it highly historical, practical, and possible.

3. Traffic organization

The Three Bridges Square is located at the entrance of the main entrance to Tibet, the northeast side of it is the 210 Provincial Highway of the Tibet Autonomous Region, and the southeastern side of it is the 318 National Road. The base is close to the river and the roads get together and have close contact with the town. It is a rare flat area in the mountains, not a deep mountain, and most of the area is pastoral scenery. With convenient transportation and favorable
location, the special historical role of Feixianguan since ancient times will surely make it a gateway to Lushan's tourism development.

National Road 318 begins in Shanghai and ends at the Friendship Bridge in Tibet. It is currently the longest national road in China. It covers the plains, hills, basins and highland landscapes across China's eastern, central and western regions with covering the connotation of Water Village Jiangsu and Zhejiang, Tianfu Basin culture, and Tibetan cultural landscapes. It has various scenery changed from the Chengdu Plain to the Qinghai-Tibet Plateau all the way to the alpine valleys with the feeling of beauty, magnificence, grandeur, surprise, uniqueness and adventure, as a result of the described above, it is chosen as China's landscape avenue by China National Geographic magazine. Feixianguan is located at the beginning of the Sichuan-Tibet line and is the veritable Sichuan-Tibet key link. The Provincial Highway 210 starts in Feixianguan Town and connects the National Highway 318 to the domestic road section of National Highway 317 in Malang to north. It is the most convenient passage connecting Sichuan West and Sichuan Northwest. The national road can contact Ya'an City and road of the direction to Tianquan County, and the provincial road can contact Lushan County. Three Bridges Square has served as a key link to the lives of several important disaster areas.

Under the advantage of convenient transportation, and in line with the concept of “three lines interweave” in planning and positioning. The Three Bridges Square is not only an important node in the landscape organization mainline, but also core public open space in the ‘three interwoven theme line (Figure 3,4), include regional culture line, traditional commercial leisure line and fitness ecologic line.

As Feixianguan's entrance to the “facade”, the square takes river as the core to create a view of the river (Figure 5), creates a situation that relies on landscapes of mountains and water, shows a feeling in many paintings, and promotes regional tourism development. The use of subsidence in layers retreats to reduce traffic disruption to the site and enables people to get closer to the water surface (Figure 6).

At the same time, the reduced layout of the ground and the roof of the fold line will buffer and divert the surrounding traffic. The Plaza has no openings on the national road. Instead, as the entrance and ground parking
guidance are set on the side of the provincial highway, and a walking path connecting the market area is set down on the side along the river to form a circle around the road to achieve a the goal of a pleasant road with the separation of people and vehicles (Figure 7).

4. Layout of function

The regional is orientation of “livable, suitable for industry, and suitable for tourism”. Accompanying with the government's plan to guide the transfer of population and industries to the low-sensitivity counties, Feixianguan, and Qingren, hundreds of thousands of square meters around the site has been established. As a result, people's resettlement houses and bazaars with the color of western Sichuan have brought a strong atmosphere of life and secular culture to the mountains. As a traditional regional culture, the folk “market” activities are well preserved here twice a week. The site design of Three Bridges Square also needs to provide a large hard space for the market. The influx of a large number of people demands new functional requirements for the construction of Three Bridges Square (Figure 8).
However, there is a limited area of the site against to the large number of problems that need to be resolved. The site is bounded by the rolling mountains of the Lushan Mountains in the northeast, and is the Tsing Yi River in the southeast, the site is close to the 210 Provincial Highway and the 318 State Road.

Under the restrictions of national roads, provincial roads, rivers, and mountainous terrain, the land for restoration and construction is limited. It is also necessary to satisfy the functions of commemorative activities, life services, and tourism assistance, as well as to form a concentrated open space and shelter space such as the objective requirements, all of the design bears many pressures.

After comparing with multiple projects, the design has abandoned the concept of expression in the form of highlighting the commemorative significance, and instead chose to use life participation to interpret the value of commemorative ideas (Figure 9).

As Mr. Qi Kang believes, the memorial square is no longer a house considered to a dead person but a broader meaning, which embodies a kind of living monument to commemorate people and things; and it is not only a memorial land, but also a land for public activities.” so that the square is truly established for the public, used by the public.

The design breaks the limitation of land use with free form of asymmetrical, and pays attention to the use of terrain height difference to the full with adopting end-bearing piles to solve the defect of tidal flat geological conditions, then drives the supporting column into the rock formation below the mudflat, and uses the method of “waterproof coating to strengthen the waterproof of concrete column (Figure 10).

The water level is used as a benchmark to design a waterfront landscape wooden trestle and corridor, which will substantially increase the square area to 5,668 m², an increase of 30%. The full use of the original shoaled land plots to be included in the landscape plaza. Combining Feixianguan Bridge with the lakeside waterscape to make maximum expansion of site will alleviate the tension of site, and enable the Three Bridges Square to allow integrated services functions.
for sightseeing, recreation, and commemorative performances and the China Unicom corridor under the bridge also needs designing in the surrounding market area to supply the area of the regional market so as to give back the use of public open space to the people in the disaster area (Figure 10, 11).

5. Coordination of characteristics

Lushan County where Feixianguan is located is a famous hometown of Han Dynasty cultural relics. The cultural heritage of the Han Dynasty is abundant. Taking full advantage of the topography of Feixianguan to restore the intention of closing entrance of Feixianguan to create a "portal" landscape image. As an important spatial node of cultural tourism routes, combing its context of cultural Feixian, pavilions of Feixian, Erlang Temple, Wangmu palace control the architectural features of Three Bridges Square (Figure 12).

The architectural styling in the plaza draws lessons from the trend of the roofline of the Han Dynasty buildings and villages, and completes the space continuity that is based on the traditional western Sichuan style and makes the site integrate into the undulating background of the mountains (Figure 13).
The overall layout also uses the matrix of the fold line to introduce the landscape art of the mountain into the network system of the large local grid, forming a visual focus through the twisting and changing of the lines, organically combining the square with the building, and expressing the tremors of the earth and setting the image in an instant. Material selection conforms to the texture of the earth, mountains, rocks found in the surrounding environment of the site.

For the protection of historic buildings, the Red Army Bridge and its bridgehead, for the sake of its structural safety considering for its long-standing disrepair, closed exhibitions are adopted. Vegetation is used to close the roads around the bridgehead, and two selected viewing pavilions arranged around the center of the Red Army bridgehead are used to enjoy landscapes on bridge. The viewing pavilion is made up with the material of the Red Army Bridge. It is downhill from the ridge line, and the bamboo-wood slope roof is arranged to form trigonal prisms. The structures on both sides are raised upward to form a cornice. With regard to form intention, once again it metaphorizes the form of residential houses in western Sichuan with forming a viewing pavilion that integrates regional features (Figure 14).

Through this carrier, designers have integrated the relationship between the square and the cultural environment, and the commemoration of reality and history to provide the Red Army Bridge and its bridgehead with an infinitely expandable emotional space and enrich the space-time experience of the visitors.

Abstract

With the rapid development of urbanization, the number and the size of various types of brownfield in urban areas are increasing, and the disordered expansion of the urban brownfield has caused the waste of resources, the destruction of urban ecological environment, as well as the disordered development of the city. An analysis of this sort makes the garden show, which until now has been discussed only in the landscape of the exhibition itself, the green space system planning and the urban planning terms, accessible for the importance of renewal of the value of urban brownfield. Based on the analysis of the relationship between the garden shows of western countries represented by Germany after World War II as well as those of China, and the value renewal of urban brownfield, this paper summarizes the characteristics of garden show in the renewal of urban brownfield value, such as prospective, location, ecological and eventual, and accompanies with its restoration methods in order to provide references for holding garden show and achieving urban brownfield value renewal.

Key words: Urban Brownfield; Value Renewal; Garden Show; Regeneration

1. Introduction

Garden show is a kind of festival exhibition with the theme of garden or horticulture [1]. It was first held in Europe and often appeared as an accessory of a large-scale comprehensive exhibition in order to cater for the social development needs of Europe in the 18th century, which included advances in plant science, the establishment of related plant associations and increased public interest in plants. After World War II, the social economy of the European countries needed to be revived urgently, as a result, the garden construction began to flourish while the site selection and planning of the garden show began to be integrated into the urban development. It has played a positive role in promoting the social, economic and ecological levels of the host city and its surrounding areas, especially in providing ecosystem services to citizens through the renewal of urban brownfield values.

Based on the analysis of the relationship between the garden shows of western countries represented by Germany after World War II as well as those of China, and the value renewal of urban brownfield, this paper summarizes the characteristics of garden show in the renewal of urban brownfield value accompanied with its restoration methods in order to provide references for holding garden show and achieving urban brownfield value renewal as well as offering ecosystem services.
2. The value of urban brownfield

The term "brownfield" is a concept corresponding to the green space in planning terminology. A series of problems, such as idle land and environmental pollution caused by urban brownfield have had negative impact on urban economy, society and ecology, thus, the renewal of urban brownfield value has become the only way for the sustainable development of the city [2]. There are many values of urban brownfield, such as ecological value, social value, cultural value and so on. The ecological value of brownfield is based on environmental protection, which means if a large area of brownfield can be effectively managed, it can bring huge ecological benefits and provide ecological services to citizens. The social and cultural values of brownfield are produced as the development of human society to a certain stage, in fact it is the memory of development of a city. The reasonable exploitation and development of this kind of brownfield can shape the culture of the city. As a landscape medium for the renewal of urban brownfield value, garden show is of great significance to give full play to brownfield value.

3. Urban restoration experience of garden show based on the renewal of brownfield value

3.1. Germany

3.1.1. Rehabilitation of postwar urban debris

After World War II, western countries entered a post-industrial period. Due to the desire of improving the urban environment and making better use of urban land, most western cities began to work on post-war reconstruction during which landscaping was concentrated in urban areas so as to restore urban public space [3]. In this period, urban brownfield was dominated by postwar urban ruins. Thus, garden show is a medium for the renewal of the value of postwar ruins and brownfields which revived the land damaged by the war.

In 1951, Hanover held the first federal garden show in the history of German with the aim of restoring the ruins of cities by restoring the city parks that had been destroyed in the war in order to give the Germans courage to start a new start after World War II [4]. The following five federal garden shows also aimed at restoring or rebuilding the ruins of the postwar cities. During this period, the garden show took advantage of building new urban parks to repair the war caused urban brownfield.

3.1.2. Restoration of abandoned land at high speed of industrialization

With the rapid development of German industry after the war, natural resources and ecological environment were constantly destroyed. Since the 1980s, industrial landscape has no longer become a symbol of national strength of Germany. The rise of knowledge economy made the heavy industry become a representative of no competitiveness and pollution. After 1980, Germany, as the most conscious awakening of ecological protection country, became the pioneer of Europe and the whole world in the field of urban brownfield reforming [5], under which background, the federal garden show began to try to find a new way to solve the problem of urban brownfield pollution and gave play to the value of urban.
brownfield through landscape planning strategy so as to complete site ecological restoration and site ecological service value.

During the transition period of Ruhr District, a Germany's old industrial zone, there were several federal garden shows and several state garden shows held. In 1969, Dortmund hosted the 10th federal garden show, which was located at an abandoned iron ore plant and turned a manufacturing industrial brownfield into a long-term urban green space for local people. The 1997 Gelsenkirchen Garden Show used ecological means to retain some industrial structures on the site of the original mine site as a historical continuation and to transform them into the Nordstern Park so as to fully reflect the cultural value of industrial brownfield in urban. After the show, it served as a city open space to fully play the ecological service function.

In 1983, Munich obtained the right to host the garden show. The garden show was located on 60 hectares of abandoned land in the western part of the city, which was the development area of the city according to the general public concept space planning of the city designated by the city in 1965. However, there was no park in the densely populated residential area consisted of more than 200,000 people in the southwest of the city due to historical and geographical reasons. Thus, there was a more obvious demand of residents to build a green space [6] (Fig.1). The city's brownfield would be transformed into a green space, by taking the opportunity of holding garden show making up for the lack of public space in the western old city.

During this period, the garden show began to assume the function of improving the urban environment and promoting the development of the region. The site planning of the garden show had been restored from a single war wasteland to gradually developed into the restoration of urban manufacturing industrial brownfield restoring the original ecosystem of urban brownfield.

3.1.3. Restoration of multiple types of brownfield in the context of urban innovation

After 1990s, a large number of urban land using in the West faced the problem of transformation. The idea of sustainable development has gradually affected the urban renewal movement in western countries [7], during which period, garden show faced with various types of urban brownfield, and began to re-optimize, re-combine and reuse all kinds of urban brownfield resources in different ways to realize the urban economic and social re-development.
Due to the fact that urban brownfield had no longer been a single postwar wasteland or a manufacturing industrial brownfield, German garden show showed a diversified trend of development. One of the most important types of brownfield was the transformation of military bases. The 1995 Cottbus Garden Show, the 1999 Magdeburg Garden Show, and the 2001 Potsdam Garden Show all completed the revival of the urban military wastelands. In particular, the Potsdam Garden Show was the most typical, in which it selected a number of scattered lands in the city, mainly based on the military bases left behind by the Soviet Union after the withdrawal of troops, and integrated the broken urban green space, and re-create pedestrian streets, squares, parks and so on to achieve the perfect interpretation of the site ecological service function (Fig. 2). The 2005 Munich Garden Show realized the successful transition of the old airport site to the new urban district by constructing a green frame of the new district and forming a perfect regional ecosystem (Fig. 3). In the 21st century, garden show has not only realized the transformation of urban brownfield, but also taken this as an opportunity to fully tap the various values of various types of urban brownfields to give full play to the ecological service function of green space. (Tab. 1)

3.2. China

In recent years, all kinds of garden show in China have developed rapidly and the scales have been increased, which have gradually become the driving force of the development of the large or medium-sized cities and a new growth point of regional
only taken as a tourist attraction for the city to promote the development of the city. Since the 21st century, the types of urban brownfield have shown a trend of diversity. Garden show has also focused on the renewal of urban brownfield value and the improvement of urban ecosystem.

The 2011 Xi’an Garden Show was located in Xi’an Chanba New District. It focused on strengthening the ecological management of the Chanba River Basin in accordance with the development idea of "River treatment drives regional development and development of the new area supports ecological construction", which solved three ecological disasters of garbage siege, illegal sand mining and river pollution in the Chanba River Basin. After the show, it became an important part of green barrier of Chanba New District. The 2015 Wuhan Garden Show directly selected the base site at the Jinshan Landfill. The garden show restored the landfill site and protected the garden site, while at the same time, it used the garden show to realize the intensive utilization of regional land resources and turned the brownfield into a park establishing the blend of environmental ecology and social and people. The 2009 Jinan Garden Show, the 2013 Beijing Garden Show, and the 2016 Tangshan Garden Show were all hold on different types of urban brownfield sites, which endowed the city with new vitality by taking the garden show as the medium. (Tab.2)

4. The characteristics of garden show based on the renewal of brownfield value

4.1. Ecology of landscape renewal

Due to the serious pollution on most urban brownfield, ecological restoration must be the first task of urban brownfield value renewal, which determines the ecological properties of garden show. First of all, in the early stage of the garden show, the ecological restoration and vegetation community establishment are carried out by reusing and disposing the waste resources of various kinds of abandoned land in the city in order to realize the self-repairing function of the site. Secondly, the garden show often leaves high quality green space, which can effectively adjust the urban greening structure and reconstruct the urban public space system as well as to perfect the city green corridor and ecological network. It provides comfortable space for people to spent their leisure time and enjoy entertainment while also provides habitat for all kinds of small animals in the city.

4.2. Place for spatial design

Urban brownfield is used to be a relic of land in a certain era carrying the memory of people and being a carrier of the historical relics of the city. In the process of planning and designing of the garden show, the elements of the past are often preserved and modified through careful design to create a new and old fusion of the landscape in order to enable people to feel the history and memory of the site itself and allow visitors to read the history of the venue. Taking the garden shows as the planning tools to renew value of the urban brownfield make the city
itself become the carrier of history and a book to be read. The public development of the renewal of urban brownfield value through garden show can not only create the space for the city, but also create public place for the city, and form the sense of place and identity of the citizen while bringing new vitality to the declining urban space.

4.3. Eventuality and sociality of the exhibitions

Garden show is conducive to mobilize all aspects of resources and initiative as a short period of horticultural urban events, during which some large-scale urban construction projects can be completed which, otherwise, are not able to be finished by conventional policy means [9]. It has a certain degree of sociality which means it force people to pay more attention to the development of the community because of the extensive attention and participation of the exhibition. After the exhibition, people would like to pay attention to the future of social public activities. Thus, it not only provides a popular leisure space for the dull urban life, but also completes the transformation of the urban land nature by perfecting the ecosystem structure, which promotes the development of the surrounding areas so as to attracting investment, increasing employment, and improving social stability.

4.4. Forward-looking development strategies

The garden show can combine its own development with the urban development strategy [7], especially for the long-term consideration of the location of the garden show and the regional development after the show because of its large-scale, and the comprehensive social benefits, intensive attention and influence it brings. The grand event of garden show is combined with the renewal of urban brownfield value and the development of the city. First of all, the government analyzes the present situation of urban brownfield combining the urban development strategy to take the garden show as the prelude of renewal of urban brownfield so as to formulate the complete site development strategy and operation mode. For example, the balanced development of the locality and integrity of the new and old city should be payed great attention to and we should purposefully use the old urban area to create new public space when choose the location of garden show [10]. Secondly, after the garden show, the site will be transformed into the specific urban space to be integrated into the urban development strategy according to the scientific space development and renewal plan made by the city.

5. The restoration mode of garden show on the renewal of urban brownfield value

5.1. Urban public space restoration model

In the case of using garden show to realize the value of urban brownfield, the restoration mode of urban public space is the most commonly adopted, i.e., in all kinds of urban brownfield base sites, the treatment of site pollution is realized by means of ecological restoration, and the planning and design strategy of landscape architecture is adopted to form a vibrant public space.
With the change of urban development model from incremental development to stock renewal, there is a serious phenomenon caused by "the law of the jungle" in the limited space of the city, especially of the public space proportion which is decreasing instead of rising, and the scale is being compressed constantly. Therefore, garden show often changes the use of urban brownfield in the form of parks and green space, which naturally becomes an effective way to solve the shortage of urban land resources and ecological space in the process of renewal of urban brownfield value. Nowadays, this mode of restoration is becoming more and more common, especially in cities where contaminated land consisting of old docks, ports, landfills and other renewable urban brownfield are being helped by the garden show\footnote{[11]}. Construction of urban green corridor, urban parks and outdoor entertainment venues provides citizens with a variety of urban public space, which gives full play to the ecological services function of urban brownfield.

5.2. **Compound land tenure restoration model**

The restoration model of different land titles, such as residential and commerce, is mostly adopted for the brownfield located in urban core areas with relatively completed infrastructure in the surrounding areas, or for brownfield that is renewed to promote the construction of new urban areas. This model has a significant impact on attracting investment and increasing tax and fiscal revenues, as well as promoting economic development. However, because residential areas and commercial districts need a ecological environment, the comprehensive restoration model combined with residential and commerce can only choose the less polluted urban brownfield to develop and construct\footnote{[12]}, or choose the site where the ecological restoration by degrading the pollution material has been carried out before the garden show. For example, the 2005 Munich Garden Show was held at the site of the less polluting new airport in the Riem New District, after which 2/3 of the land was used for residential and commercial purposes.

5.3. **Combination of "top-down" and "bottom-up" modes of repair through show operations**

The garden show, as a means of updating the value of the urban brownfield, is run in a "top-down" manner under the leadership of relevant government departments or institutions at all levels considering the initiation of the garden show, the establishment of the related organizations and the important sources of funds in the early stage. However, the implementation and operation of each sub-project in the garden show is promoted in a "bottom-up" manner, which means it is not entirely implemented by the government's blueprint\footnote{[13]}. The implementing plans or designs of some sub-projects are selected through the project competition of landscape, which is gradually implemented through the "bottom-up" model including public participation consisting of designers, citizens, government, and so on. Encouraging people to participate in the planning of the garden show with the greatest enthusiasm indirectly realizes the renewal of the value of urban brownfield.
This combination of "top-down" and "bottom-up" repair models allows a larger number of actors to be involved from the outset which includes governments, regulators in the planning phase and the developers, stakeholders in the stage of development and construction as well as the citizens in the use phase, and etc. This model can fully play the role of multidisciplinary coordination and public participation in the implementing process of garden show so that the public, governments, developers and other roles can benefit from it, which is a win-win process.

6. Conclusion

Since the development of the modern garden show, it has been more than 60 years, during which the planning strategy of the western garden show in the renewal of urban brownfield value has been changed from a single strategy of war abandoned land transformation to become a complex and diverse planning and development strategy dealing with various types of urban brownfield, and a relatively complete development model has been formed which includes the before, during and after stage of show. In this way, I hope to learn from the valuable experience of holding garden shows of different countries and cities in order to closely combine the planning and design of garden show with the renewal of urban brownfield and the provision of ecosystem services by exploring the development mode and restoration mode of garden show under different conditions.

b School of landscape architecture, Beijing forestry university. 35#Tsinghua Eastern road, 100083, haidian district, Beijing, China

Abstract

Urban development are faced with many problems, such as the lack of the pressure of grain production, high unemployment, etc, which prompted people spontaneously in the community in the messy "exclusive" in the rapid development of urbanization whose planning and management experience are not mature enough. The urban fabric of many North American cities has been radically altered over the past few decades, and a combination of dispersed settlement patterns, decentralized and abandoned urban cores, economic downturns, political shifts, rapid suburbanization, and deindustrialization have led to large inventories of vacant land. The issue of urban vacancies, and the processes that created them, has been well documented in such seminal work as Stalking Detroit and Shrinking Cities. Much of this vacant land is now contaminated or in various states of decay and dis-use; the time is ripe for innovative reclamation efforts. Today, Philadelphia has one of the highest per capita vacancy rates in the country. Through the method, engagement of critical resources and business models, and community input, such production can become an integral component of a neighborhood environmental system of green infrastructure that includes stormwater management, bicycle and pedestrian circulation, soil production and composting operations, along with recreational programming. The project in the black community of Philadelphia builds on past efforts of city agencies and organizations to advance conceptual ideas to a prototype tree production operation. It will allow testing of species and growing methods to ascertain suitability, allow refinement of spatial requirements, generate research data on efficacy, and provide a laboratory for the development of a long term maintenance and management strategy.

Keywords: suburban landscape; therapeutic landscape; garden health; landscape architecture
1. Introduction

Populations around the world are growing and becoming predominately urban, fueling the need to re-examine how urban spaces are developed and urban inhabitants are fed. One remedy that is increasingly being considered as a solution to inadequate food access in cities, is urban agriculture. As a practice, urban agriculture is beneficial in both post-industrial and developing cities because it touches on the three pillars of sustainability: economics, society, and the environment. Historically, as well as currently, economic and food security are two of the most common reasons for participation in urban agriculture. Urban agriculture not only provides a source of healthful sustenance that might otherwise be lacking, it can also contribute to a household's income, offset food expenditures, and create jobs.

A garden or communal farm is a place where people come together for mutual benefit, often enhancing the common social and cultural identity for city residents. Larger urban farms also participate in community enrichment through job training and other educational programmes, many of which benefit underserved populations. Finally, urban agriculture can play an important role in the environmental sustainability of a city. As a form of green infrastructure, urban farms and community food gardens help reduce urban heat island effects, mitigate urban stormwater impacts and lower the energy embodied in food transportation[1].

Urban communities can form farms of extensive-metropolitan region in transition areas between cities and suburbs. During this period, entrepreneurial farmers are connected to urban consumers through direct market which includes farmers’ voluntary markets.

2. Transformation of the wasteland in West Philadelphia Black Community

As Philadelphia continues to grow into a world-class city, the issue of urban blight must be addressed. Pocked with thousands of vacant lots, the city was faced with a unique opportunity to turn concrete deserts into inner-city oases. The urban fabric of many North American cities has been radically altered over the past few decades, and a combination of dispersed settlement patterns, decentralized and abandoned urban cores, economic downturns, political shifts, rapid suburbanization, and deindustrialization have led to large inventories of vacant land. The issue of urban vacancies, and the processes that created them, has been well documented in such seminal work as Stalking Detroit and Shrinking Cities. Much of this vacant land is now contaminated or in various states of decay and dis-use; the time is ripe for innovative reclamation efforts. The economic realities of urban reclamation strongly suggests that today’s solutions must be resilient and phased over time; the cost of regenerating vast acreages of potentially toxic land and the public’s desire to see immediate progress indicates that interventions must be carefully crafted, embraced by the public, and cost-effective.

As an urban land use activity, agriculture presents itself as oddly out of place. It seems wholly “incompatible” with the management of space under the rule of the commodity form in the global city with its astronomical “ground rents” and inflationary, even speculative, real estate markets. Urban
community gardens embody a pattern of resistant use and the re-codifying of space wherein local neighborhoods assert control of places for communal uses that lie outside the purview or control of the market. These gardens are thus heterotopias in the making. The project of this paper was selected in the west Philadelphia black community and west fairmont park, surrounded by low-income, low-wage and high-vacancy communities. However, the community is adjacent to large public spaces, and there is a huge space for development.

2.1. Analysis of the status quo of the vacant communities.

The community is a representative black community in west Philadelphia, as the number of African americans in the west park is 73.7 percent, and the age of the population is mainly concentrated in the young adults, who are between 20 and 44 years old, accounting for about 36 percent of the population.

The low employment rate has led to a lack of vitality in the community and the accumulation of a large number of unemployed black youth, which result in few immigrants moving into west Philadelphia. Throughout the western garden area gradually appeared the vacancy area and the high altitude area. Without interference, it will lead to higher vacancy rates and a larger area of the upper air. Most of the family income is between $40 and $50, which is in low income groups in the United States. So how to increase the income of local residents, how to raise the employment rate and how to reduce People’s Daily expenses is the focus of the project.

The dismantling of empty and abandoned buildings costs about $15.5 million a year for government funds, and they have lost taxes on these wasteland, which often exceeds the value of the wasteland itself. These wasteland will bring tax economic losses and security threats to the surrounding communities. The landowners around the wasteland are likely to give up the house because of the security factors and the poor commercial interests, which leads to a vicious circle around the wasteland. The present situation of the site is mainly the trash left behind by buildings, mostly for abandoned brick, gravel, sandy soil and so on, covering a small amount of vegetation, and there are remaining trees on the edge.

2.2. The implementation of urban agriculture strategy for vacant community.

Urban Arboreta’s hybrid design will increase storm water absorption, improve air quality, and add value to the community. Community farms intends to establish a template for possible replication. Primary goals will focus on building and sustaining nurseries that grow and sell product to the City of Philadelphia, other municipalities, and commercial or residential developers. The site will be designed to include public space and support education and job training programs to support the community. Initially funded by the Knight Foundation, Community farms will seek additional funding from foundations and philanthropic donations for ensuring sustainability and future expansion of the project.

As such, Urban Arboreta in the community farm aims to satisfy a “triple bottom line” of proving economically sustainable, while also...
improving the environment and increasing community engagement.

1. Economics

Community farm must be financially sustainable. Sale of trees and shrubs must meet the primary objective of economic viability, such that revenue from the urban tree nursery allows for self-sustainability. Successful business operations will serve as proof of concept of replication of Urban Arboreta throughout Philadelphia.

2. Environment

Partnership with the Philadelphia Water Department will mitigate overuse of the city’s drainage and sewer system by employing the development of community farm to increase storm water runoff management. Riparian buffer product grown and sold by Urban Arboreta will enhance watershed health, while the transformation of a formerly-impermeable lot into fully-permeable nursery grounds will aid in ground-level water absorption.

3. Community

Community farm will truly thrive with the addition of community buy-in and a sense of ownership from the surrounding neighborhood. Citizens will play, learn, and volunteer. Economic multipliers include shared green space, improved municipal environment, and potential partnerships with schools and other civic groups.

Community farms are mostly small green spaces within five acres, and the two community gardens are designed to include agricultural landscapes and nursery for urban arboreta. Considering the economic factors, the design must be carefully calculated landscape scale, the scale is not confined to irrigation, compost and soil, fertilizer production, planting media mixing and storage and other material storage, services, and security.

The research and design for the community green space system in this area which is the research template will meet the community production standards and coincide with the vision created by the community landscape. City agencies and schools work together to construct a community farm that will provide a nursery management technology of on-the-job training and the skills can solve some problems of employment, support the public services.

2.3. The vision of the community garden

The vision of the community garden is the function of "production" and "transaction" in community farms and community seedling bases through the improvement of the environment and the regional economic circulation of the community. Both of them are based on "expansion and construction-stage economic cycle-economic output". Community gardens gradually gain better returns through low investment, and gradually scale up until they are planned. The operation of agricultural landscape in social garden is mostly family business model. Seedling and management are hard physical labor, but also a way of life for staff. The winter nursery works mostly for sale, mass transfer and preparation for the growth of spring trees.
The "farming symbiosis model" of community farm application is a sustainable green food production system, combined with aquaculture (farmed fish, chicken) and hydroponics (the cultivation of non-native plants).

2.4. The establishment of the community farms.

Community farm in the community garden and plant nursery base will meet some of green plant needs in the city and daily vegetable supply for residents in the community as well as providing professional training in nursery production technology and improving the quality of urban environment so as to create a positive open space for residents.

In the gardens, four plastic sheds that can be grown and nurtured in the community and "Bare-root tree planting area" and "rapid potted planting area" of different plants were designed here in the context of taking into account the problem of uneven rainfall in Philadelphia and combining rainwater harvesting and respecting the status quo. Nurseries and crops grown in the garden are sold on community farms and proceeds will be used for garden expansion and maintenance. Seedling methods include container seedling, ground plant and pot-in-pot. The container has the advantages of simple operation, convenience and removable, which is conducive to transplanting and retailing.

Having established the most suitable growing methods, as well as outlining potential peers and competitors in the nursery market, this report next addresses the potential for customers. In general, three customer segments are identified, which include strategic partnerships with city agencies, obtaining status as a preferred vendor, and directly servicing local business and consumers. The bidding process for obtaining a landscaping contract with the city of Philadelphia is first addressed, with further insight on partnering with existing contractors in a subcontractor relationship to provide nursery stock for ongoing projects. A strong emphasis then focuses on Philadelphia Water Department’s Rain Check program, which subsidizes small business’ efforts to simultaneously green their premises while also improving storm water runoff management. This initiative may serve as a key driver of sales, as Urban Arboreta can both provide riparian buffer stock directly to customers, as well as potentially consult with consumers on how best to develop their land for storm water runoff management. Finally, a comprehensive list of shared riparian buffer species recently purchased by both Philadelphia Water Department and the Department of Parks.
The south side garden of the community is based on farm seedling base and aquaculture where are mainly planting bed, fish pond, chicken house, home vegetable plot, bare-root tree planting area, export exhibition venue and central plaza. Both community gardens are designed with soil fertility ponds and septic tanks to improve the soil environment. Community garden plants choose local plants and drought-resistant perennial herbs, as well as common fruits and vegetables.

2.5. The operation of the community farms.

The Philadelphia rain flood division (PWD) partnered with the Penn state horticultural society (PHS) would help the Philadelphia neighborhood reduce the stress of the rain and the project's rainwater management has free fund support. The beneficiaries of rainwater management devices and measures are local residents, customer groups of community gardens and local contractors. By selling seedlings and vegetables, community gardens can help achieve the goal of rainwater management in Philadelphia and reduce runoff.

It is necessary to take into account the plant seedling of different size containers (from 1 gallon to the size of suitable planting device). The nursery water is often used for running water, and there are lakes and rivers and other surface water. Small-scale nurseries use public water, and rainwater is collected from the roof of the nursery to help with irrigation. Community gardens are operating throughout the year, however, there is a great demand for rain flood facilities especially in spring and summer.

Considering the mostly perennial seedlings, the existence of potential risks of the project: First, the influence of customers on seasonal demand of seedlings and vegetables; Second, the time period for community gardens to provide plant and food materials to contractors or residents, which are not conducive to profitability.

Farming symbiosis can help improve the supply of communities with limited food sources because of the low food prices, organic, and mostly local production.

It has the potential to completely change the way that the food source in the city. The new mode of production transforms the gray space of community green site into production space so that can bring income to the family and integrate into the urban environment more easily.[3]

“The garden is the smallest parcel of the world and then it is the totality of the world,” wrote Foucault. The community garden is a small parcel of agricultural land in the urban behemoth that is the Greater West Philadelphia region. Each huerto familiar at West is a site for the reconstruction of the gardeners’ sense of place. This involves simple acts of auto topography in which they etch a story with elements drawn from the home world, the very plants and landscaping practices that allow them to produce a familiarized space. The survival of these heterotopias must confront the totality posed by its opposite – the commodity-form ever yearning to usurp and fetishize space as a merchantable good destined for consumption as fodder in the expansion of the neoliberal grid city.
3. The role of national policies and social guidance in the operation of community farms.

3.1. The role of national policies and social guidance for urban agriculture.

In metropolitan areas throughout North America, long characterized by sprawling residential suburbs and more densely developed city centres, there is a growing interest in urban agriculture. Some cities, such as Portland, Oregon and Vancouver, British Columbia, support local farming that provides a growing supply of fresh produce to residents. Some older industrial cities with large amounts of vacant land, such as Detroit, have a few vibrant local growing projects and many ambitious plans for large-scale production on the vacant land resulting from decades of housing abandonment[4]. Many cities have had active associations of community gardeners, some of whom produce food for local consumption[5]. The Growing Power project, which began in Milwaukee, Wisconsin, has become a prominent model for expanding production beyond the scale of the typical community garden[6-7].

Agriculture is in the basic position. The national policy mainly promotes the smooth progress of various industries by law and regulation and supervision mechanism. As a branch of the urbanization development of traditional agriculture, the agriculture landscape can’t be separated from the government’s policy guidance and a benign government examination system. For example, Since the hairstyle urban agriculture action plan of Toronto, many urban agriculture projects have appeared in Toronto. These projects are located in the open space, on the roof and in the yard of the school, and become the means of building and strengthening the community[8].

Secondly, the implementation of a new thing is inseparable from the concern and influence from the society. Germany has taken four new short films, "green dawn" for urban gardens, spreading urban gardening and its social and cultural activities in different dimensions: Urban Agriculture in the Princess Garden in Berlin; a community farm as a starting point for urban development; a Turkey teenager cooked in a cultural garden in the green park; guerrilla. The moving "Rose" in the garden[9]. The intervention of education, the construction of demonstration projects and the commercialization of edible landscapes can make more people understand the multi-dimensional role of landscape architecture, and realize that urban and agricultural production can coexist harmoniously.

3.2. The principle of creating edible landscape in community.

Proper planning guidelines indicate that when designating an area as suitable, that knowledge of past site history, existing soil properties and distance from possible nearby sources of pollution, especially traffic, be taken into account in order to prevent crop contamination. Similarly, the overuse of chemicals needs to be prevented[10]. Exceedingly high heavy metal concentrations in urban grown fruits and vegetables must be strictly related to specific safe zones in the city where plants are going to be grown. [11]As such, when plants are cultivated near pollution-emission sources, risks of heavy metal contamination are increased approximately 1.5-fold when fruits and
vegetables are grown 10 m from the road as compared to 60 m. [12]. Examples of more effective governance instruments and experiences are also needed to better identify successful approaches for integrating city-based food production into urban sector policies and urban land use planning instruments, and to facilitate the development of safe and sustainable urban agriculture[13].

Future research should also address the application of climate-smart agriculture practices for the design, planning, and management of urban GI and NBS to mitigate climate change effects, increase food security, and provide sustainability-based guidelines[14].

Abstract

With the development of the urbanization process, the urban water system has been seriously damaged and sensitive. The combining of water environment and water landscape is an important task to be considered of urban river landscape planning. This paper constructs the evaluation index system of urban river landscape. The weights of each index layer is determined by Analytic Hierarchy Process (AHP), and also constructed by distance index method. Taking Pan Long River as an example, the evaluation model was used to evaluate the landscape environment of the PanLong River. The AHP method combines quantitative evaluation with qualitative evaluation, which has certain guidance to the landscape environment planning of urban water system.

Keywords: Analytic Hierarchy Process; urban water systems; landscape; evaluation

1. Introduction

With the development of urbanization, urban water ecology is seriously damaged, and the contradiction between urbanization water ecology is increasingly prominent. [1] Most of the river water quality in the city is polluted, and the biological diversity is gradually decreasing. The river landscape is facing many ecological problems. It is an important method to solve the river ecological problems and improve the landscape effect by combining the ecological restoration method of water body with the urban river landscape construction process, which can also promote the restoration of the river ecological system to a benign state.

In 2017, the Ministry of Housing and Urban -Rural Development issued the guidelines on strengthening ecological restoration of urban remediation, which called for “restoration of urban ecology, improvement of ecological functions, restoration of urban functions and improvement of environmental quality”. This document has become a good opportunity to restore the urban river landscape ecology. Since then, many cities began river landscape planning and construction, but most of its landscape planning did not pay attention to the restoration of water ecology, the effect is not much different from the past. [2] The river landscape planning and construction in most cities is only based on aesthetic and cultural needs, and has not effectively restored the river ecology or solved the water problems. This paper attempts to explore the specific
methods of river landscape planning from the perspective of the relationship between river landscape planning and construction and urban and ecological restoration.

River landscape construction based on water ecological restoration has important ecological significance. This is conducive to balancing the relationship between water resources and human activities, improving the ecological environment, perfecting the urban functions and enhancing the quality of the landscape. At present, the river landscape design based on water ecological restoration has not been studied deeply in China. Due to the large number of rivers in China, the urbanization process of most cities shows the urgent need to restore water ecology. This research has made some progress in plant landscape planning and green infrastructure. Most of these studies start from the perspective of ecological restoration technology, and rarely involve the planning steps and methods of river landscape based on water ecological restoration. Based on this, this paper will describe the methods, steps and connotation of river landscape planning through comprehensive water environment management and the expression of characteristic landscape.

2. Methods

2.1. Research Object

Panlong River is located in Kunming, central Yunnan province, with a total length of 26km, a widest point of 56m, a narrowest point of 19.2m, and an average width of 30m. Panlong River’s upstream is the Muyang River, which originated from Baisha Slope, west Liang Wang Mountain, northwest Songming county. It wounds from south Huangshiyian into Guandu district Xiaohe town. Panlong River originates from Songhua dam and ends in Dianchi Lake. In the master plan of Kunming city (2011 - 2020), Panlong River is planned as "a main river to meet the basic flood control and drainage of the city; a gorgeous landscape link that highlights the charm of the city and inherits the river water culture; an important ecological corridor to maintain the ecological safety of urban landscape". Panlong River wounds through villages, suburbs and cities. Both sides of the river are rich in natural and human resources.

2.2. Data

Landscape hydrology evaluation is the basis of water ecological restoration planning. In the early planning stage, the study group sampled and evaluated the hydrological data of Panlong River, and AHP and distance index were applied to evaluate the landscape environment of Panlong River. From the source of Songhua Dam in Panlong River to the entrance of Dian Lake, the study group collected and analyzed the water samples and evaluated the surrounding landscape environment. The total number of collection points was 84. Evaluation factors include water quality, plant coverage, water fluidity, flood control effect, public space quality, region, landscape accessibility, greening quality, surrounding building quality, etc. The water quality, plant coverage, flood control effect can query the objective data. The other indicators are determined by expert scoring. The
observation points of the upper, middle and lower sections of Panlong River were recorded by the study group. In this paper, 40 landscape architecture undergraduates and postgraduates were invited to evaluate the water landscape, and 60 local residents and tourists were randomly interviewed to evaluate the observation points. There were 100 participants in this study, 98 of whom completed the questionnaire and submitted the results. The age range of effective participants in the study was 16 to 67 years, with a ratio of 1: 1.16 for men and women.

The reasons for the selection of the personnel involved in the investigation: 1) the participation of relevant professionals is conducive to improving the rationality of the evaluation results. Landscape architecture students have certain space perception ability and professional quality. By participating in the basic investigation of river landscape, they can objectively evaluate the water landscape. 2) The local residents and tourists feel more intuitive water landscape, reflecting the real needs of users and participants. To sum up, this paper chooses the method of landscape evaluation by combining professionals with residents and tourists in the site, which provides favorable support for water ecological restoration planning. Analytic hierarchy process weight set questionnaire by the relevant professional professors and engineers to score. The effective part is 15 parts. The evaluation matrix was constructed with 15 valid questionnaires.

2.3. Planning Procedure

2.3.1 Survey

Field investigation and data collection are the basis of water landscape planning. The depth and breadth of the investigation directly affect the follow-up evaluation of river landscape elements, the progress and development of landscape planning. The main contents of the survey include water ecological environment, socio-economic environment, landscape quality and so on. The water ecological environment aspect mainly includes water quality, vegetation coverage and water fluidity. Socio-economic mainly include flood control effect, public space quality, regional cultural characteristics. The aesthetic aspect mainly includes traffic accessibility, afforestation quality, surrounding building quality, etc. In the process of field investigation, it should be combined with the river landscape situation and development direction and characteristics to adjust the survey content.

2.3.2 Evaluation Index System

In order to select the key river water restoration areas according to the river water situation, the study group needs to carry out river ecological restoration layout planning. Urban river landscape has three important characteristics: ecological environment, social economy and aesthetics. River landscape evaluation can be divided into three layers: target layer, criterion layer and index layer. The study group should establish a set of evaluation index system: river landscape evaluation as the target layer; ecological
environment index, socio-economic and aesthetic indicators as the standard layer; water quality, plant coverage, water fluidity, flood control effect, public space, regional cultural characteristics, traffic accessibility, greening and surrounding buildings as the index layer. The evaluation index system is shown in table 1.

2.3.3 Evaluation

This paper uses AHP to determine the weight of the index system and evaluate the index of single river course.

The indexes of each layer in the index system can be compared with the indexes of the previous layer in turn, and finally the judgment matrix is established. For the criterion layer, the importance of ecological environment, economic society and aesthetic value is \( f_1 : f_2 : f_3 = 6.3 : 2.3 : 1.4 \). In the eco-environmental criterion layer, the importance of water quality index is slightly greater than that of plant coverage rate and water fluidity index \( f_{11} : f_{12} : f_{13} = 4 : 3 : 3 \) in the socio-economic criterion layer, public space and flood control effect index is greater than that of historical and cultural protection index \( f_{21} : f_{22} : f_{23} = 4 : 5 : 1 \). In the aesthetic criterion layer, afforestation, landscape accessibility and the importance of surrounding building indicators are relatively equal \( f_{31} : f_{32} : f_{33} = 3.5 : 3.7 : 2.9 \). According to these, the judgment matrix can be established on the premise of consistency check. The calculated weights are shown in the following table:

Taking Panlong River as an example, the landscape environment of the upper, middle and lower reaches of Panlong River was evaluated by using AHP and distance index method. A questionnaire was created according to the AHP method. The weight setting questionnaire was graded by landscape professors. The effective part is 15 parts. An evaluation matrix was created using 15 valid questionnaires. Because the AHP is used, it is necessary to check the consistency of the calculation results. Through the test and calculation, 15 valid experts questionnaire through consistency test calculation, the result is Cr < 0.1. Therefore, the judgment matrix finally meets the requirements of consistency test, and the obtained weights conform to the scientific law. To sum up, the evaluation index system of Panlong River landscape with weight is as shown in table 3:

Secondly, in order to eliminate the problem that the dimension of each evaluation index in the evaluation index system is inconsistent and cannot be directly compared, the standardization treatment is carried out on each index in the index system. The standard value range after the evaluation index standardization is Water quality, plant coverage, water fluidity, flood control effect, public space, regional cultural characteristics, traffic accessibility, afforestation and surrounding buildings and other index layer ideal value is determined as follows:

(1) Water quality indicators. Urban river water quality target is the third level of water, so its ideal value is third level. By obtaining the river water quality monitoring data, if it meets the third level standard, then it is 1, otherwise it's 0. [8]

(2) Plant coverage indicators. A plant coverage rate of 80% is ideal. The ratio of
the coverage rate of the river plant to the ideal value is the standard value.

(3) Water fluidity. The flow velocity of water body is fast, smooth, and the change is not single, so it is an ideal state. Scores are determined by expert scoring.\(^9\)

(4) Flood control standards. If the flood control standard can reach 50 years, then it is ideal.

(5) Public space. The ideal state is to have a variety of green space park, and public space can fully integrate the humanities and natural ecological landscape. Scores are determined by expert scoring.

(6) Historic buildings. The ideal state is to preserve historical buildings well and to highlight regional characteristics. The score is determined by expert scoring.

(7) Accessibility. Ideal state is that the traffic is convenient with three-dimensional multiple lanes and sidewalks.

(8) Afforestation. The ideal state is to establish a tree - shrub - vegetation complex plant community, as well as reasonable and beautiful type of trees and flowers. Scores are determined by expert scoring.

(9) Surrounding buildings. The ideal state is the building along the coast and river scale coordination, height is appropriate, facade effect is good. Scores are determined by expert scoring.

Thirdly, distance index and analytic hierarchy process is used to evaluate.\(^9\) The distance scores are within the range of \([0,1]\). When the distance score approaches 0, the system evaluation is not ideal. When the distance index score approaches 1, the system evaluation is ideal. The corresponding relationship between distance score and river landscape evaluation is: less than 0 ~ 0.25 for poor, 0.25 ~ 0.5 for general, 0.5 ~ 0.75 for good, more than 0.75 for good.

Lastly, by distance index method, experts grade the specific evaluation factors in each index layer and calculate the results.

### 3. Results

Taking the water restoration planning of Panlong River as an example, 25 undergraduate students majoring in landscape architecture in senior year were invited as survey objects, and the specific evaluation factors in each index layer in the upper segment of Panlong River were scored, and the calculation results were obtained by distance index method. The distance indices are in the \([0,1]\) range. The corresponding relationship between distance index and landscape evaluation of Panlong River is as follows: less than 0 ~ 0.25 for poor, 0.25 ~ 0.5 for general, 0.5 ~ 0.75 for good, and more than 0.75 for excellent.

The upper, middle and lower sections of Panlong River are evaluated. The upper part of Panlong River begins at Songhua dam and reaches the access point of water diversion and drinking water. It is about 2.21 km long and its average width is about 30m. The construction density around the upper reaches of Panlong River is small, and the nature of land is mainly unused. Therefore, the human activities in this section have little impact on Panlong River. The natural landscape of this section is rich, the hydrophilicity and accessibility of the embankment are high, and the balance of water quality and ecosystem is the greatest among the three parts.

Through calculation, the distance index score of the upper segment of Panlong River
is 0.94, which is excellent. Socio-economic and aesthetic indicators score of 0.45 and 0.44, respectively, generally. The overall greening is original with a high sealing degree and a dull space. Water quality is up to class II water standard and the water flow rate is fast. Landscape activities on both sides of the facilities are not unified whose use efficiency is low. In terms of landscape quality, revetment form is single without motor vehicle lanes on the east coast. There are no bike lanes or system of traffic on both sides of the east and west. The middle section of Panlong River begins at the second north ring road to the second south ring road, with a length of 6960 meters and an average width of 30 meters. The surrounding land mainly is for residential, commercial, educational use. It flows through the most prosperous central area of Kunming, and is also the area where historical and cultural resources are concentrated. A bronze cow sculpture with long history also stands on the edge of the river.

The distance index of ecological environment in the middle part of Panlong River was 0.72, which was excellent. The scores of socio-economic and aesthetic indicators were 0.68 and 0.55, respectively, which was general. The afforestation rate of the middle riverside is higher with trees growing well. The urban space is lack of organic connection with the river. There are a certain amount of public service facilities, and there is insufficient display space for historical context inheritance. Revetment form here is single but the rail style varies. This section of the traffic flow is large and chaotic. On both sides of the riverside road, the transportation of people and car is mixed. There is no link between walking road and waterfront space. Panlong River’s low section begins at the south around the city high-speed to Dianchi Lake with a width of 15m. Panlong River’s lower section is relatively desolate with bungalows on both sides. This section of the river is polluted and has poor water quality due to pollutants discharged by the surrounding residents. The lower part of Panlong River has flowed out of the center urban area of Kunming city, and the width of the river channel has become more and more narrow. The afforestation effect on both sides is poor.

Each index layer factor in the lower section of Panlong River is evaluated and a conclusion is drawn. The distance index score of the lower reaches of Panlong River is 0.53, which is good. The socio-economic and aesthetic index scores were respectively 0.42 and 0.51, which were general and good. The lower section of the riverside environment quality is poor, the surrounding afforestation rate is high with a lack of public service facilities. Since it’s close to the downstream, its water quality is poor with much sediment pollution. The distance index score is low, and the surrounding landscape features are unified but lack of diversity. In general, the upper part of Panlong River is better than the middle and lower parts in ecological environment. From social and economic aspects, Panlong River has less public facilities and a lack of public space in upper and lower parts, which is complete in middle parts. In the aspect of comprehensive evaluation index, landscape environment of the upper and middle reaches of Panlong River gradually decreased.

Previous to planning and layout, the key water restoration areas are screened by AHP, and the areas to be restored (river bend,
population gathering area, industrial polluted area, etc.) are determined according to the comprehensive score. In the process of planning, the index layer should be analyzed to put forward the ecological restoration strategy according to the importance level of ecological restoration classification. Taking Panlong River as an example, because its comprehensive score is gradually reduced from the upper to the lower, the study group can set up aerobic landscape in the key improvement area of water quality, using elevation difference. In the area with low vegetation coverage, purification plants can be selected, and landscape planning and water quality improvement can be combined to carry out the restoration of plant landscape ecology.

4. Conclusion and Discussion

In the process of urbanization, the research on the combination of river landscape construction and water landscape restoration is of great significance, but the previous research lacks quantitative guidance on hydrological indicators such as water quality, water fluidity, and flood control effect and so on. In this paper, the urban river water resources index is introduced to provide quantitative support for river landscape planning, which improves the scientificity and rationality of planning and design. But in the concrete implementation process, we should pay attention to the following aspects: first, in the selection of evaluation indicators, this paper takes Panlong River as an example to test the water quality, water fluidity and other indicators. However, in the planning of different projects, designers can choose different index layer factors according to the actual situation and data acquisition situation, in order to improve the rationality of the planning. Second, in the process of professional landscape evaluation, picture data is used more often in landscape quality evaluation except for the objective indicators of water resources. Picture data has the advantages of easy collection and convenient display, and disadvantage of the difference with the actual space feeling. Therefore, in the process of evaluation, researchers should adopt the method of field investigation and evaluation or VR image as far as possible to represent the real scene.

The Landscape Renewal Strategy in Suburban Hilly Areas
Based on “Zero External Water Input”

Sujing Huangfu, a Qiang Zhu, a Xiong Li a,

a Beijing Forestry University, No.35 Tsinghua East Road, Haidian District, Beijing, China, Beijing and 100083, People’s Republic of China

Abstract:

The suburban hilly areas is a vulnerable area between the city and the mountain body, which contains a large amount of land that is under non-intensive use conditions. It is also a key factor in limiting the urban expansion and building a sustainable ‘outer circle’ for the Eco-city. However, the sprawl of the city has put the suburban hilly areas at risk of disorderly development. The green space in the suburb of shallow mountainous area not only extends the Green Infrastructure of the city, but also can link up the ecosystem inside and outside the city to meet the increasing recreational demand. This particular mode should be different from urban landscape renewal and closed forest project, it is supposed to make full use of shallow mountain resources, improve ecological status. According to the functional characteristics of its natural resources protection, land rational use and entertainment and leisure experience, it puts forward the objectives of resource intensive, ecological service value maximization and cultural continuity.

This paper puts forward the landscape renewal idea of "Zero External Water Input". The process of this mode can be summarized in the following five steps:

This paper takes Shijiazhuang Mountain Front Park in Hebei Province as an example, practices and explains the renewal strategy proposed by the author. It responds to the development trend of self-sufficient biological city from the perspective of landscape architecture, explores a new way to build Green Infrastructure in suburban hilly areas.
1. Introduction

1.1 Conceptual Definition

1.1.1 Suburban Hilly Areas

In this paper, Suburban Hilly Areas is considered to be consistent with Suburban Hilly Areas. A shallow mountain area is a part of a mountain area, which has a certain elevation and slope fluctuation relative to the plain. The landform of Shallow Mountain Areas is dominated by low mountain, hilly land, platform, foothills plain and alluvial fan. Meanwhile, it is the buffer area between artificial construction and mountain natural habitat. [1]

The shallow mountain area is a special part of the mountain area, which is different from the concept of “deep mountain area” and “high mountain area”. To be more specific, the defining factors relate to altitude, relative height difference, human disturbance and so on. [2] The shallow mountain area is the transition zone between the mountain area and the plain. It is a region with certain development value and has already endured certain development pressure or is likely to be affected by urbanization. At the same time, it is also a vital part of the urban ecosystem.

1.1.2 Piedmont Plain City and Suburban Hilly Areas

It is easy to form the urban agglomeration in the mountain front plain because it holds abundant natural resources and the dense water system composed of mountain catchment water. Usually, the urban space of the piedmont is in the form of plane or band, and there is a distance between the construction area and the mountain body. Due to the impediments played by the surrounding mountains in the process of urban development, the suburban space is banded or dendritic, the green space is wedge-shaped, and the boundary with the city is blurred.

1.2 Necessity of Landscape Renewal in the Suburban Hilly Areas

1.2.1 Characteristics of the Suburban Hilly Areas

(1) The Complexity of Resources

First, the natural and cultural resources are very rich in the suburban hilly areas. They are located at the junction of the plain and the mountain, as a result, the ecosystem shows mixed features. The topography of the region is rich, and the low mountains, hills, terraces, foothills plains and alluvial fans are good habitats for plants and animals. The annual temperature, rainfall, evaporation and other natural indicators are also relatively moderate. Meanwhile, the height difference
and slope bring about certain vertical difference, which makes its geographical space type more diverse. Besides, the shallow mountain area has long been affected by human behavior, which means it holds valuable cultural heritage resources.

Secondly, the scarcity of water resource. The geographical characteristics of the suburban hilly areas determine that the catchment of the mountain body in this position will flow naturally along the slope. The deep and narrow gullies formed by the confluence of the mountain body are mostly formed by erosion of the earth's surface, which makes it hard to form the catchment water. Therefore, water resource is the main constraint in the development of shallow mountain areas.

(2) The Transitivity of Space and Function

The transition is the most typical feature of the suburban hilly areas, which is reflected in both space and function. From the spatial point of view, it is not only a transitional zone between urban built-up areas and ecological conservation areas, but also a transition region between agricultural farming areas and natural vegetation areas. From the perspective of function, it connects the city center with the rural hinterland and drives the urbanization of mountain area.

(3) The Dynamics of Regional Development:

The scope of suburban hilly areas is constantly changing, the expansion of urban scale directly leads to the buffer surface between built-up areas and ecological conservation areas constantly advancing to the mountain. The suburban hilly areas is greatly affected by the development of the piedmont plain city.

1.2.2 Necessity of Regeneration in Suburban Hilly Areas

Corresponding to its characteristics, there are three problems in the landscape development of suburban hilly areas:

(1) Neglecting the ecological environment condition, insufficient consideration of resource conservation.

(2) Excessive urbanization, the protection of ecosystem and ecological performance are ignored.

(3) Failure to conduct a thorough survey on the needs of the users, insufficient understanding of the needs and functions of the site.

From the perspective of landscape architecture, in order to continue the Green Infrastructure of the city and link up the ecosystem inside and outside the city, it is very necessary to study the suitable landscape renewal strategy for the suburban hilly areas.

1.3 Objectives for Landscape Renewal in suburban hilly areas

This particular mode should be different from urban landscape renewal and closed forest project, it is supposed to make full use of shallow mountain resources, improve
ecological status. According to the functional characteristics of its natural resources protection, land rational use and entertainment and leisure experience, it puts forward the objectives of resource intensive, ecological service value maximization and cultural continuity.

This paper puts forward the landscape renewal idea of "Zero External Water Input".

2. Overview of the Case

This paper illustrates the process and approach to achieve the goal with a practical case. The project, called Mountain Front Park, is located in Shijiazhuang, China. Shijiazhuang is a typical piedmont plain city, which is located in the middle of the east edge of the second largest geomorphologic ladder in eastern China. There are a variety of mountain types on the west side of the city. The project site extends from the east side of Piedmont Avenue to the west side of the channel, and extends north and south to the boundary of the village. The total designed area is 50.1 hectares. (fig.1)

The site is basically agricultural land, and the existing large area terraced fields constitute the basal texture of the site; Stone is a common material in the site, there is a legacy of stone construction (fig.2); Three gullies traverse the site, which constitute the basic resource structure of the site and can be utilized. (fig.2)
Through modeling and GIS analysis, the natural base conditions of the site are analyzed, and the following conclusions can be drawn: The site itself has 27m height difference, and the whole is a complex single slope. Three typical seasonal stable gullies pass through the site, and the runoff is larger in the rainy season. Through the GIS analysis of the site (including solar radiation analysis), it is clear that the climate condition is conducive to the formation of rich park landscape; More than 80% of the site has a good foundation for construction, but some steep slopes have formed a limit.

3 Research Approaches and Results

3.1 Water Collection

In order to achieve the goal of zero input of external water resources, the first step is to calculate the amount of site Rain Water can accumulate and determine the collection method. The west side is bounded by the surrounding mountain ridgelines, the eastern boundary is the red line of the site, and the village is the border of the south and north, with a total drainage basin area of 5.6 million square meters.(fig.3)

Through GIS software, the surface runoff in the basin area was analyzed and the maximum, minimum and average precipitation of Shijiazhuang in the last 50 years was found in Shijiazhuang hydrogeological condition analysis. The net flow coefficient of park green space and rainfall data are obtained from the practical
hydrological manual of Hebei province\(^3\), China. The above data can be used to calculate the total amount of surface runoff, which is 31.88 million cubic meters. (fig. 4)

Fig. 4 Calculation table of watershed catchment in site (by author)

Based on site status and geographical environment of Shijiazhuang, surface runoff is collected in Low Impact Development way.

Rain water garden is set up at the source of the gully to intercept rainwater. In order to reduce process water consumption, organic imperative material is used to rebuild gully.

The waterscape sets in the existing terrain depression. Simultaneously, underground storage facilities are set at the lowest place of the site, to maximize the collection of Rain Water resources in the basin. (fig. 5)

3.2 Allocation of Water

The second step is to determine the distribution of rain water collected. The landscape renewal should meet the needs of ecology and landscape recreation at the same time.

According to the principle of maximizing ecosystem service value, by introducing the concept of ecosystem service value per unit area, this paper compares the value of wetland ecosystem with that of forest ecosystem, and then distributes rain water reasonably.

Among them, forest ecosystem includes forest land, shrub land, unformed forest land, heavy cutting land and nursery.\(^4\) Wetlands are natural or artificial, permanent or temporary marshes, wet plains, peat bogs, or water areas, whether the water is still or flowing, fresh or salt. Further more, the water depth should not exceed six meters at low tide.\(^5\)
We focus on the ecosystem service value of forest ecosystem and wetland ecosystem. By comparing the value of 1 cubic meter of water itself with the value of 1 cubic meter of water used to irrigate plants, the value of 1 cubic meter of water itself is 3.4476 yuan and 1 cubic meter of water used to irrigate plants is 6.3702 yuan.\textsuperscript{[6]} Value of forest ecosystem > value of wetland ecosystem. Therefore, in the design process, the least amount of water should be used to create the waterscape, the rest more of the water is used for plant maintenance.

The waterscape construction technology we use should base on the current situation (existing potholes, depressions, gullies), so that the surface runoff can go from high to low, fill each catchment area in turn. It calculates design water and evaporate water to restore the waterscape and water system with minimal impact. According to the accumulation of long-term observation data obtained in the “Water Surface Evaporation Scale Effect and Its Relationship with Meteorological Elements”\textsuperscript{[6]}, the evaporation amount is inversely proportional to the area, that is, the law that the evaporation amount decreases with increasing area. Therefore, only four large water surfaces are arranged in the whole garden.\textsuperscript{[7]} (fig.6)(fig.6)The amount of water that can be stored in water is 54300 cubic meters, plus the amount of water used to fill the water, the total water consumption is 85300 cubic meters.

![Diagram](image)

After subtracting water consumption from total water storage, it can be determined that the remaining 233500 cubic meters of water can be used for plant maintenance. (fig.7)
3.3 Technology of Waterscape

3.3.1 Selection of waterlines: Based on the need of connecting water systems and increasing the abundance of waterscape, considering the elevation of the site and the current situation of water catchment, three waterlines are selected to link the water points with the three gullies in the site. (fig. 8)

3.3.2 Composition of water networks: The selected water points, waterlines and current gullies form a water network that highlights the characteristics of site resources.

3.3.3 Accounting rain water's demand for slow discharge:

The rainy season and dry season of Shijiazhuang are distinct, and the rainfall in the rainy season reaches more than 70% of the annual rainfall, and there are often heavy rains in summer.

The site is located in the middle of the largest catchment area in the planning park, and receives a large amount of rain water. Meanwhile, the site is located on the east side of Piedmont Avenue, which is the largest surface of runoff, so it is very necessary to manage the rain and flood during the rainstorm period.

At present, the total amount of water collected in the design site is 54300 m³.

The latest heavy rain in Shijiazhuang is used as a reference for calculation (happen in 2012, once in five years). [8]

\[ P = 5 \]
\[ rt,P = 2497.652(1+0.862\lg P)/(t+12.61)^{0.781} \]

- \( rt,P \) - When the recurrence period is \( P \) and the rainfall duration is \( t \), the rainfall intensity is \( \text{L} / (\text{s} \cdot \text{hm}^2) \);
- \( rt,P = 12.21 \text{L} / (\text{s} \cdot \text{hm}^2) \).

It is calculated that the rainfall of this intensity is 105mm, \( rt,P = 12.21 \text{L} / (\text{s} \cdot \text{hm}^2) \).

\[ Q = CA \cdot rt,p \]

- \( Q \) - design runoff \( \text{L} / \text{s} \);
- \( C \) - runoff coefficient
- \( A \) - Water catchment area

The total net flow is: \( Q \) total = \( Q \cdot T \)

Conclusion: If the heavy rainstorm last for
24 hours (once in five years), it may result in a runoff of 60600 m³

\[ 60600 \text{ m}^3 > 54300 \text{ m}^3 \]

Heavy rain will exceed total site storage capacity. To regulate the water storage and slow the emission rate, the site also needs to set up the immersible area that can be submerged under the condition of heavy rain, and the amount of rainfall that can be accumulated is: \(6.06 - 5.43 = 0.82 \) (10000 thousands of cubic meters)

Combined with topographic and catchment factors, the immersible area is selected at the junction of water system or lower depression, the average water depth of submerged area is 0.3 m, the total area is 3.1 ha, and the maximum water volume can be adjusted to 8200 m³ under heavy rain. (fig. 9)

![Fig.9 Water system layout(Drawn by author)](image)

The designed runoff paths are: the rain flood source from the western mountain body is purified by storage ponds, surface flow wetlands and storm water wetlands. Partly of the purified water may be discharged along the stream. It can basically meet the requirements of rain water storage during the rainstorm period, and form the seasonal dynamic water system landscape.

3.4 Ecology Native Plants

3.4.1 Plant irrigation water requirements are equal to plant water consumption minus effective rainfall. Annually effective rainfall can be calculated by annual historical rainfall. The average effective rainfall coefficient RF is 53. The annually effective rainfall of the site is \(5522 \times 53/100 = 292.67\) mm. Plants that can survive by using natural precipitation are classified as "self-supplying plants", and plants that require additional irrigation become "irrigated plants" that cannot be satisfied with natural precipitation. The site uses local self-supply plants on a large scale to form a keynote landscape with nostalgic memories. At important nodes, 379300 cubic meters of water are used to conserve irrigated plants. (fig. 10)
Referring to the water consumption of common garden plants in Hebei Province, we can see that the average water consumption of 1 m² irrigated plants is about 266.06mm per year, so it can be estimated that the irrigated plant area can be controlled within 142900 square meters in the whole garden. These irrigated plants are often used to embellish important landscape nodes to form delicate landscape effects.

3.4.2 Plant Arrangements based on Habitat

According to the formed landscape system, plant habitats in the site can be clearly divided into terrestrial habitats, short-term immersible habitats, wet habitats and aquatic habitats.  

3.5 Reasonable continuation of the site context

Changes in the nature of land use: The conversion of the site from cultivated land to country park will result in a change in the nature of the site. Considering the position of the site, as well as the excessive water consumption of crops, the farmland will be completely reserved in the field. Considering the factors such as convenient irrigation and reducing pollution, the reserved farmland area is determined as the area nearby the water source.

The designing concept for the site texture is ‘complete reservation’ and ‘extraction of features’. The ‘complete reservation’ method means retaining its integrity, preserving the morphology and function of farmland intact. The ‘extraction of features’ method means drawing the wisdom of terraced fields to apply it to the site, which creates a harmonious shape composed of curves and fold lines that fit the contour lines.
Functional requirements: Through the derivation and collision of three keywords: ‘agriculture’, ‘arts’ and ‘countryside’, the demand for the function of the country park was selected by the questionnaire, and the functional partition of the site was determined as: natural art experience area, countryside landscape recreation area, peaceful forest recreational zone and agriculture sightseeing area. (fig.12)

Fig.12 (Drawn by author)

4. Design Achievement

In general, under the guidance of the concept of "Zero External Water Input", this paper tries to promote a landscape regeneration model for the shallow mountains area.

The final design results of the Mountain Front Park (fig.13) are as follows: Taking water as the main landscape elements, it contains four wetlands, three streams, three waterfalls, two islands and three water terrace landscape. According to the analysis and research, the site is divided into four parts: Wind Valley (natural art experience area), Leisure Area (countryside landscape recreation area), “Returning to My Farm” area (agriculture sightseeing area) and Peaceful Forest Recreational Zone (forest recreation area). (fig.14)

Fig.13 Plan and aerial view (Drawn by author)
5 Thinking and Discussion

5.1 Innovation Points

This paper focuses on the relationship between the shallow mountain area and the city, it puts forward the characteristics of the present situation of the suburb shallow mountain area and the landscape renewal target. Based on the concept of "Zero External Water Input", this paper puts forward a new strategy of landscape renewal in the suburb shallow mountain areas, which can solve the problem of resource shortage from the source. Moreover, it raises a thought about how to benefit the ecological and landscape factors of suburb shallow mountain areas under the rapid expansion of cities. It is a new respond to the biophilic city from the landscape architecture perspective.
5.2 Research Limits Future Development

The generalizability of this research is subject to certain limitations. For instance, this method is based on a case, which requires more practical projects to verify and enhance its reliability. Moreover, considerably more work will need to be done to determine the estimation of water consumption of native plants, as the current statistical data on plant water consumption are too small and the regional differences are notable. Meanwhile, further research should be undertaken to explore how to determine the irrigated plant planting area, which would help us to establish a greater degree of accuracy on this matter.

Abstract

With the rapid development of the city, the gray infrastructure, including urban road, mainly serving for municipal function, occupies a large part of the urban space, which loses vitality and makes the living environment worse. In this context, how to reuse the gray infrastructure becomes a big problem to be solved. Taking the transformation of Beijing Marathon Track in 2008 as an example, the paper aims to explore the opportunity to embrace the road system as a part of urban public space and turn "gray" into multi-functional "green", by the means of intelligent Interactive Device.

With the end of the marathon race in 2008, this route was almost entirely as a transport infrastructure in the city or region and lost public space vitality. The nature and size of land make it difficult to be activated and reconstructed. Based on the research and evaluation of the surrounding building scale, the nature of the buildings, green space, green space usage, physical flow of people and so on, the article explored potential space on the site and formed several "circles", which means non-motorized system. The public can choose their daily trip from it. What's more, there will be many "points" which provide space for exercise and communication.

The change from "gray" to "green" is approached through the installation of intelligent interactive devices along the road, including perceived vibration pedal, water storage tank and energy conversion equipment. Through collecting vibration energy generated by pedestrians, automobile, and underground trains, the electrical energy converted from the vibration energy will be used for road lighting, green belt irrigation, active facilities supplying and so on. At the same time, the relevant data can be sent back to users through mobile applications, in order to encourage public participation in sports.

In this paper, we try to use a kind of minimum intervention——Intelligent Interactive Device, integrating the single function of municipal engineering into a more comprehensive urban public system, and enhancing the diversity and multifunction of the city. By proposing the "intelligent infrastructure", this article aims to set a base for further development of urban open space system-the integration of inner-city road system, outdoor walking network and ecological framework.

Key words: gray infrastructure, green infrastructure, urban public space, interactive devices, smart city

1. Introduction

1.1. Landscape as Infrastructure

Urban infrastructure, socio-technical systems of facilities and services that are essential to the basic functioning of cities and regions. In the early days of social development led by the industrial revolution and socio-economic development, urban infrastructure was often defined as a network of roads, bridges, railways, and other public facilities necessary to ensure the basic operation of the industrialized economy. However, with the development of landscape urbanism theory, "Landscape as Infrastructure" is increasingly accepted by people. At the same time, green infrastructure, which protects and maintains the balance of natural ecological processes, natural resources, and urban resiliency, has also increasingly implied in city development. In the urban conditions, the open space system formed by the natural resources green space system will not only function aesthetically, meeting citizens' entertainment needs but also becomes functioning ecologically.

1.2. Intelligent Infrastructure Systems

In this paper, green infrastructure will be redefined beyond its physical design meanings and ecological functions — but also refer to urban intervention that alleviates traffic congestion, promotes energy conservation and emission reduction, and a more walkable lifestyle. The proposal takes the least intervention — smart interactive devices but promotes sustainability in an efficient way. The extension of this definition means that "Landscape as Infrastructure" not only refers to a physical design of landscape features or facilities but also can refer to a virtual and subtle change in lifestyle that promotes by the green infrastructure system itself. In this high-technology era, taking advantages of the power of media and interactive devices provides landscape architects new perspectives and roles to work with. entity that works together to contribute to the city. The interactive device system presented in this paper visualizes the conversion of kinetic energy to electrical energy, and at the same time, it is also a visualization of the strategy of smartly transforming the gray infrastructure into a green infrastructure. Breakthrough the traditional understanding of the green infrastructure, with intelligent means, the language of the landscape, re-interpretation of the urban greenway.

2. A Case Study — Beijing 2008 Marathon Circuit Renovation

2.1. Background Study

With the rapid development, traffic congestion and excess energy emission has become a severe issue in China. Road infrastructure connects various urban fabrics in modern cities. However, due to the long-term lack of comprehensive consideration of the natural environment, social ecology, and aesthetics, the traditional way of planning and design roadway systems cannot meet the requirements of urban development anymore. This article takes the renovation of the Beijing 2008 Marathon track as an example. With the end of the Beijing Olympic Games, this route exists almost entirely as a transport
infrastructure within a city or a region. There is a large limitation on the nature and size of the land on both sides. Without the conditions for large-scale reconstruction and development, people's travel and leisure are squeezed into the gray space. The purpose of this paper is to explore how to integrate road grey infrastructure into urban public spaces through smart landscape approaches, achieve synergies with the green infrastructure, maximize the potential for space use and capacity, and become the driving force for urban regeneration and sustainable development.

2.2. Urban Open Space Analysis based on Beijing 2008 Marathon Route

2.2.1 Existing Conditions and Problems Analysis

1. Stormwater Management
Acknowledged from the survey results, the site of the original competition route is located in or adjacent to the Yishui section. The drainage system of these areas is not perfect, and there is no suitable green space nearby to absorb the water, rain, flood, heavy rain, flooding, this problem has caused many inconveniences and even threats to the safety of people walking and driving on rainy days. Therefore, the transformation of the grey infrastructure that contains water and stagnant water into a green infrastructure with hydrophobic water will be a key point in the use of the track.

2. Pedestrian Circulation & Green Network
The race route passes through the central urban area, important high-tech zones, and cultural and educational districts. It is the most densely populated area in Beijing. The traffic congestion along the roads with a large number of traffic flows and poor planning is extremely common. Congestion brings a lot of tail gas and noise pollution, resulting in pedestrians walking on the road, non-motorized travel experience is poor, some people reduce outdoor activities, some people join the motor vehicle travel to intensify congestion.

At the same time, along the track, historic parks such as the Summer Palace, as well as community parks, are also along the route. These urban green spaces scattered in the green space system have not been fully utilized, either from the perspective of civic activities or from the perspective of urban ecology. As a result of the green space system analysis map, the use of marathon tracks to promote smart walking and bicycle travel will greatly reduce the pressure on traffic congestion in the downtown area of Beijing and enable the sports spirit conveyed by the original marathon to be promoted in daily life. Enhance public awareness and recognition of the marathon competition, make the green space system more perfect, and the infrastructure functions become more effective.

3. Urban Identity
The starting point of the 2008 Beijing Marathon course starts from the eastern side of Tiananmen Square, passing through the
Changan Street, Yuyuantan Park, the Summer Palace, the Forbidden City and other iconic historical and cultural centers, as well as the CCTV TV Tower, the World Trade Plaza, the Bird’s Nest, the Water Cube and the Olympic North. New landmarks such as stadiums are an urban linear space that carries the long history and culture of Beijing and the vitality and sportsmanship of the new era. However, the current road landscape construction is the same, and does not reflect the urban characteristics. Therefore, how to restate history through landscapes and reshape urban features will also become the most important aspect of landscape design and promotion.

2.2.2 Renovation Potential Analysis

The area along the race track can be divided into five major areas with different characteristics according to the surrounding building properties, building size, green area, green space usage, and potential functions of green areas: historical and cultural sites, high-tech industry start-up areas, college culture and education areas, Commercial area, Olympic venue area. According to the different characteristics of each area, landscape design should also be focused on local conditions. Finally, in combination with other marathon tracks and the potential space on the site, multiple “rings” are formed. These “rings” are sports track and jogging system, and the public can select daily exercise routes according to their needs. Secondly, multiple points are set on the route to combine the green space or the venue to provide space for exercise and communication.

2.3. The transition from "gray" to "green"

The transition from “gray” to “green” on the site is applied by the installation of intelligent interactive devices along the roadway, including pedals that senses vibration; stormwater tanks that direct and harvests rain water; and devices that promotes clean energy. By collecting the energy generated by the urban road infrastructure, and utilize it in lightening the street lamps, irrigating street vegetation, and supporting street amenities, citizens will easily aware of their involvement in this invisible transition. As a result, more and more people will be participating in the activities, and promoting the green lifestyle gradually.

Firstly, installing energy collection devices along the sidewalks, driveways, and subways, harvesting vibration energy generated by pedestrians, vehicles, and subways (Figure 2.3.1), and then convert the energy into electrical energy, also storing it in the devices for future use. (Figure 2.3.2).
The stored energy is utilized in two aspects. On one hand, it can be used to irrigate green spaces and help alleviate stormwater flood issues. According to the Marathon route surrounding area open space analysis (see section 2.2), it is easy and beneficial to harvest rain water in the rainy season. When it comes to the large rainwater event in rainy season (June-September), the excess rainwater on the roadway and sidewalks will flow into the sediment forebay collection box, to be cleaned and then stored in the tank. When it comes to the small rain event in normal season, water in the storage tank is pumped out and sprayed through the sprinkler device, irrigating the green belt around the road (Figure 2.3.3), also supporting some on street water features which will adjust micro-climate in dense urban conditions.

Secondly, taking advantage of the renovation, the green spaces along the roadway can be redesigned as recessed lawn area or bio-retention pond, etc. The process of rainwater collection and reuse in urban roads combined with the park green space system can become a unique landscape of the city.

At the same time, the stored energy can also be used for the activities of citizens in the open space along the route. People can interact with the devices by easily stepping on them, and observing the energy transformation processes through the devices. In certain areas, by pedaling the trigger device, playful public open space is formed to stimulate people's interest in the activity. Convert energy into electricity to provide billboards, street lights, etc. on both sides of the sidewalk, saving energy (Figure 2.3.4).

Finally, various data is uploaded to personal social account through the Internet, with which personal travel and sports data can be updated simultaneously.

The installation of such micro-facilities will achieve the goal of transform gray transportation facilities into intelligent green infrastructure that people can interact with. At the same time, combine with the urban open space to better exert ecological, social, and economic effects (Figure 2.3.5).

2.4. Landscape Design Approach

In the Chinese industry standard “Planning and Designing of Urban Roads”, the urban road greenbelt is defined as the land that can be green within the scope of
roads and plazas, including road green belt, traffic island green space, square green space and parking. Green field. Therefore, this paper plans to select three representative venues for the marathon track, which are green roads, traffic islands and square green spaces, and carry out specific examples of landscape design analysis.

The first site was selected in the road green belt on both sides of the road (Figure 2.4.1). When rain flows through undulating terrain, it slows down the flow and sparse more time for infiltration. At the same time, after the rain passes through the first permeation unit of the inlet, it is initially filtered out of the larger litter, when the amount of rainwater in the pond exceeds the design. At depth, rainwater overflows from the first permeation unit into the second permeation unit, and so on. When the last permeation unit is saturated, excess rainwater will flow into the underground water storage facility. At this point, the water flowing into the water storage facility has undergone preliminary filtration and purification of the plant roots, which can be used for irrigation and landscape water use. When a large-scale rainfall occurs and the rainwater that enters the underground water storage facility from the storm water inlet still cannot be absorbed, the rainwater will be directly discharged into the urban underground rainwater pipe network system.

After the tests of the model, the road green belt can reduce 80% of the runoff of the storm water once in 25 years. Integrate the functions of rainwater management and utilization into street greening and combine landscape elements to create urban streetscapes with local characteristics.

The second site is chosen in the three-dimensional transportation system (Figure 2.4.2). The number of pedestrians and vehicles in the traffic lanes are all relatively large. The continuous vibration can provide energy for the site. 1st floor for passengers traffic 2nd floor for a person who in lack of exercise, with runways, seats and green climbing plants hung over the 2nd floor.

The third site is selected in the square green space on both sides of the road (Figure 2.4.3). The paving and green space in the plaza can stay in the rain and infiltrate the rainwater. The reservoir in the site can also collect rainfall through the collected roads. Energy, on the one hand, can increase air humidity through spraying when the city is relatively dry, creating a good urban microclimate. On the other hand, it can be used as dry spray square to form an interesting street corner park.
2.5. Benefits Analysis

1. The original track areas are all high-density and high-congestion roads in Beijing. However, this paper proposes to convert the gray infrastructure wading and reuse into green infrastructure, and collect and purify the rainwater by placing water collection tanks in the inner city area. Irrigation road trees, plants on the green road, so as to create a green environment of urban roads. The use of rainwater is resource-based during the different phases of urban rainfall. It also alleviated the problem of water accumulation caused by poor water flow through the urban pipe network in heavy rain weather in Beijing.

2. Based on the track, build a chronic system of urban green travel. With intelligent interactive devices as the media, the company will attract people's attention and participation by means of visualizing energy and increasing interest, so as to achieve energy conservation and emission reduction, ease traffic congestion, link multiple green areas along the route, and tap the green potential space. Integrate the infrastructure on the scale of the human, connect the original single gray infrastructure through pedestrian traffic, rejuvenate and create an open green innovation environment.

3. Based on the establishment of a green and chronic system, residential areas and commercial areas along the race track will also be injected with new vitality. The gathering of people contributes to the agglomeration of cultural connotations in residential areas; for the business district, it means that the promotion of consumption drives the regional economy.

4. The ultimate goal of this design is to promote green travel and achieve energy conservation and emission reduction as well as the use of clean energy. As a highly industrialized and highly mechanized city, Beijing still has a very high use of fossil energy. In the process of improving the level of intelligence, cities can only achieve constant and efficient exchange of information, energy and materials in an open and innovative environment, and then realize the flow and agglomeration of innovative entities. The smart city green innovation ecosystem The dissipative structure can achieve orderly operation. In the proposal of this article, the public will be introduced to the thinking of science and energy conversion, and at the same time, the public will be made aware of the practical significance of using clean energy in a visual way. This move has long-term significance for the development of the city.
3. Conclusion

This paper attempts to integrate a single-function municipal project into a more comprehensive urban public system with a minimum intervention—the intelligent interactive device—in a limited urban space, creating urban complexity and multifunction. Through such smart infrastructure construction, it provides a reference for the development of an integrated urban open space system and the integration of inner-city transportation networks, outdoor walking networks, and ecological networks.

However, in practice, how to effectively transform the gray infrastructure into green infrastructure still has many difficulties and problems. Take this article as an example to make some suggestions.

1. Integrating with Microscopic Green Infrastructure

In today's rapid economic development, the areas that are in urgent need of transformation are often urban areas with a high degree of construction. It is difficult to have a lot of room to build green spaces, and only to see the green in the seams to improve the existing urban environment on a microscopic scale. However, in large cities, frequent rain and flood disasters, it is difficult to completely solve urban water problems by simply relying on micro-scale green infrastructure. All kinds of microscopic green infrastructures only slow down flood peaks and retain part of the rainwater. Rainwater that exceeds their capacity needs to pass through the urban pipeline. The network to deal with, how to coordinate the micro-scale green infrastructure and other urban infrastructure is a consideration.

2. Post-maintenance issues

The good operation of the micro-scale green infrastructure requires continuous maintenance and regular testing and evaluation to ensure its normal operation. On the one hand, continuous maintenance and management can summarize the experience in design and improve the insufficiency of design. On the other hand, it can adapt to the continuously evolving usage requirements and improve accordingly. Some current infrastructure construction "reconstruction of light pipe", follow-up investment, inadequate management and maintenance, making the project greatly reduced the effect. Only by paying attention to late-stage maintenance and management can we ensure that we can continue to function well after completion.

3. Public participation

Public participation is also a very important aspect. In urban areas with a higher degree of construction, it is difficult to have a large amount of space to build green spaces. People's travel and leisure are squeezed into the gray space. It is necessary to build green infrastructure, provide citizens with public space for activities, and mobilize the enthusiasm of the public. At the same time, they need to solicit the views and suggestions of the site users to design a micro-green infrastructure that is convenient and easy to use. However, the current level of public participation in China is relatively low, including the lack of willingness of the residents themselves to participate and the related policy procedures are not perfect. It is necessary to strengthen the construction in this area.

Abstract

With the proceeding of urbanization in China, especially in megacities such as Beijing, urban land use patterns were confronted with problems such as geographic imbalance, space fragmentation, inconvenient slow traffic and low environmental quality. In a matter of speaking, as a multifunctional public space network deep into city, the construction of urban greenway network, which can effectively improve the traffic condition, raise the residential quality and promote slow traffic lifestyle, is an important means of urban stock space optimization. The present research of urban greenway in built-up areas was relatively insufficient, especially in the study on the one key factor---------the potential of urban land conversion in network identification. From what we have mentioned, this paper is aimed at the characteristic of this kind of greenways that is closely connected with urban life and is easily constrained by urban land use and residents demand. In the new data environment, multiple heterogeneous spatial information is used to intentionally explore the means of urban greenway network identification with the mature land suitability assessment process based on GIS spatial analysis(the evaluation of urban land use potential) . An empirical research is also conducted in Beijing Haidian district, exploring an effective way for the development of compact and intensive city in the future of China.

Keywords: Urban greenway; spatial network; green infrastructure; landscape urbanism
1. Introduction

Since the reform and opening-up, Chinese cities have experienced unprecedented rapid development and expansion. With the increase of urban area and population, a variety of urban lands are developing rapidly and the internal spaces are rapidly reducing. And what’s worse is that the surrounding lands have been severely encroached and the degree of land fragmentation is increasing. At the same time, the pattern of urban land development also has a geographical imbalance[1]. Residents' daily life, works, cultures and recreational spaces have been placed in different places without any connection, which forms the urban lifestyle that relies heavily on motor vehicles[2]. As a matter of fact, the convenience of slow traffic is inhibited and the transport infrastructure is overwhelmed. More serious is that the related pollution causes the constant deterioration of the environment[3]. All of these are considered to be one of the major causes of urban crisis. Many cities are facing a series of serious problems, such as protecting environment, culture and improving residents' quality of life, while realizing the demand of continuous and balanced development of land.

The greenway is a "green infrastructure" that connects people to the site while building an open space network. In addition, it provides a new development model for urban renewal and sustainable use of land[4]. With the development of the concept of the greenway, it has developed into a kind of complex network with functions of ecological improvement, cultural protection, entertainment and green travel from the original linear plant area only used for protection[5]. Meanwhile, it can promote the further optimization of urban spatial structure, which is of great significance in the process of compact and refined development in Chinese cities.

Urban greenway network, which is closely related to residents' life in urban area, can effectively improve urban traffic condition and improve residents’ quality of life. Simultaneously, it promotes a city lifestyle led by slow behavior and as the main way to optimize the spatial structure of urban land storage[6].

However, Chinese greenway has encountered many difficulties in its promotion. Firstly, for the built-up areas of a compact city like Beijing, incremental lands are insufficient, short of lands need to be optimized and the land that can be used to build urban greenway is seriously insufficient. More importantly, government departments are more willing to invest money, land and other resources to build a wider road to provide more vehicles to ease urban congestion. Unfortunately, after a long construction, traffic jams in compact cities such as Beijing have not been solved. Secondly, academic research has lagged behind the development of practice and cannot respond to the problems encountered in the development of urban greenway in real life. At present, the potential assessment of urban land use in integration, transformation and borrowing is seriously insufficient. More scholars devote their energies to the methods of route selection of greenway.
Most of these methods are mainly based on the suitability analysis of greenway ecologic al function, cultural function and recreationally function. All of these reflect that the focus of China greenway planning and construction are still focusing on the regional level and the outskirts of the city, and there is a serious shortage of attention to the urban greenway in the built-up area[7]. Therefore, it is very urgent to pay much more attention to the urban greenway in the built-up area. At present, there are several driving keys make the idea of developing urban greenway based on space potential become reality. On the one hand, under the background of the apparent inadequacy of incremental land, the land use efficiency of city is greatly improved with the progress of technology, which makes the optimization of the stock land have broad development foreground. On the other hand, the huge pressure from transportation, energy and environment requires us to develop the chronic transportation network with the main characteristics of green behavior, especially the shared bicycles, one of the new four inventions in China, is developing rapidly, with a cumulative amount of over 10 million vehicles. Many of these shared bicycles exist in dense urban areas, and many of them still have to share the driveway with the motor vehicles. Fortunately, urban greenway can provide a safe and green travel environment.

Combined with the actual situation of China, exploring a set of technology framework of urban greenway network identification and construction which may base on the urban space development potentiality, leisure, ecology, cultural service function and the citizen social life demand is very important practical significance and promising.

2. Method

The following methods are used in the research process.

2.1. Literature, case reading and induction

By using relevant books, academic journals and network resources, we systematically classify the excellent urban greenway design examples at home and abroad. At the same time, the related construction ideas and the innovation space utilization patterns are summarized. Then on the basis of the current classification standards of urban land use, the potential land resources of greenway in built-up area are excavated. Moreover, it puts forward the refinement land classification, which is beneficial to the identification and development of urban greenway based on spatial potential.

2.2. Analytic hierarchy process (AHP) for land suitability analysis

For the potential land resources of greenway in built-up area, the evaluation factors are screened from the function level of ecology, culture, leisure and social service, and then the analytic results are obtained by using AHP. Furthermore, the spatial suitability map of Haidian District is drawn, which is based on geographic information system.

2.3. Field research and empirical research
A detailed field survey is conducted in Haidian district of Beijing. Besides, the relevant upper planning and basic data are obtained, and then the spatial characteristics of the built-up area are systematically summarized and analyzed. On the basis of the space suitability map for drawing, partial empirical research is conducted. In addition, according to its spatial characteristics, a differential greenway construction model is proposed.

3. Result

By using the above research methods and combined with relevant information, we get the following results.

3.1. The main type of urban greenway and the mode of innovation space utilization

Through the reading of relevant literature, we found that, in the course of greenway classification, scholars usually divide it on the basis of the function, the scale and the main resource type. What’s more, these classification experiences are instructive for the classification of urban greenway based on spatial potential[8].

However, we believe that there are still some drawbacks in this classification. First, now the urban greenway is carrying more diverse functions, and a single function to classify the kind of method is inaccurate; Second, the urban Green Road is mainly located in the urban built-up area, the scale is similar; Thirdly, the type of urban greenway is classified by the main resource type, and the coincidence degree is high, which makes it difficult to classify accurately; Last but not the least, such classification method is not conducive to the storage space optimization of urban concentration areas and the promotion and construction of urban greenway.

Through sorting and summarizing, we have found that there are currently three kinds of construction ideas, namely integration, transformation and borrowing, for how to build urban greenway based on space potential. Dividing urban greenway with different construction concepts can accurately reflect the specific tactics of releasing space potential under the guidance of corresponding concepts. In addition, it is advantageous to carry out the statistical analysis of resources in the course of actual construction by identifying the types of urban land to be relied upon. At the same time, it provides convenience for finding similar urban land and excavating the potential of space and provides development space for the popularization and practice of urban greenway. Therefore, we believe that there are basic and objective conditions for classifying research in these two points which include the concept of urban greenway construction and the type of urban land relied on.

1. Divided by different construction concepts
   1.1. Integration

In recent years, the development of landscape ecology and green infrastructure ideas has provided theoretical support for the development of greenway. In particular, with the deepening of research in the fields of ecological network structure and ecological connectivity theory, scholars
have come to an agreement on the basic cognition of urban greenway. That is to say, the greenway has the characteristics of linearity and connectivity. It not only has the function of a biological corridor, but also carries the functions of connecting broken natural spaces, integrating history, culture, ecology, social resources, and building a complete greenway network. However, due to the fact that most urban greenways are located in urban built-up areas, they usually cannot provide sufficient land resources to meet the needs of greenway construction. Therefore, the development of urban greenway should not only make full use of the existing greenways and greenbelt resources, but also actively expand its regional scope to form the overall effect and release the space potential. This is the idea of "integration", such as the east coast greenway construction in America and so on.

1.2. Transformation
At present, the concept of "urban regeneration" has been adopted by people. More and more people have realized that "urban regeneration " is a more prudent, sensible and harmonious development than simply "pushing and rebuilding". This process takes a series of smarter and more diverse renewal approaches, such as protection, repair, reuse, and redevelopment[9]. It is more suitable for the development of compact cities in China. For urban greenway, it can effectively promote the storage space optimization of compact city and release the space potential by actively striving for the land allocated for green space in planning as reserve. Especially, it is necessary to transform the abandoned land and land facilities in the former city to develop urban greenway. This is the idea of "integration", such as high line park in New York and so on.

1.3. Borrowing
For the built area of the city, the restriction of land ownership of present situation makes the planning and implementation of green space system more difficult[10]. Under such pressure, "borrowing" and other new construction ideas emerged. It refers to the use of the land compound urban greenway function on the premise of no change in land ownership or property rights. For example, the Singapore Park Bureau in the greenway land requisition project “borrow” land that does not belong to the Park Bureau. The land ownership of the latter has not changed, but the Park Bureau invests in the construction of greenway and is responsible for maintenance and management[11].

2. Divided by different types of urban land relied on
Based on the idea of "integration", "transformation" and "borrowing", we conclude that we can carry out detailed classification in five aspects: planning land reservation, current ecological land integration (green land, mountain forest, wetland, etc.), other types of land use function transformation, regeneration of abandoned land facilities and upgrading of compound urban greenway functional land.

In order to facilitate the understanding with other practitioners, explore the potential of space beyond the green space and effectively promote the construction of urban greenway in China, we use the Code for classification of land use and planning standards for development land (GB50173-2011) as the basis for classification. In order
to be able to put forward a set of refined land classification that has localization characteristics, which is conducive to tapping space potential, and covers all urban lands completely by the detailed study of urban greenway at home and abroad. The results of classification are as follows:

**Form. 1. Land classification based on different types of urban land(Appendix)**

**3.2. Precise land classification based on space potential**

We use the current Code for classification of land use and planning standards for development land (GB50173-2011) as the basis for classification. It can cover current examples of excellent urban greenway design at home and abroad, but there are still deficiencies. However, through the above form, we find that not all land covered by the listed urban land types can build urban greenway. Some types of urban land still need to continue to refine the classification. Only in this way can we select and identify the land with spatial potential from the imprecise type of urban land.

Under the constraints of technology and environmental benefits, we no longer list land types with no spatial potential.

1. Planning land reservation

At present, water classification is mostly inefficient use of land and has the characteristics of linearity and connectivity. With the current technical conditions, except for a small amount of land, most of the land can be regarded as the land with spatial potential to develop urban greenway.

**Form. 2. Precise land classification of planning land reservation(Appendix)**

2. Current ecological land integration

 Code for classification of land use and planning standards for development land (GB50173-2011) requires: "Nature reserve, scenic spot and forest park are classified as ‘water area’ (E1), ‘agroforestry land’ (E2) or ‘other non-development land’ (E3) according to the actual use of land.” However, for the convenience of statistics, these types of land are unified into "other non-development land(E9)".

**Form. 3. Precise land classification of current ecological land integration(Appendix)**

3. Other types of land use function transformation

In the process of urban development, because of the need for planning and construction, many types of land have changed. In addition, many of these lands are gradually becoming idle lands on account of the loss of vitality. However, urban greenway can find new development potential from these modificatory types of land.

**Form. 4. Precise land classification of other types of land use function transformation(Appendix)**

4. The regeneration of unused land facilities

These abandoned land facilities are the inevitable products of urban development, which are widely distributed in cities. We can combine the original features and develop the urban greenway while solving...
its problems. By this means, it not only improves the urban environment, but also adds urban public function to these abandoned land facilities.

Form. 5. Precise land classification of the regeneration of unused land facilities(Appendix)

4. The promotion of compound greenway function land

At present, there is such a part of the land in the city, which can be developed into urban greenway without changing its main function and the types of land. It not only improves the urban environment, but also optimizes the allocation of urban resources.

Form. 6. Precise land classification of the promotion of compound greenway function land(Appendix)

3.3. The method of Land suitability assessment

At present, the planning and construction of urban greenway in China is still in the exploratory stage. More scholars pay their attention to the planning method of Greenway line selection. For example, w. Mille [12]and a. Conine[13] provide the basis for the selection of greenway through quantitative analysis of site suitability[14]. However, these planning methods only do suitability analysis from the functional aspects of ecology, culture and recreation. At the same time, they pay more attention to the regional level and the outskirts of the city. As a result, the association with the urban built-up area is weak.

Therefore, with the help of the current greenway route planning method, it is difficult for us to effectively evaluate the potential of urban land in the development of urban greenway in built-up area. According to the present research shortcoming, we believe that an effective and applicable land suitability evaluation method needs to be established. Moreover, the social life service function level and the evaluation factors selected from it are included into the suitability evaluation system. The above problems can be avoided by re-focusing and examining the important functions of urban greenway, such as daily transportation.

The study is based on the analytic hierarchy process. Meanwhile, combined with expert scoring method, we determine the weight coefficient of all levels of objectives, and then relevant professional scholars are invited to score. Finally, the target evaluation index is calculated to comprehensively evaluate the potential of developing urban greenway in the corresponding built-up area.

1. Setting up the hierarchical structure model

After studying, we selected 8 evaluation factors from the function level of ecology, culture, leisure and social life service. The following form shows the hierarchical structure model of the development of urban greenway potential evaluation in built-up area.

Form. 7. The hierarchical structure model

2. Reach the weight of each coefficient

To determine the weight of each factor at all levels, the scale of Santy is introduced to get a quantified judgment matrix when
compare the evaluation indexes with each other, and then reach the weight of each coefficient \( W_i \) by calculating. Finally, the calculated consistency is under 0.1, indicating that it is has a satisfactory consistency, which can be accepted.

3. Obtain the evaluation index of the calculated target

We will invite relevant experts to score. First we need to get all index layer scores which can be obtained form index layer corresponding evaluation score \( P_i \) multiplied by the weight coefficient \( W_i \), then add all the index layer scores to get the final index layer score. And then we will get the evaluation index of the target to evaluate the land use and develop urban green road space potential.

4. Discussion

The results what we have been discussed are guiding our empirical study in Haidian District, Beijing. By refining the land classification standard, we can find out the space potential of developing urban greenway from the current land. At the same time, according to the evaluation of land suitability, we can quantitatively analyze the land with space potential. Therefore, we think that our research has some research value and can provide guidance for the following urban green route selection and put forward the development suggestion for the existing urban greenway.

5. Conclusion

Under the technical and ideological conditions at that time, Charles Eliot intended to commandeer the land, such as wetlands, steep slopes and rugged mountains, for which it was difficult to exploit, and set up an open space system in Boston. The greatness of Eliot’s thoughts is that he looked for an available space in the crack of the city and turned it into a useful place[15].

At present, the technological conditions and the thoughts of land utilization have undergone profound changes and unwieldy lands are becoming less and less for mankind. However, be that as it may, we believe that Eliot's thought is not outdated, but the way we look for space potential needs to be constantly updated. And our research is updating the way to explore the potential of space, in order to build a better compact city.

Acknowledgments

After repeated revision, the paper was finalized through half a year. Thanks again to my teachers for the guidance and encouragement during my writing.

Construction of Biophili city: Taking Freiburg, Germany as an example.

Geyunyu², Lixiong³

Beijing Forestry University,(No.)35 East Qinghua Road,Haidian District,Beijing 100083(zip code),China

Abstract

Biophili city is the trend and mainstream direction of urban development. It is the requirement of adapting to the era development, building a harmonious society and implementing circular economy. According to the view of ecology and ecological ethics, all the development of human economic society should transform from ‘centralism of human interest’ into ‘centralism of ecological interest’, from ‘priority of human interests’ to ‘priority of ecological interests’. The past urban planning mode with the human interests as the main body and the environment as the object of human rights should also be transformed, and need to establish the ‘ecological first’ urban development view. With the rapid development of the world economy, the high urbanization in the world has caused a series of negative impacts on the natural environment we live in. Therefore, the city planning construction and management scientifically and reasonably could make the city under the state of a virtuous cycle of sustainable development. It is an urgent need in today's urban planning development basic task. Famous ecological city Freiburg in Germany, for example, the paper studied its further study green ecological planning and construction management measures, to learn from it in urban ecological planning and construction management good measures and methods.

Keywords: Biophili city, Freiburg
1. General Information

Freiburg is the city of Baden-Württemberg, the capital of the Freiburg district, with an area of 153km² and a population of about 200,000. The city of Freiburg is located in the western part of black forest in Germany. Freiburg boasts pleasant scenery, and is especially abundant in sunshine. It is regarded as the warmest and sunniest city in Germany [1].

The city was once badly bombed during world war II and rebuilt after the war while making full use of the city's sunshine resource conditions and implementing the sustainable development policy of renewable energy. Starting in the 1970s, Freiburg began to build eco-cities. In 1986, Freiburg became one of the first cities in Germany to set up the E.P.A. In 1992, Freiburg was awarded the ‘green capital’ of Germany for building smog and ozone warning systems, as well as the achievements in environmental public transportation. Although Freiburg is a small city, but it has been recognized as one of the best ecological

2. Ecological Measures

2.1. Restore the natural landscape.

Freiburg pays special attention to social and cultural factors in urban environmental protection. The most important principle of landscape planning is to restore the natural landscape. First of all, all the hardened ground (except for the roads) was completely removed in the city and replaced by various kinds of permeable ground (including the permeable bricks, gravel, groove brick, gravel, organic debris, etc.). This transformation has brought great improvements to Freiburg’s environment in many ways. Secondly, urban residents in Freiburg had come up with many ideas in order to improve their hygiene, environmental quality and living comfort level to a very high level, such as the courtyard self-help greening, vertical greening, balcony greening, roof greening and so on. These methods have helped the city back to green, and effectively helped the strong solar radiation city reduce the heat island effect. Thirdly, the rivers in Freiburg were made to simulate the natural river, which could keep the transition structure between river and land. The principle of maintaining natural vegetation for protecting the environment of the shore could also improve the water quality as well as the natural beauty of the river with less maintenance costs.

2.2. Using new energy

The development of economic in Freiburg follows the laws of ecology. It combines the clean production, comprehensive utilization of resources, ecological design and sustainable consumption together, in order to reduce and recycle the urban waste. Maintaining the natural ecological balance could also resulted from waste reduction, resource recycling and safe disposal in the end.
In 1986, the city council of Freiburg decided to use solar energy instead of nuclear power, and set up the city Environmental Protection Bureau at the same time, which made Freiburg became one of the earliest cities in Germany [2]. The weather in Freiburg is warm and sunny all year round, with sunny days and an average annual sunshine of more than 1,800 hours. Citizens were aware of the importance of harnessing solar energy for climate protection, economic development and urban prosperity. Not only in football fields, city hall, exhibition halls, schools, churches, houses, or the surface of the high-rise buildings, they even installed solar cell device above the abandoned dirt. This constitutes to a special landscape in Freiburg.

Germans have a good habit of classifying and disposing of rubbish. In Freiburg, has reached its acme. Garbage classification is required to be done from the beginning of the household, and each resident learns how to classify the garbage accurately. Handing over part of the classification work to the residents could greatly reduce the difficulty and complexity of the waste disposal work. The smart Freiburg people know how to turn waste into treasure by scientific treatment. 80% of the city's paper is made from recycled paper. The unrecyclable waste can be burned while the heat generated by the incineration can be used for heating. The heat generated by waste fermentation can also generate electricity. Garbage is no longer a stinking thing, but instead, could be used as inexhaustible resource, which could bring economic and social benefits to the city. Freiburg not only attaches great importance to garbage collection, but also values the importance of garbage reduction. To reduce the amount of garbage, residents should try to reduce the production of garbage. Germany has very advanced social education, so the quality and ideological level of their people is high. Even without penalties, citizens in Freiburg, known for their ‘environmental protection’, have high levels of self-consciousness. However, the government has adopted a number of incentives to control the amount of rubbish at its source. For example, the use of environmental protection baby diapers can be subsidized; the residents who do not throw garbage can reduce the waste treatment fee; and subsidises the residents who make the garbage compost and so on. The average number of waste dumped by Freiburg residents was significantly lower than the state and national levels. Citizens in order to make an effort to stop global warming are actively involved in the activity ‘lose weight for carbon dioxide’. They develop their own carbon dioxide ‘lose weight’ plan while comparing with others’ emissions. It can be seen that environmentally-friendly low-carbon construction has been integrated into the details of civic life, rather than just shout slogans.

2.3. Promote energy-saving buildings.

Solar community and its ancillary commercial facilities were designed by the famous solar architect Rolf Dischi. The solar community in Freiburg were built in 2004, with an area of 15574 m² and 59 apartments. As the pioneer for energy saving, there are a large number of
ecological tourists come here to visit his design every year. For example, the famous Heliotrope is a good case. The city showed the development and utilization of renewable energy. But using solar energy as a conventional energy, we still have a long way to go. Although solar panels are widely used, only 1% of the city's power is provided by the solar energy in the use of renewable energy.

At the same time, reduce building energy consumption is also a main aspect of building energy efficiency. The new district has the perfect heating system. The residential houses are mainly low energy consumption and solar energy. In order to ensure the construction of low energy consumption, every house builders must sign on in a low energy consumption building contract to guarantee the houses they make are low energy consumption buildings. Additionally, government support and encourage residents to install solar facilities. At the same time, the law stipulates that the social housing must be Passive House. It is called a passive house because passive construction should meet the need for comfortable life environment without external energy consumption for heating and cooling. Buildings need to adjust themselves. In fact, it is impossible that the buildings could adjust without external energy at all currently, but the energy consumption standards are very strict.

Used for building ontology and indoor air heating and cooling energy consumption for each year of building energy consumption Which includes the energy consumption of the residents Including heating and cooling, domestic hot water and electricity for more than a certain family life can only be used for the renewable energy efficiency standards from current energy consumption standard of German law Price is still lower. Energies of heating and cooling the buildings are 15KWh/m$^2$ per year. The total energy consumption is120 KWh/m$^2$ which includes the energy consumption of the residents, heating and cooling, domestic hot water and electricity. The rest could only be using the renewable energy. That is a quarter lower than the current German law requires.

3. Referential Significance

3.1. Combination of management policies and incentive policies.

The development and construction of the city cannot be successful without the guidance of urban planning. The high quality urban planning is the basic guarantee for the healthy development of urban construction. The city is a place for people to live, work, study and entertain. The basic tenor of urban development and construction is to serve the people. Therefore, the good urban planning requires public participation.

The public participation in German urban planning has a very strong legal basis, extensive social foundation and effective institutional guarantee. The public participation system in German urban planning and construction has been effectively and effectively implemented. Through public participation, the urban residents' willingness and ideas can be fully integrated in future city renovation. The city
could serve the people better, and at the same time, it can also set up strong ownership of the city residents, thus they would be more voluntary to protect the ecological environment of the city.

3.2. Mobilize the public participation

Every July, Freiburg hosts the ‘city pageant’, in which the government invites industry experts and urban citizens to participate actively. The pageant is a chance to brainstorm the strategies of future urban development. In addition to the support of high and new science and technology, various financial security measures and ecological compensation have generated good incentives and guidance for cities, governments, enterprises and even individuals. In the ecological construction of Freiburg, the city council had played a good leading role of innovation. It integrated the development of urban ecological technology effectively into the planning and construction. Combined with the active public participation in urban planning and the fine tradition of construction, the sustainable development of Freiburg could be pushed forward well. Other countries should learn from Freiburg and combine with the feature of their country’s national conditions and project optimization. It could lay a good foundation of theory and experience for the domestic development of green ecological city.

3.3. The combination of planning concepts and technologies.

The urban water management in Freiburg is mainly embodied in four aspects: sewage treatment, rainwater utilization, water-saving device and river technology. Freiburg has a complete set of modern sewage treatment system, which provides a richer choice for the utilization of urban water resources. During the construction of the new district, it paid attention to the concept of low impact development for discharging, recycling and utilization of rainwater. In addition, in order to motivate residents' initiative to protect and utilize water resources well, the city has also adopted a method of charging sewage and rainwater separately. The method could encourage residents to use water-saving devices extensively.

In the aspect of river technology utilization, the relationship between energy development and river ecological protection was deeply considered in the construction of modern hydropower station [3]. Freiburg paid much attention on the characteristics of the city itself with the selection of ecological technologies.

Aristotle once said, people come to cities to live, and people live in cities to live better. However, with the rapid development of the world's highly urbanized economy, it has also contributed to the ecological environment problems such as global warming, the deterioration of natural environment and the explosion of energy consumption. It has become an important issue of global sustainable development in the 21st century to utilize the green
ecological technology scientifically and rationally. The ecological city construction of Freiburg brings us a lot of experience: first, always give priority to ecological interests, let the environment return to nature; Second, choose the unexpected problem to start with in order to obtain the biggest effect with the smallest input; Third, stimulate the pride of residents and the spirit of ownership in order to expand the biophili city construction to a further extend.

The Construction of Botanical Gardens in Tokyo Metropolis in Japan from the Perspective of Green Infrastructure

Hu Nan, Li Xiong

"Beijing Forestry University, No.35, Qinghua East Road, Haidian District, Beijing 100083, China"

Abstract

Green infrastructure (GI), which is constructed by the central hub and link corridor, is proposed to build a green space system with interrelated and organic unity, and steadily play the ecological value of green space in the city. The botanical garden, as an important part of the urban green space system, is one of the key points in GI central hub construction. With the urban development and social evolution, as a facility for plant collection, cultivation and exhibition activities, botanical garden’s landscape, social and economic value is more significant.

Tokyo, as the capital of Japan, is the origin of the Japanese botanical garden. From the Koishikawa Botanical Garden, Tokyo has built 15 botanical gardens of different sizes and types, accounting for 1/8 of the total number of botanical gardens in Japan (115 places). From the perspective of GI, Tokyo botanical gardens, as GI central hub, play important ecological value, and the construction effect is also very prominent, mainly reflected in three aspects, the overall planning and system development process, the function expression and facility construction, and the plant application and plant landscape.

TBGS has diverse types and abundant facilities. There are Shinjuku Gyoen National Garden, Harumi Island Triton Square, Hoshi University Medicinal Plant Garden, Koishikawa Botanical Garden, that are the representative of comprehensive national and public botanical gardens, the botanical gardens operated by a company or a person, medicinal plant special gardens and university affiliated botanical gardens, respectively. With the continuous improvement of the botanical garden construction, the facilities in the garden, such as buildings, transportation, and signs are also more abundant.
TBGS has diverse plant species, rich plant landscape and obvious plant types. The number of plants preserved in each botanical garden is not less than 500 species, also there are more than 4000 species in the Koishikawa Botanical Garden and the Jindai Botanical Gardens. The four seasons plant landscape in TBGS, such as Sakura in spring, *Hydrangea macrophylla* in summer, acer and chrysanthemum in autumn, *Prunus mume* in winter and rose in four seasons, enrich the wonderful green space. Also, different plant types, such as ornamental plants, medicinal plants, economic plants and cultivated plants are applied in different kinds of botanical gardens.

Through the above three aspects, it can be seen that TBGS, as an important carrier of GI central hub, has three main characteristics, ecological sustainability and permeability, function perfection and comprehensiveness, landscape diversity, and has a good enlightenment to the current botanical garden as well as the GI construction.

**Keywords:** landscape architecture; green infrastructure; botanical garden; Tokyo metropolis

1. **Introduction**

Green infrastructure (GI), which is constructed by the central hub and link corridor, is proposed to build a green space system with interrelated and organic unity, and steadily play the ecological value of green space in the city [1]. The botanical garden, as an important part of the urban green space system, is one of the key points in GI central hub construction. With the urban development and social evolution, as a facility for plant collection, cultivation and exhibition activities, botanical garden’s landscape, social and economic value is more significant.

Tokyo, as the capital of Japan, is the origin of the Japanese botanical garden. From the Koishikawa Botanical Garden, Tokyo has built 15 botanical gardens of different sizes and types, accounting for 1/8 of the total number of botanical gardens in Japan (115 places) [2]. From the perspective of GI, Tokyo botanical gardens, as GI central hub, play important ecological value, and the construction effect is also very prominent, mainly reflected in three aspects, the overall planning and system development process, the function expression and facility construction, and the plant application and landscape.

2. **The overall planning and system development process of Tokyo botanical garden system**

Tokyo botanical garden system (TBGS) has long time history and wide space distribution. After Koishikawa Botanical Garden (KBG) has been established in 1638, TBGS has begun a history of 380 years, including five period of Edo, Meiji, Taisho, Showa and Heisei [3]. During this period, despite of the war, earthquakes and other irresistible factors, the overall style is well preserved. Also, TBGS is widely distributed in the Tokyo area and the tama area, with Tokyo as the center of the 50km service radius, to meet different users’ traffic demand.

2.1. **Edo period (1603-1867)**

The original of Japan botanical garden is the KBG which was built in the Edo shogunate period. This garden is the Edo shogunate facility, which was subordinated to the state organ. In this period, some herbal works, such as the Chinese ‘Compendium of Materia Medica’ and the Holland ‘Herb Record’ was introduced into Japan. Meanwhile, the number of shoguns who were interested in medicinal plants
gradually increased. Also, the increasing needs for the plant breeding and plant site resulted in the appearance of planting function in the garden. The owner of the garden not only planted herbs picked from Japan in the garden, but also introduced herbs and logs picked from China and Korea. This development made the garden become a place for the public health care and medicinal research. At the same time, Japanese sweet potatoes were experimented here and then popularized in the whole region of Kanto of Japan. In the middle of the Edo period, the Kyōhō Reforms appeared, and made the garden take the function of free medical service. After more than ten years, the cold summer and pest caused famine in Edo, and the sweet potatoes taken as the relief food were the first time cultivated in the garden.

2.2. **Meiji period (1868-1912)**

In 1868, Japan entered the Meiji period after the Meiji reform. Besides the KBG, the Shinjuku Gyoen National Garden (SGNG) opened, and the administration rights of botanical gardens were transferred to the court with the land rights to the state. With the extensive learning of western European technology, Japan introduced various tropical and subtropical horticultural plants and wild plants from Europe and America, and began to plant these plants in the two botanical gardens. The two gardens also began to build greenhouse in this period. The Meiji period is the industrial revolution stage, in which a lot of cultural products from the western country were input into Japan. At the same time, western industrial technology and various varieties of fruits, vegetables and flowers began to flow into Japan. The greenhouse construction not only provided conditions for the study of cultivated plants, but also provides the premise for the development and exploration of Japanese botany.

2.3. **Taisho period (1912-1926)**

In 1923, the great Kanto earthquake occurred and the KBG was used as a refuge for a part of the victims that made the function of the botanical garden extended. In 1918, the SGNG become the venue of viewing Sakura. In 1921, the predecessor of the Tama Forest Science Garden (TFSG), Royal Forest and Field Bureau, was built, as well as the official building. In this period, some publications related to the urban planning, such as ‘Research on the modern city’ and ‘Research on free urban space’ began to appear some discussion about the botanical gardens. In 1919, the ‘Urban planning law’ was promulgated. Parks and gardens have gradually become the urban planning facilities and been under the legal protection. It could be said that the development of botanical gardens in this period gradually established under the guidance of urban planning, and synchronized with the urban development.

2.4. **Showa period (1926-1989)**

From 1939 to 1945, Japan was involved in the Second World War, because of which, the facilities in KBG, such as the greenhouse, the gate, the meeting place and the classroom building was destroyed, as well as the pavilion in SGNG and the official buildings and laboratory in TFSG. At the same time, the Jindai green space, as the facility of Tokyo, began to become the air defense base and the place for teenager exercise and food production in the war. In 1941, the Hoshi University Medicinal Plant Garden (HUMPG) established with the opening of the Hoshi University, however, the land waste was very serious for being used as barracks. After the war, all the
Biophilic Cities

botanical gardens began to carry out a large area of repair work. In this period, some botanical gardens were newly built, such as the Medicinal Plant Garden of the school of pharmacy in Showa University (MPG-SU), the Medicinal Plant Garden of Tokyo University of Pharmacy and Life Sciences (MPG-TU), the Itabashi Akatsuka Botanical Garden (IABG), and the Yumenoshima Tropical Greenhouse Dome (YTGD).

2.5. Heisei period (From 1989)

From 1989, Japan has entered into the stable Heisei period, the greenhouse of KBG was finished in 1993, the SGNG belonged to the environment department in 2001, the TFSG was open to the public from 1992 and has been developed as the largest research agency related to the forest, forestry and timber, the Jindai Botanical Gardens (JBG) opened aquatic botanical garden in 1997, the HUMPG increased practical function and began to enhance the facilities in the garden such as the entrance gate. During this period, six new botanical gardens set up, respectively for the Medicinal Plant Garden in Showa Pharmaceutical University (MPG-SPU), the Itabashi Botanical Gardens (IBG), the Medicinal Plant Garden (MPG), the Harumi Island Triton Square (HITS), the Shibuya City Botanical Garden FUREAI (SCBG-FUREAI), and the Institute for Sustainable Agro-ecosystem Services of the graduate school of Agricultural and Life Sciences in the University of Tokyo (ISAS-TU).

To sum up, the scale and scope of botanical gardens have been increasing with time, and the network system has been gradually expanded. As the core of GI, the botanical gardens in Tokyo effectively connected with the urban traffic belt and green belt. The combination of point and line could fully play an important role of ecological radiation of urban green space. Meanwhile, as most of the botanical gardens have been located in the metropolitan area of Tokyo, and less of them on the edge of the urban fringe, these gardens meet the needs of all kinds of people from the perspective of spatial distribution.

3. The function expression and facility construction of Tokyo botanical garden system

TBGS has diverse types and abundant facilities. There are Shinjuku Gyoen National Garden, Harumi Island Triton Square, Hoshi University Medicinal Plant Garden, Koishikawa Botanical Garden, that are the representative of comprehensive national and public botanical gardens, the botanical gardens operated by a company or a person, medicinal plant special gardens and university affiliated botanical gardens, respectively. With the continuous improvement of the botanical garden construction, the facilities in the garden, such as buildings, transportation and signs are also more abundant.

The university affiliated botanical garden is mainly used as a place for students and teachers to research and teach, as well as a park for opening to the public. The KBG and ISAS-TU are both of this type, and have important functions of scientific research and education. For example, in 1877, the KBG, as a botanical garden affiliated to University of Tokyo, in which professor Yatabe Ryoshi and Itou Keisuke began the study of botany. In 1897, the botanical classroom was set up to become a place for botanical cultivation teaching in Japan and to play the function of the research and education center. The Japanese Institute of Botany (JIOB) and the bachelor's Association were also established in this
garden in 1882 and 1886 respectively (Fig.1).

The comprehensive national and public botanical garden always has plenty of ornamental and rare plants. Some are aquatic or forestry botanical gardens which collect characteristic plants, the others are huge scale botanical gardens which were built with museums, and there are also some botanical gardens to popularize plant knowledge or provide rest places for surrounding residents. The SGNG, TFSG, JBG, IABG, YTGD and SCBG-FUREAI are all of this type and have close connection with the public. In these botanical gardens, there both have public and ornamental plants area, and the combination of pleasure and cognition is the obvious feature of this type.

The botanical garden operated by a company or a person often has a large collection and centralized display of some kind of plants according to the company’s own characteristic, such as displaying some orchid, bamboo or alpine plants as well as displaying with insects and animal rearing. This botanical garden is suitable for people who are interested in ornamental plants or plant species relationship. The HITS belongs to this type, and has been used as urban space for protecting the season colors. In this garden, stuffs have been arranged to introduce the rich plant changes in different seasons and develop investigation and adjustment schedule of the garden’s condition in different stages, aiming to help the public set up their awareness of protecting and cultivating plants. This garden has also become an urban green space near the sea for integrating the urban function of basic necessities of life.

The medicinal plant special garden not only collects plants as pharmaceutical raw material at home and abroad, but also collects and cultivates some aromatic compounds, dyes and poisonous plants for study. As the garden is often subordinated to university, most of the facilities in garden are not open to the public. The HUMPG, MPG-SU, MPG-TU, MPG-SPU, and MPG are all of this type. This type of botanical garden mainly has three aspects of function, that are the medicinal plants collecting, cultivating, researching and displaying, the practical activities for teachers, students and pharmacists, and the popularization and inspiration of knowledge about medicinal plants to public.

From perspective of development process, botanical garden in Edo period had obvious medicinal function and always planted a lot of rare plants. In Meiji period, the modern botanical gardens came to appear and began to develop scientific and research institution attached to university. Also, along with the botany development, facilities such as greenhouse, plant cultivation and experiment grounds began to build, and the botanical garden’s function of social education, public relaxation and health care began to appear. Even though the function and facility development of botanical garden was slow in Taisho period, every aspect entered the stage of rapid development in Showa period. Although the war had great influence on various botanical gardens, it also made the gardens undertake more functions. In Heisei period, facilities of TBGS continued to improve, and four types of botanical gardens developed mature along with the various functions of botanical gardens. Because of the opening to public, gardens have also created more and more facilities for practical activities, and the progress of botany also has promoted the botanical gardens to pay more attention to the function of scientific education and research.

In 2006, the JIOB established the national plant diversity protection botanical garden system according to the climate, location
and characteristic of botanical gardens. This system clearly shows the order of plant protection, the collection and preservation method of plants and seeds, and the plant education and inspiration to public (fig.2) [4]. The KBG, SGNG, and JBG are all in this system and has made great contribution to the natural environment protection career.

To sum up, different from the general GI, botanical gardens of different types have various functions. At the same time, as there have kinds of facilities in gardens, including appreciation type, practical type and functional type, the botanical gardens have become the places for people activities centralized in. The perfect service facilities in gardens have also made sure to meet people’s needs. It could be said that botanical gardens have enhanced the richness and diversity of the overall GI system function.

4. The plant application and landscape of Tokyo botanical garden system

TBGS has diverse plant species, rich plant landscape and obvious plant types. The number of plants preserved in each botanical garden is not less than 500 species, also there are more than 4000 species in the KBG and JBG. In addition, in the SGNG, there have been more than 270 kinds of trees, and about 2700 kinds of plants in the greenhouse, among which about 140 kinds of plants have been recorded as the endangered species. In the ISAS-TU, there have been about 250 kinds of ornamental lotus, 200 kinds of foliage plants and 30 kinds of orchid. In the TFSG, there have been 500 kinds of woody plants and 600 cultivated Sakura system [2].

Different plant types are applied in different kinds of botanical gardens, such as ornamental plants in comprehensive national and public botanical gardens, medicinal plants in medicinal plant special gardens, economic plants in botanical gardens operated by a company or a person and cultivated plants in university affiliated botanical gardens. Taking the JBG which belongs to the comprehensive national and public botanical garden as an example, there have been different kinds of rose, rhododendron, plum and Sakura in the garden. The MPG of the medicinal plant special garden has mainly collected the original plant medicine for the Japanese medicinal administration. The HITS of botanical garden operated by a company or a person has developed different flowers exhibition according to the season changes (fig.3). The KBG of university affiliated botanical garden has been widely collected different kinds of plants, and arranged them in order according to the new Engler System for easy visit.

The four season plant landscape in TBGS, such as Sakura in spring, Hydrangea macrophylla in summer, acer and chrysanthemum in autumn, Prunus mume in winter and rose in four seasons, enrich the wonderful green space. For example, there have been about 65 kinds and 1100 Sakura in the SGNG, thus resulting in different flowering period (fig.4). People will have long time to appreciate different flower colors, such as about 400 ‘Somei Yoshino’ blooming from late March to early April, about 20 kinds of 300 double cherry blossoms from early April to late April [5]. The sunken garden in the JBG planted roses which have bloomed twice in one year, among which 409 kinds of 5200 roses bloom in the late May in spring and about 300 kinds of more than 5000 roses bloom in the middle October in autumn (fig.5) [6]. Even though the flowers are very small, the color are very bright.

To sum up, various plants is the obvious characteristic of botanical garden which is
Different from the general green space. The plants not only enhance the species diversity but also ensure the stability of community structure, thus helping release the ecological function of the botanical garden taken as the core of GI. At the same time, the various shape of plants help create different plant landscape space and sightseeing experiences for users through diverse configuration methods, which further complements the landscape function of GI.

5. Conclusion

Through the above three aspects, it can be seen that TBGS, as an important carrier of GI central hub, has three main characteristics, ecological sustainability and permeability, function perfection and comprehensiveness and landscape diversity. The TBGS have been playing important role in many fields, such as plants diversity study, alive plants exhibition, social education, plants resource development, plants system preservation and public recreation. As the important part of Japanese urban green space, the botanical gardens have been the main carrier of Japanese GI and have a good enlightenment to the current botanical garden construction as well as the GI construction.

Biophilia in Human Settlements Construction in Ancient China - A Case Study of the Northwestern Suburbs of Beijing

Qiang Zhu, Dongchen Li, Sujing Huangfu, Zitong Feng

*Beijing Forestry University, No.35 Tsinghua East Road, Haidian District, Beijing, China, Beijing and 100083, People’s Republic of China

Abstract

Famous historic gardens of China such as the Summer Palace are usually interpreted from the perspective of culture and art. In this paper, however, the northwestern suburbs of Beijing where the Summer Palace is located are demonstrated to be a complete human settlements system. While handling the relations between human beings and nature, they represent distinct biophilic characteristics. In the meantime, both macroscopic regional planning and microscopic garden design by ancient Chinese have fully verified authenticity of the Biophilia Hypothesis. The application of ancient experience to modern urban construction and the unique role of landscape architecture are discussed at the end of the paper.

Keywords: biophilia; ancient Beijing; human settlement; planning & design; case study

1. Backgrounds

Chinese people have pursued the concept of “harmony between man and nature” during human settlements construction since ancient times, which is mainly because they have a profound understanding of the harmonious and unified relations between man and nature. In other words, people can survive and develop sustainably only by conforming to the objective laws of nature when production and life cannot be separated from nature. It is in this context that China’s agricultural civilization came into being and the unique cultural structure - Chinese gardens - emerged. As an important demonstration of ancient civilizations, Beijing and its northwestern suburbs are particularly noteworthy.

Northwestern suburbs of Beijing, which is a rare combination of natural mountain forests and plain wetlands in northern China, mainly refer to Haidian District – a region that is historically distinct from other areas in Beijing. They have served as an important water source and scenic spot since ancient times. For example, the region served as a water source and scenic spot for nobles in the Jin Dynasty (1115-1234), and a dwelling place for royal aristocrats, political center of the empire, crucial water source and rice production area in the Qing Dynasty (1644-1911). This paper attempts to explore changing laws and driving factors of the entire region from regional and dynamic perspectives.
2. General Introduction

The northwestern suburbs of Beijing reached an unprecedented peak after 128 years (1684 to 1811) of construction by four emperors (Kangxi, Yongzheng, Qianlong and Jiaqing) in the Qing Dynasty, thereby being rated as a model for the construction of human settlements in ancient China. According to statistics, the northwestern suburbs of Beijing covered a total area of more than 85 square kilometers, which far outweighs the ancient city (66.2 square kilometers). In addition to five imperial gardens that occupied an area of 9.7 square kilometers, there were lots of mountains, waters, small and medium-sized gardens, villages, farmlands, temples and barracks (Fig. 1). In other words, the northwestern suburbs of Beijing contained all infrastructures necessary for high-quality production and life. Gardens, as one of the core components, not only provided comfortable accommodation for a large number of upper class people, but also carried rich history and culture. All these took place in the suburbs rather than highly populated cities, which amply demonstrates the extraordinary yearning and dependence of ancient Chinese on nature, and effectively demonstrates the instinctive love of human beings for nature according to the *Biophilia Hypothesis*.

![Fig. 1. The layout of ancient Beijing city and its northwestern suburbs in 1860s](image)

Source: Redrawn according to reference [1]

3. Macroscopic and Microscopic Biophilia

3.1. Macroscopic Biophilia

Judging from the regional perspective, ancient Chinese made full use of the superior natural conditions and resources in the northwestern suburbs of Beijing to build a biophilic system that was jointly supported by artificial and natural forces. A fully functional, comfortable and pleasant living environment was formed on the basis of giving priority to water distribution and agricultural production (Fig. 2, attached in appendix).

3.1.1. Rise of Water Conservancy and Agricultural Infrastructure

Due to the unique geological structures and climatic conditions, the northwestern suburbs of Beijing have enjoyed abundant groundwater resources and natural precipitation [2]. The ancients not only overcame the unfavorable topographic
factors and built the Long River that transported water to the southeast, but also reclaimed land from lakes on a large scale to produce rice. In the meantime, peasant-oriented agricultural settlements and gardens centered on nobles and literati emerged and reached a certain scale early in the Ming Dynasty (1368-1644) [3]. According to historical records, areas between the Long River and the West Lake (Kunming Lake) and the Jade Spring Hill served as public tour destinations and lots of ancient poems indicated the strong yearning of urban residents for nature. Although the publicity disappeared for the privileges of Manchu rulers, water conservancy and agriculture reached unprecedented development in the Qing Dynasty (1644-1911). They were greatly promoted by national projects such as water source development and reservoir construction in Emperor Qianlong’s period, significantly boosting social and economic development. It was in this context that the Kunming Lake Reservoir was built. (Fig. 3)

3.1.2. Scientific Site Selection

Ancient Chinese developed the habit of living in the highlands and farming in the lowlands in long-term agricultural practices. The name of “Haidian” originally referred to lakes in the northwestern suburbs of Beijing and later became a settlement name. According to the topographic analysis, Haidian, the agricultural settlement, was located on the plateau in the east of the waters, which is mainly attributed to the following reasons: the high altitude protected the settlement from flooding. In addition, it was close to the farmland on the west, thereby enjoying convenient traffic [4]. However, gardens in the Ming Dynasty were located in low-lying areas to draw water into gardens, despite the threat of flooding, which was the reason why the eastern dyke of Kunming Lake played an important role. Rivers built with natural and artificial forces enabled Wanquan River on the south and Kunming Lake on the west to supply water simultaneously. The river water and lake water flew through the garden, got fully utilized and merged into natural rivers, which reflected the strong control and application of water by ancient people.

3.1.3. Clustered Development of Gardens

Gardens of the Ming and Qing dynasties differed in nature. Qinghua Garden and Shao Garden in the Ming Dynasty belonged to country villas while gardens in the Qing Dynasty consisted of politically powerful and grand-scale imperial gardens. Emperor Kangxi, the second emperor to rule over all of China, built the first imperial palace Changchun Garden on the site of Qinghua Garden, and two temporary imperial palaces on the site of the Fragrant Hill and the Jade Spring Hill respectively. He awarded lands around Changchun Garden to nobles to facilitate their living and working gardens. The historic change directly laid the
foundation for the development of the “Three Hills and Five Gardens” into the political center of the Qing Dynasty and the contiguous development of gardens. With the prosperity of national economy and culture, gardens in this region had peaked in both scale and art. They maintained garden communities in the east and famous mountain scenic spots in the west before the destruction by Anglo-French invaders in 1860. Therefore, garden construction in the Qing Dynasty precisely reflected people’s needs for higher-quality nature and significantly improved the ecological environment.

3.2. Microscopic Biophilia

This paper selects GARDENS as the research objects. Although the various imperial gardens and awarded gardens distinctly differed from each other in scales and characteristics, they mostly reconstructed the relations between man and nature by mimicking and humanizing nature, which reflects strong biophilia – clearly verified in the construction of gardens.

3.2.1. Construction of Artificial Landscapes

Ancient Chinese attached great importance to the construction of living environments and tended to create ideal landscape patterns through earthwork. Based on the few constraints, strong plasticity and large effective use area of flatlands, landscape architects fully practiced this notion in low-lying areas in the eastern region. They simulated various kinds of natural landscapes by virtue of the original soil, waters and rocks. Although the mountains were not high and the waters were not deep, the exquisite space art provided a wealth of touring experience and visual experience. As one of the masterpieces, Yuanming Garden (the Old Summer Palace, with an area of 355 hectares) had more than 150 themed scenic spots, thereby being known as the Garden of Gardens (Fig. 4-5). The garden boundaries, which were composed of low mountains and stone walls, enhanced their beauty with plants and enabled people to look into the distance in specific positions. The West Mountain in the distance, Jade Spring Hill and Longevity Hill nearby, dense rice fields and hardworking peasants on the plains constituted a layered and poetic picture.

It was on these bases that architecture with different functions (enormous and regular palace architecture, small and flexible residential and recreational architecture, and mysterious religious architecture) were designed and built. In addition, all these buildings were closely related to the external landscapes. Therefore, gardens should not only satisfy people’s demands for comfortable and spacious residential and recreational space, but also meet the needs of getting close to nature. These excellent gardens have presented optimal solutions after unremitting exploration of the ancients.
3.2.2. Creation of Animal and Plant Landscapes

Mountains and waters are not the only thing of this artificial biologic system while humans, animals and plants are the real protagonists. As the Biophilia Hypothesis advocates, the cross-species affection of humans for plants is a product of evolution. The creation of animal and plant landscapes in highly artificial places like gardens is also an art. Landscape architects shall select plants (including horticultural species that need to be carefully managed) in accordance with the habitats and themes, so as to create a natural atmosphere. For example, ancient Chinese planted pines, peaches, apricots, bamboos and lotuses, and raised rare birds, fish and beasts (waterfowl, deer, crane, koi, etc.) in imperial gardens, so that people living in these gardens could maintain a reverence for life. Both plant changes with season and animal sounds were sources of spiritual enjoyment. Although everything was artificially controlled, the scene presented was harmonious. In other words, the gardens, which are artificial, are comparable to natural wonders (Fig. 6).

3.2.3. Implantation of Culture and Religion

The various natural elements have been endowed with humanistic and symbolic meanings under the influence of traditional Chinese culture over the past few thousand years, which is referred to as “humanized nature”. In other words, natural things are interpreted from the perspective of human beings. Therefore, the creation of gardens is actually the reverse process of cognizing nature and culture is one of the most important driving factors. The austere garden landscapes tend to have deep cultural connotations such as traditional political and philosophical ideas and classic literary
works, which is the reason why gardens were historically exclusive to scholar-bureaucrats. In such a specific space, everything (climate changes, sun, moon, mountains and water, plants) can trigger thinking and emotional changes (Fig. 7).

In addition to these controllable factors, biophilia is manifested as religious beliefs and close relations with the uncontrollable nature. For example, precipitation directly affected crop yields in the farming age, making the dragon king (the dispenser of rain) highly respected. Emperors not only gave honorary titles to the dragon king, but also held sacrifice ceremonies regularly to pray for abundant precipitation. Dragon king temples can be found in many imperial gardens, including Yuanming Garden, the Summer Palace and Jingming Garden. In addition, land god in charge of local security, flower goddess in charge of plant growth and gods in charge of climate were honored in different degrees, leading to a mysterious religious culture.

3.3. Conclusion

According to the above argument, the construction of human settlements in the northwestern suburbs of Beijing has demonstrated biophilia in many respects and experienced four stages: depending on nature (canals digging and farmland irrigation), yearning for nature (picnic places yearned by urban residents), recreating nature (rise and prosperity of gardens) and realizing nature (penetration of landscape culture into literati’s minds). Nature has been an eternal topic over the thousands of years of development, which is quite touching.

4. Discussion

Biophilia is not a brand new concept, but a concept that has been amply demonstrated in ancient China, especially in the northwestern suburbs of Beijing. In the meantime, there is some reason to believe that this is not the only case. However, it is still difficult to effectively translate such characteristics in agricultural civilization in the context of industrial civilization and ecological civilization, which is also an important foundation for landscape architecture to gain a foothold in the human settlements science system. Therefore, it is necessary to have a firm grasp of changes and inheritances: changing the productivity, the ability to transform nature and people’s lifestyles while inheriting the yearning for nature and the expression of feelings through nature. Only when the core of inheritances is grasped shall landscape architects reasonably express, guard and sustain the long repressed biophilia of people by virtue of design and guidance.
when dealing with the relations between cities and nature.

Abstract

Due to the pressure of urbanization, urban animal habitats are losing at an alarming rate in Beijing. Birds are often used seen as symbolic species in biodiversity research to test the complexity and stability of city ecosystems because of their key position in the food chain and their strong environmental sensitivity. Therefore, the protection of urban bird habitats is particularly important. Beijing is a stop point on the bird migratory route from "East Asia to Australia". With urban areas gradually replacing natural habitats, the meeting rate and diversity of birds in Beijing have been decreasing. GI (Green Infrastructure) is an interconnected network with natural areas and open spaces. It preserves the value and function of natural ecosystems, maintains landscape connectivity and reduces habitat fragmentation, which thus it plays an important role in the habitat conservation. This paper firstly describes how the green infrastructure, as a life support platform, provides birds the life supportive services such as food, water sources, nesting grounds and flight corridors for birds. And then explains how the green infrastructure it affects the survival and reproduction of birds by environmental factors. Taking the Beijing city as an example, the paper secondly subsequently explores the way to build an urban bird habitat system with the planning of green infrastructure network. Based on RS and GIS platforms, researchers extracted basic elements of urban green infrastructures, identified habitats and classified them. On the basis of acreage and position information of patches, ecological corridors and habitat islands. According to the result above, current GI elements can be recognized with function importance and be planned hierarchically to protect the bird diversity. simultaneously, target species are clearly defined for every core areas of various habitats, and those broken islands are connected to improve the network system. Finally, this paper put forward an ideal model for the construction of GI network in Beijing from the angle of bird habitat protection. In addition, it proposes some suggestions on the current construction of urban green space.

Keywords: Green Infrastructure, Avian habitats, Biodiversity

1. Urban birds habitats status

Due to the rapid expansion of cities, China is one of the countries where the destruction of habitats and loss of biodiversity are extremely serious. With the reduction of vegetation, pollution, population density and pressure from
climate change, animal habitats in cities are disappearing from our side at an alarming rate. As the main area where humans live, a large number of natural areas in cities have been converted into construction land. The original habitat of plants and animals was invaded, species migration corridors were cut off, and habitats were seriously islanded. All of the above reasons have made the city a hard-hit area where species richness has declined.

Urban green space is the main habitat for birds. As the only living part of urban infrastructure construction, green space provides food, water, breeding grounds and hidden conditions for birds, which has a decisive influence on the survival and reproduction of urban birds. However, urban green areas are mostly designed according to people's use. They are mostly affected by other types of construction lands, so habitat qualities need to be improved. Main problem of urban habitats are as follows.(1) The total amount of habitat is insufficient.(2) The type of habitat is single and it is difficult to meet the diversity of birds.(3)Lack of reasonable layout planning and zoning which lead to the lower utilization of birds(4) Landscape fragmentation(5) The vegetation cover level is simpler than natural forests. (6) Excessive artificial surface, human interference intensity.

2. Green infrastructures and bird habitats

Green infrastructure is a network of interconnected natural areas and open spaces. It preserves the value and function of natural ecosystems, maintains the connectivity of landscapes, and effectively reduces the fragmentation of habitats. Because of the function of protecting biological habitats, Green infrastructure plays an important role in biodiversity conservation.

As the life support platform for urban birds, the green infrastructure provides food, water, nesting sites, flight corridors, and other life supply services. It also exerts a tremendous influence on the survival and reproduction of birds through these influence factors. Analysing the relationship between urban greenland structure and birds, studying ways of optimal allocation of urban greenland structure and building methods of bird habitat will provide important scientific basis and play an important guiding role in urban ecological environment construction and bird diversity protection.

3. Urban bird habitats conservation based on the green infrastructure network - Beijing case

The study site in this paper is a stop point on the "East Asia-Australia" migratory route of the birds. With the gradual replacement of natural habitats for urban construction land, the bird encounter rate and diversity in Beijing are gradually reduced. Even once the city was referred to as a “no-birds capital”. Some bird species with strong adaptability to the artificial environment have become dominant species, which are not conducive to the improvement of urban biodiversity. This research takes Beijing as an example to explore ways to build a network of urban bird habitats and to protect urban bird habitats based on the idea of building a green infrastructure network.
3.1 Target species selection

It is not realistic to create habitats for each type of bird in the city. It is feasible to follow the natural characteristics of all types of green space to plan and create suitable habitats for different bird populations. Therefore, it is necessary to select appropriate target species to analyse and evaluate the value of various birds to humans.

Protected objects in Conservation Biology may include endangered species, threatened species, endemic species, flagship species, umbrella species, focal species, key species, and indicator species. In the special environmental conditions of urban green space, the following types of birds deserve attention by landscape architects. (1) Flagship species that have special charisma and can serve as public relations tools to protect specific regions, such as those large birds that are easily visible from space, or small birds with bright colours, or birds with unique or pleasing sounds. (2) Occasional species in urban areas, which are very attractive to urban residents who have a bird watching habit. For ordinary people, these birds also increase their chances of experiencing more abundant biological forms. (3) Focal species. Through the restoration, protection and management of the habitats needed for these bird communities, people can achieve the goal of protecting most species and even the overall biodiversity. (4) Common species. They adapt to the urban environment and are relatively stable in terms of quantity. They are "emotional ambassadors" that link the emotional connection between humans and other creatures.

This research is based on the current conditions of habitats in urban green space. With reference to the principle of bio-protection, the following species are selected as representative species for each type of habitats. According to the environmental sensitivity and requirements on the environmental quality of target species, researchers selected indicator species, focal species, common species that are respectively represent the birds ‘demand for green infrastructure at three different levels of high, medium and low.

Different birds are selective to their habitat. For example, if the floating birds mainly inhabit the open water and catch small fish and shrimp in the water, the wading birds mainly live in the shallow water areas or the banks of the wetlands. The climbing birds, songbird, and land birds live mainly in forested habitats. Raptors have a large habitat scale which can cover the whole urban area. Therefore, they are not included in specific habitat discussions.

Table 2 the Suitable Habitat Characteristics Of Target Species

### 3.2 green infrastructure network construction

#### 3.2.1 data sources

This study mainly used the Landsat Landsat 8 OLI_TIRS satellite remote sensing data in Beijing in summer 2017 (mainly using the NIR, R and G bands). The researchers used ENVI5.3 to fuse different bands, subset and sharpening the image. Through the above operations, the full-scale false color image of Beijing was obtained, which has enhanced the spectral characteristics of plants. Image accuracy is 15M. At the same time, Beijing’s latest land use change survey results on the scale of 1:10,000 were used as supplementary data. Through E-cognition, we implemented a classification operation, and Beijing land use type map (Figure 1) and NDVI variation map (Figure 2) were extracted. Among them, forest land (natural forest land, artificial forest land), farmland, shrub-grassland, water area, and shallow water area can all satisfy bird inhabitation activity to a certain extent. These area can be used as a component of the green infrastructure.
3.2.2 Habitat suitability evaluation

3.2.2.1 Suitability Evaluation Index System

The core purpose of green infrastructure is to protect biodiversity and guide natural ecology. In the green infrastructure construction based on the protection of specific species, the extraction of various network elements based on the suitability of species habitats is very important. The study summarized the characteristics of the habitats of three types of typical habitats—forest habitats, near-water habitats, and aquatic habitats. The results are summarized in Table 2. The evaluation of habitat suitability of 9 representative birds in the Beijing area was also conducted.

The construction of the bird suitability evaluation matrix is mainly to establish the corresponding relationship between habitat impact factors and suitability index and the contribution value of the total suitability index of the target species of each impact factor. According to the comprehensive analysis of expert experience and knowledge, it is possible to establish the different degrees of importance of various habitat factors in the suitability analysis and assign different weight values to each factor. The determination and allocation of weight values is a very critical step in suitability analysis. The scientificalness, objectivity, and authenticity of this process play a decisive role in the evaluation results. The weighting process of this study uses the method of factors ‘relative importance.

In the suitability analysis of bird habitats in Beijing, the researchers selected the land use, vegetation coverage (using the NDVI index), and the human disturbance as the first-class evaluation factor. The distribution of weight values is shown in Table 3. For the birds living in forest habitats, their requirements for vegetation coverage are high, and the density and species of the vegetation have a great impact on their nesting and foraging. Therefore, compared with aquatic birds and wading birds that depend on aquatic habitats, the NDVI index has a more pronounced impact on them. In addition, for common birds in
Biophilic Cities

cities, their adaptability to human disturbance is strong, so the interference intensity has little effect on these birds. In the establishment of the evaluation matrix about second-class factors, the urban land use condition is divided into six categories: natural forest land, urban green land, water area, shallow water area, farmland, and constructed land. The NDVI indexes are evenly divided into three levels. The specific classification of human interference intensity is determined by the distance from the specific habitat location to the central urban area. Among these target birds, birds that rely on aquatic habitats have a larger radius of activity and a larger field of vision, so their demand for plant coverage are moderate. In contrast, birds living in woodland habitats require higher vegetation densities to meet their requirements for nesting and avoiding natural enemies.

Figure 3 Habitat Suitability Analysis of Target Birds
Bird habitats suitability evaluation

The bird habitat suitability analysis method of this study effectively combines mathematical models with remote sensing and GIS technologies. The spatial quantification of the habitat impact factor data is based on the homogenous polygon unit extracted by the object-oriented image segmentation technology. Each polygon evaluation unit is composed of multiple remote sensing pixels. The suitability of birds reflects the comfort of the bird's survival and reproduction in the environment. The influence of each factors on the habitat does not exist in isolation. In different combinations, their influence is different, but they restrict and complement each other. In the calculation of the bird suitability index in this study, the researchers used linear functional relationships to describe habitat suitability and impact factors. The formula is:

$$HS_{i} = \sum_{n=1}^{m} (A_{ni} B_{ni}) i=1,2,...,x$$

In the formula, $HS_i$ is the value of the habitat suitability index of the $i$ types of birds. $A_{ni}$ $(n=1, 2,3,...,m)$ represent the contribution rate or weight of the number $n$ factor to the number $i$ bird group. $B_{ni}$ $(n=1,2,...,m)$ is the suitability value of the number $n$ factor to the number $i$ bird species. $m$ is the number of influencing factors involved in the analysis. $x$ is the number of birds that participated in the analysis.

Dividing Beijing into a suitable polygon habitat evaluation unit, and calculating suitability values for individual evaluation units based on suitability analysis models and habitat geography spatial quantification values. The high value results in the analysis unit correspond to the good bird living environment, and the low values correspond to the poor living environment of the birds with poor habitat suitability. In this study, the calculation results are also divided into four levels in accordance with the evaluation grade index, that is, the habitat evaluation of birds is divided into four categories: high-suitable area, moderate-suitable area, low-suitable area, and unsuitable area. With the support of the GIS platform, suitability analysis figures of 9 target bird groups was obtained. The results are shown below in Figure 3.

During the process of comprehensive suitability assessment of the three groups of target species, --indicator species, focal species, and common species--we can assume that the those birds communities are threatened in the same degree. Therefore, we use the same weights in complex overlay calculations. Through the data recalculation, three sets of bird comprehensive suitability evaluation maps.
were obtained. And the results are shown below in Figure 4.

From the comparison results, it can be found that the suitable areas for birds of the three groups differ greatly. The indicator species groups have the least range of suitability due to their high environmental sensitivity, high requirements on habitat quality, and vulnerability to human activities. The focal species represents the degree of adaptation of most types of birds, and common birds’ activities area cover most of the city

### 3.2.2 Green Infrastructure Network Composition

#### 3.2.2.1 Elements Extraction

The study used the assessment of habitat suitability with the three groups as a base map to extract the elements of the green infrastructure network. According to Forman’s "concentration and decentralization combined" landscape ecological landscape pattern, the overall landscape optimal layout model includes: some large natural vegetation patches to conserve water resources and maintain the survival of key species; There are wide enough and a certain number of corridors for species diffusion and energy flows; Small natural vegetation patches serve as temporary habitats or shelters. Based on this, the study uses morphological principles to segment the base map, identify existing green infrastructure elements, and identify potential ecological corridors. The contents of each element are as follows.

<table>

</thead>
<tbody>
<tr>
<td>Core Area</td>
<td>Large-scale natural patches are the &quot;source&quot; of many ecological processes, providing habitat or migration destinations for wildlife. In urban areas, the core area usually corresponds to large parks, nature reserves, scenic spots, etc. in urban areas.</td>
</tr>
<tr>
<td>Ecological Island</td>
<td>The isolated small patches, which are equivalent to the “ecological hopping island” in the ecological network. It can provide scattered island species, or the flow of matter and energy, and play an intermediary role in the ecological network.</td>
</tr>
<tr>
<td>Buffer</td>
<td>The transition zone between the core area and the peripheral cities is to protect the ecological process and natural succession of the core area, and reduce the impact of the outside landscape. It has a marginal effect. In the urban environment, the main area is the intersection of green landscape and the outside world, such as the forest belt outside the park.</td>
</tr>
<tr>
<td>Connecting Corridor</td>
<td>The corridor connecting the adjacent core area is a channel for species dispersal and energy exchange between patches in the adjacent core area.</td>
</tr>
</tbody>
</table>

Table 5 Basic Elements of the GI network
3.2.2.2 Hierarchical planning

(1) Hierarchical planning of core areas

The organic integration of the core area and connecting corridors is essential to provide ecological functions and improve the landscape connectivity. We classified the importance of the green infrastructure network centre by distinguishing the suitability of the three groups of target species, identifying the patch area and the landscape structure inside the patch. Classification criteria include (1) plaque area (2) plaque quality (3) suitability of target birds in each group.

Core areas in first-level group, which are composed of higher avian suitability area and peripheral buffers, can meet the habitat requirements of important indicator species. These areas are large in area and have high connectivity and biodiversity. Core areas in first-level group are consist of moderate suitability area and buffer area. At least, they can meet the adaptability of the focal species. Although the area and connectivity of them are smaller than that of the first-level network centre, they also have the function of maintaining urban biodiversity and other ecological environments. However, such areas are mostly surrounded by urban constructed land, so these area in second-level has high ecological sensitivity and poor system stability, and are easily affected by external disturbances. Core area in the third-level group consists of island patches and low habitat suitability area. They can meet the demand of common bird habitats, and can serve as as an “eco-hopping island” for species migration, material and energy flow channels. And they play a role in media and links in the green infrastructure network.

(2) Hierarchical planning of corridors

The principle of the corridor grading is similar to that of the core area. The reference indicators mainly include (1) the corridor width (2) the corridor connection degree (3) the core area level of the corridor connection. The first-level corridors are used to connect to the first-level cores, which helps the flow and exchange of energy between large-scale green space patches. The Two-level corridors, used to connect the first-level cores and the second-level cores, or contact different second-level network centres. Such corridors are mainly based on branches, combined with urban river riparian zones and urban secondary roads for greening, which helps to strengthen the interrelationship between patches in different grades of core areas. Three-level connection corridors, used to contact three-level network centres, can reduce the fragmentation of the landscape and increase the overall continuity of the green infrastructure network.

4. Conclusion

According to the related superposition and calculation, the results of urban green space infrastructure planning based on bird protection are shown in Figure 5. The results showed that the green infrastructure can set up three intensity ranges of high, medium and low levels for birds. The indicated
species with higher ecological environment requirements can perch in the primary core area, and the focal species representing most bird habitats can live in a wider space for inhabiting, as well as common birds. However, there are more bird species in suitable woodland types in Beijing, but less suitable for water birds. Due to the lack of shallow water areas, the existing river channels shrink the living space of wading birds. In the green infrastructure, we should appropriately increase the buffer area of water and construction land and the degree of connectivity between corridors.

Research on Water Saving Urban Forest Plant Planning in Beijing Based on Plant Water Requirements

Renjing Zhao,*Xiong Li*

*Beijing Forestry University, No. 35, Tsinghua East Road, Haidian District, Beijing, 100083, China

Abstract

With the rapid process of urbanization, the urban natural ecological environment is replacing by reinforced concrete successively. With the concept of eco-friendly construction becoming deeply into human mind, the urban ecological construction has been paid more and more attention. Under the background of retreating the non-capital city function of Beijing and improving the city living environment, the urban forest construction in Beijing has been developed step by step. The urban forest is based on the spirit of eco-friendly city construction in the aspects of improving the urban ecological environment, promoting the harmony between human and nature, and maintaining the balance of urban ecosystem. The combination of urban forest construction and urban ecological construction is also an important way to express the characteristics of natural ecological landscape in the city. Among them, water-saving urban forest construction is the important method to build low-maintenance, self-recycling natural ecological system. This paper is taking the water-saving city’s forest plants strategy planning as the entry point, then taking the urban forest construction of Hengjiezi in Beijing as an example, according to the rain Water resources collected within the urban forest construction scope to calculate the effective rainfall which could be used by the plants. In order to realize the self-balance and self-maintenance of irrigation water for urban forest plants, the calculated effective rainfall can be combined with the average annual water demand of plant growth, the selective use of water in urban forest plant planning is carried out. A plant landscape planning method based on the calculation of plant water consumption is put forward through the micro level, and the content, connotation and steps of the method are further explained. This paper expounds how to calculate plant water consumption to provide quantitative support for the determination of planting area and vegetation type, and makes a strategy study on plant selection and community allocation of urban forest in Beijing. This paper discusses the combination of urban forest and natural ecological environment, establishes a new eco-friendly model of water-saving urban forest, and tries to provide new ideas for urban forest plant planning in Beijing.

Keywords: Plant Water Requirements; Urban Forest; Plant Planning; Ecological Friendliness
1. Introduction

The rapid urban development has caused great damage to the natural ecological environment in the city. Although some achievements have been made during the urban greening construction in China, the problem of wasting resources is common in this process, while the optimal allocation and efficient utilization of resources have not been realized. China has a large population, and its per capita water resource is only 28% of the world's average per capita level. In this situation, the water consumption of green space, especially the amount of water consumed by plant irrigation, has been increasing with the construction of green spaces year by year, and the construction of water-saving green spaces has become the inevitable requirement for urban ecological development.

In the context of relieving Beijing's non-capital functions, setting aside vacant land and adding green space, urban forest is gradually emphasized due to its high ecological value. Since China's per capita urban forest area is greatly below the world average, urban forest plays an important role in improving urban ecological environment, promoting harmonious coexistence between human and nature, and maintaining the balance of urban ecological system, which greatly correspond the spirit of ecological civilization construction. In this way, the restoration of urban natural ecological environment is of great importance.

2. A review of water-saving landscape and urban forest research

2.1. A review of water-saving landscape research

Water-saving landscape is a crucial aspect of resource-efficient landscape construction. It is to allocate and recycle resources rationally, save water resources to the maximum extent, and improve the utilization rate of water resources. It intends to achieve the maximum ecological benefit with the least amount of water and minimum interference pattern. Although many studies have been working on the issue of the water-saving landscape at present, most of them focus on the maintenance management of water-saving technology, such as reclaimed water recycle, permeable pavement material and ecological revetment design, which intend to save landscape water consumption. Although there are some concerns about plants in these studies, most of them are from the perspective of the development model of traditional garden, while the issue of great water consumption of irrigation plants in the garden water is often neglected.

2.2. Review of urban forest plant landscape research

Since the 1960s, scholars have begun to study urban forest and defined urban forest from various perspectives. At present, though the concept of urban forest is not uniformed, it contains the same argument: the urban forest is mainly composed of trees, including the configuration and layout of the plant community. And urban forest has its important ecological significance, which plays an important role in promoting social
economic development, urban ecosystem health as well as the infrastructural service for urban residents.

Nowadays, the researches on forest plant community is mainly from the macro perspectives, which evaluate urban forest landscape pattern, ecological service value and aesthetic value, as well as investigate and evaluate current urban forest plant community. The planting configuration of urban forest, as an important approach to promote the restoration of urban natural ecological environment, should be different from that of traditional city parks and advocate the construction mode of low-maintenance and self-recycling.

2.3. Existing problems

As the only living organism in the green space, plant carries its important ecological functions and also behaves as an important carrier and manifestation of landscape. As an artificial ecosystem, a stable artificial community is more conducive to realize the virtuous cycle of urban forest internal organization system. The construction of artificial plant community should be based on the concept of natural landscape, local landscape, protective landscape and other related theories. Among the discussion of urban forest, the research on the selection of water-saving plants and the strategy of community collocation is very scarce. Therefore, based on the water consumption of plants, this paper studies the issue of how to carry out low-input, self-sustaining and high-efficiency water-saving construction in the case of water shortage, at the same time, conducts strategic research on urban forest plant planning to improve the ecological service function of urban forest.

3. Research on water-saving urban forest plant planning based on the calculation of water consumption

3.1. Research object

The design area is located in the southern in Beijing, close to the Fifth Ring Road with the total area of 43.6ha. It has the typical monsoon climate of medium latitudes, zonal vegetation type belongs to warm temperate deciduous broad-leaved forest and has warm coniferous forest distribution. The annual average precipitation in Beijing is 638.8mm. Water shortage has become a prominent contradiction for the green space construction in Beijing. It is imperative to rationalize the utilization of rainwater resources to construct the water-saving goal and provide more ideas for urban forest construction. Corresponding to Beijing's development model which is leaving blank space and increase green space, the establishment of urban forest in this area not only creates good ecological benefits, but also serves as the elastic threshold of urban expansion, so as to provide more possibilities for the future urban development.

3.2. Research contents and methods
3.2.1. The calculation of water consumption utilized by plant irrigation

After the study of current situation and basic materials, the site is analyzed with the elevation and rainwater collection with Geographic Information System (GIS),
according to its annual precipitation in this area. (Fig. 1) Referring to the runoff coefficient, the total amount of rainwater collected in the site is 112950 m$^3$. Combined with the principle of low impact development, according to the total amount of rainwater collected from the site, the amount of water required for the current potting pit is 78750 m$^3$, the total amount of water available for plant irrigation is calculated as 34200 m$^3$.

![Fig. 1. Elevation analysis.](image)

3.2.2. Classification of plant irrigation types

According to the rainfall in Beijing, the rainfall utilized effectively by plants, which is called effective rainfall, should be at the first priority. According to the effective rainfall coefficient, the effective rainfall as the critical value, it is believed that when the water requirement of plants growth is less than the effective rainfall, plants could meet their own growth and development needs through rainfall, and no artificial irrigation is required, which are defined as self-supporting plants. While the water demand is greater than the effective rainfall and the plants could not satisfy its growth and survive under the condition of natural rainfall, the artificial irrigation is needed to maintain its good growth status in this situation, these plants are defined as irrigation plants.

Summarizing the previous research results on plant water consumption, with the effective rainfall as the critical value, plants, which consume less water per year than the average annual rainfall, include trees, shrubs, herbs, such as *Pinus tabuliformis* Carr, *Robinia pseudoacacia* L, *Sabina procumbens* (Sieb.ex Endl.) Iwata et Kusata, *Euonymus japonicas* Thunb, *Miscanthus sinensis* Anderss.

3.2.3. Calculation on planting area of irrigated plants

In the urban forest construction, we need to follow the principle of water-saving and choose self-supporting, reduce water consumption. In this way, it could ensure the diversity of plant species, strengthen the plant community of ecological benefit, give full play to its ecological function at the same time, and also utilize irrigation type plants with high efficiency. According to the amount of rainwater for irrigation and average water demand of water-saving irrigation plant communities, it could be calculated that the largest amount of irrigation plants should be planted under certain circumstance of the irrigation water consumption.

Previous researches have studied the water consumption patterns of the existing plants in Beijing. For the purpose of water-saving, the area ratio of trees, shrubs and
herbs which are suitable for the allocation of green spaces in Beijing is (10:11:17), which is consisted with the green space of 100m², the tree layer of 50m², the shrub layer of 55m², and the herb layer of 85m². Considering plant species and density, microclimate, plant collocation model, as well as factors such as species richness, combined with the water consumption of plants, the above conditions are used to match the plant community. Weighted calculation of water consumption among different communities and averaged the data, the average water demand per 1m² of plants is 266.06mm/year in the configuration mode of the water-saving type.

It could be seen from the data above that, with the 34200 m³ total amount of irrigation water for plants, the planting area of irrigation plants on the site is 12.875 ha. (Fig. 2)

3.3. Planting strategy

According to the landscape demand and the analysis of the basic natural conditions, self-supported plant communities and irrigated plant communities are constructed. Simultaneously, the distribution of points, groups, belts, and sheet among the plant communities is formed. Based on the landscape demands in different regions, we should build the tree-shrub-herb communities, shrub-herb communities and herb communities, as well as increase the diversity of landscape types, and enhance landscape effects. (Fig. 3)

During the construction of self-supporting plant communities, combined with the characteristics of urban forest to build a natural ecological base based on self-supporting native plants, with the thematic plant landscape like rock gardens and xeric botanical gardens as embellishment, self-supporting plants are fully displayed. For example, planting self-supporting plants such as Miscanthus sinensis Anderss in the rock garden, and planting various types of
self-supporting plants in xerox botanical garden demonstrate the landscape and also play a role in popular science. The low-maintenance and self-recycling characteristics of the self-supporting plants also bring about the possibility of low-interference management, as well as play a role in promoting the ecological succession of plant communities.

In the construction of irrigated plant communities, regarding the water saving as a premise, use ornamental species, with self-supporting plants as much as possible to form plant communities. Improve plant species diversity and plant landscape richness. At the same time, considering the seasonality of plants, the landscape elements of different spatial levels are enriched. Focus on building important landscape nodes and make efficient use of the limited water resources. For example, the use of *Ailanthus altissima* (Mill.) Swingle and *Koelreuteria paniculata* Laxm, which have a relatively low water consumption among irrigated plants, can be the supplements of upper-level plants, while combining with self-supporting plants, like *Pinus tabulaeformis* Carr, *Platycladus orientalis* (L.) Franco, etc. Also, the shrubs were designed as embellishments with the low water consumption plants, such as *Hibiscus syriacus* L, *Lagerstroemia indica* L and Floribunda Roses, which could form mesmerizing plant communities in all seasons.

Self-supporting plants and irrigated plants are combined to create a landscape of rustic charm. A natural base is created with self-supporting plants, and the irrigated plants are used as embellishments. The natural and playful landscape will be constructed with a water-saving urban forest, in order to create a landscape forest and an ecological forest. Choose self-supporting herbs with ornamental characters, such as *Duchesnea indica* (Andr.) Focke, *Oxalis corymbosa* DC, to form the landscape with wildflowers as ground materials. Add irrigated plants with ornamental flowers at important landscape spots, such as *Kerria japonica* (L.)DC, *Weigela florida* (Bunge) A.DC, *Lagerstroemia indica* L, to enrich visual diversity. Integral forests as background, shrubs have a variety of flowers with great visual appearance, combined with a large area of wildflowers, create the natural atmosphere of the forest rustic altogether.

4. Water saving urban forest plant landscape planning strategies

4.1. The selection and application of native plants

To build the urban forests, the artificial plant communities should tightly correspond to the principles of nature, and the advantages of the native species should be well utilized in the nature-approximate landscape design. Native plants not only include native plants with high environmental adaptiveness, but also alien species that have been able to grow well, proliferate locally and develop local cultural connotations after long-term cultivation and domestication. It is easier to construct stable artificial plant communities by taking full advantages of native plants. Native plants
are widely used in the green space construction as the most adaptable plant group.

82 kinds of trees, shrubs and herbs were recommended in the "Indigenous Plant Resource Development List" of Beijing Municipality. These native plants not only have strong environmental adaptability, but also contain the characteristics of water saving and drought resistance. For example, *Quercus* can grow for hundreds of years under natural conditions. Combined with hundreds of native plants that have been widely used in the construction of green space in Beijing, the selection of native plants with water-saving, drought resistance characteristics and other excellent resistance to build urban forests is beneficial to the stabilization of urban artificial forest communities.

4.2. Application of spontaneous herbaceous plants

In the research of the application of native plants in Beijing, the proportion of herbaceous plants is relatively great. Most of them are not planned plantings in the process of greening, but spontaneous growth and survival under natural conditions, such as *Dendranthema lavendulifolium* var, *Orychophragmus violaceus* (L.) O.E.Schulz. This kind of self-initiated growing herb, without artificial management required, is called spontaneous herbaceous plants. The existence of spontaneous herbaceous plants greatly improves the plant species diversity in the urban green spaces.

In addition to its low-maintenance properties, its aesthetic value should also be taken into consideration during the construction of urban forests. In the previous research on the status quo of Beijing's own spontaneous herbaceous plants, investigation and statistics of the ornamental characteristics among 142 kinds of spontaneous herbaceous plants in 181 species shows that 86 species of them have ornamental floral organs, accounting for 60.6% of the total. Most of the remaining species also exhibit great group landscape effects. [5]

The characteristics of self-contained, self-growth plant and great landscape effects of spontaneous herbaceous plants provide the possibility for the construction of low-maintenance, self-recycling, water-saving urban forest. It also lays a solid foundation for the realization of species diversity, enrichment and stabilization of artificial plant communities.

4.3. Plant community configuration

During screening and applying different plant species, it is also necessary to consider the vertical and horizontal structure of plant communities, as well as the more scientific and rational use of interspecific relationships like symbiosis, competition. When considering the use of horizontal mingled forest, the characteristics of the plants should be carefully considered in order to avoid the occurrence of pests and diseases. At the same time, full use was made of the special nature of mixed planting to coordinate the levels and richness of the landscape, according to their ornamental characteristics. On the vertical direction, a careful study should be conducted on natural factors such as light and moisture, while the
advantages and disadvantages should be taken into consideration to satisfy the complementarity and diversity of different plant niches.

Based on the full consideration of the horizontal and vertical structures of the plants, to achieve the stability of the artificial communities, the natural base conditions of the site should be fully utilized to create plant communities with different bases, densities, and abundances, as well as improve the heterogeneity. The ability to respond to external factors, self-repair ability should be enhanced. Stable plant communities are more likely to achieve the goal of low-maintenance and self-recycling development of urban forests, while at the same time, lay the sound foundation for realizing the ecological restoration of urban natural ecosystems.

5. Conclusion

In the context of relieving Beijing's non-capital functions, setting aside vacant land and adding green spaces, the construction of urban forests can serve as an elastic threshold for urban expansion and provide more possibilities for future development. The study of water saving urban forest landscape planning provides new ideas for the creation of stable artificial plant communities and plays an important role in building an urban eco-friendly development model. This article starts from the microcosmic point of view, combined with the calculation of the water consumption of plants, systematically expounds the new ideas of the water-saving urban forest plant selection and community collocation. Based on this research, the future planning can be distinguished with the traditional urban parks, more detailed allocation of plant configuration, highlighting its unique characteristics of configuration.

Building urban forest is an important approach to imply the construction of ecological civilization. Building water-saving plant communities is a starting point for urban forest landscape planning, but it is the only method. The production, recreation and cultural expression function of urban forest also need to be considered and paid careful attention. Therefore, for different urban forest construction with different purposes, we need to consider all aspects and select the optimal choices and establish different systems to provide more possibilities for urban forest construction.

Abstract:

Learning the history of the development of Japanese cities, we can clearly realize that most of cities be created from the belief of mountain culture in the early modern period of Japan. Fujimi Historical Town is a series of cities that can see Mount Fuji and take Mount Fuji as the object of belief and live together with the surrounding ecological environment, even we can call it a kind of Biophilic City we imagine. This paper will start from the historical phenomenon of Fujimi, combined with mountain belief, Japanese Ukiyo-e, and the idea of harmonious development of human and nature, to find the location and urbanism of Fujimi Historical Town in Japan. Taking Fujiyoshida, Shizuoka and Tokyo as examples to discuss the landscape feature of Fujimi Historical Town under the background of different distance from Mount Fuji. Using graphical language to restore the urban space changes in different Japanese historical periods.

In general, this paper will summarize the landscape feature of Fujimi Historical Town in three aspects: landscape scale, urban design, and culture. Meanwhile, according to the social problems, this article will solve the problem by using the original historical environment, explore the regenerative strategy of the Fujimi Historical Town under the belief of the Mount Fuji, the future possibilities of positive relationship between the city and the people, and the imagination on the key features and qualities of Biophilic City.

Key words: Fujimi Culture; Landscape Scale; Urban Design; Cultural Landscape
1. Introduction

The city is an important factor that affects the quality of people’s lives. At the beginning of urban construction, each city relied on its own unique charm to make people easily distinguish the differences. In the process of globalization, more and more scholars are aware of the loss of local characteristics and the disappearance of landscape features in the city. With the rapid development of the city, how to consider and construct biophilic city from the perspective of landscape architecture has become a common urban environmental problem today.

Japan’s excellent urban planning tradition is the historical basis for the construction of Japan’s modern urban planning theory. In addition to the garden city and the landscape city, the Fujimi historical town formed under the belief of the Mount Fuji is also one of the bases for the birth of modern Japanese cities.[1-2]

2. Background of Fujimi Culture

2.1. Mountain belief and Fuji belief

The mountain belief is a belief that regards the mountain as a sacred object of worship. It is derived from the natural worship, prospered in the religious worship, and integrated into the social worship. In Japan, people have had deep emotions with Mount Fuji since ancient times. Therefore, the Japanese regard Mount Fuji as the god, as well as the object of belief and worship.

2.2. Mount Fuji Ukiyo-e

Mount Fuji Ukiyo-e, which is based on Mount Fuji, belongs to the “famous places” of the Ukiyo-e, and it mainly depicts the scenery of Mount Fuji from Kanto Area in Japan. “The Great Wave off Kanagawa” is Katsushika Hokusai’s most famous work, and one of the most recognizable works of Japanese art in the world. In addition to Katsushika Hokusai’s “Thirty-six Views of Mount Fuji” (1823), another famous ukiyo-e painter in Japanese history, Utagawa Hiroshige, was also depicted the scenery of Mount Fuji in the “The Fifty-Three Stations of the Tokaido” (1832), “One Hundred Famous Views of Edo” (1856) and “Thirty-six Views of Mount Fuji” (1859).

2.3. Fujimi

The meaning of Fujimi is looking at Mount Fuji. Fujimi is an expression of the Fuji belief under the influence of Japanese mountain beliefs. It is also a new form of Mount Fuji research that is formed from the visual perspective of “Looking”. Mr. Tashiro Hiroshi, a famous Japanese geography scholar, was keen on the research of Fujimi and published the “Mount Fuji Visible Map” in April 1986. Mount Fuji Visible Map is the first graphic representation of Mount Fuji visible analysis in Japan.[3]

2.4. Fujimi 100 of Kanto

“Fujimi 100 of Kanto” was selected with the aim of promoting beautiful community development through selection of a place where good views to Mount Fuji can be obtained and support for conservation and utilization of surrounding landscapes from May 2004 to October 2005 by Ministry of Land, Infrastructure, Transport and Tourism Kanto Regional Development Bureau. From the aspect of landscape and activity, 128 views and 233 viewing spots of Fujimi in the Kanto area were selected.
3. Materials and Methods

3.1. Area of research

According to the 13 states (Kai, Totoumi, Suruga, Izu, Musashi, Sagami, Awa, Kazusa, Shimousa, Hitachi, Shinano, Kozuke, Shimotsuke) that can see Mount Fuji, “Fujimi Thirteen States Map” was drawn by Akiyama Nagatoshi in thirteen years of Tenpo (AD 1842). The 13 states are provincial administrative divisions established based on the Japanese rule of law, also called decree country, was used from the Nara period until the early Meiji period. The Mount Fuji in the map appears in the form of a plan, which is rare in the maps created during the Edo period. After the Meiji Reform, Japan's administrative division was changed. Thirteen states had become the present Tokyo, Chiba, Kanagawa, Shizuoka, Yamanashi, Ibaraki, Nagano, Tochigi, Gunma and Saitama. They are collectively referred to as “Tokyo and Nine Prefectures” within the paper. Therefore, this article will use 13 states as the basis to define “Tokyo and Nine Prefectures” as the area of research. (Fig. 1)

3.2. Materials and data

Japan has a large amount of research on Mount Fuji, but there are relatively few results and basic data on the systematic research of Mount Fuji, Fujimi culture, and the city based on the perspective of landscape architecture. Therefore, the article selected Thirty-six Views of Mount Fuji (1832), The Fifty-Three Stations of the Tokaido (1832), One Hundred Famous Views of Edo (1856), Thirty-six Views of Mount Fuji (1859) and Fujimi 100 of Kanto (2005) as the basic database from the two aspects of depicted objects and history.

3.3. Methods

Using Geospatial Information Authority of Japan (Fig. 2), Eris Japan and Mt. Fuji Visible Map (by Tashiro Hiroshi) as the image processing platform (Fig. 3).
Utilizing spatial humanistic methods and the spatial, computational, and visualization capabilities of GIS to imported the geographical coordinates of Mount Fuji Ukiyo-e and Fujimi 100 of Kanto into the map software for spatial visualization. Analyze the spatial distribution characteristics from the perspective of spatial visualization. At the same time, with the help of the spatial distribution characteristics of Fujimi culture, this paper further analyzed the interrelationship between the historical and cultural phenomena of Fujimi and the urban construction in Japan.\(^4\)

4. The Spatial Distribution of Fujimi Culture

4.1. Spatial distribution characteristics

In the Thirty-six Views of Mount Fuji (1832), there are 44 ukiyo-e paintings in the area of research, which are mainly distributed in the Mount Fuji area, the coastal area of Tokaido, and the Tokyo area. (Fig. 4)

In The Fifty-Three Stations of the Tokaido (1832), there are seven Ukiyo-e paintings located on the area of research and depicting Mount Fuji, which are mainly distributed in the historical cities along the coast of Tokaido. (Fig. 5)

The One Hundred Famous Views of Edo (1856) mainly depicted the famous scenery of the Edo region. Among them, there are 19 Ukiyo-e prints depicting Mount Fuji in the Ukiyo-e, which are mainly located on the east and north sides of the Imperial Palace, and the Megurogawa area where have a large amount of fujizuka. (Fig. 6)
In the Thirty-six Views of Mount Fuji (1859), there are 35 ukiyo-e paintings in the area of research. Unlike the Thirty-six Views of Mount Fuji (1832), there are no Ukiyo-e depicted in the Mount Fuji area. (Fig. 7)

In Fujimi 100 of Kanto (2005), we selected 26 locations that have historical connections with Mount Fuji, and the distribution of the locations was scattered, except for the northern of Mount Fuji. (Fig. 8)

4.2. Spatial distribution of cities with Fujimi culture

According to Japan's administrative divisions and the spatial distribution of Fujimi culture, each district municipality with Fujimi culture is used as the basic unit to sum up the Fujimi culture within the area of research.

As shown in Table 1, the number of Fujimi culture is 52 in Tokyo. The number of Fujimi cultures in Yamanashi Prefecture, Shizuoka Prefecture, and Kanagawa Prefecture which around Mount Fuji is 18, 14, and 21. There are relatively few Fujimi culture in Tochigi Prefecture, Ibaraki Prefecture, and Gunma Prefecture, because they are far from Mount Fuji. As shown in Table 2, the number of Fujimi district municipality in each prefecture is also different. There are a total of 17 Fujimi district municipalities in Tokyo, of which 13 are located in special wards of Tokyo, and the other four are concentrated in the west of Tokyo. 39.39% of district municipalities in Kanagawa Prefecture have Fujimi culture.

Utilizing spatial humanistic methods and GIS to import the geographical coordinates of Fujimi district municipality into the map software for spatial visualization. From the amount of Fujimi and the importance of the district municipality, we got a map for spatial distribution of cities with Fujimi culture.

(Fig. 9)
5. The Landscape Feature of Fujimi Historical Town

In the spatial distribution of cities with Fujimi Culture, although these cities are known as cities with Fujimi culture, most cities do not have a strong connection with Mount Fuji in terms of urban construction. Therefore, we define Fujimi Historical Town as a city that is closely connected with Mount Fuji in urban construction and analyze the landscape feature of Fujimi historical town in landscape scale, urban design and cultural landscape.\[5\]

5.1. Landscape scale

Combining ancient literature, historical maps, historical images, and practical research, it has been found that the landscape scale of ancient Japanese cities has the spatial characteristics of a city as the core and circular distribution. It can be summarized as three scales: castle scale, urban scale and regional scale. In the castle scale, castle as the core of the city, it is one of the forms of cities in Japan. It is a city established around the lord's castle. In the urban scale, it is the main body of the city where people live. The natural environment and landscape around the city constitutes the regional scale.

The Fujimi Historical Town has different spatial characteristics from the ancient Japanese cities in terms of landscape scales. The Fujimi Historical Town’s observations of landscape are not limited to the areas surrounding the city's landscape, but they will cross the regional scale to find the connection between the city and Mount Fuji. As a result, the unique landscape scale of Fujimi Historical Town is formed. That is the territorial scale which is the territory of the Fuji belief and looking Mount Fuji. (Fig. 10) (Fig. 11)

5.2. Urban design

Urban design has its own unique understanding of landscape since the early modern period in Japan. Not all Japanese cities use unaltered urban design techniques. Instead, they adapt to the natural environment while also incorporating the surrounding landscape into the city to create landscape. Fujimi historical town used “Yama-Ate” design method to use Fuji Mountain as a reference axis or borrowing axis to complete urban road planning and water network planning, and completed the overall urban design that integrated the natural environment with local culture.

5.3. Cultural landscape

When Fujimi historical town was consciously planning and building Fujiyama,
it was not only the use of Mount Fuji as a visual target for urban road planning, but also more closely connected Mount Fuji with the cultural landscape of the city. The cultural landscape in Fujimi historical town is not isolated, but is integrated with the city and Mount Fuji in accordance with certain organizational principles. It integrated urban functions, culture, landscape, and Mount Fuji into an overall landscape network.

6. Three Typical Fujimi Historical Towns

Based on the distance from Mount Fuji, landscape feature and the map for spatial distribution of cities with Fujimi Culture, we select 3 typical cities within the three ranges of 25km, 50km, and 100km, and study their respective characteristics of evolution. The three typical cities are Fujiyoshida (0-25km), Shizuoka (25-50km) and Tokyo (50-100km). (Fig. 12)

In terms of landscape scale, all three cities have the territorial scale which is the territory of the Fuji belief and looking Mount Fuji. However, the three cities are different in urban design. Fujiyoshida is a city formed on the basis of Oshi town on both sides of the approach of Kitaguchi Motomiya Fuji Asama Shrine. The approach uses Mt. Fuji as the reference axis and is the main axis of the city. Unlike the Fujiyoshida, Shizuoka City is a grid-shaped city when it takes Mount Fuji as the main axis of city. Urban design in Tokyo did not form a clear urban main axis. However, in the area around the Imperial Palace, the area axis of the area is formed with the Mount Fuji as its axis. (Fig. 13)

In terms of cultural landscapes, the approach of shrine and Oshi town in Fujiyoshida City, the reconstruction of the Suruga Castle and the Aoba Avenue in Shizuoka City and the axis of Yasukuni Shrine and the Surugamachi Commercial Street have integrated the urban cultural landscape and Mount Fuji scenery. The Japanese Imperial Palace was established on the basis of Edo Castle. In Japanese, Fujimi has the same pronunciation as invulnerability. At present, there are still buildings named after Fujimi in the Imperial Palace, such as Fujimi Yagura and Fujimi Tamon. These Fujimi buildings express the Tokugawa Ieyasu's longing for rule. Fig.13 Urban design pattern of Fujiyoshida, Shizuoka and Tokyo.
7. Discussion and Conclusions

Through the analysis of the landscape features of Fujimi historical town and the analysis of three typical cities, we can conclude the following three urban regenerative strategies applicable to Fujimi historical town. (Fig. 14)

7.1. Protecting the natural symbiotic landscape

The natural symbiotic landscape is a feature of the urban planning that has evolved through the practice of thousands of years in Japan. We should fully understand the inseparable relationship between the city and the surrounding natural environment and promote the harmonious development of the city and the surrounding natural environment.

7.2. Inheriting the concept of sustainable landscape

In the urban construction practice of Fujimi historical town, a unique landscape recognition was formed. Bringing the concept of sustainable landscape into modern urban planning and construction, respecting the traditional landscape of each city.

7.3. Creating the walk-friendly landscape

The walk-friendly landscape creates a high-quality outdoor public space by building a linear space environment, bringing new functions and vitality to the old city. The historical landscape and humanistic space in the process of urbanization can all be organically linked with walk-friendly landscape. In the renewal plan of the old city, the use of walk-friendly landscape instead of a motor-driven urban space has important practical significance for the protection and inheritance of urban culture.

Coexisting with nature: traditional knowledge and modern practice of the urban natural landscape system – in case of Kyoto, Japan

Yuxin Ti

Beijing Forestry University, Tsinghua East Road 35, Beijing 100083, China

Abstract

The relationship between human and nature should not be conflicts or conquests, but a harmonious coexistence. The purpose of this study is to seek out experience from traditional cities in Japan, like Kyoto, to find ways for the construction of a biophilic city. This article firstly compares the natural environment changes of Kyoto Basin into the process of urban development to seek for the inside dynamic balance. Then, the study subdivides the natural landscape system into five elements, which are closely related to the traditional cities: mountain, water, forest, farmland and green space, to analyze their relationship with the urban structure respectively and summarize the traditional knowledge of the urban natural landscape system in Japan. Finally, the article analyzes the planning and management system of urban natural landscape by Japanese government in recent years, to explore what role landscape architecture is playing in Japan in order to coexist with nature.

Keywords: Kyoto, natural landscape system, coexisting with nature, landscape architecture, ecosystem services

Nowadays, rapid growing cities has brought many problems, such as urban waterlogging disasters, massive devastation after earthquake, biodiversity decrease, haze, lacking of places for citizens to relax in leisure time……. The relationship between human and nature is getting worse day after day, while we gradually recognize that the relationship should not be conflicts or conquests, but a harmonious coexistence. The purpose of this study is to seek out experience from traditional cities in Japan, like Kyoto, an ancient capital has a 1200-year long history and now is one of the most famous historical and cultural cities in the world which appealing to more than 50 million visitors each year, to analyze the Japanese concept of ‘coexisting with nature’ and methods in urban construction and management, which can be expressed in the dynamic balance between human and nature systems.
1. Kyoto Basin

The Kyoto Basin is about 300 km² and located in Kyoto Prefecture. The topography is high in the north and low in the south, like an inland basin surrounded by mountains on three sides, the east, north and west. In the ancient ages, it was once a lake, and gradually formed the land. To give birth to hot summers and cold winters, at the same time, it brought high groundwater level and fertile soil. The formation of rivers and deltas made an increasing numbers of migrants after the 5th century. People lived along the river and developed agriculture through the fertile soil of alluvial plain, and the remarkable development of farming techniques also changed the landscape pattern of the basin (Fig. 1).

In October 794 AD, Emperor Kanmu moved from Nagaoka-kyo to Heian-kyo, from then the city had been the capital of Japan until Tokyo finally became the capital in 1868. Prior to this, Japan had relocated capitals several times, such as Naniwa-kyo, Fujiwara-kyo and Heijo-kyo. Nagaoka-kyo, a city located in Kyoto Basin as well, became the capital in 784 and had only existed for 10 years. In case of the inconvenient land transportation in the ancient ages, water transport was significantly important. Closing to the junction of Yodo River, Katsura River, Kizu River and Uji River and Ogura Lake, Nagaoka had a more convenient waterway than Heian-kyo, however, once it rained heavily, the entire city would submerge in the flood. Eventually Emperor Kanmu moved the capital to Heian-kyo, which was in the highest point of the northern basin ¹1.

In addition to the height advantage, there were no natural rivers inside Heian-kyo, which suffered lower flooding risks. The city was modelled after the Tang dynasty Chinese capital of Chang’an in block planning and the planning area was one-fifth of Chang’an. The internal drainage of the city is based on digging trenches on both sides of the road, although not fully along with the terrain, a conscious improvement has been put forward by making the width of the ditch proportional to the road ²2. Two artificial canals were dug on both sides of the city, called Hori River and Nishihori River, simultaneously guarding against the flood and becoming the water traffic ways. The palace was built in far north of the city and surrounding by office area. The commercial area was in the south and residential area mainly in the east, the cultivated land was scattered in the west (Fig. 2).

At the end of the 10th century, Yoshishige no Yasutane wrote in Chiteiki: “Population in the west zone (Ukyo) was decreasing and going to ruin. Only those who have moved out but no moved in and houses collapsed.” People lived crowded in east zone (Sakyo), especially in the north. The functional distribution has changed: the city was spanning across the Kamo River and developing eastwards. There were new urban centers such as the Shira River area, Toba and Rokuhara (Fig. 3). The weakness of the legal system and aristocracy led to citizens’ self-organization and then separated the city into upper and lower parts. The commercial centers and streets have developed.
The chaos Onin War lasted from 1467 to 1477 made one-third of Kyoto burned in the flames of war, especially the upper area. Then starting with Toyotomi Hideyoshi, a series of urbanization campaigns were planned to restore and redevelop the city, such as the construction of odoi, the new city of Fushimi and the dig of Hozu River and Takase River (Fig. 4). The pattern of urban space has been further changed as the gravity of center was developing along the Kamo River, laying the prototype of modern city.

2. Natural landscape elements

The pattern of urban space is closely related to the surrounding natural landscape and is the result of both human and natural conditions. Natural landscape system which is composed of mountains, water, forests, farmlands, and green spaces, continues to interact and infiltrate with urban system in the process of human construction and eventually forms a landscape complex that integrates natural and human environments.

2.1. Mountain system

2.1.1. Site selection

According to Nihon Shoki, Japan's first capital was "surrounded by beautiful green hills, though small, the enclosed space makes people feel peace and leisure." This site selection concept was derived from Chinese Feng shui. "Feng shui" first appeared in the Book of Burial by Guo Pu in 4th or 5th century, which means places where could gather “Qi” (energy). Kyoto is a natural city with mountains in the north and rivers in the south, which is definitely a perfect spot with good qi.

In addition to Feng shui, there was also "Four Gods Suitability" widely spreading, which originated from the concretization of ancient Chinese astronomical concepts, and corresponded the site conditions to nature landscape in four symbols - Azure Dragon of the East, White Tiger of the West, Vermilion bird of the South and Black Tortoise of the North, which represents natural mountains and rivers to form a symmetrical place. There is still no conclusion of what four symbols
precisely represent [4], but the corresponding relationship between the city and the surrounding mountains is meaningful.

Mount Mandala, Hidaridaimonji, Funa, Nishi, Higashi and Daimonji form the first layer of the city from west to east in the north, where are also places of “Gozan no Okuribi” - a traditional festival to "send-off fire". The combination of natural mountains with religion and history carries spiritual desires and develops together with the city.

Outwards, Mount Ponpon, Arashi, Sajikigadake, Kurama, Hiei and Daigo continue to form the “Three Mountains” of Kyoto. The Western Mountain is from Mount Ponpon to Atago with the altitude from 400m to 600m; The Eastern Mountain is from Mount Hiei to Inari, includes areas from Mount Daimonji to Mount Otowa and Daigo; Connecting the two, The North Mountain is mainly from 400 to 600m with some mounts over 900m, such as Mount Minago, Minetoko and Mikunidake. Mountainous areas account for approximately half of the city area and the vast northern regions are filling with mountains (Fig. 5).

2.1.2. Axis and boundary

The axis and boundaries are constantly changing during the developing of the urban pattern. Mount Funaoka - Suzaku Avenue – Rajomon – Mount Kannabi formed the original north-south central axis. Unlike China, Japanese cities do not have defensive walls and are directly connected to others through streets with a name of "Kyoto’s seven entrances". Streets passed through mountains and rivers, and some formed villages at the nodes. For instance, Street Kurama is the vital road connecting Kyoto with Tamba. Villages and streets developed rapidly after the construction of Kurama Temple. The valley terrain and the wild arable farmland formed by the scouring of the Kurama River created a characterized village environment.

After the eastward movement of the city, the Suzaku Avenue was gradually abandoned and some residents turned it into farmland.
The new axis was located between Nijojo and Kyoto Imperial Palace. The establishment of odoi enabled the city to have a three-meter-high city wall and formed a new distinction between the city and suburbs. The current urbanization continues to erode towards the mountains and the relationship between the city and mountains is becoming more and more intimate.

2.1.3. Villas and overlook viewpoints

The diversity of landforms in mountainous area makes it a perfect site for gardens, temples and villas down the ages. Since Heian Period, there have been countless villas in the rolling foothill area, like Saga Villa, Shirakawa Villa and so on. Buildings and gardens are distinctive thanks to a variety of terrains and become precious cultural heritage (Fig. 6).

2.2. Water

2.2.1. Water system

The alluvial plain creates a large number of rivers, lakes and swamps, and the historical urban construction has also brought countless artificial water canals. The main natural water system consists of Katsura River and Kamo River, which flow from north to south and meet Uji River in the south. The artificial water system has 12 artificial canals built during early Heian period: Hori River (12m wide) and Nishihori River were mainly used as water transport and drainage channels, other drainage channels included Tenjin River, Sahi River, Nishiomiya River, omiya River, Nishinotoin River, Machi River, Muromachi River, Torimaru River, Higashinotoin River and Tomikoji River, arranged from west to east and were based on the planning and topography to dig from north to south with most only existing in street names. In modern times, Hozu River, Takase River and Lake Biwa Canal were excavated for water transport. There are also Lake Biwa in the east, Ogura Lake in the south and Midoro Pool in the north, but Ogura Lake has already vanished due to urbanization.

2.2.2. Water Transport

Rivers used for water transport in Kyoto include Katsura River, Uji River, Kamo River and artificial rivers such as Takase River and Lake Biwa Canal. The Katsura River, which originates from the northern mountain, is the primary channel because of its deep depth, flow rate and quite a few tributaries. It was this river to be used to transport timber from Yamakuni, Tamba, Yamashiro and Settsu in the north to build the city of Heian-kyo through an approach called "raft flow". In the 17th century, Suminokura Ryo, a wealthy businessman, excavated the Hozu River under the permission of the shogunate, making it possible to use a wooden boat called “Takase Boat” to transport timber more conveniently and efficiently, creating an important traffic route
connecting Kyoto to Tamba and San-in, which prospered the villages alongside – like Sonobe, Hozu, Yamamoto, Umezu and so on, and turned Mount Arashi into a tourist resort.

Uji River and Takase River are also important waterways. Uji River is located in the south of the city, flows from east to west and eventually merges into Yodo River. The river was turbulent with a shallow depth and only put into use after several modification works for a long time. Takase River is a canal belonging to Kamo River. Due to the unstable flow rate and frequent flooding of Kamo River, in 1611, Suminokura Ryoi decided to open up a new water traffic artery to replace it for better transport. It began in Nijokiya Street and flowed southward to Fushimi Port with 7 meters in width and 10 kilometers in length. In this way, through the connection to Fushimi Port and Osaka, the economic circle of Kansai has formed. The economy of Kyoto was developing rapidly and streets, ports and villages along the rivers were prosperous, too.

2.2.3. Kamo River

Every well-known city around the world is associated with an equivalent famous river, such as Paris and the Seine, London and the Thames. When it comes to Kyoto, it must be the Kamo River. Due to the early decline of Ukyo and the shift of the city center to the east, Kamo River has become the primary river which profoundly influences the development of the city and the daily life of citizens. The history of Kamo River and the city is not only the history of flood control and disaster prevention, but also culture and recreation.

Kamo River flows from the highest peak Sajikigadake in the north to Katsura River in the south with about 100m changing in elevation. The water flow is rapid and unstable, which causes frequently floods. In the Heian Period, there has been a specialized position for flood prevention and levee construction, called Bokashi. Because of the floods, Emperor Shirakawa described it as "one of the three most unmanageable things in the world." In the Azuchi-Momoyama period, the war continued. In 1591, Toyotomi Hideyoshi built the odoi surrounded by moats to defend the city and prevent the flood. The construction of Takase River and the renovation of Kamo River itself also improved the preventing level to a certain extent. In the process of continuous floods and transformation works, Kamo River gets its current embankments and waterfront parks.

Frequent flooding and flow changes brought Kamo River a broad river plain, making it a habitat for homeless people. As time passes, the plain had gradually become a public space which allows residents to gather around to talk, taste tea or watch art performances freely, and develops feature landscape like Noryo-Yuka (platforms above waterfront). Public spaces led to commercial prosperity on both sides of the river, light industry such as textile and wine developed, population grew. Shijo Kawara for instance, is still a vital cultural and commercial area in the city. Nowadays, Kamo River has become a landmark with its picturesque scenery and various views at all seasons.
2.3. Forests

Forests are not only the treasure house of genetic resources and urban green lung, but also significant cultural resources. Since ancient times they were sites for temples and shrines, backdrops for gardens and overlook views of the city. There’re immense biodiversity with 55% of endangered plant species and 50%-60% of familiar species’ habitats in Kyoto.

Forests account for 74% of the city area, with broad-leaved most and mixed ones also a lot due to long-term artificial logging and ecological succession. The Tadasu no Mori, located in Shimogamo Shrine, preserves the ecological condition of primeval forests in the northern mountain. It is both a sacred grove for nature worship and a place for people to hang around, talk, rest in shade, taste tea and get close to nature.

Planted forests are parts of the forest landscape. For example, in the Northern Mountain area, relatively steep and narrow terrain and low-humidity air are suitable for the growth of fir trees, making it a well-known forestry production area. Production and operation activities prompted the formation of villages, and the terrain and wood production modes also led to a unique village distribution architectural structure, created characteristic wood culture for Kyoto.

2.4. Farmland

In addition to supplying food, farmland plays a significant role in the transition between nature and the city - buffering rainstorms and floods in the mountains and preventing over-expansion of the city. Together with the surrounding mountains, it forms a green belt to protect the city.

Since the Edo period, residents’ excrement was shipped to farmland in the suburbs, Settsu and Kawachi on the banks of Yodo River to be valuable agricultural fertilizers through the canals. This self-sufficient circulation system laid a firm foundation for the development of agriculture and also improved the public sanitary environment. As the city expanded outwards, there were mixed modes of residences and farmyards, such as the Kamigamo Shrine area, where still remains such historical buildings.

2.5. Green space

As a part of urban planning, the green space planning is closely related to the social background and the trend of the times. Urban green space in Japan can be divided into parks, cemeteries, traffic spaces and others. In the 1200-year long history of Kyoto, there were numerous classical gardens, shrines, temples, villas and Machiya courtyards to form the biophilic city.

Kyoto is the epitome of Japanese classical gardens. Karesansui gardens like Rosan-ji garden and Zuiho-in garden, promenade gardens like Katsura Imperial Villa, the Paradise Gardens like Byodo-in Temple and others like tea gardens, pond gardens and so on. Shinsenen, founded in 824, had abundant water sources with springs gushing and was a sacred place to pray for rain and ward off evil.
There are nearly 700 parks in Kyoto including the Umekoji Park, Kyoto Gyoen, Okayama Park and so on, which are both places for sightseeing and refuges against disasters. The acres of parks per capita is $4.68 \text{m}^2$.

Machiya is a historical component of Kyoto. Its courtyard is used to entertain guests and provides ecological regulation services in the narrow and crowded neighborhood, which is honored as the forest of the city.

3. Modern natural landscape system

The planning and management of the natural landscape system needs constantly revising, adding and integrating. It was firstly accepted into the Japanese landscape system as chapters of the National Park Law, Urban Planning Act and Conservation of Natural Historic Monuments Law. After the 1960s, people gradually realized that it would only bring about more and more problems due to increased economic-oriented urbanization. In 1966, The Old Capital Preservation Law was established to regulate the development of the city from a historical perspective. Afterwards, the Basic Environmental Law (1993) and Landscape Law (2004) were successively issued.

Kyoto has experienced the conversion from policies focusing only on economy to taking nature as priority. Because the government moved to Tokyo in the Meiji period, there was Kyoto Development Policy to be formulated in case of a decline. The policy was divided into three phases aimed at modernizing and rejuvenating the economy and then transformed Kyoto into an industrial city. With the rethinking of national policies, people recognized that the natural landscape system played an important role in the old capital’s tradition - rich resources of material and tourism, however, would be harmful if not taken seriously. In 1995, the Natural Landscape Preservation Regulation was promulgated.

In the urban planning, began with the Kyoto’s Basic Concept in 1999, the Kyoto’s Basic Planning and several classification plans were successively formulated, including Urban Master Planning, Landscape Planning, Green Space Planning, Comprehensive Transportation Strategy with a goal of walking, Tourism Promotion Planning and Historical Landscape Improvement Planning and so on.

The Landscape Planning, formulated in 2005, aims to protect and renew the ancient landscape of more than 1,200 years and preserve regional features. The first measure is the conservation of characteristic basin landscapes and coexistence with nature. Others include the adjustment of urban streets, regulations of overlook landscape and urban building construction. The Kyoto’s Overlook Landscape Regulation, published in 2007, selects 38 locations and makes it possible to borrow distant natural scenery without being obstructed by modern buildings.

The green Space system is also an indispensable part of modern cities, which integrates the natural landscape into the urban planning system to plan as a whole. The Green Space Planning, established in
1999, aims to defend against climate change, improve the environment and protect the beautiful scenery. The objects are all of the plants, surrounding lands and spaces, divided into five areas to form an ecological resilient network of water and green.

4. Conclusion

The natural landscape system is an important part of the urban system. With the development of technology, environmental and humanistic consciousness and the increasing demand for the quality of human living environment, the natural landscape will take an ever-increasing significant place. What role is a landscape architect playing to help get a harmonious coexistence between cities and nature? Japan's experience provides us a good model. Kyoto is a calamitous city, but every disaster has led to a more perfect rebirth, where the urban construction intelligence lies. Seeking out experience from traditional cities in Japan, combining traditional knowledge with modern theories and practice - coexisting with nature and making a city biophilic, is the direction for future urban development.

Acknowledgments

This study is inspired by my professor’s studies in human living environment, based on various books, government documents and materials from the internet and libraries.

Preliminary Analysis on the Vertical Farming Landscape

Yilan Wang, a Yuhong Wang, a Xiaoming Liu a*

Beijing Forestry University, No.35 Qinghua east road, Beijing 100083, China

Abstract

The concept of vertical farming put forward due to food shortage and other urbanization issues has received more and more attention in landscape, ecology and social fields over the past 20 years. This paper reviews the development and extension of vertical farming theory and practice, and discusses three vertical farming landscape strategies from the perspective of landscape architecture through a wide-range literature and case studies: building a biophilic city with massive green facade, innovating high-density community communication space model and making landscape grow inward by leading vertical farming techniques into the interior of building. Subsequently, the Vertical Farming Indicator System Framework was formulated based on the objectives and potential of sustainable development of vertical farming.

Keywords: vertical farming; vertical landscape; strategy; biophilic; indicator system framework

1. Introduction

1.1. Background

As urban population continues to grow and as arable land is diminishing rapidly across the globe, food shortage issues has become a huge hidden danger. Some of the worlds’ leading agronomists concede that an additional 109 hectares of land (roughly the size of Brazil) will meet human needs for food by conventional methods. [1] A fundamental change in food production is needed, [2-3] thus led to the proposal of the concept of vertical farming in 1999. The concept of vertical farming has been in progress. The original proponents were more concerned about the field of agriculture to solve the actual food supply problem. With the intervention of other fields such as landscape architecture and ecology, vertical farming applications gradually focus on people's work and life, and it spreads to facades and interior space of city building, also appears in community gardens under the strain of the urban land resources. Vertical farming makes green and brings nature back to city, creates a biophilic city to promote human health and living environment.
1.2. Methods

This paper assesses existing and future vertical farming practices: relevant websites, media and literature studies from 1999 to 2018. It examines a wide-range of literature related to agronomy, urban agriculture, vertical farming, landscape architecture, ecology and sociology, and tries to understand the theory and practice of vertical farming from the perspective of landscape field. It also reviews involved technologies, principles and evaluation models for qualitative research.

The research includes an extensive literature review of over 65 references, 18 case studies from 16 cities, expert consultation and peer review in salons. It evolves systematic examination of generic and specialized literatures on vertical farming by using various online search engines and databases including Scopus, ProQuest, and Google Scholar. These sources comprise 42% peer-reviewed academic journal articles, 20% books and book chapters, 6% theses, 9% conference papers, and 23% websites. Most of the reviewed literature is relatively recent, dating 2010–2018. The reviewed projects come mainly from North America, Europe, and Asia.

1.3. Vertical farming development and extension

The idea of "vertical farming" was attributed to the discussion in classroom taught by Dickson Despommier, a professor of public health and ecology at Columbia University in 1999. He came up with the idea of taking urban rooftop gardens a step further, creating vertical farming “towers” in buildings, that would allow all of a building’s floors, not just the rooftop, to be used for producing crops. He described vertical farming as “the mass cultivation of plant and animal life for commercial purposes in skyscrapers”. [4]

In 2001, the Dutch architects of MVRDV designed a “Pig City” high tower network and waste collection system merely dedicated to pork production, indicating that buildings could use waste to power. [5] The idea of La Tour Vivante- The Living Tower was conceptualized in 2005, for first time designer proposed a self-contained multifunctional vertical farming building combining agricultural production, housing and activities in a single system. [6] In 2007 Graff Gordon pointed out the necessity of sustainable energy for vertical farming based on economic and ecological benefits, and designed The Sky Farm theoretically prove the feasibility of its economic fundamentals. [7] In 2009, Vancouver, Romses architects pointed out the ecological benefits of a multifunctional vertical farm in support of the City’s 2030 Challenge of reducing carbon emissions and addressing climate change. [8]

The exploration of Sky farming is limited to design drawings due to economic factors, but the middle and low-rise vertical farms have been put into commercial operation. Sky Greens is the innovator and builder of the world’s first low carbon hydraulic water-driven vertical farming system in 2012 achieving objective of significantly increasing output per unit area with a minimum amount of land use, water and energy, and carrying out educational projects in surrounding communities. [9] In 2016, Pasona in Kyoto realized the idea that indoor vertical farms not only provide food, but also create a landscape into a healthy working environment for employees by blending work space with farm space. [10]
Thus vertical farming has solved urban diseases within landscape method.

2. Vertical Farming Landscape Strategy

In 2014 Professor Dickson Despommier mentioned the role of landscape in vertical farming: create an environment that encourages sustainable urban life, promoting a state of good health for all those who choose to live in cities. [4] From landscape perspective, vertical farming actually excavates unexploited three-dimensional spaces for over-exploited cities, adds massive green space for city façade and creates a biophilic city. The use of vertical farming to create landscape facilities also provides new opportunities for urban high-density development and provides technical support for the environmental renewal and transformation of land space such as financial streets, high-density residential areas, shanty towns, slums and hutongs. In addition, vertical farming is beyond aesthetic and visual improvement. It creates a unique workplace environment that promotes worker’s productivity, mental health, and social interaction and engages the wider community by showcasing the benefits and technology of urban agriculture.

2.1. Building a biophilic city with massive green façade

According to a theory of the biologist E.O. Wilson, biophilia means “an innate and genetically determined affinity of human beings with the natural world” [11] Passion for life and closeness to nature are human nature. Skyscrapers will transform into sky farms, changing conventional buildings into late-model landscape buildings of sky farm and this new architectural system from vertical landscapes will seek to invite nature back into our city facade and return human to agricultural experience. They have magnificent appearance, impacting people's vision and mind, add a much needed touch of green, help clean the city air and possibly even produce small scale crops, thus make it a landmark of the city's iconic, productive, sustainable giant green landscape architecture. (Figure 1).

In addition, the conversion of middle and low-rise buildings with prototypes to vertical farms has been slowly changing our urban landscape. The invention of lightweight hydroponic farm systems makes vertical farming attach to any unused wall space along sidewalks or behind buildings. [12] Green wall of vegetables is changing landscape into a powerful thing not just for food production, but for people, because we weren't designed to live in the concrete jungle. (Figure 2). Study shows the green wall between buildings reduces the levels of nitrogen dioxide and suspended particulates by 40% and 60%. It acts as a huge steel tree: it provides oxygen, filters the air, relieves urban heat island effect and provides a home for nearly a dozen bird species. [13]
2.2. Innovating high-density community

Vertical farming enters community gardens, providing a new model for community greening and activity space to meet people’s demand for nature and biophilic communication space. Vertical farming technology actually compresses community gardens into three-dimensional dimension, saving land area and obtaining optimum crop yields. In addition to planting vegetables or flowers, this model provides community residents with a space for sharing labor and fruits, and has a positive effect on promoting social interaction, providing environmental education opportunities for all age groups, especially children, cultivating citizens’ sustainable development and ecological awareness and increasing the type and number of pollinating insects, and maintaining the urban biodiversity. [14]

The vertical farming hybrid housing proposed by Singapore SPARK company can solve the problem of population aging. The project called “Family Farm” combines vertical farming and roof planting with high-density residential housing to provide affordable housing for retired people. Residents will be employed by caring for green leafy vegetables growing on the external walls and roofs of buildings, in return, the greenness provides residents with an ideal living environment. Once the project is realized, it will greatly improve the economic and living conditions of the old Singaporeans. (Figure 3).

Under the promotion of international organizations, universities, and other civil institutions and technology companies, vertical farming has enabled low-income people to obtain fresh food and certain economic subsidies. For example, planting
vegetables on the wall in a slum of Los Angeles, named “Vegetable Walls”, shaped by rapid assembly of unit modules adds greenness to the crowded environment. [15] Vertical farming is also increasingly investing in high-density urban greening. At the 2016 International Vegetable Science and Technology Exposition, ornamental vegetables featured with strong aesthetics, high economic value, and profound educational significance were demonstrated for use in vertical landscape facilities, which promoted landscape development of vertical farming. [16]

2.3. Making landscape grow inward to the building inside

The biggest benefit of vertical farming entering buildings with each floor growing a different set of edible plants including fruits, vegetables and rice is to lead nature into human being daily life and work environment. Vertical farming facilities integrated within the building bring a world of indoor greenness, such as offices, an auditorium, corridors, reception area and cafeterias. Using both hydroponic and soil based farming, crops and office workers share a common space. For example, tomato vines are suspended above conference tables, lemon and passion fruit trees are used as partitions for meeting spaces (Figure 4), and salad leaves are grown inside seminar rooms. The main lobby features a rice paddy and a broccoli field. Vertical farming facilities help isolate noise, absorb carbon dioxide to improve indoor environment, and significantly alleviate modern sick building syndrome, etc. urban issues.

3. Vertical Farming Indicator System Framework

3.1. Confirm target

Cuello’s Law has articulated this sustainability potential of the Vertical Farm industry. In support of the global vertical farming industry and as a way to inspire and incite the industry to proactively work toward achieving its sustainability goals and potential as embodied in Cuello’s Law, the Vertical Farming Indicator System Framework is hereby launched. It is based on five strategic objectives for sustainable development of vertical farming and three strategies of vertical farming landscape field discussed in this paper. [17]

3.2. Build framework

Vertical farming planning and construction involves four key dimensions:
1. agricultural production, ensuring that high-tech production obtains optimal crops, including monitoring of quantity, scale, quality, and safety.
2. Eco-efficiency, ensuring vertical farming's assessment of water resources, energy and land sustainability, climate and ecological environment.
3. Social economy, the health benefits of urban residents' lives and work, and the economic benefits and costs of vertical farming.
4. Landscape performance, vertical farming assessment of urban greening, space use, and aesthetic experience.

3.3. Indicator classification

In order to achieve these four dimensions, each vertical farming project should strive to achieve 16 indicators in order to achieve sustainable development of vertical farming. The research shows that these indicators
have dual roles of supervision and assistance for each vertical farming company or institution. These indicators provide guidance and recommendations when they face the contradiction between environmental protection and economic benefits while furthering or fulfilling their corporate social responsibilities. We need to recognize the relative importance of each indicator within the framework and how to achieve the uniqueness of each vertical farming project. (Figure 5).

Agricultural production indicators: 1. High crop yields, optimized vertical farming production efficiency, and measurement of crop yields 2. Fresh food transport, producing fresh crops that remain fresh when delivered to buyers 3. Sustainable production system, vertical farming system separated from natural functions enables sustainable food production in the face of environmental changes and resource shortages. 4. Quality and safety, nutrient content of crops, and food safety.

Eco-efficiency indicators: 5. Species diversity of animals and plants, species richness of inhabiting or passing animals and planted species 6. Recycled water sources, recycling water resources systems 7. Ecosystem restoration, allowing large areas of land to restore ecosystem functions and services, and build natural landscapes 8.
Air quality improvement, and the level of air purification and renewal of crops.

Social economy indicators: 9. Social security, ensuring people of different social classes benefit from vertical farming. 10. Mental health, creating a good living and working environment for people, promoting people's physical and mental health. 11. Economic stability, a certain scale of sustainable agricultural production to bring stable income. 12. Technical cost, balancing the contradiction between high-tech input costs and sustainable production system benefits.

Landscape performance: 13. Aesthetic sensory experience, vertical farming building facade and indoor landscape on people's feelings of the visual and spiritual experience. 14. Urban green volume update, vertical farming greening volume data. 15. Communication space innovation, the transformation and update of vertical farming in city's communication space. 16. Use of abandoned space, to make use of abandoned or unused space in a city for vertical farming production.

A Study of Close-to-Nature Urban Forest Evaluation and Design -- Taking the Beijing Bai-wang Urban Forest Park as a case

Sijie Wang, a Xiong Li a,*

Beijing Forestry University, No.35 on Qinghua East Road, Haidian District, Beijing 100083, China

Abstract

In the context of greening strategies within rapidly growing cities, more and more city managers emphasize the conceptions of nature and ecology in urban landscape designs and planning, including the recent policy calls for Biophilic City construction which is also called the National Forest City in China. The National Forest City is aimed at rebuilding a natural circumstance which reduces the industrial pollution and urban heat island effect and provides a natural urban environment for all the living beings. However, there is lack of an evaluation to estimate if a specific urban forest is close-to-nature or how natural it is. It is the first study in China that attempts to build a close-to-nature evaluation system of urban forest and gives a case of how to design a close-to-nature urban forest based on this evaluation. This study is divided into two parts. The first part expounds the construction process of the close-to-nature evaluation system. In the first step, evaluating indicators from landscape architecture and other subject related to landscape architecture, such as bionomics, aesthetics and forestry, are comprehensively considered in the evaluation system. AHP (Analytic Hierarchy Process) analysis is used in this study to balance the influence of eighteen indicators in five criteria Layer that include species diversity, horizontal structure, vertical structure, stand state vitality and landscape aesthetics of the forest community. Then two typical urban forest parks around the site of Beijing Bai-wang Urban Forest Park are evaluated so that the practicability of preliminary evaluation system can be tested and proved. According to the result of final evaluation system, the grades of evaluation are divided from 0 to 1.0 which are regard as from fully artificial to completely natural. Forest community is identified as a close-to-nature urban forest only when its evaluation grade is higher than 0.8. The second part proposes to plant forests and design a close-to-nature urban forest park based on particular combination of eighteen indicators in five criteria Layer which are required to achieve the close-to-nature standard of the evaluation system. Beijing Bai-wang Urban Forest Park Design is a case that puts nature first in its design. In the first five years, trees and forests are planted in a close-to-nature way and people are forbidden from bothering the succession of forest. Only simple hiking road are allowed to build in the first decade. Then more roads and more playgrounds are added to the forests during the second decade without breaking the structure of close-to-nature forest. Finally, the study of close-to-nature urban forest achieve its aim that create a natural urban environment for all the living beings.

Keywords: Biophilic City; Close-to-nature forest evaluation; Close-to-nature urban forest design; Ecosystem services of urban forest; Nature first
1. Introduction

1.1. Study background

As a developing country, China’s economic and society have been developing rapidly in a short period of 30 years. Besides the fast growth rate of urbanism, the environmental pollution and ecological destruction has been one of the most serious problem across the country. As a result, the concepts such as nature, ecosystem and biophilic design are frequently mentioned in Chinese landscape architecture projects Nowadays. From the large-scale planning like the Call for National Forest City Construction in ‘Beijing city master plan from 2016 to 2035’ to the tiny-scale design such as a rainwater garden project, almost every landscape architect considers that their project is a biophilic and natural design.

1.2. Objective and meaning

It is quite significant for a biophilic design that how to estimate whether the landscape architecture projects are a biophilic design or how close-to-nature the design is as the biophilic design is usually regard as an artificial nature. These two basic questions can never be answered if there is not a quantitative evaluation system to estimate the degree of close-to-nature in landscape architecture. On the other hand, with such a quantitative evaluation system, citizens will be convinced and landscape architects will be more distinct to design a close-to-nature project. Therefore, it is significant to construct an evaluation system to estimate the degree of close-to-nature in landscape architecture. It is not difficult to find out that the conception of close-to-nature evaluation is firstly proposed as a quantitative evaluation system in forestry management after literatures concerned. Also, regarding as a response to the Call for National Forest City Construction, this study attempts to construct a close-to-nature evaluation system of urban forest and then verify this evaluation system by attempting to design a close-to-nature urban forest project.

1.3. Technical route

In the first step, as a response to the Call for National Forest City Construction, this study aims at establishing a close-to-nature urban forest evaluation system and attempt to design a close-to-nature urban forest park based on the system (Fig. 1. Technical Route).

![Technical Route Diagram]

Fig. 1. Technical Route

The detailed process of how to establish a close-to-nature urban forest evaluation system is the second step of the technical route, which includes Indexes collection and Selection, Standardization and AHP (Analytic Hierarchy Process) analysis of index and the Close-to-nature urban forest grade division. The third step is a practical test of the close-to-nature urban forest evaluation system which is used to evaluate the build-up urban forest park around the site area which is going to be designed as an example of a close-to-nature urban forest.
park. In the fourth step, the experience obtained from the practical evaluation is conclude and used to guide a new urban forest park design which is regard as an example of a close-to-nature urban forest park.

2. Methods

2.1. Close-to-nature evaluation system construction

2.1.1. Indexes collection and Selection

Owing to seldom close-to-nature evaluation system can be found after literatures concerned, a great number of indexes from several subjects including forestry, ecology and landscape aesthetics, which are closely connected with landscape architecture, are collected widely. According to the frequency of occurrence and importance, 18 indexes including species richness, evenness index, Shannon-Wiener index, dominance index, average diameter, average crown, crown density, mixed degree, canopy structure, average height, combination of tree, shrub and grass, trees’ age distribution, proportion of native species, health condition, forest form’s characteristic, seasonal characteristic, ornamental characteristics and spatial diversity, in 5 criterion layers, which are Trees’ species diversity, Horizontal structure, Vertical structure, Standing forest’s vitality and Landscape aesthetics, are selected to form the preliminary framework of close-to-nature evaluation system.

2.1.2. Standardization and AHP analysis of indexes

The indexes in the preliminary framework were standardized and each of the index’s weight is calculated through AHP (Analytic Hierarchy Process) analysis (Table. 1.).

</table>
While calculating the weight of indexes in the close-to-nature urban forest evaluation system, this study collected 9 relevant experts’ consideration of the importance between the indexes and used YAAHP software to calculate the weight.

2.1.3. Close-to-nature urban forest level division

According to the standardization of indexes in close-to-nature urban forest evaluation system, the degree value of close-to-nature urban forest is a comprehensive result that made up of 5 criterion layers including species diversity, horizontal structure, vertical structure, standing forest’s vitality and landscape aesthetics. The value of calculation results distribution between 0 and 1, which is also considered convenient in the practical design of the close-to-nature urban forest. Combining with studies of German close-to-nature urban forest level division and the feature of the urban forest on plain in Beijing. Considering of combining both quantitative and qualitative methods, the close-to-nature urban forest level division is divided into five levels, which is shown in Table 2. The lower value level indicates a difference from close-to-nature design, and the level of high value that beyond 0.8 represents a close-to-nature urban forest community, which is showed in the table.

Table 2. Close-to-nature urban forest level

<table>

<td>Highest (0.8-1.0)</td>
<td>Top forest community with lowest human disturbance. Multi-layer structure and diverse growth stages forest. The maximization of ecological benefits and with great aesthetic value.</td>
</tr>
<tr>
<td>II</td>
<td>Higher (0.6-0.8)</td>
<td>At the middle or late stage of the forest succession with lower human disturbance. Uneven aged forest community with multi-layer structure. The ecological benefit is prominent.</td>
</tr>
</tbody>
</table>

| III   | Medium (0.4-0.6)       | Succession forest with pioneer forest community occasionally. Multi-layer structure of different type of forest such as coniferous forest, coniferous mixed forest, broad-leaved forest and broadleaf mixed forest. |
| IV    | Lower (0.2-0.4)        | At the early stage of succession, the forest of pioneer community with mainly native species. Single-layer structure of the Even-aged Forest. |
| V     | Lowest (0-0.2)         | The non-adaptive forest community with foreign tree species. Single layer structure of plantation and shrub with high level of disturbance, low ecological benefits and lack of landscape aesthetic. |

2.2. Close-to-nature evaluation of build-up urban forest parks

After the close-to-nature urban forest evaluation system is established, two build-up urban forest park are chosen to be evaluated by this evaluation system. There are five quadrats (20M*20M each) of tree communities selected and evaluated randomly in each park, which are used to reduce the error by calculating the average value.

2.2.1. Evaluation of the Baiwang Mountain Forest Park

The Baiwang Mountain Forest Park is located on the Baiwang Mountain which and has various terrain and abundant habitats. It is covered by plantation planted two decades ago.

According to the evaluation result of the field research showed in Table 3., the average value grade of the Baiwang Mountain Forest Park is between 0.4-0.6, which is identified as medium close-to-nature level. It also shows that the levels of species richness, crown density, proportion of native species and canopy structure are high in the Baiwang Mountain Forest Park. However, the levels of the whole landscape aesthetics indexes are in a relatively low level.

2.2.2. Evaluation of the Baiwang Urban Park

Baiwang Urban Park is a normal and flat urban park that emphasize on the landscape aesthetics of the tree communities. According to the evaluation result of the field research showed in Table 4., the average value grade of the Baiwang Urban Park is between 0.2-0.4, which is identified as lower close-to-nature level. Different from the Baiwang Mountain Forest Park which is various in terrains and habitats, the Baiwang Urban Park is outstanding in landscape aesthetics. On the other hand, without considering about the community’s age distribution, all the communities are plant by full-grown tree with large diameter and height. Besides, it has lower crown density, mixed degree and combination of tree, shrub and grass.

2.3. The close-to-nature urban forest park design

2.3.1. Surrounding analysis of the design site
The design site is located in an area with natural surrounding environment. At the north side of the site is the Baiwang Mountain which is part of west mountain range of Beijing. Jingmi diversion canal, the main water supply line in Beijing, flowing by south of the design site.

2.3.2. Objective of the design
Basing on the study of the close-to-nature urban forest evaluation system and the experience from the field research evaluation of build-up urban forest parks, this design aims at attempting to find the method of building up a close-to-nature urban forest park, which means the close-to-nature degree of this urban forest park is beyond 0.8, besides the basic function of other urban forest park.

2.3.3. Process of the design
According to the principle of the close-to-nature urban forest evaluation system, the evaluation result of an urban forest community will reach the highest close-to-nature level, which is equal to its Close to nature degree is beyond 0.8, if the grade of each 5 criterion layer of this community is higher than 0.8. Therefore, the process of the close-to-nature urban forest design starts with figuring out how to design a close-to-nature urban forest community pattern whose grades of each 5 criterions layer are all higher than 0.8. According to the relationship between the grade and the actual meaning of each index identified in the standardization of index, it is feasible to figure out the actual form of each 5 criterion in a highest level close-to-nature urban forest community. Meanwhile, based on the different weight given to the indexes by the AHP analysis, nine indexes of the heaviest weight are selected to build up the close-to-nature urban forest community pattern in the highest level (Fig. 2. Close-to-Nature Urban Forest Community Pattern).

![Close-to-Nature Urban Forest Community Pattern](image)

Two indexes are selected in the Trees’ species diversity criterion that the species richness is more than 80% of the urban forest species in local nursery garden and the number of advantageous tree species is more than 35%. In Horizontal structure, the crown density is higher than 0.75. In Vertical structure, combination of tree, shrub and grass is considered the most representative that all area should be cover by grass plants and the proportion of tree to shrub is more than one third. In the Standing forest’s vitality, the proportion of young tree to full-grown tree is more than two thirds and there should be more than 80% native species among them. As for the Landscape aesthetics, three indexes are involved that indicates obviously winding canopy line, having ornamental characteristics of flowers, leaves, fruits or barks in at least three seasons. After that, the overall planting design covering the site area is created by the combination of the close-to-nature urban forest community pattern and vertical design, which is also in a natural way that continues the Baiwang Mountain range. The combination is necessary that the
specific plant species of each community pattern are able to be selected according to the specific habitats which is influenced by the vertical design. In the end of the design process, considering of the basic function of an urban forest park, the tourism facilities are overlaid with the vertical design and the overall planting design (Fig. 3. Superposition) and the final design of the Baiwang urban forest park as a highest level close-to-nature urban forest project is accomplished.

3. Results

3.1. Result of the close-to-nature urban forest evaluation system

This study establishes a close-to-nature urban forest evaluation system including a calculation table with 5 criterion layers and 18 indexes, and a close-to-nature urban forest level division which is used to evaluate the level of a close-to-nature urban forest.

3.2. Result of the close-to-nature urban forest design

Based on the close-to-nature urban forest evaluation system, this study proposes a new attempt that the planting design is firstly considered before the tourism facilities design and the vertical design (Fig. 4. Master plan of the Baiwang Urban Forest Park). It is also a completely new perspective of planting design that the planting of whole site area is designed after the close-to-nature planting pattern is designed.

Biophilic Cities

Researching On Urban Park Landscape Planning With Industrial Heritage

Yunshan Song, a Xiong Li, a

aYunshan Song, School of Landscape Architecture, Beijing Forestry University, Beijing 100083, China

Abstract

In the history of urban development, industrial facilities have an important historical status, which is a witness to the economic development and historical process of cities and regions. With the rapid development of urban construction, all major cities are actively adjusting the layout of industrial land and improving the urban environment, resulting in a lot of industrial wasteland in this process. It is an important way to construct a biophilic city and transform the abandoned industrial facilities into green infrastructure through ecosystem restoration. This article will update for the study of industrial culture landscape to start. Taking a space along the Jialing River in Chongqing as an example, this paper expounds how to realize the transformation of industrial facilities to green infrastructure through ecological means. The aim of this study is to provide urban residents with good leisure and recreation, meet people’s demand for green, improve the function of urban ecosystem, and provide reference and reference for the construction of a biophilic city.

Keywords: landscape urbanism, industrial landscape renewal, green infrastructure

1. Introduction

In the history of urban development, industrial facilities have an important historical status, and they often bear witness to the economic development and historical process of a city and region. For nearly half a century, developed countries such as Europe and the United States have received more and more general attention on the reuse of abandoned industrial land, which affects the whole world. Transforming the urban industrial wasteland by ecological system restoration and landscape renewal would find a new way to solve social and environmental problems.

At the same time, China is at the stage of accelerating urbanization, and the city construction is developing rapidly. Faced with the integration process of the global economy and the pressure of urban competition, all major cities are actively adjusting the layout of industrial land and improving the urban environment. A great deal of industrial wasteland has been produced in this process. Recently, there has been a succession of landscape renewal practices in industrial wasteland and urban industrial districts in China. However, it is still urgent to learn and develop the ideological method of the urban industrial wasteland renewal in western developed countries to solve specific problems in China.

Taking a section of the space along the Jialing River in Chongqing as an example, this study expounds how to realize the transformation of industrial facilities to green infrastructure through ecological means to make the industrial wasteland reused again. Besides, it provides comfortable green spaces for urban residents, meets the needs of
tourism and improve the function of the urban ecosystem.

2. Relevant Theory

2.1. Industrial Landscape Renewal

The objects of the study, namely industrial heritage, were defined in the “Nizhny Tagil Charter”. It points out that "industrial heritage consists of industry cultural relics, and historical, technical, social, architectural or scientific value. These relics include buildings, structures, machinery, workshops, and other related material and non-material manifestations. In addition, social sites associated with industry, such as residences, religious places of worship, and educational institutions, are also areas of industrial heritage.” These abandoned industrial heritage have important historical and research values. At the same time, they also reflect important social values and regional cultural values [1]. The industrial relics in the planned site mainly include the remaining industrial plants and some industrial facilities and materials.

2.2. Green Infrastructure

"Green Infrastructure" is a concept that is broadly defined and it needs to be understood according to the specific situations. There is no clear definition of this concept. The green infrastructure encompasses human activities in the landscape at the broadest level. This includes not only the structure that is close to nature, but also the human factors in the open space.

The green infrastructure is a low-cost, resilient landscape that links all systems, including ecosystems, to one another, and transforms unused space and infrastructure in cities into comfortable green spaces that people can reuse. It also enables people and other creatures to create versatile and dynamic living environments [2]. The transformation of abandoned industrial facilities into green infrastructure is the focus of this study.

Here are some of the green infrastructure commonly used in urban parks.

Rain gardens are diverse and widely used. They are one of the most important facilities for flexible landscapes. They can collect and absorb surface runoff, optimize the ecosystem, and create a beautiful landscape.

Grassed swales are actually a kind of narrow and long rain garden and often distributed on the roadside in a linear landscape form.

Permeable pavement uses lower-cost pavement materials to filter, process or store rainwater.

Ecological parking is a good choice for the application of green infrastructure where many green infrastructure elements are put to good use, including permeable pavement, rain gardens, grassed swales and so on. It can effectively reduce the heat island effect in densely populated areas and make people use a more comfortable environment.

Roof gardens can purify rainwater, effectively control the quality of roof rainwater collection and reduce the cost of room temperature maintenance.
3.3. Planning Strategies

3.1. Study Area

This study area is located along the Jialing River in Chongqing, which is the key area of the overall strategic planning of the Yangtze River in Chongqing. According to Chongqing city master planning, the area of 15 hectares as the park green space in the region. The eastern side is connected to the urban roads. The south side faces the Jialing River. In addition, the western and northern sides are the existing brick factory buildings. The area is one of the landmark gateways for the Jialing River to enter Chongqing's downtown area.

3.2. Planning Goal

Focusing on the characteristics of the site and combining with the needs of ecology, landscape and function, the planning goal of the research area was proposed. It is to create a site that fully respects the texture of the site and to achieve the collision and integration of the industrial landscape and the natural scenery while the urban park area satisfying the artistic display, recreation and comprehensive service functions. It will mean realizing the transformation of industrial wasteland to green infrastructure.

3.3. Planning strategies under the green infrastructure framework

3.3.1. Landscape strategy -- the shaping of industrial landscape renewal

The industrial plant left over from the site is an important part of the planning, and there are generally three aspects of the processing strategy.

The first is to preserve the physical architecture and optimize functions. For example, by partially changing the material of the roof or facade, the industrial plant will be transformed into a greenhouse, a tearoom, and a promenade. For the production and transportation facilities left behind by the original brick factories, they were treated and preserved for a few moments to form a positive response to the industrial culture, causing people's associations and memories.

The second is to retain only the physical structure of industrial buildings and form gray spaces. For example, the pillar net framework of the industrial plant is used to transform it into a landscape gallery though growing climbing plants.

The third is to dismantle the building and integrate it into the natural environment, such as...
as the removal of the building's roof into a horticultural garden, the preservation of the basement as an activity site, the preservation of the pillars as lampposts, or the preservation of the rails to shape the site's texture. The traces of the stains left behind by nature in industrial facilities are not deliberately concealed or destroyed. Instead, we respect the texture of the site and use artistic processing methods to make it an important element in the landscape [3].

This three-point strategy optimizes the space for industrial buildings, so that abandoned industrial relics can be reused, and better integration with the surrounding green space improves the landscape value of industrial wasteland.

3.3.2. Ecological strategy -- the construction of sponge system

The current terrain has topographic features such as high platforms, mountains, depressions, and gullies. The planning sufficiently respects the current situation, increases micro-topography, strengthens the water transfer lines, connects the gullies and forms the site's water system. This strategy can fully collect site rainwater, combine its own microcirculation system, and play a role in the sponge function of the green infrastructure [4].

According to the vertical elevation of the site, water collection facilities such as grassed swales and rain gardens are arranged near the source of surface runoff. When rainfall occurs, the natural elements are sufficiently used to transport, filter and infiltrate surface runoff. In the stage of rainwater retention, the use of current state storage of rainwater will not only enrich the landscape of the area, but also facilitate the reuse of groundwater, irrigation and other purposes.

In addition to the existing landform and terrain collection facilities, the original industrial facilities can be converted into rainwater collection devices such as reservoirs, drains, and bio-retention pools to achieve the perfect transformation from industrial facilities to green infrastructure while satisfying the landscape.

3.3.3. Functional strategy -- the implantation of recreation system

Industrial wasteland often presents a passive state that has not been utilized. In addition to solving the problem of rain collection in a sponge city, the green
infrastructure is more important to transform unused space and infrastructure in cities into comfortable green spaces that people can reuse. At the same time, it will be a versatile and dynamic living environment for people.

The entire site is divided into three areas based on function, including the main entrance and integrated service area, industrial garden area and ecological recreation area. The site mainly uses the original industrial relics as the carrier to implant the park's recreation system.

The existing railway texture of the site can be designed and transformed to form a Riverside bicycle path. Some industrial buildings or industrial structures formed in
the activity area can provide a place for people to exercise, exercise and think. It is beneficial to improve people's physical and mental conditions. Low-lying rain gardens have positive implications for maintaining and enhancing biodiversity through the retention of rainwater and the cultivation of aquatic plants.

4. Conclusion

The research area is mainly based on the relevant theories of Industrial Landscape Renewal and Green Infrastructure. Taking a space along the Jialing River in Chongqing as an example and formulating a clear research goal, strategies for the three aspects of landscape, ecology, and function were studied to achieve the transformation of industrial wasteland to urban parks. It will provide urban residents with good leisure and recreation, meet people's demand for green, improve the function of urban ecosystem, and provide reference for the construction of urban green spaces.

At present, China's urban industrial landscape planning with its industrial heritage is still in the experimental and demonstration stage. For the creation of industrial landscape, there are still many difficulties in the process of element definition, planning and design, protection and restoration, and construction and implementation. The transformation of abandoned industrial facilities into green infrastructure and the construction of parks through ecological means are all options and attempts to renovate the landscape of industrial wasteland and the construction of a biophilic city.

Landscape Planting Design of Garden Expo in the Eco-City perspective
—A Case on the second session of the Hebei Provincial Garden Expo in China

Ruiqi Wang a, Lixiong b
a Beijing Forestry University (No.) 35 East Qinghua Road Haidian District, Beijing 100083 (zip code) P.R.China
b Beijing Forestry University (No.) 35 East Qinghua Road Haidian District, Beijing 100083 (zip code) P.R.China

Abstract

The basic requirements of eco-city is that a city should put nature first in its design, planning, and management and plant landscape is the essence of nature. This paper bases on documents review and the special semi-humid continental monsoon climate as well as intense weathering geographical conditions, taking the second session of the Hebei Provincial Garden Expo in China as an instant to analysis the landscape planting design on space and time. The space included three aspects. The first one was dotted plant landscape in terms of the specified plant garden, the featured theme garden and the functional entrance. In the second aspect linear plant landscape contained the aquatic plant coastline and the park boundary. The third one included the present plant groups and the local plant groups as plane plant landscape. The case is a primary trial integrating the eco-city in landscape planting design of garden expo, aiming at exploring how the plant landscape works during the eco-city construction. Addition, future research and design is warranted for more efficient and profound methods.

Key words: landscape architecture, eco-city, garden expo, landscape planting design

1 Background

The concept of eco-city is brought forward with the continuous development of human civilization and the continuous distillation of the relationship between man and nature. Huang et al. (2004) indicate that eco-city is a human settlements form with harmonious society, efficient economy and virtuous circle of ecology, as well as an organic whole include nature, city and people in harmony to form a symbiotic structure. Eco-city is a diversified and
sustainable development urban pattern formed by the combination of economic development, social progress and environmental protection, and the ecological virtuous circle form an ideal regional shape. Chinese emphasis more on traditional characteristics in research of ecological urban construction and planning, focus on grasping the direction of urban ecological construction with integrity and systemic to achieve harmony between man and nature, but the research is mainly in the fields of ecology department and architectural planning cause a more macroscopic theory which is lack of comprehensive subject research and limited to play a guiding role in the specific practice.

China International Garden and Flower Expo (hereinafter referred to as "Garden Fairy") to some extent, is a city of major events, in terms of major events activities, influence on the building of ecological city, and the effect significantly, is currently China's cities government to one of the basic motive of these activities have a high enthusiasm. The plant landscape of Fairy Park is important natural elements in the overall landscape elements, it is not only beautify the urban environment ornament materials, especially to build ecological city, regional sustainable development an important driving force. Fairy Park industry is a new technology, new ideas, new model of a centralized exhibition, this way of communication makes the new technology, new idea, new model of promoting more rapidly, the study of the landscape to build ecological city play a good demonstration effect.

2. Overview of the overall planning and design of the second session of the Hebei Provincial Garden Expo

2.1 Site profile

The project area is located in west Qinhuangdao economic and technological development district of Hebei in China, covers an area of about 1.33 square kilometers, and the area development potential is huge due to intersection of the mountain tourist area, the coastal tourist area and the central city area,. The surrounding water and land transportation are very convenient, Jingha and Qincheng expressway are on the north side, the west is close to the coastal highway, Qinfu expressway is in the south side, the east is near to Bohai bay. The city is 60 kilometers away from Beidaihe airport, and is half an hour traffic circle at Qinhuangdao railway station, Beidaihe railway station and Qinhuangdao Port.

The Fairy Park in Hebei clasps national strategic positioning, response to regional integration development needs, carry out innovation, coordination, new development
of the green, open and sharing ideas, chose "Mountain Harbor city, Green Dream" as the theme. The project’s goal is five one garden expo, junior communion Qiyun Mountain, to create innovation Fairy Park, low carbon Fairy Park, sponge Fairy Park, wisdom Fairy Park, people's Fairy Park.

2.2 **Overall structure analysis of the second session of the Hebei Provincial Garden Expo.**

The figure 2 show that the overall planning structure of the Fairy Park is three valleys, one vein, and three nuclear as well as double groups. The structure is striving to display the elegant style of contemporary garden art and the Beautiful China plan with a multi-dimensional innovation perspective. First, three valleys is the characteristic valley landscape formed on the basis of the present situation. Second, the one pulse is the water vein landscape throughout the North and South Park. Third, the three nuclear is a core control points formed by the three core buildings, namely the main pavilion. Finally, the northern city exhibition garden group and the southern special exhibition garden group formed the double groups. There are four categories 30 different exhibition garden are constructed, including exhibition garden of city in Hebei province, Qinhuangdao and District County exhibition garden, Theme Creative garden, Regional Customs garden and etc. There are also 10 specialty theme garden including the Children Science Park, the Jing-Jin-Ji Regional demonstration garden, the Rose garden, the Chrysanthemum garden and so on.

3. **Plant landscape planning and design of the second session of the Hebei Provincial Garden Expo.**

The total area of green space in the Fairy Park area is as high as 68.8 hectares and the overall plant landscape planning is closely related to the theme of "Mountain Harbor city, Green Dream" to build the green engine in the area of Qiyun Mountain. The plant configuration is based on the basic principle of local conditions, taking into account the seasonal changes and the landscape effect during the Garden Expo, forming a plant landscape with “three quarters of flowering, every green”, giving full play to the ornamental characteristics of all kinds of plants and enriching the overall view layer of the Garden Expo.
Rich garden plant species, 30 species of evergreen trees, more than 100 species of deciduous trees, more than 40 species of trees, flower shrubs more than 200, more than 110 kinds of flowers, more than 110 kinds of perennial flowers, and more than 50 species of ornamental grasses, and more than 40 species of aquatic plants.

3.1 The overall structure of plant landscape in Garden Expo

The Garden Expo plant landscape of the North and South Park is featured with different styles. Qinhuangdao and District County exhibition garden and there theme Creative gardens are distributed in north garden. Plant landscape in north garden combined with three kinds of different terrain of city exhibition garden group in Hebei province. The frame of north garden plant landscape is the realm of typical plant materials in different regions formed with the realm of public landscape. Among them, three theme parks are focused on the plant landscape, which forms the features of the plant landscape. While, the south garden is lined with Hydrangea macrophylla (Thunb.) Ser. along the two sides of the primary road, which connects the five Specified gardens, Theme Creative garden and Regional Customs garden. The plant landscape is abundant in layers and characterized by science popularization.

The North Garden focuses on the three main types of landscape in Hebei province, including Mountain-Plateau group, the River-Lake-Wetland group and Sparse-Forest-Grassland group. In addition, this garden distribution three theme parks, Aquatic Botanical Garden, Children's Garden and Golden Leaf Garden.

The south garden contains six specified garden, the Chinese Rose Garden, Characteristic Botanical garden of Jing-Jin-Ji, Chrysanthemum Garden, Crape myrtle Garden, Shade tolerant Botanical Garden and Herb garden. They are connected by the unique Hydrangea macrophylla (Thunb.) Ser. strip, formed the plant landscape structure of the south garden which takes science popularization as the main part.

3.2 Dotted plant landscape of Garden Expo

The Children's Garden, also known as "Ocean Dream Garden," is located in the northeast corner of the park and covers an area of approximately 1.94 hectares. The overall structure connects the four theme activity areas in a sea blue ribbon path, including a children's garden, a popular science garden, a sports paradise, and a
future garden. Science Garden displays the five marine organisms at the time of extinction and the existing saline-alkali-resistant plants. From figure3, the sports park organizes wood platform activities in conjunction with the beach. In the future, the garden plants perennial flowers and arranges walking paths. A large area of grass slopes next to the site is planted with *Helianthus annuus* Linn. and *Kochia scoparia* (Linn.) Schrad. to guide children to experience the beauty of nature. Many green islands are also designed on the site to ensure vegetation coverage and provide children and parents with comfortable recreational space.

The Aquatic Botanical Garden is located on the east side of the main lake area of North Park and covers an area of about 1.33 hectares. The overall structure of the wooden plank road tandem pool, science shows a variety of aquatic plants and related water features culture. One of the three fish ponds is an independent water surface, and the other two are connected to large water surface. The revetment treatment consists of two types of wooden stakes and steps into the water. 15 kinds of *Nymphaea tetragona* Georgi, 13 kinds of *Nelumbo nucifera* Gaertn. and 15 kinds of other aquatic plants are planted. There are also and *Salix babylonica* Linn. and *Salix matsudana* Koidz. to enclose the space. On one side of the wooden plank roadway, there will be a Lotus Fragrance Pavilion on the side of the boardwalk. The pavilion faces the main lake so as to smell the fragrance of *Nelumbo nucifera* Gaertn. At the same time, a Louts Wind pavilion is set up on the hillside of the east side of the wooden plank road. Take the mean of “The fragrance is far away, the wind is full of wind”.

Golden Leaf Garden is located in the southeast corner of North Park and covers an area of approximately 1.3 hectares. With two golden landscapes belt combined with three golden mini gardens to form a golden plant viewing interface, it stands out in the dark green nature of the summer, giving visitors a unique visual experience. Among them, the two golden landscape belts rely on the roads in the theme park and are planted with gold branches and gold leaf plants on both sides, with *Sophora japonica* ‘Winter Gold’ and *Acer negundo* ‘Auea’ forming a golden garden road; three golden mini gardens along the primary road layout is planted with 25 kinds of gold herbs, such as *Gaillardia*
Biophilic Cities

pulchella Foug., Rudbeckia laciniata Linn., and Coreopsis basalis (A.Dietr.) S.F.Blake. Looking out at the Golden Leaf Garden, five kinds of gold leaf arbors such as the Ulmus pumila cv., Acer negundo ‘Auea’ and the golden leaf trees leafhopper cooperate with the topographic design, and visitors can enjoy a strong visual impact of the golden color of the whole mountain.

3.3 Linear plant landscape in Garden Expo

There are two kinds of border in Fairy Park, one is the boundary of the red line result in closed management of Garden Expo, and another kind is land-water boundary.

The park border has two kinds of processing way, north close to the boundary of the broad road garden as close to the parking lot, stream, fence planting ornamental effect is good, flowering and session consistent double gland cane, cane for annual double gland vines, not suitable for large area planted, so the park east, west, south three boundary fence are planting flower vine shrubs of the relatively small amount of red roses, artificial barrier for shelter.

There are two methods to deal with the boundary of the red line. The border of the north side is close to the garden Bo Avenue, which is close to the parking lot and the flow of people is large, thus the Dipladenia sanderi. is planted on the landscape fence as an annual vine which is good ornamental effect during the Garden Expo and the period of the flowering is the same with the opening time of the Garden Expo. As a biennial plant, The Dipladenia sanderi. is not suitable for large area planting. Therefore, the fences on the three borders of the Fairy Park are planted with Rosa Rubus which is a twining shrub with relatively small amount of flowers, but has a certain shelter for artificial fences.

The treatment of land-water boundary mainly utilizes the transition of aquatic plants, so that the two sides of the boundary can be integrated with each other but not rigid. In close quarters, plant many kinds of delicate aquatic plant in small area to reflect the purpose of high-quality goods exhibition garden. From the boundary far away from the people, the landscape of the River-Lake-Wetland group in Hebei Province was reproduced in a large area and a single species of planting.

The Highland Plateau group is located in the northwest corner of North Park and covers an area of about 2 hectares. The plant landscape is dominated by cool plants, which embodies the rich forest atmosphere, and combines the landscape of large-scale wildflowers to reproduce the natural features of Hebei’s highland plateau landscape. The center flowers sea choses 12 species of native perennial flowers were used to seed mixing so as to create the atmosphere of alpine meadows. Five types of plateau trees, Quercus mongolica Fisch. ex Ledeb., Quercus wutaishanica Mayr, Betula platyphylla Suk. and other two kinds of evergreen trees: Picea asperata Mast and
*Pinus tabuliformis* Carrière were used to enclose the boundary of the group with. Visitors can enjoy the sea of flowers and *Betula platyphylla* Suk., and feel the atmosphere of the alpine meadows.

### 3.4 Plane plant landscape of the Garden Expo

The River-Lake-Wetland group is located in the south-central part of the North Park. It consists of a vertical and horizontal water system and covers an area of about 3.5 hectares. It is the core of the water system connecting the North and South Park. The plant group is mainly composed of the display of the rich mountain forest atmosphere and the natural features of the plateau mountain in Hebei Province, creating a horizon landscape based on the wetland of the river and the lake and the mosaic of the urban exhibition garden. Within the group, based on the rich water types, combined with the height difference of the water system, the two thematic landscape belts of Peach Blossom Valley and Begonia Island were designed in order from the west side of the shallow mountain valley area to the main water surface on the east side. Go west, enjoying the beauty of Peach Blossoms on the clear springs and the outside of the forest. And turn east, you can walk down the creek along the river and enjoy the sea view and the view of the lake between the dotted islands. The plant group consists of *Salix aureo-pendula*, *Salix matsudana* var. matsudana f. umbraculifera Rehd., *Pterocarya stenoptera* C. DC. and so on as skeletons, and *Malus halliana* Koehne, *Chaenomeles cathayensis* Schneid., *Amygdalus davidiana* (Carrière) de Vos ex Henry, *Amygdalus persica* cv. Pendula and so on as flower viewing belts. *Phragmites communis*, *Acorus calamus* L. and other aquatic plants to enrich the waterfront and form a waterfront space.

Sparse Forest group is located in the middle of North Park and covers an area of about 2.4 hectares. It displays the rich landscape of plain grassland in Hebei Province around a special service building. The sparse open space of the Sparse Forest group is in contrast with the rich and compact exhibition garden system surrounded by it, enabling visitors to enjoy a comfortable viewing experience during a relaxing visit. The group’s terrain is high in the north and low in the south, and the whole is relatively gentle. The plant group utilizes the Autumn Discolored Tree such as *Sophora japonica* Linn., *Acer buergerianum* Miq. as the skeleton, together with lots of *Yulania denudata* (Desr.) D. L. Fu, *Malus spectabilis* (Ait.) Borkh., and *Cerasus serrulata* var. lannesiana (Carr.) Makino, scented trees and shrubs as well as herbs flowers in various colors to form a rich viewing interface and create a largescale open space which spring flowers and autumn leaves.
4 Conclusion

The Garden Expo is the highest event that shows the level of a country or a regional gardens. It will have a profound impact on the development of regional or even world landscapes. The development trend of plant landscapes is to create a soft space composed of plant monomers or communities that exhibit habitat characteristics, lasting, and pleasant, and that have regional characteristics, but at the same time can adapt to the laws of natural evolution. Simultaneously, this plant landscape could propose the establishment of design ideas based on habitat, function and regional characteristics, Garden Expo will undoubtedly provide a stage and guidance for the display of landscape plants.

The overall plant landscape planning of the second session of the Hebei Provincial Garden Expo follows the planning strategy of “respecting the status quo, highlighting the theme, distinctive features, and taking into account development”. Plant landscape design is based on the utmost preservation of the status quo. The current status Chinese pine forest in North Park, the mixed forests in the southwest corner of South Park, the *Populus tomentosa* Carrière forest of South Park and beautiful tall trees are maintained, fully respect the site status. In order to highlight the theme of the Garden Expo, a large number of seasonal flowers and various green sculptures will be used during the exhibition to underline the overall atmosphere of the session. The entire park will become a permanent green space for residents to enjoy in the Qiyun Mountain area, and will be integrated into the community greenway system to provide leisure and recreation services for the Qiyun Mountain area.

Study on the Construction of Taiyuan Ecological City in The Northern Song Dynasty to the Ming Dynasty (A.D. 960 to 1644) from the Perspective of Landscape

Jiaqi Sun, a Junming Feng, a Xi Zheng a

*Beijing Forestry University, NO.35, Qinghua East Road, Haidian District, Beijing, 100083, China

Abstract

The construction of ancient cities in China is closely related to natural Ecologicals. The inadequacy of human production technologies leads to the limited ability to transform nature. Therefore, people are filled with relevance of nature and hope to reach the harmony between man and nature to build human settlements with the help of natural forces. Compared with the tensions of land use and modern cities as well as the plundering of resources, ancient cities are more focused on local conditions and ecological sustainability. As the foundation of the Ecological construction, Ecological and scenery researching on the construction of ancient urban Ecologicals helps to understand the contemporary urban Ecological and explore the unique regional culture of the city. Taiyuan City is a national historical and cultural city with a 4700 years history of civilization and a 2500 years history of as a city. Historically, its political strategic position has been valued by rulers of all ages. This land has left a wealth of experience in urban construction. Taiyuan City is built on the basis of the Ecological environment. After artificial transformations and interactions, the Ecological pattern of the artificial environment and the Ecological Environment are formed. This article takes the interior and exterior urban and rural environment of Taiyuan in the Northern Song Dynasty to Ming Dynasty as the research object. From the perspective of landscape architecture, it summarizes the process of landscape evolution in Taiyuan and analyzes the urban development of Taiyuan, including the boundary of the city wall, rivers and lakes, road systems, and explores the characteristics of the layout of urban zoning, such as the official residence area, the city workshop area, neighborhood residential area, etiquette ritual area. This study which is about the construction of Taiyuan ecological city landscape may throw some light on urban conservation and development.

Keywords: landscape perspective; ancient Taiyuan; ecological city; Ecological construction
1. Introduction

The construction of ancient ecological cities in China is based on the Ecological environment. After human development and construction, the basis for creating a human settlement environment, cities are integrated with the long-term coordination of nature, and ultimately are closely linked with the environment on which they rely. This article explores the Ecological pattern and urban construction of Taiyuan. It refers to the regional Ecological pattern that includes the combination of cultural landscape and natural landscape, including Taiyuan City, surrounding natural landscapes and artificial buildings. The development of the city has undergone a long evolution with the development of the times. However, the landscape environment has always played an important role in the development of the city. It is the basis for the construction of an ecological city and the basis for the development of an ecological city. While adapting to the Ecological environment, the city also changes the Ecological environment and forms a continuous regional overall environment within and outside the city.

2. "Controlling Mountain and Water Stream" - Ecological Environment of Taiyuan Region

The Taiyuan Basin is high in the north and east, low in the south and west. Historically, the Taiyuan area has abundant precipitation and many lakes. The Taiyuan Basin is surrounded by mountains on three sides, the eastern side of the Lvliang Mountains, on the west side of the Taihang Mountains (Figure 1). The Fen River flows into the Lvliang Valley and passes through the basin from north to south. According to the earliest written records, Zhou Cheng Wang ruled it to his uncle Tang. “Because the building is located in the north of Jinshui, the name of the ancient city is “Jinyang”. Jinyang City is located in the Jinyuan District of Taiyuan City today. The surrounding historic sites are built with Jinyang City as the regional center. However, the Jinyang City is located in the southeast of the basin and cannot effectively control this area. Then the center of the area shifts toward the center of the basin.

The Northern Song Dynasty was built and the state government chose Tangming Town as the foundation and moved more than tens of kilometers to the northeast from Jinyang City, which is located in the center of the basin.
Taiyuan Basin. However, because of the close proximity to the Fen River, it lacks effective flood prevention facilities, and the state towns are often affected by floods. However, the rich water system provides the conditions for urban Ecological construction. The northern, eastern and southern plains also provide space for the development of the city. The Ecological pattern of the Taiyuan Basin directly affects the location and expansion of the city, and the construction and development of the Taiyuan City also promotes the evolution of Ecological patterns outside the city. The environment after mutual influence is more suitable for human habitation.

3. "Fairview Taiyuan City" - Ecological City Construction

The Song Dynasty is a city built for political and military purposes. “The government was set up Beijing State Administration, and the official ownership system was the same as the second Beijing”. After building a city wall on the basis of Tangming Town, the internal development of the city, so the pattern of Tangming Town laid the axis and the basic pattern of Taiyuan City; the expansion of the Ming Dynasty city also first built Jinwangfu and the city wall after the development of new cities. Compared with cities developed due to economic needs, the subjective initiative of Chinese traditional cities has more influence on the layout of cities. From this, the traditional planning concept can be clearly seen, and the structure is adjusted accordingly based on the current conditions. The city has ingenious local features, as is Taiyuan City.

In the first year of Tang Dynasty (713), Tangming Town served as the resident of Hedong Jiu; Song Taiping seven year (982) and the State City built Tangming Town on the basis of the preservation of Tangming Town as the Zi Cheng in Taiyuan. In conjunction with the state city, Tangming Town is retained as a sub-city, and the State City (Luo cheng), Nanguan City, Beiguan City, and Dongguan City are expanded. In the golden and the Yuan period, the sub-city was destroyed due to the war and was converted into a square. In the year of Ming Hongwu nine year(1376), Jinwangfu was newly built on the east side of the state capital, and the wall of Mingfucheng City was moved eastward, southward and northward. The area of Fucheng District was 9.32 square kilometers, which was second only to Beijing in the north of the Yangtze River. The walls of the Ming Dynasty are tall and magnificent. They spread over the lakes and meadows. The west of Yeosu River and the west of Liuxi Liantang become public gardens. The city and the surrounding rivers and rivers are known as the “Fairview Taiyuan City”. During the peak period of the ancient Taiyuan City construction in the Northern Song Dynasty and the Ming Dynasty, Ming Taiyuan City left a rich historical and cultural landscape. Therefore, this article takes the Northern Song Dynasty and Ming Dynasty as the research category to explore the
formation of the Ecological pattern of Taiyuan City.

3.1. The hills and the lakes

The superiority or inferiority of the geographical location directly affects the scale and layout of the city's development. The water in south to the mountain in north is the ideal Ecological Environment for the city, and the location of the Jinyang city meets this principle. However, the city can be prosperity with water or ruin by water The Fen River in the Northern Song Dynasty was introduced into the city of Jinyang, resulting in the destruction of the city.

The town of Tangming is located in the center of the basin. The Fen River is the main target for the construction of the city in the state of Bingzhou. At that time, there was a constant stream of ships from and to the Fen River, and the shipping was busy. The poet Zhang Yun of the Ming Dynasty wrote a poem “The Late Rivers at the Fen River”:

“The mountains are set in a thousand forests, and the ferry is returned as a colony”. And the state city site is located on the east bank of the Fen River. First, it is conducive to military defense. The Fen River becomes the natural moat of the Bingzhou City. Second, it is convenient for waterway transportation. The goods passing through the Fen River can be easily entered into the city. At the same time, the landscape of the Fen River will also be within the sight of Taiyuan City. The Fen River has slowed down the vertical slope in the basin, so flooding is often poor. At the beginning of the Song Dynasty, the Fen River often collapsed in the northwest of Bingzhou City the state’s state magistrate, established the five miles new embankment on the eastern side of the dam to control the flooding of the Fen River. This will bring the water from the Fen River to the dam bank, which can act as a buffer during the flood season. The riverbank mud is full of lotus flowers, named "Furongzhou", and tens of thousands of willows will be planted along the embankment. It will be called "Liu Dike," and will be built on the embankment. The Jianhua Hall and Tongxia Pavilion will be built on the embankment. A view of the stream pond. This governance will transform the uninhabited flood-stricken areas of the suburbs into a beautiful public garden. In addition, the state towns and cities draw water to form moats. Today, Yuchi, Houxiao River, Donghouxiao River and other places can infer the location of the moat at that time.

During the expansion of Ming Taiyuan Prefecture, Liuxi Liantang and Xize River, Yinma River, Yangyu Pond, Xihaizi, Nanhaizi and other urban west river systems were included in the urban scope. In addition, the southeastern side of Tangming Town formed two water pools called Yuanhaizi and Changhaizi due to its topography. The name Taiyuan City was expanded into a lake in the

![Image of Taiyuan city water system recovery map in Ming Dynasty](image-url)
city. Due to its proximity to the Gongyuan, it became a student excursion site for the examination of the province and had the name of “Wenying Lake”. The New South Lake outside the city is about three kilometers away, and the trees on the banks of the shore are overcast. The natural scenery is so beautiful that it captures the scenery. It is like a moat in the river Shahe, and the Beisha River is a north city wall moat (Fig. 2).

Prominence on the plane is an important starting point for the construction of the city. Tangming Town is closer to the Taihang Mountains, creating a basis for subsequent urban development. The north city wall of Song Dynasty is located along Meishan Mountain, and the east wall is located under the Jinji Hill. The Ming Dynasty palace was built in front of Songhuapo, Songhuapo and Guizishan became the palace gardens; the north city wall and some of the eastern city walls of the prefecture city remained in the city and became the commanding heights of the northwest of the city. Jinji Hill became the commanding point of defense and observation in the southeast corner of the city (Figure 3).

The ancient Taiyuan area has abundant terrain, terrain, rivers, lakes and springs which provided the basis for the development of the city and created conditions for the creation of urban landscape.

3.2. City Wall Boundary

There are few records of Tangming Town in historical materials. According to the “Yongle Grand Ceremony,” the “Song on the Fifty-seven Steps on Friday” was recorded in Song Bingzhou, and the sub-city was built on the basis of Tang Ming Zhen. Therefore, the size of Tangming Town is presumed to be different. Similarly, the city is a square, about 3 kilometers.

In the Northern Song Dynasty, Pan Mei was ordered to build a state capital. The north and west borders of Luocheng were adjacent to the sub-city walls, and the east and south boundaries expanded outwards. They were “two hundred and seventy steps” in the week. In comparison with the town of Tangming, the area of Bingzhou City has nearly doubled. The sub-city is located in the west of the state city and is located to the north of the west. The “South Gate has military forces from the east and the east”. It is the balance left by the Tang Dynasty. It is called the “Hedong Army Gate.” The remaining three gates are commensurate with "Zidong, Zinan, and Zibei." The state city also "built four gates: the east towers and the south towers, the south tower sailed away, the west towers Jinsu, and the north towers run wild." Not to each other. Song Chunhua three years (992) for the establishment of the South Guan City for the use of troops, the East Gate City, North Gate City also built for the Chunhua
years. Song Bingzhou City built a closed urban inward-looking space, which laid the general scope and development direction of the city in the future. However, the development scope defined by the city wall for the city cannot meet the required space with the development of the city.

According to "Taiyuan House Records," the records of the Ming Dynasty City Wall "Twenty-four years of the city week, thirty-three feet high, three bricks out of bricks and three feet of Yao Shen", two walls on each side of the city walls, and eight city gates were built on the city wall. There are a total of 12 buildings on the four corners of the city wall. There are also 90 small buildings on the walls. After the Ming and Qing dynasties, three small towns of Nanguan, Beiguan, and Xinbao were successively built outside the city (Figure 4). It can be described as "a magnificent world."

The expansion of Taiyuan City is to include the original city inside the new city (Figure 2), continuing the original city's texture. The west wall and south wall of the Song Dynasty merged into the Ming City Wall, and the northern section of the East Wall was transformed into part of the Western Wall of the Jinwang Palace. The Northern City Wall became the internal series of hills in the city; the west side of the moat became the water system in the Ming City. The Ming City Wall provides land for the city’s internal construction. Twelve buildings and 90 small buildings enrich the city’s sight. With two expansions, the relationship between the city and the Ecological Environment is closer, and the beautiful scenery of the river and the lake hills are contained within the city.

3.3. "T-Street"

The road of Taiyuan City is different from the road system of the “Nine-ninth-south and nine-latitude” cities of the contemporary capital, but it is a unique “T-shaped Street” layout. According to investigations and studies, Ting Street has appeared in Tangming Town during the Tang Kaiyuan period. The Song Zi City is located in the northwest of Bingzhou City. There are five main streets in the city, Dongmen Street and Ximen Street form the east-west main shaft, and Beimen Street, Nanmen Street and Fuqian Street form a T-shaped intersection with each other. "Six" shaped three north-south t-shaped street. According to the “Yongle Grand Ceremony” record, the four gates of the state city are not connected to each other, and the south gate is centered. The north gate is west, the east gate is centered, and the west gate is south. The four main avenues facing the four are T-shape Street, Dongmenzheng Street and Zicheng East Wall, Nammenzheng Street and Zicheng South Wall, Ximenzheng Street and Nammen Street, North Gate Zhengjie and Zicheng North Wall. Sizheng Street and Xiaojie District divide the city into 4 major districts and 23 community districts.
The suburban city of Taiyuan disappeared during the Ming dynasty, and the regular pattern of the state city was disrupted. The South Gate Street and the North Gate Street were connected. The West Gate Street and the East Gate Street were connected and extended to the Jinwang Palace. The pattern of T-shaped Street gradually shifted to the Cross Street, and the closed “Lifang System” was transformed into an open street-level space. Some streets and lanes between the square and the Fang disappeared into the long river of history, while other streets developed along with the eastward movement of the city center. (Figure 5).

3.4. City partitioning

From the city of Taiyuan in the development process analysis, the city functions There are five main types, the first is the Government Office administrative functions on behalf of the rulers of the city administration and political things, responsible for protecting the city safe is the core function of a city, generally located in the city’s most important place and is usually not the geometric center; secondly city restaurants trade functions, in order to meet consumer demand for the ruling class and the upper class, "where", "Square" began to emerge and become the city city restaurants trade area, but also to the people, and opening transactions in goods it is a basic requirement of urban social activities; tied with a square inside residential function, and the people of the most basic requirements of daily life, but also occupy most of the city space function; followed by worship ritual system function, when the settlement developed to a certain extent The function of religious belief came into being and became the spiritual sustenance of the people. In the process of development, Taiyuan City formed an open space based on the lake's water system to meet the needs of the people for their outings and public exchanges at the weekend. These functions were gradually completed during the development of Taiyuan City. The study of changes in urban functional areas in different periods can provide a more comprehensive understanding of the evolution of the city.

The sub-city within the Song State of the Northern Song Dynasty follows the administrative centralized layout of Tangming Township Administration. Within the Luocheng City, the Lifang system and the T-shaped road pattern are adopted. The residence and the barracks are distributed at intervals. The city’s streets are arranged on the south gate where the downtown area is more prosperous and concentrated. Lifang is more concentrated at the northern gate. Changes in the spatial pattern of the Taiyuan City during the Ming Dynasty took place mainly in the Wanggong aristocratic houses and city trade. The construction of the Jinwangfu in the northeastern corner of the city changed the administrative pattern of the Taiyuan City's administrative office and became a new political center, which in turn
affected the urban structure. Daguan nobles built government houses in front of the Jinwang Palace to form a new axis, and drove the development of the neighboring city's trade districts, which were linked to the city's old district of the South Gate; the closed Lifang district became an open alley. The market and religious ceremonial space are interspersed with more flexibility.

Fig. 4-8. Schematic diagram of the functional distrib

4. Conclusion

Taiyuan City used its advantageous terrain to gradually improve the urban functions through the development from the Northern Song Dynasty to the early Ming Dynasty. It gradually became the regions’ political and economic center from a city focusing on the military function and formed a special cityscape. This article focuses on the evolution of the Ecological Environment and the urban pattern in the process of Taiyuan City's construction and development. It explores the Ecological city process based on the natural barriers and basements of the Fen River and the Three Mountains. The rivers and lakes, the city wall boundary, streets and lanes, and the district selection and location are all combined with the Ecological Environment. Using the Taihang Mountain extensions as the official residential area place near the basin with a convenient transportation as the municipal business workshop area, the flat land as the residential area of lifang, place along with the Fen River and its landscapes as etiquette and rituals. City is not an independent part, but closely linked to form a unique urban Ecological.

The city continues to develop. The place of prefectural city still inherited its ancient functions. It forms the political district of the provincial government, the commercial area of Gulou Liuxiang, the cultural temple of the Chongshan Temple, and the residential area scattered on the original site of prefectural city. It inherits and continues the historical functions. Taiyuan has been listed as a historical and cultural city. Research on the ancient city of Taiyuan can help maintain the characteristics of the city and cultural continuation of the city. It hopes to provide theoretical support for the protection and planning of the city.

THE LANDSCAPE RESTORATION OF CHAKA SALT LAKE

DAN SHEN

Abstract

The Chaka Salt Lake, 3000 meters above sea level, 200 miles to Xining City, is also known as the “Mirror of the Sky” in China. The existing salt refinery area, built in the 1960's, is a multi-functioning building cluster with an early-new-China architectural style, and includes public primary school, hall, business buildings and residential buildings. The scenic railway for salt transportation has a long history and has also witnessed the developments in the salt industry over 110 years. We can still find the words "Carnegie 1906" on the rusty rails, and display these rails as precious cultural relics in the museum that was renovated from the auditorium. While the majestic natural scenes in Chaka Salt Lake attracted plenty of tourists to the area, the related damage done by car parking, vendors selling goods and visitors trampling the ground took a terrific toll on the weak ecosystem around the salt lake. The salt bed was broken down, silt was upwelling and the Mirror of the Sky was fading from the scene. Consequently, we were invited to participate in the design of Chaka Salt Lake.

The damage from tourist activity is concentrated on the sides of the lake, so special attention should be paid to the lake sides in the design process. After studying the formation cause of the salt lake and considering tourists' needs, we planned to shift non-core functions like parking, tourist services and vendors to the salt refinery residence zone 700m from the lake district and to add a sightseeing stand and a paddling pool that can separate the activity square from the salt lake, in order to protect the salt lake. Considering thrushes and other plant wetlands in the area, we plan to make good use of reclaimed water to preserve and extend this wetland system, protecting the salt lake. The main foundation of the trail that passes through the lake is a small train; the track foundation is made of straw bags filled with rubble, and paved with timber bunks; no concrete is used.

Buildings with an early-new-China architectural style, like the auditorium and primary school have been preserved and renovated into a tourist center and museum. Open space between buildings are renovated into a welcome square and distribution transfer square which can serve a daily capacity of 40,000 tourists. Steel frames are used to connect the existing buildings into a whole, to highlight industrialization characteristics and provide shade...
facilities. All existing trees are preserved. Salt-transporting infrastructure extends to the transfer square in front of the auditorium, providing a convenient system for visitors.

Sensitive Land; Restoration; Chaka Salt Lake

1. Project Overview

Chaka salt lake (Graph. 1.), a scenic area west 200 miles to Xining City, had experienced a rags-to-riches story from 2013 to 2015. Its resources amenity attracted 160,000 visitors in 2013, 480,000 in 2014 and 1.1 million in 2015. The booming tourists brought in considerable benefits to the local economy. However, the rise in economic development was followed by a series of problems. On one hand, excessive tourism exerted unbearable press on the salt lake (Graph. 2.), which resulted in a degrading of the habitat of the salt lake. On the other hand, recreation facilitates were incapable of supporting such a massive of tourists.

The series of problems in Chaka salt lake aroused highly attention of local authorities. In August 2015, this scenic area was closed and asked to be renovated. The government set an ambitious goal to finish the renovation before June 1st, 2016. By this, limited time is left to the design and construction team. Against this background, project team of Tsinghua Tongheng started to work on this case on September 12th, 2015, which consisted of numerous urban planners, landscape architectures and architectures.

Consequently, we were invited to participate in the design of Chaka Salt Lake. Our work had two primary responsibilities, the first was to better protect and restore the ecosystem of the lake area, and the second was to resolve the chaos brought upon by the high quantities of tourists.

2. Site Analysis

2.1. Site History

The railway for salt transportation had a long history over 110 years. We could still find the words "Carnegie 1906" on the rusty rails. Furthermore, we discovered salt excavation, salt transporting, and salt refining machinery in the factory. The existing salt refinery area, built in the 1960's, was a multi-function building cluster with an early-new-China architectural style, including primary school, workers hall and residential buildings (Graph. 3.).

2.2. Salt Flat

Our team now had a better understanding of the causes of the Chaka Salt Flat. When water is about 15 cm deep on the salt crust, it will get the strongest light reflection. On days where there is no wind, the lake would create a beautiful mirror, reflecting the surrounding mountain, the blue sky, and everyone who stands on it.

2.3. Nature’s Force

The damage done by car parking, vendors selling goods and visitors trampling the ground took an enormous cost on the weak ecosystem around the salt lake. The salt bed was broken down, silt was upwelling and the Mirror of the Sky was fading from the scene.
Our team found that the edge of the lake was the most vulnerable area, which was badly destructed by tourists. Normally, it was difficult for this area to form the salt shell through crystallization on account of the fluctuating water level. The hall would serve as a transfer center for electric vehicles and small trains.

The plaza in front of the hall would be used as a venue for festivals and tourist activities. Even the medical center would be converted into a youth hostel, with 80 available beds.

And finally, salt machines would serve as landscape features (Graph. 9.). Steel corridors linked all of these old buildings and features together. It not only functioned for strength and structural integrity, but also provides shelter from severe weather conditions.

### 3.2. Protection Priority

Due to the lake’s unstable edges, our team utilized two methods to protect it from further deterioration.

The first method tapped into ecological restoration. We devised a 600-meter ecological restoration area within the site (Graph. 10.). We then used straw bags filled with gravel to create a cofferdam, stabilizing water levels. This design also accelerated the speed of crystallization, aiding in the recovery process of the salt flat landscape.

The second method was through designed navigation. Understanding that tourists are eager to interact with the salt flats directly, our team designed artificial pools between the plaza and the edge of the lake, which acts as a barrier to prevent direct contact with the flat (Graph. 11.).

Additionally, after considering the lake’s salt layer structure, tourists are now not
permitted to approach within 1km of the lake’s shore. The salt layers further than 1km from the shore are quite thick, some parts reaching a thickness of 30m, in these areas tourists can have a more pleasant environment to enjoy the beauty of the “Mirror of the Sky.”

Acknowledging the limits of the ecosystem’s carrying capacity and the distribution of space, we still strictly controlled the quantity of tourists coming into the area. The daily maximum amount of allowed tourists is now 40,000, which has both protected the lake, and ensured a high quality and comfortable experience for the tourists.

3.3. Special Technics

Poor engineering conditions coupled with tight schedule forced our team to adopt a fast and sustainable construction and mechanical system. The lake itself would integrate a specialized mechanical technology system to aid in salt flat recovery.

Traditional technics were used both on the boardwalk and dock. Sloped boardwalks were made up of straw bags filled with gravel, which could withstand lake erosion. Walkways and ground material varies according to traffic flow: sleeper pavement, sleeper salt combination, salt. All of this can be recoverable easily (Graph. 12.).

The flexible paving with geogrid and gravel is beneficial to the infiltration of rainwater in parking lot. It would reduce ground subsidence caused by winter construction The team used sureblock bricks as the garden wall design feature to reduce construction lead time, and selected local stones as foundation and structural material to reduce transporting time from off site.

4. Implementation effect

From October 2015 to June 2016, which includes 6 months of winter construction, we completed the project. 240,000 square meters of lake was dredged and repaired, 10,000 square meters of artificial pond was constructed, 110,000 square meters of new pavement was layed, and the new 2 km Lake Road was created. Not to mention the 100,000 square meters of parking lot and 10,000 square meters of building facade renovation and interior design also rounded out the project build.

On June 1, 2016, Chaka Salt Lake Scenic Spot was opened on schedule. In October 2016, Chaka Salt Lake was rated a Class 4A Scenic area. In December 2016, it was awarded the “Best Order” scenic spot by the National Tourism Administration. In 2016, Chaka Salt Lake received 1.7M visitors, totalling $15M USD, doubling from the year before.

5. Conclusions

The concept of conservation priorities and local modification techniques effectively solved the problems encountered in the development of Chaka salt flat, which can provide a reference template for the restoration of ecologically sensitive scenic spots.

Landscape Design for Ciliwung Riverside in Sudirman Business District Central Jakarta Indonesia

Dewi Rezalini Anwar, Alam Galih Wicaksono

Abstract

Jakarta is the capital city of Indonesia with a high population density. This phenomenon gives social and environmental problems such as crimes, flood, traffic jam, and polutions. Jakarta passed by many rivers, the river as one of Jakarta open space also give contribution for city’s environmental problems. It is can be resolved by a good space utilization. Ciliwung riverside area is an open space that has potential to be developed. Therefore, it is necessary to study the Landscape Design for Ciliwung Riverside in Sudirman Business District Central Jakarta Indonesia. With the establishment of a riparian park, the park is not only provide aesthetic functions, but can be used for ecological function and as a space of social interaction. The purpose of this study are to identify the conditions and characteristics of the landscape at the site, analyze and make synthesis at the site to get the appropriate space, and make the concept and design of the riparian park. The study is using the method of Gold (1980) with adjustment. The main concept of this design is green urban framework, which is simple, futuristic, and give more spacious visual effect by put some sculptural form in the site. The landscape design is using several concepts as its development concepts such as city view concept, waterfront concept and pedestrian concept. The design also gives the identity for the park by it green sculptural form such as photo frames for user, framing the artworks and framing the plants.

Keywords: riparian park; urban landscape; central business district
1. Introduction

Jakarta is the largest metropolitan city in Indonesia. It has an area of 664.1 km² and a population of 10,036,939 people. The current situation is getting worse as the population of Jakarta grows rapidly year by year. Central Bureau Statistics of Jakarta 2015 mentioned that the current population of Jakarta increases by 105,760 people per year. Can we imagine the condition of Jakarta in the following ten years if it remains this way? This phenomenon raises the problem of population, spatial, and environmental.

The increasing number of the population results in the decrease of environmental carrying and supporting capacity in Jakarta. It triggers the occurrence of floods, traffic, increasing pollution and even criminality. One effort that can be carried out to improve the quality of urban environment is by managing the riparian area. According to Presidential Decree of the Republic of Indonesia No. 32 of 1990, riparian area is the area along the right and left side of the river, including artificial river/canal/primary irrigation canal, which have important benefits for maintaining the sustainability of river functions. Furthermore, Presidential Decree of the Republic of Indonesia No. 32 of 1990 and Government Regulation of the Republic of Indonesia No. 47 of 1997 set the width of the river path in which it is sufficient for the inspection road; around 10-15 m. Therefore, it is necessary to improve the spatial management of Jakarta, especially in riparian areas as an effort to improve the quality of the environment.

Arranging and managing the riparian areas in Jakarta are still lacking in action. Many empty riverside areas are utilized by communities without permits. The utilization is not appropriate and even damaging the environment. The form of management that can be carried out is to utilize the riparian areas into a riparian park. According to Big Indonesian Dictionary (KBBI), riparian means edge, in this case riparian means the river bank.

One of the underutilized riparian areas is Ciliwung Riverside in the Sudirman Central Business District of Central Jakarta. In addition to not being well-managed, the riparian area of Ciliwung River is a central business district with dense activity so it is appropriate to be used and designed as a park. By having the park, it is expected to be a new place for the city community, especially around the site such as office workers and residents in doing their activities and enjoying their leisure time. The location is strategic; it is in the middle of central business district. In addition, there are two stations directly adjacent to the site that make it has the potential to become a functional park. The design of riparian park of Ciliwung River can be a pilot of a functional and aesthetic riparian park design in the central business district. It is the background of the study of “Landscape Design for Ciliwung Riverside in Sudirman Business District Central Jakarta Indonesia.”

2. Objectives

The objectives of this study are as follows:
1. Identify the landscape conditions and characteristics on the site
2. Analyze and synthesize on the site to obtain the appropriate space

3. Make the concept and design the riparian park of Ciliwung River in the central business district at Sudirman Street, Central Jakarta

3. Research method

3.1. Research setting and time

This study was conducted at Ciliwung river bank in Menteng Sub-District of Central Jakarta. This study was conducted from April to August 2016. The orientation map of the research setting can be seen in the following Figure 1.

![Figure 1: Research Setting](http://google.maps.com)

3.2. Research Method

The study was conducted by referring to Gold’s (1980) designing process with some adjustments of preference method of potential users of the site on preliminary design to obtain the final design. According to Gold, conducting the design required inventory data, analysis, and synthesis that could then be used as a reference to produce a design. The following are the description of the methods used in this study. The methods used in this study were as follows:

1. Inventory of primary and secondary data through survey, interview, distributing questionnaire, and literature study through books, undergraduate thesis and graduate thesis.

2. Analysis and synthesis using descriptive analysis method and spatial analysis, including: physical, biophysical, and social aspects to generate the arrangement of zoning and the concepts.

3. The concepts to be developed were basic concepts, design concepts, development concepts, vegetation concepts, circulation concepts, visual concepts and form-pattern concepts. The concepts had been made into a reference in making the design development. The end result of this stage was the block plan of the concepts concatenation that had been made. The first entry in this list

4. Design

4.1. The preliminary design referred to the block plan. All three alternative designs were then selected one to be a site plan with the interview method of the potential user preference on the site. According to Gay and Diehl (1992), this interview was conducted on 30 respondents. The chosen design alternative was made into a site plan and the basis of design development.

4.2. The design process was continued with the design development to obtain the detail of the design.
4. Findings and discussion

4.1. General Condition

Physical and Biophysical Aspects

The research setting was located along the river banks of the Ciliwung River on the bridge of HOS Cokroaminoto Street to the bridge of KH Mas Mansyur Street, Menteng Sub-District of Central Jakarta with an area of ± 1.8 hectares and with length of 1350 meters. The northern boundary of the site was the railway line from Mampang Station and Sudirman Station to Karet Stations. The western boundary was the bridge of KH Mas Mansyur Street. The southern boundary was Galunggung and RM Margono Djiojohadikoesoemo Streets while the eastern boundary was Ciliwung River. The average height of the site was 1 mdpl. There was a quite high flood retention level on the site of 1 meter which blocked the view from the site toward the river. The soil of the site was the alluvial soil mixed with the remaining soil of the embankment construction. The hydrological condition of the site was quite good because it had a fairly high contour and had been completed by the embankment so that it was not affected by the flood. The site had an average temperature of 28.1°C, average rainfall of 332.8 mm/month, and 70%-85% of humidity.

Vegetation on the site was mostly planted by related agencies and already had a fairly regular planting pattern with the function as the shade and absorber of the pollution. The vegetation includes Tabebuia Chrysantha, Cocos Nucifera, Tamarindus Indica, Delonix Regia, Samanea Saman, Swietenia Mahagoni, Muntingia Calabura L., Erythrina Crista-galli, Plumeria Rubra, Spathodea Campanulata, Eucalyptus Deglupta, Mangifera Indica, Cerbera Manghas, Ficus Benjamina, Polyalthia Longifolia, Pometia Pinnata, and Tectona Grandis. Animals on the site were the animals that naturally presented in river bank ecosystems such as snakes, rats (Rattus Norvegicus), and frogs (Fejervarya Limnocharis).

The research setting was directly adjacent to the entrances and the exits of Sudirman and Karet Railway Stations so that it was an easy access for railway station users. Access to the site was for pedestrian only. The circulation conditions on the site were mostly natural pedestrians without any pavement.

Social Aspect

The majority of site users were office workers. There were also street vendors selling around the site. The site was adjacent to two stations so that the site had the potential to become a new place in the center of the city. In addition, there were also routine activities held every week; it was car free day. In regard to that matter, the site was very potential to facilitate the activity. Based on the results of interviews with some users of the site in which the majority of them were the office workers, it was expected that the design of the park on Sudirman Street was not only a decorative park but also can facilitate the users of the surrounding site.

4.2. Analysis and synthesis

Physical and Biophysical Aspects

The site was a riparian area located in the Central Business District area and directly bordered with two railway stations that
potentially had many visitors when it was used as a park. The park could be used as a pedestrian lane for railway station users and as a rest area for the surrounding users in which the majority of them were the office workers who took a break from the hustle and bustle of the city.

The topographical conditions and the flat tread slope making it suitable for the park. Obtaining the comfort of the space and the aesthetics of the park could be performed by soil dredging until the soil surface was flat to the embankment limit. By changing the height of the soil on the site, the park would also be more comfortable because the user can be more free and enjoyable in taking a look around the site. In addition, the surface of the site became more visible from the outside, so the site will look better. The existing site conditions and the site conditions with grading can be seen in Figure 2.

Based on the average annual climate data on the site, the site was quite hot. According to Robinnete (1993), a comfortable air temperature for humans was 21º-27ºC. It meant that the air temperature at the site was less comfortable. Then, according to Laurie (1986), the ideal humidity was 40-75%. Meanwhile, the humidity of the site was about 70-85% and it had entered human discomfort. Average wind speeds of 11.2 km/h were quite moderately moving from south to north, and the direction of the sun moves from the east side of the site to the west.

Existing vegetation contained on the site had a function as shade, control and wind controls so it would be maintained and rearranged to make it more interesting. It was necessary to add functional and aesthetic vegetation such as screen/ border vegetation, sound suppression vegetation, and identity vegetation. Animals found on the site included snakes, rats, and frogs in which must be reduced because it will disturb and endanger the park's visitors. Animals such as birds were few and needed to be maintained.

Accessibility on the site could only be made up of four entrances. These four entrances must be maximized for the accessibility to the site. All entrances should be widened, easily visible and accessible. Near the railway station should be given more close-to-the-inside room and entrance to make room for the crowds of the station.

The potential (good view) on the site such as Green open space on the beautiful site can be utilized. Along the south side of the site, there was Ciliwung River which could be utilized its potential appropriately as a river view and be made its esplanade to explore the water feature. The most prominent thing was the view of the city scape of Central Jakarta.

It took a lot of time making the facilities and utilities of the park. A park must meet
several facilities such as parking lots, security posts, hygiene facilities, toilets, water installations, electrical installations and drainage systems (Hakim and Utomo, 2004).

Social Aspect

The social aspect was analyzed based on social principles in designing the garden based on what was mentioned by Lennard (1987) by having some adjustments for the user preferences as the following:

1. Provide security and easy access for users
   The security in the tread was still very poor so there must be a special guard post to manage the site so that the park user could feel comfortable and feel more secure.

2. Facilitate the function of the space as a social place
   The majority of respondents wanted a social impact from the park. One of the social impacts was to provide new places to gather in the middle of the hustle and bustle of the city. In addition to the social function, the respondents also wanted a park function for sports, community parks, decorative parks and other park functions.

3. Direct and facilitate community activities
   Based on its location, the majority of the users around the site were office workers around the site. This site was potential as a pedestrian access connecting the offices on HOS Cokroaminoto Street to Sudirman Railway Station. It also connected Sudirman Railway Station to the offices on KH Mas Mansyur Street.

There were routines on every Monday around the site; it was car free day. The park of this site allowed such activity because the site was directly bordered with Sudirman Street which becomes the implementation place of such activities. To facilitate the activities of car free day, it must be provided with adequate pedestrian in the site because all people walk for sports.

4.3. Concept

The basic concept of riparian park design of Ciliwung River was a park that provided pedestrian facilities and a place to rest for a moment to the users of the site whom the majority of them were office workers. The design of this park optimized city view and waterfront on the site.

The design of this site included in the urban design. It was based on the site location which was in the middle of central business district and downtown. The concept of urban flow design was in accordance with this site because it met the criteria of the theme and the needs of the site in which it accommodated the movement of the office workers. The concept of the design was simple, futuristic and would also make an impression of wider area of the site.

4.4. Development Concept

1. Waterfront concept. In the application of the design, this concept was applied by turning the gazebo and bench view directions to the waterfront. Another development was by developing an esplanade. This esplanade would be developed slightly indented to the waterfront so that the park users will get
different sensation on it. The promenade could not be applied because the water surface of Ciliwung River was very volatile.

2. City view concept. The site had a nice city view so that the potential will be maximized in this design. The design would maximize the borrowing scenery of city view. The application of the design was by not creating a barrier that can block the view. In addition, the placement of the bench and gazebo must face the city view as well.

3. Social space development concept. Based on respondents’ preferences, most of them expected that the park had also social functions such as hangout and relaxation. The arrangement of bench at some point would be the user place to gather around.

4. Vegetation concept. The vegetation concept of this site largely followed the analysis and synthesis that had been made before and adapted to the development concept. Some concepts of vegetation to be applied were:

4.1. Aesthetic vegetation
   Aesthetic vegetation on the site should not make the site to look narrower. Aesthetic vegetation to be made was vegetation with rare canopy and palm vegetation to make the site more spacious. Shrub vegetation was minimally carried out because it reduced the space.

4.2. Guide vegetation
   The guide vegetation would be very prominent in the welcome area of the site. The design of the welcome area that formed the corridor of the plant desperately needs the role of the guide vegetation. The vegetation used was

   Fig. 6. Illustration of guide vegetation concept

   Thuja Orientalis.

4.3. Shade vegetation
   In this study, the shade vegetation to be used was the existing vegetation. Most of the existing vegetation was shade plants, such as flamboyant, rain tree, and cape.

   Fig. 7. Illustration of shade vegetation concept

4.4. Screen/ border vegetation
   The meaning of border vegetation in this study was the vegetation whose function as a barrier between the site with the railway. This vegetation was expected to reduce the noise and air pollution from the trains.

   Fig. 5. Illustration of aesthetic vegetation concept
5. Circulation concept. The pedestrian would be made wider because of the high intensity of users around the site. Pedestrian on the site was designed widely to anticipate the site user from Sudirman and Karet Railway Stations. In addition, there was a routine car-free-day activity held at Sudirman Street on Sunday. The location was directly border to the site so the pedestrian on site would also be designed to facilitate that activity.

6. Visual concept. The arrangement of other vegetation and landscape elements of the site was designed not to disturb the user’s view of the site towards the waterfront and city view. The visual concept was designed not to deviate from the concept of waterfront and city view development. The visual concept of this design would still provide its own aesthetics and character for the visual aspect from the outside of the site.

7. Color and shape pattern concept. According to the survey results, the pattern to be used was a flexible organic pattern. Moreover, the color concept would be designed in harmony with the basic concept of this park design to provide comfort for users to relax. The colors to be used were cool colors that give the impression of calm, comfortable and refreshed and analog color (adjacent color mix), such as neutral and not flashy colors. The basic colors of this design were green and brown because the two color were dominant as plants, soil and river water in the site existing.

5. Design

5.1. Preliminary design

Site plan began by creating three preliminary designs that would be selected based on respondent’s preference. From the preference results, it could be concluded that the most preferred preliminary was preliminary 1 that was chosen by 53% of respondents. So, the site plan would be made according to preliminary 1. Three preliminary design can be seen in the following Appendix 1 and site section can be seen in the Appendix 2.

The survey was conducted for two days on weekday and holiday with the number of respondents 30 people per day. The number of respondents was chosen based on the theory of Gay and Diehl (1992) that the number of representative minimum samples in correlational research was 30 subjects. Pedestrian design.

5.2. Welcome area design

Welcome area design of this park was green corridor concept. The corridors were formed from pine trees that were arranged lengthwise. The aim of this concept was to provide a clear boundary between the inside and outside of the site so that park users enter the park in a new refreshing atmosphere.
5.3. Esplanade design

This esplanade served as a resting area for the user so as not to disrupt other pedestrians. Promenade would not be made in this site because the water level of Ciliwung River was fluctuated and it was feared to be a danger area on the site.

5.4. Social space design

The social space of the site was applied to the gazebo and bench. All designs referred to the initial design concept of urban flow. The shades on the site were considered as sufficient for the standard of comfort.

5.5. Park design

The park of the site referred to the design concept. The application on the site was by the use of plants that did not vary in term of color. It was enough for adjacent colors so it had a simple impression. The selection of plants had not much variation so that it would be more simple became the identity of the site at the same time. Perspective view illustration can be seen in the following Appendix 3-6.

Conclusions and suggestions

The site was located in the central business district which had a high enough density. This site connected the central business district of Sudirman Street, HOS Cokroaminoto Street and KH Mas Mansyur Street. There were two railway stations on the site namely Sudirman and Karet railway stations. Therefore, it required appropriate road access and space facilities as a social place for gathering and relaxing for the majority of the office workers. The design concept applied the urban flow concept. The development concept applied to the site was the concept of city view, waterfront and pedestrian parks. The vegetation design of the garden, gazebo, and other buildings on the site was designed not to spend so much space so the site impressed widely.

Designing the park in the central business district needed to pay attention to the characteristics of the surrounding user activities and the facilities required by the site users. Thus, it will provide the appropriate space function. Green open space on riverbank must be realized in accordance with the applicable regulations. Community and urban planners should work together to create a new space in the city center to optimize land use and the available space to have appropriate function.

Explorative study on benefits of vertical landscape to achieve sky rise interior spatial quality in terms of thermal, acoustic, visual and air quality in urban areas

Chamara Sanjeewa Mendis Wijesinghe
Dunwattha, Weraduwa, Matara, Sri Lanka. 81000

Abstract
It has been known for some time that the benefit of greenery in urban spaces extends to many facets of public and private life. The more recent implementation of sky rise greening in the form of vertical greenery has highlighted even more the ways in which landscaping can become an integral part of urban development, ensuring communal interaction with the natural world. As one proponent of green spaces has emphasized, “The integration of the living, organic systems are characterized by green walls and green roofs, with the inorganic and lifeless structures that have come to dominate the modern architecture, holds the promise of a new type of living architecture and interior. Especially sky rise building interior spaces need lot of energy to function the spaces as those are filled with thermal uncomfortable areas, poor air quality, acoustic issues and poor visual quality. If vertical landscape is applying to the high rise building’s exterior and interior, the interior can be maintained good manner in thermal, acoustic, visual and air quality.

Key words – sky rise vertical landscape/ sky rise interior
1. Introduction

It has been known for some time that the benefit of greenery in urban spaces extends to many facets of public and private life. Vertical and rooftop gardens are not a new concept; they have provided occupants with shade, aesthetically pleasing views and functional live façade create diversity and fresh feeling to the building user.

During more recent implementation of sky rise greening in the form of rooftop gardens and vertical greenery have highlighted even more the ways in which landscaping can become an integral part of urban vertical development, ensuring communal interaction with the natural world. As one proponent of green spaces have emphasized that, “The integration of the living, organic systems are characterized by green walls and green roofs, with the inorganic and lifeless structures that have come to dominate the modern architecture, holds the promise of a new type of ‘living’ interior”. Further green building rating systems are trying to implement and maintain energy saving buildings to the world and during that journey vertical landscape plays a big role.

Especially sky rise interior spaces need lot of energy to function the spaces as those are filled with thermal uncomfortable areas, poor air quality, acoustic issues and poor visual quality.

When we consider about the urban areas, if vertical landscape is applying to all the high rise buildings, urban heat island effects can be reduced effectively. Vertical landscape applied sky riser's interior is having good thermal, acoustic, visual and air quality. With all these the building interior quality improvement can be maintained with low energy.
Objectives

- Built-up connectivity in-between sky rise interior and vertical landscape.
- Get more benefits from vertical landscape to the sky rise interior.
- Identify the issues in sky rise interior spaces.
- Analyze sky rise interior spatial issues through thermal, acoustic, visual and air quality
- Find out solutions to improve urban sky rise interior spatial living quality by the vertical landscape.

Method

Best on a literature review by exploring the building’s interior spatial quality with vertical landscape and without vertical landscape based on interior thermal quality, interior acoustic quality, interior visual quality and interior air quality.

Result

Based on the literary evaluation of the sky rise with vertical landscape and sky rise without vertical landscape, we can find changes based on interior thermal quality, interior acoustic quality, interior visual quality and interior air quality.

2 Environmental issues with sky risers

Together with many social and economic benefits of urbanization, there are also environmental problems. Cities comprise less than 3% of the Earth's surface, but there is an extraordinary concentration of population, industry and energy use, leading to a massive local pollution and environmental degradation. In the cities, approximately 78% of carbon emissions are due to human activities. The ecological footprints of cities (through emissions, consumption and other human activities) go far beyond their urban boundaries to forests, agriculture, water and other surfaces, which supply their residents so that they have an enormous impact on the surrounding rural, regional and global ecosystem.

Cities are therefore centres of consumption (energy, materials ...), greenhouse gas production, waste and emissions of pollutants in water and air. Ecological and sociological footprints of cities have expanded over increasingly large areas and created urban - rural continuum of communities, who share similar aspects of individual lifestyles. There are less and less areas in the world which are not under the influence of the dynamics of cities.

The world faces enormous environmental challenges in terms of climate change, resource use and protection of the natural environment. Urban areas have a high environmental impact that can be felt globally, as well as within its own borders.
With regard to these environmental issues, urban sky risers are having interior spatial issues which are based on thermal quality, acoustic quality, visual quality and air quality.

**Thermal issues** - Sky risers create heat island effects with building materials in city areas. Most of the sky rise interiors are having full glass windows and those openings are getting more sun light to the interior which results in creating thermal uncomfortable situation in the interior. And also sky rise building’s envelope exposes to more sunlight without any barrier and building material temperature goes up and eventually leads to an uncomfortable building interior with high temperature.

**Acoustic issues** - Sky risers which are located in middle of the city areas with heavy traffic road network and motor vehicles are disturbed by large and endless noise throughout the day. And also aircraft and building construction sites are producing significant sound pollution which creates an uncomfortable acoustic quality in interior.

**Visual issues** - The visual quality of sky risers has created with the materials such as glass, steel, cement, cladding, etc. It looks dry and dull without soft landscape. Windows without green background do not create a fresh feeling and it always creates a grey feeling and aesthetic imbalance.

**Air issues** – Most of the city area are having polluted air, because of large number of vehicles and other human activities. In this situation, sky rise interiors have also affected by this polluted air and most of the time, interior spaces are not using fresh air as interior oxygen level goes down and carbon dioxide level goes up. In this type of situation, people feel uncomfortable which results in *sick building syndrome*.

### Benefits of vertical garden

- Reduces urban heat island effect and cleans outside air of pollutants and dust and offsets the carbon footprint of people and fuel emissions
- Cleans interior air space by removing VOCs and other harmful toxins like benzene and formaldehyde
- Acts as a sound proofing barrier
- Soil and plants are a natural filter that can clean the water that flows through the wall
- Insulates and cools the building envelope, as well as protecting it from the elements
- Creates habitats for birds and beneficial insects, increasing biodiversity
- Can be used for growing food in urban settings, creating sustainable and local control of food sources
- Increases real estate value
- Reduces sick building syndrome in the workplace and boosts employee morale
- Opportunity for building passive cooling methods
Vertical landscape issues and benefits-03
5. Conclusion

The purpose of this research was to highlight the benefits of vertical landscape in creating a better living environment in the urban vertically developed building interior spaces. Currently urban areas are having many vertical developments and with these we have faced many environmental and spatial issues. As a result of this scenario, building developers have to improve interior spatial quality by using lot of energy in converting it into a livable and working friendly interior space. But applying the vertical landscape for these buildings, in the meantime we can save lot of energy by improving building interior thermal quality, interior acoustic quality, interior visual quality and interior air quality. In this sort of scenario; vertical landscape plays a major role by uplifting interior spatial quality. So this analysis has emphasized that the vertical landscape is having many benefits in urban vertical development.

Biophilic Railway Stations: Re-imagine the Nature of Transit Design

Phillip Roös¹, David Jones¹, Paul Downton², and Josh Zeunert³

¹ School of Architecture and Built Environment, Deakin University, Locked Bag 20001, Geelong, 3220, Australia;

Abstract

Across the world railway stations, transit centres and transport interchanges are rapidly evolving from purely functional transit spaces to new urban centres and destinations, resulting in activity hubs and gathering places. These stations generate high footfall creating life and vitality, and form the centre of daily routines for many urban dwellers. Train stations are places of connection, they are gateways to the city, and can be one of the most exciting places in an urban environment to experience. Some stations make great destinations with shops, restaurants, museums and exhibition spaces. New architecture for railway stations acknowledges the functions of transit; whilst the heritage of place, culture and the surrounding urban spaces can provide excellent public areas to celebrate our innate human connection to nature. Similar to the grandeur of old railway stations, new majestic spaces with biomorphic-inspired monumental elements can include the fundamental pattern language that underpins the principles of Biophilia.

Rail transport infrastructure, especially railway stations, significantly contributes to the quality of human life, sustainability and the economy of urban centres. Station buildings play a major role in efficient and vibrant places, and can be at the forefront of innovation and modernity. Due to the current unprecedented levels of global urbanization, cities and their governing entities are investing in more sustainable public transport systems. The rationale for this investment is to aid reduction in greenhouse gas emissions and, assist economic efficiencies in goods and people movements across and within cities providing better forms of transport, whilst assisting in the creation of improved sustainability and healthier urban environments. New major transit projects massively impact the city fabric, but also provide opportunities to reshape urban environments to include innovative biophilic design.

This paper investigates the opportunities that new transit hubs and railway stations and their associated infrastructure can provide for creating more sustainable and healthy urban environments, through the lens of Biophilic Design. In the foreword of a recent study Creating Healthy Places (2017, p9), Professor Tim Beatley raises the question, “might we re-imagine the very nature of a transit trip? Could it be not simply a trip to work or a travel to the high street, but perhaps a visit to the forest, a chance to hear and celebrate native birdsong, or a chance encounter with a butterfly. Perhaps food production becomes part of transit design, so that one picks a tomato or a desert plum on the way to catch the train. Why not a transit station in a forest?”
This paper explores the patterns of Biophilia and its application to railway stations. It further benchmarks old and new examples of railway stations across the world against Biophilic patterns, and reflects on the Creating Healthy Places (2017) study recently completed for the Metro Tunnel Project in Melbourne, Australia. It concludes with recommendations of key principles to be considered for Biophilia-inspired railway station design that can assist in advancing the larger vision and agenda of ecologically sustainable and Biophilic Cities.

Keywords: Biophilia, Biophilic Design, Biophilic Cities, Railway Station Design, Healthy Cities

1. Introduction

Railway stations and rail transport infrastructure contribute significantly to the economy of urban areas, improving quality of life due to availability of public transport, and increasing the sustainability of cities. Station buildings can play a major role in achieving efficiency and creating vibrancy, and are often at the forefront of innovation and modernity. These buildings are also the hubs of many inner city and suburban precincts, acting as transit centres and transport interchanges which are evolving rapidly from purely functional movement spaces to new destinations and gathering places. Some stations make great destinations with shops, restaurants, museums and exhibition spaces, and railway stations can be the gateways to the city [17, p159]. These stations generate high footfall creating life and vitality, and are the centre of daily routines for many urban dwellers [16].

Due to the current unprecedented growth in urbanization, cities and their governance entities invest in more sustainable public transport systems to aid the reduction in greenhouse gas emissions, improve economic efficiencies in goods and people movements in and out and across and within the cities, provide better forms of transport, and assist in creating sustainable and healthy urban environments.

Core to the investments in rail infrastructure is the provision of railway stations. These provide opportunities for a new architecture that acknowledges the functions of transit and the heritage of place and culture, while the surrounding urban spaces can provide excellent public areas to celebrate our innate human connection to nature [21].

Similar to the grandeur of old railway stations, new majestic spaces with biomorphic-inspired elements and the principles of Biophilic Design can include the fundamental pattern language [1] that underpins the principles of Biophilia: humans’ innate connection with nature.
2. The Innate Human-Nature Relationship

In the Biophilia Hypothesis (1986), Edward O. Wilson notes that humans need daily contact with nature to be healthy and achieve longevity. His reasoning was that humans have co-evolved with nature and are part of nature, noting that biophilia is “the innately emotional affiliation of human beings to other living organisms. Innate means hereditary, and hence, part of ultimate human nature” [10]. Biophilia supports the proposition that environments around humans need to include the essentials of nature to provide us with psychological and physiological health:

Over thousands of generations the mind evolved within a ripening culture, creating itself out of symbols and tools, and genetic advantage accrued from planned modifications of the environment. The unique operations of the brain are the result of natural selection operating through the filter of culture. They have suspended us between the two antipodal ideas of nature and machine, forest and city, the natural and artifactual, relentlessly seeking, in the words of the geographer Yi-Fu Tuan, an equilibrium not of this world [19, 21].

Figure 1: Grandeur of old railway stations with biomorphic-inspired elements: Antwerpen Central Station. Image Credit: Laurent-Jonathan Meyvaert, 2008.
Affiliation with nature continues to be critical in modern-day human health and wellbeing literature and practice [7], and has been strongly identified as a valid concern by the health sciences. In the research area of human health and wellbeing, a growing body of research reveals that exposure to nature continues to result in positive health benefits in a wide range of sectors; at work, home, recreation, community areas and even within the urban environments where people work and live [3, 9].

While humans may have an inherent affiliation with nature, the benefits as a result of contact of nature depend on repeated exposure to the elements that generate the biophilic effect. This biological tendency needs to be nurtured and developed to become embedded in contemporary metropolitan environments [9, 12]. One method to develop this affiliation is to design places that facilitate the biophilic experience and repeated connections with (real and surrogate) nature in peoples’ daily lives. Dubos acknowledges this opportunity as being the need to re-establish an in-depth and loving relationship between humans and nature:

*The relationship between humankind and nature can be one of respect and love rather than domination ... The outcome ... can be rich, satisfying, and lastingly successful, but only if both partners are modified by their association so as to become better adapted to each other ... With our knowledge and sense of responsibility ... we can create new environments that are ecologically sound, aesthetically satisfying, economically rewarding ... This process of reciprocal adaptation occurs ... through minor changes in the people and their environment, but a more conscious process of design can also take place. - Rene Dubos, The Wooing of the Earth; cited in Kellert & Calabrese, 2015 [11].*

Alexander (1977) strongly argues that this affiliation to nature is needed, and that the fundamentals of a ‘more conscious process of design’ are necessary. In ‘A Pattern Language’ (1977), Alexander states:

*People need contact with trees and plants and water. In some way, which is hard to express, people are able to be more whole in the presence of nature, are able to go deeper into themselves, and are somehow able to draw sustaining energy from the life of plants and trees and water. - Pattern 173 ‘Garden Wall’ [1, p806].*

This indicates that psychological benefits for us as humans are deeply rooted in the connections with nature. The fundamental benefits of physiological and psychological wellness due to biophilic exposure are further explored by Kellert (2005), with findings demonstrating numerous health benefits and a better quality of life [8, 12]. These benefits can be achieved if we design and plan our built environments to include the considerations of Wilson’s biophilia, more specially identifying the structures and patterns that occur in the form-making processes of the living systems of nature, and design and plan with a regenerative process that unfolds living environments of place [14, 18].
Healthy psychological benefits are rooted in the connection between humans and nature. Image Credit: Aporlo, 2011.

**Figure 2:**

3. **Biophilic Design**

To be able to apply the context of biophilia in our daily lives, the concept of Biophilic Design promoted by Kellert et al (2008) and further interpreted and celebrated by Newman (2012) and others, particularly Beatley in *Biophilic Cities* (2010), must be able to help us establish and nurture healthy and living environments in our cities that supports healing and wellbeing [2, 5, 12].

To establish whether biophilic design can achieve this goal of healing and wellbeing, we first need to identify and understand the meaning of biophilic design. Biophilic design is the deliberate attempt to translate an understanding of the inherent human connection to natural systems and processes, known as ‘Biophilia’ into the design of the built environment [12]. Salingaros (2013) explains that biophilic design involves ‘deep connections’ to nature that include links to geometric structures and patterns that occur in the form-making processes of living systems, resulting in the ‘biophilic effect’ [18, p8].

Further, biophilic design:

... seeks to create good habitat for people as a biological organism in the built environment.
environment that advances people’s health, fitness and wellbeing [11, p6].

4. Codes and Patterns

Widespread application of biophilic design in practice requires some codification and agreement by practitioners on which design elements produce particular replicable biophilic results [5]. Browning et al (2014) propose 14 Patterns of Biophilic Design (Table 1) within a framework that relates human biological science and nature to the design of the built environment [3]. Their 14 Patterns build upon the inquiries of biophilic researchers over a number of years:

... developed from empirical evidence and interdisciplinary analysis of more than 500 peer-reviewed articles and books [3, p62].

As noted by Downton et al (2017), this research offers both tools for understanding design opportunities [4], and avenues for the application of design as a way to enhance health and well-being at both the individual and societal level (Ryan et al 2014). According to its authors, inspired by Alexander (1977), the term ‘pattern’ is used [1, 3]:

... to propose a clear and standardized terminology for biophilic design; to avoid confusion with multiple terms (metric, attribute, condition, characteristic, typology, etc.) that have been used to explain biophilia; and to maximize accessibility for designers and planners by upholding familiar terminology [3].

Using this strategy, and to apply biophilic design to the built environment in its simplest form, Potteiger & Purinton (1998) and Browning et al (2014) include the following design principles aligned with ‘biophilic patterns’ that can guide design decisions [3, 13]:

<table>
<thead>
<tr>

<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Of particular interest to the Biophilic City concept is the realisation that some biophilic effects can be achieved with no physical or tangible link to ‘nature’ or living systems at all [4]. Indirect experiences of ‘nature’ or
living systems, which may include artistic representations of nature, virtual reality and other illusions of nature can also generate biophilic psycho-physiological responses. Biophilic effects are measurable in environments at a distance from immediate interaction with nature, such as hospital rooms, when people are exposed to images or illusions of nature such as artificial sky. These kinds of illusory, or virtual, systems are part of a range of design tools available to the biophilic designer [4, 5].

The inclusion of an additional pattern, Pattern 15 – Virtual Connection to Nature (Table 2), is predicated on the observation that virtual experience of nature can result in some of the same beneficial effects as ‘real’ experience with human physiological and psychological evidence pointing to stress reduction that lowers blood pressure and heart rate; cognitive performance improvements through mental engagement and attentiveness; and emotions, moods and preferences that positively impact upon human attitudes and overall happiness - Brown, Barton & Gladwell, 2013 cited in [4].

These 15 biophilic design patterns have been recommended to be used in the design of railway stations in Creating Healthy Places [4] as follows:

<table>
<thead>

</tr>
<tr>
<td>15. Virtual Connection with Nature:</td>
<td>A view to a simulacrum of natural elements, living systems and natural processes</td>
</tr>
</tbody>
</table>

Using these 15 patterns can potentially support and enhance the design of railway stations as noted by Beatley (2017), stating that “Nature in cities, we increasingly recognize, is not something optional, but absolutely essential to leading a happy, healthy and meaningful life. And this extends to the design of every element in the city, including transit stations.” - cited in Downton et al, 2017, p9 [4].

5. Creating Healthy Places - A Case Study

With partnership support from the Melbourne Metro Rail Authority (MMRA), a research team from Deakin University prepared and developed an international technical benchmark study on biophilic design and rail transport infrastructure – Creating Healthy Places (2017), to identify the potential opportunities to consider biophilic design in the new Metro Tunnel railway stations [4].

Creating Healthy Places (2017) offers biophilic design insights and performance guidelines towards the enrichment of each of the proposed Metro Tunnel Project (MTP) railway stations to provide opportunities for biophilic design to be incorporated in the design process. It also offers avenues and principles that may better address the Project’s sustainability alignment, and achieve certification of the railway stations under the Green Building Council of Australia-Green Star Rating system by supporting the potential targeting and achievement of a 6 Green Star rating for the railway stations [4, p3].

This research project specifically focuses on two key outcomes:
Interrogation of the biophilia (and urban design quality) possibilities of the 5 new MTP railway stations (Arden, Parkville, CBD North, CBD South, Domain) in terms of their underground concourse areas and vertical circulation area, as well as their above ground plazas, entrances and integration with the larger streetscape and immediate environments, and;

- Contributing practice-rich knowledge and exemplars to inform the Metro Tunnel Project as to key opportunities, issues and ideas for biophilic design formulation of the overall project [4, p13].

The approach taken for the potential application of biophilic design to the railway stations was to firstly align the biophilic design principles and 15 patterns (14+1) with the MMRA Sustainability Policy, secondly, with the MMRA Urban Design Strategy, and thirdly, through a design narrative that matches the patterns with general principles of station design in a priority hierarchy. Finally the ‘Biophilic Design Toolkit’ was applied to provide a summary of recommendations for each station, using 17 actions or recommendations for the application of the biophilic design patterns [4].

### 6. The Toolkit

The ‘Biophilic Design Toolkit’ is a simple method to align 17 identified biophilic design recommendations/actions (Table 3) to support the application of the 15 biophilic design patterns to railway station complexes and environments (Figure 3). To demonstrate the possible outcomes, the ‘toolkit’ was used to assess exemplar projects indicating the biophilic toolkit qualities evident in the projects [4, pp88-94].

An example of the application of the 17 recommendations (Recommendation 1: Adopt a Biophilic Design Program), is indicated in the following Figure 3.

#### Table 3: Summary of 17 biophilic actions/recommendations as indicated in the biophilic design toolkit - adapted from: [4]

8. Use materials as natural analogues
9. Create distinct spatial environments
10. Layer texture & modelling over undifferentiated planar surfaces
11. Explore transitioning of biophilia effects
12. Use signage and wayfinding to raise public awareness of local nature
13. Apply fractal design techniques
14. Use public art to achieve biophilic effects
15. Avoid abstraction
16. Make visible and incorporate the skyline
17. Make visible and incorporate the local pre-European/pre-industrial environment

**Figure 3:** Example of the Biophilic Design Toolkit Application - Recommendation 1. Source: [4]

### 7. International Examples

There are very few examples of railway or metro stations that have been designed with the specific intention to evoke biophilia qualities for their users. There are, however, stations that have been designed with elements that are intrinsically biophilic. There are also public sector/infrastructure buildings, urban spaces and landscapes that are strongly biophilic. One notable example of a public infrastructure project is Singapore’s extraordinarily successful and well-visited ‘Gardens by the Bay’, where the specific intention to evoke biophilia is,
arguably, the primary driver of the project. Two examples of railway stations identified in this paper include the Stockholm Metro Stations (Figure 3) and the Atocha Railway Station (Figure 4).

**Stockholm Metro Stations**

The Stockholm Metro is a good example that demonstrate how local character, culture and place-making are celebrated in the distinctiveness of the underground railway stations in contrast to otherwise typically generic and placeless metro station environments [4, p91]. The Stockholm Metro is one gigantic art gallery. More than 90 of the 110 stations feature artworks created by some 150 artists. For the price of a Stockholm Metro ticket you can see sculptures, mosaics, paintings, art installations, inscriptions and reliefs from the 1950’s through to the 2000’s at most metro stations [6].

Using the Biophilic Design Toolkit, an assessment of the Stockholm Metro Stations indicates that the design adopts a biophilic design program (or partially), includes biomorphic forms and elements, use materials as natural analogues, create distinct spatial environments, and makes strong use of public art.

Biophilic Cities

Atocha Railway Station

The Atocha Railway Station’s concourse includes a 4,000m² covered garden arranged in neat garden beds. Around 260 species and over 7,000 plants improve the internal ambience, climate and environmental air quality of the station.

Using the Biophilic Design Toolkit, an assessment of the Atocha Railway Station indicated that the design also adopts a biophilic design program (or partially), includes biomorphic forms and elements, maximises the use of daylight, makes creative use of water within the station complex, and manipulates the soundscape and olfactory landscape to reinforce biophilic effects. Further, the station demonstrates the creation of distinct spatial environments and makes the skyline visible from within.

8. Discussion and Conclusion

This paper proposes a fresh design approach to city infrastructure that demonstrates how biophilic design can bring together the realms of the built environment and nature so that we as humans can experience the wellbeing benefits of biophilia. The Biophilic Design of railway stations provides opportunities to re-imagine the nature of transit design and can assist in the enhancement of urban environments, including the possibilities for extensive vegetation, improvement and enrichment of ecological systems and their communities, and strengthening connections between humans and nature [4, 5].

The Creating Healthy Places (2017) study indicated that biophilic design can deliver visual, aural, and thermal stimulation(s) in urban environments, whereby such environments can become living laboratories as exemplars of what future Biophilic Cities could be [4]. However, the designing of cities and urban environments needs to be undertaken with the awareness that the inclusion of biophilia is not only limited to the provision of vegetation, but that biophilic design is a scientifically-informed design method that involves a raft of variables and attributes including environmental features, natural shapes and forms, ecological patterns and processes, light and space, considerations of place-based relationships, and the psychological and physiological evolved human-nature relationships as part of a holistic design solution.

Key to achieving this vision is the use of the 15 Biophilic Design Patterns [4], supported by a Biophilic Design Toolkit applied to city infrastructure design and planning that includes 17 biophilic recommendations/actions, as well as an accompanying biophilic design narrative [4, 5]. This paper concludes with the following recommendations to be considered for Biophilia-inspired railway station design, which can assist in advancing the larger vision and agenda of Biophilic Cities:

- The need to include the principles of biophilic design in large infrastructure projects of cities to improve the biophilic city agenda;
- Adopt a biophilic design programme for new rail infrastructure projects (similar for other city shaping infrastructure projects);
- Go beyond standard railway station design and use the 15 patterns of biophilic design to inform the architecture, planning and urban design of the stations and their surrounding urban environment and precinct;
- Adopt the 17 actions and recommendations of the Biophilic Design Toolkit to integrate the biophilic agenda as a fundamental part of the design programme;
- Make biophilic design a key requirement in the sustainability policies and standards of city planning; and
- Include biophilic design outcomes in the performance requirements for infrastructure design and delivery.

Acknowledgments

The authors wish to acknowledge the Melbourne Metro Rail Authority (MMRA) and Deakin University, for access to technical information and human resources during the completion of the research project.
Creating Healthy Places (2016 - 2017). In particular the visionary leadership of the MMRA who initiated the research to potentially consider the inclusion of biophilic design in the railway stations of the Metro Tunnel Project (MTP).

The authors express our great gratitude to Professor Tim Beatley for providing support on this project, and for writing a highly inspiring foreword for the Creating Healthy Places research report.

Abstract

Recently, the concept of biophilia has been used frequently in landscape architecture design, architecture design, and urban planning theory and practice. Biophilia is an important vinculum between the human world and the natural world. However, is it expectable adding biophilic elements without a limit? From a Chinese perspective recognizing the Chinese idiom, “月盈则亏, 水满则溢” (full moon will turn wane, full water will turn overflow), meaning that everything has its appropriate scale. The other understanding of this term is that everything should keep balance in the world. In this sense, the authors believe that for a balance between nature and cities biophilic design should has its own scale that can be divided into the primary biophilic scale and regional biophilic design. In addition, the issue, how to do biophilic design in high-density building area, also caused the space value conflict.

This paper will analyze the biophilic scale and space value conflict for discussing and considering the Biophilic City strategy, Vertical City concept and Liuzhou Forest City project. In so doing, a question about how to deal with vertical green space in future cities is raised and a concept of Architectree is proposed.

Keywords: biophilic city, vertical city, forest city, vertical green space, architectree

1. Introduction

In recently, Biophilic design, derived from “biophilia”, is widely spreading in landscape architecture, architecture, and interior design and urban planning. Biophilia, popularized by Edward Wilson in 1984, represents an innate affinity that human have with nature and is a sort of relationship between human and nature both in psychological and physical. Biophilic design aims to create the space of human activities that has more connections with nature. In 2014, Terrapin Bright Green published ‘14 patterns of biophilic design’, which summarized and introduced the details of these patterns. In this sense, the Hanging Garden of Babylon (or Nineveh) might be the first biophilic exemplar in the world. According to the record of ancient literatures, the Hanging Garden almost conform all the patterns of biophilic design. From Hanging Garden to now, more than 2000 years have passed but little advance in technology and theory has occurred. Despite this, Singapore
is playing a lead role in advancing biophilic urbanism as cross-compared in Figure 1.

Fig. 1. The Hanging Garden, Babylon/Nineveh & Marina Bay, Singapore

This paper seeks to answer several questions about concepts of bophilic city, vertical city, and forest city and what is the relationship between them. The questions raised are as follows:

(1) Why people should consider biophilic scale in biophilic urbanism and how to define it?
(2) What is the method of keeping balance in Vertical City and Liuzhou Forest City?
(3) What is the largest challenge in biophilic urbanism and other theories of urban planning or architecture design?

Finally, this paper proposes a concept of “architectree” for trying to heal the urban ills and to keep balances between nature and city, green value and land value, psychological and physical, aesthetic and functions, human and other creatures.

2. Biophilic elements in theories

In order to find out that how biophilic elements relevant to theories of urban, following urban planning theories (Figure 2) are listed:

a. Garden City
The theory of Garden City provided a comprehensive planning that includes areas of residence, agriculture, and industry, and this concept aims to solve the overcrowding and create a self-sufficient city. According to the central parks, gardens, and grand avenues in Ebenezer Howard’s planning, people can realize the necessity of green space had already existed in this great planner’s mind. [1] The Garden city focus on dividing functional areas in cities and allocating their location reasonably, so that the proportion of vegetation factors in the concept is relatively small. Despite this, green
spaces were planned in different areas as buffers and connectors.

b. Contemporary City and Radiant City
Le Corbusier provided an idea of Contemporary City, which is a project of urban planning that would accommodate 3 million people, in 1922. As the blow four basic principles which developed by Le Corbusier,
(1) Relieve the congestion of central districts,
(2) Increase the population density of central districts,
(3) Improve traffic flow,
(4) Increase planted areas.

He indicated, “We must plant trees!” just after he analyzed mental health in a situation of people walking down the street in a future city.

The Radiant City is another urban planning theory of Le Corbusier; this concept is more like a complete version of the Contemporary City. Le Corbusier said that materials of urban design are sun, sky, trees, steel, and cements, and he defined the goal of the radiant City is like “sun in the house, a view of the sky through large window, trees people can see from their house”. [2] The Contemporary City and the Radiant City aimed to provide a new urban form with reasonable management and convenient traffic and the importance of plants began to be valued in this form.

c. Eco-city
Eco-city theory comprehensively expounded how people should build cities in balance with nature. Richard Register expressed his idea of building cities and nature coexist as the completely sustainable human settlement with zero carbon emissions and renewable resources. Eco-city emphasize sustainable application and have a higher natural participation. [3]

d. Shanshui City
Qian Xuesen, a Chinese great scientist, first proposed Shanshui City theory in 1990. The term “Shanshui” means mountain and water, and Shanshui City is a future city concept based on Chinese traditional landscape and natural philosophy. In this theory, the city is located beside the mountain and waterscape like lake, river, and bay; therefore, Shanshui City values the merging of city and nature. However, Shanshui City are more of a concept compared to other future urban theories, because the urban planning rely too much on geographic location in this theory.

In conclusion, the urban planning movement (Garden City), the urban form design (Contemporary City & Radiant City), the future city demand (Eco-city), and the natural city concept (Shanshui City), they are all inseparable from the nature and related to nature in varying degrees. Through the study of Garden City, Contemporary City, and Radiant City, people can know that the tree plays an important role in these theories but the buildings are still the dominator in the city. Eco-city theory began to advocate the transformation from nature in cities to cities in nature and stressed the equal position of
natural elements and architectures. Although the landscape city is confined to geographical location, experts can continue to research its concept extendedly and apply it to the appropriate cities to make it a sort of Biophilic urbanism.

3. Biophilic scale and Space value conflict

Whether or not the Hanging Garden had really existed in the world, according to the description in literatures and records people could see a comprehensive artwork. However, the altitude and scope of modern cities have already exceeded the limits of Babylon; in this case, people should consider more issues in planning and designing the cities with high-density skyscrapers and population.

3.1 Biophilic scale

For thousands of years, there is an old saying in China that "full moon will turn wane." This idiom comes from the famous Chinese ancient book “Book of Changes”, “Sunset after midday, full moon will turn wane”, meaning that the sun began to go west after it reach the highest point of the sky, the moon
will become crescent gradually after full moon night. After that phrase evolved into a “full moon will turn wane, full water will turn overflow,” which means that everything has scales and limits.

Thinking from this proverb, the authors proposed even biophilic design also has its scale and limits. Could a biophilic space full of natural elements? Could we call it nature if this space exists and satisfied infinitely close to 100% natural environment? In scientific sense, a complete nature is without any human factor; in philosophical sense, the only difference between artificial nature (artificial nature environment that people create by using only natural substances, no any device) and original nature is whether humans are involved, such as the relation between wild corn and agricultural corn. Conversely, the space cannot be called biophilic space if it have no nature. Another considerable situation is that should people make different biophilic design principles in cities of different regions?

According to above contents, there are two biophilic scales; one is the primary biophilic scale and the other is the regional biophilic scale. Primary biophilic scale involves quantitative change, sequence change, and form change that can influence human psychology. Assuming biophilic rates can be modified, the enhancement of biophilic qualities can easily be escalated on all built environment projects. As depicted in Figure 3, scales of 3%, 20%, 50%, 100% of biophilic evidence on building facade offer the question, which one is more suitable for daily streetscape viewing? Regional biophilic design warrants the need to consider its regional/climate, seasonality, vertical limits, user ranges, etc. This scale involves qualitative changes to the built environment. Different climates, different plant species, different seasons can vary considerably whether the city is in the tropics, Mediterranean or temperate climes. Regional biophilic scale also relevant to primary biophilic scale. Considering that different plants show different states and colors in different seasons and regions, if we estimate a suitable scale of 70% plants-covered on a building in Singapore, then the number might be change to 40% in Beijing and 50% in Melbourne.
3.2 Space value conflict

The value of land/space results in a conflict between land space value and green space value. The closer to the city centre, the higher the land space value. At the same time, the green space value is constant. The value of a street tree in CBD is equal to the same one in suburban area. In this comparison of the two values, the space value conflict is raised. Space value conflict is the reason why people fail to see green space in the CBD of a city.

For example, using a 10,000m\(^2\) allotment in Hong Kong CBD, faced with a choice between a 40-storey apartment that could bring about USD$160 million versus a park with minimal economic benefit less health values, the government and business people will choose the apartment option because of economic gain. Figure 4 depicts a high urban density for people, and Figure 5 illustrates what a future Melbourne could look like if growth was concentrated in the inner city without middle suburban infill.
Figure 4. Urban building density in Hong Kong
4. Cases of Biophilic, Vertical, and Forest City

4.1 Biophilic City

In Singapore, architects, planners, and other design practitioners made seven main programs or projects between buildings. To create more green spaces (The Singapore Green Plan 2012). [4] To create linear parks or tree-lined road and make them to link the residential areas, commercial areas, and green areas (The Streetscape Greenery Master Plans). A 300 kilometers of green connectors’ network cross over the entire island so that people could walk or bicycle through parks in the city (The Park Connector Plan). Earnestly implement green walls and green roofs all around the city since 2003 (Hort Park biophilic R&D). Naturalised the concrete canals, build up green land to replace the concrete watercourse, replant trees to cover the demolished boundaries of the canals (The ABC of water management). Made the communities green, made both public and private places more close to natural (Community in Bloom). As a start of developing gardens around the Marina Bay, a biophilic landscape architecture has built in public open space (Gardens by the Bay). Newman, P also provided seven case studies of biophilic design. In conclusion, these cases are all completed through one or several fallow designs: green wall, green roof, green balcony, green campus, and interior biophilic design.
4.2 Vertical City

King and Wong provided a Vertical City (Figure 6) based on skyscraper development, this concept is a multi-skyscraper city that the highest building could reach over 1 mile, and the ground area covers 0.5*0.5 mile. [5] This concept includes about ten skyscrapers, 4 to 5 platforms consisted of skybridges connect each building, and a large base ground area at the bottom as a city central business district. The skyscrapers have cordless elevator system, garbage classification transport tubes, high-level wind power system, and transparent solar panels. Skybridges connect skyscrapers as the pathway from one to the others make the high-rise transport more convenient. In addition, huge width of these bridges could offer space for soccer, tennis, walking and jogging, for planting areas and recreation areas, for children outside-activities’ areas. This emerging concept aims to enhance land utilization to response the growth of city population, reduce the pollution and CO$_2$ emissions to improve city environment, narrow the horizontal space of the city to save the time of working and living and food transportation.

4.3 Forest City

Liuzhou Forest City (Figure 7) is a program that could host 30,000 people and 40,000 trees. Buildings in the first Chinese forest city would be covered by plants and trees, including apartments, schools, hospitals, and office buildings. [6] The planning of this program, based on the “vertical forest” project in Milan, is the sustainable residential buildings with a vegetal system, which includes 800 trees, 4,500 shrubs, and 15,000 plants distributed on balconies of the building façade, therefore, Liuzhou Forest City could be treat as a program made of Vertical forests. Once completed, this terrific city could absorb almost 10,000 tons of CO$_2$ and 57 tons of pollutants per year and contribute nearly 900 tons of O$_2$ to this new city. Liuzhou Forest City also could decrease the average air temperature, create noise barriers and improve the biodiversity of living species, generating the habitat for birds, insects and small animals that inhabit the Liuzhou territory. Although the whole program showed the determination of architects and governments to change the urban environment, what we should get a clear understanding of is the “forest” is still built up with reinforced concrete and municipal pipelines.
4.4 Conclusion

Biophilic City, Vertical City, and Forest City: one strategy, one concept, and one project. Biophilic City or biophilic urbanism focus on increasing connections between citizens and nature in order to strengthen stress reduction and keep the city’s health and resilience. According to Newman (2014), the main methods of Singapore to achieve biophilic city is green wall, green roof, green balcony, green campus, interior biophilic design, and green connector. From the perspective of space availability, green campus and green connector have less limitation than the others do. From the scope of cities, biophilic design would encounter many obstacles work with skyscrapers in high-density building areas like CBD. At present, the vertical green space is a relatively suitable solution for the space value conflict.

Vertical City aims to increase vertical space utilization for more natural space and agricultural land. The Vertical City like a huge super high-rise complex with functions of housing, employment, education, recreation, health care, and other services. It provides a new urban form from horizontal development to vertical development. As the other new urban form, the Forest City increases the number of plants, especially trees, and greatly increase the rate of greening. The common points of the Vertical City and the Forest City are that they would reduce population pressure and the energy consumption, improve the city environment,
and more green space is created (enhancing the three-dimensional greening rate). However, their common disadvantage is that people cannot determine whether people are attracted to the new cities because they have no same characteristics as the long-time-existed cities, such as fame, historical, local cultures, opportunities, high-quality education, metropolitan atmosphere, commercial diversification, etc. In fact, implementing the program like Vertical City and Forest City in China may need to take certain risks. According to the report of China Household Finance Survey and Research Center (CHFS) of Southwestern University of Finance and Economics on June 10 in 2014, the overall housing vacancy rate in China's urban areas in 2013 was 22.4%. [7] Same as these two concepts Utopian Cities also have lofty goals and ideal plan. Unfortunately, the development theories and practices of many utopian cities ended in failure in history.

energy and its root system can collect and store water underground.

Architectree could be an ecological and sustainable architecture model, which could be more than 200m tall and located amongst cement constructions, its branches and leaves could cloud other lower buildings nearby it. As an ecological architecture, it can offer shelter to residents and isolate outdoor noise. As a sustainable architecture, its canopy of leaves can convert light energy to electric energy and its root system can collect and store water underground.

Architectree could be tree(s), which could absorb CO$_2$ and produce O$_2$. It can reduce air pollution, light pollution, noise pollution, and soil contamination. It can mitigate smog and improve air quality. It could improve city ecosystems, and cloud streets using natural elements. It could provide a better city environment for the mental health and wellbeing of both human and animal citizens.

5.1 Similarities

There are hundreds of plants in the world, why trees are most suitable to be imitated for architectures. Firstly, in human unconsciousness, myths, legends and religions, trees are a symbol of origin, positivity, hope, protection, and life, etc. Secondly, excluded herbaceous plants and fungus because of lacking strong and sturdy characters. Thirdly, the height and volume of the tree can satisfy a shelter for animals and human. At last, there are several similar structures between trees and buildings:

1. Root/foundation.

Support the trunk/construction and make the tree/building stable, in addition to these, the root system can
absorb moisture in the soil and dissolves the ions therein, and has the function of supporting and storing synthetic organic substances. The roots purify the earth, reduce soil contamination, and prevent soil erosion.

2. Trunk/superstructure.
   As main body of tree/building on the ground, trunk/superstructure afford the shelter to residents. In addition, there are vessels and sieves of xylem and phloem in the bark, the surface of trunk. They can transport moisture and organic matter to the branches and leave by transpiration.

   Canopy/roof on the top of the trunk/superstructure, can withstand the effects of wind, frost, rain, snow, solar radiation, temperature changes and various unfavourable factors on the building.

5.2 Challenges

As a concept of future architecture, Architectree will face a number of challenges in materials, technologies, construction, management, etc. Materials, closer to the nature of trees, are required to build the superstructure, canopy, and root system of Architectree. Technical expertise is need to explore energy conversion issues including devices that can extract energy from photosynthesis without negating the biological functions; a water supply system that can drain water for using by humans from the water absorbed by the root system. Prefabrication offers a viable choice to build an Architectree. However, what procedures need to be understood to enable sound connections between vessels and sieves, and the step of placing root system underground. Finally, Architectree has all the disadvantages of a tree: diseases and pests, fire risk, root damage, and falling objects, etc., so the maintenance of the entire Architectree to be discussed. We might need to train and hire more gardeners in our future cities.

6. Conclusion

Above all, to a future living place, what people require is a city that could cooperatively organize green spaces and vertical spaces. On this basis, cities also should satisfy functional requirements like sustainability, safety, entertaining, education, hospital, resilience, etc. However, the concept of Architectree, which aims to stand on a balance point between natural world and civilization, between economic benefits and green space benefits. As a biophilic element, Architectree provides more green space value without affecting the land space value. Architectree could be built in blocks, to improve city environment penetrating into the city.

As a concept has both the vertical space benefits and green space benefits, authors will research the impact of architectree in a city in next stage, and the future available materials, technologies, construction methods of “architectree”.

Abstract

Introduction/Aim:

The biodiversity of our surroundings is continuing to decline worldwide in many high-density urban areas due to the conversion of nature to the built environment. A reasonable case can be made to assume that people living in high-rise apartment buildings built in place of greater biodiversity have a reduced exposure to soil, plants and animals. It has also been shown that urban populations worldwide are increasingly disconnected from nature. What might be the consequences and can this trend be reversed using greening strategies? The research reported in this paper evaluates the efficacy of one such strategy, which involves growing plants on balconies in high-rise apartment buildings located in urban areas. The aim of the research is to measure nature relatedness and health differences between apartment residents with plants on balconies and without.

Methods:

Eighty-seven respondents have provided health and/or lifestyle survey information as part of a 12-month study in the metro area of Perth, Western Australia, which investigates the relationships between high rise apartments, environmental biodiversity and the human skin microbiota. Preliminary data analysis of the health surveys, and the lifestyle survey factors ‘nature relatedness’ and ‘visits to green spaces’, was calculated using Qualtrics and SPSS. Nineteen respondents had plants on their balconies, and 68 had no plants. Mental health of respondents was captured using the SF36 survey. Nature relatedness attitudes, perceptions and experiences were captured using the 21-question Nature Relatedness Scale; and frequency of visits to green spaces and gardening was captured using a set of scale questions regarding frequency of respondents’ visits to different types of green spaces and respondents’ participation in gardening.
Results:

Interim results indicate that although the majority of high-rise apartment dwellers agree that they are not separate from nature but are a part of it, they do not have high nature relatedness. Forty-four per cent of respondents visited local parks less than once per month, if at all; 38% never visited bushland areas; and 46% never went to national parks. However many had preferences for green spaces to be around them, with over 80% of respondents saying that they would prefer a park and street trees around their apartment buildings. Almost half (45%) of health survey respondents stated that they experienced emotional problems that interfered with social activity, and 61% felt worn out at least some of the time. Statistically a significant difference was found between the two groups of respondents and the frequency of visits to green spaces. Respondents with no plants were found to visit green spaces less often than those with plants on their balcony.

Conclusion:

High-rise apartment dwellers with no plants appear to be further disconnected from nature than those with plants on balconies. The consequences of limited contact with nature may be a reduction of beneficial ecosystem services, and this may lead to various health issues such as higher stress levels. For whatever reason apartment dwellers cannot access nature, most have a desire to be near nature and we should look for ways to bring greening strategies to apartment buildings.

Keywords: Nature relatedness; high-rise apartments; biodiversity; disconnect, ecosystem service, green spaces, stress, wellbeing

1. Introduction

This paper is part of a broader longitudinal study of high-rise apartment dwellers in Perth, Western Australia that is investigating the links between occupant lifestyles, stress, physical and mental health, nature relatedness and the diversity of human skin microbiota. Participants living above the third floor in high-rise apartment buildings have received either real or fake indoor plants and are being monitored over a 12-month period. The study includes administering health and lifestyle surveys before and after the intervention. Data has been captured and analysed from surveys administered before the intervention.

Environmental biodiversity is a holistic expression of the natural environment that surrounds humans [3]. Environmental biodiversity provides a range of ecosystem services that include health benefits; however biodiversity (trees, plants and all other living species) is continuing to decline worldwide in urban areas due to the conversion of natural areas to urban infrastructure [12]. In Australia singles and couples spend less than 25 minutes per day outdoors, which underscores a disconnection between people and nature in high-density urban areas due to both declining biodiversity and modern technology [6-8].

Biophilia is a human’s innate need to connect with nature [9]. Research conducted over recent decades has suggested that environmental biodiversity is good for our health [7]; however, this does not appear to have filtered through to urban planning and developmental policies in many cities [28], including Western Australia where this study is located [29]. Disconnection from nature relates to the loss
of essential microbes for human microbial diversity, which may cause dysbiosis and compromise our immune system [8]. An interdisciplinary call to action between planners, landscape architects, ecologists and health professionals is warranted. This is becoming a matter of urgency because the number of high-rise apartment buildings is rapidly increasing along with the incidence of chronic diseases in our highly urbanised world [4].

Modern high-rise apartments are near major transport hubs and city centres, and are a less expensive form of housing for many. Some of the downsides are that affordable apartments may be placed in suburbs with industrial or commercial outlooks, built with no greening infrastructure, or in new estates that have no green space. What happens when the demolition of older housing and private gardens make way for a high-rise building that takes over the entire building envelope? Does policy allow for any of that greening to be put back? What might it mean for high-rise residents to have little greenery or soil around them? How do they connect with the natural world? Some strata companies will not allow plants on balconies because of possible paintwork damage from pooling of water, and even deny occupants the ability to have plants indoors because of possible moisture problems. Unfortunately some modern apartments in Australia and elsewhere do not have windows that open for ventilation, but only a sliding door to a balcony and a mechanical ventilation system. If the mechanical ventilation system is not used the apartment can be affected by moisture issues. In addition, if an indoor environment lacks good outdoor airflow, the microbial population will mainly consist of the occupant’s own microbial clouds and the built synthetic environment, and this has the potential to cause dysbiosis [1, 3-5].

This paper focuses on nature relatedness and why a connection to nature is important for human health and shares the results of preliminary findings. This paper will also discuss wellbeing of high-rise apartment dwellers in relation to green spaces, and look at how wellbeing might be affected by disconnection from nature. Finally, recommendations reveal how we might consider moving towards a biophilic city, a city that recognises the need for daily contact with nature, the ecosystem services provided by nature, and by prioritising nature in its planning and development policies [32].

This paper presents the preliminary results of lifestyle surveys from high-rise apartment respondents with plants on their balconies and those without plants. The relationship between nature relatedness, visits to green spaces, and health is presented, and the paper asks the question ‘what might be the consequences and can this trend be reversed using greening strategies?’

2. Green Spaces and Wellbeing

Studies from many sources and countries over the last 30 years have shown that there is a positive link between environmental biodiversity and health [10-12]. The creation of large biodiverse areas such as parks and green belts has been shown to improve the mental and physical well-being of people living in urban areas, but due to
Because of the threat of biodiversity loss, subsequent ecosystem impairment and the role of environmental microbiota, researchers propose that living in high density urban environments may lead to an inability to adapt to microbe-poor environments which is termed ‘immune adaption syndrome’ [13]. People living in high-rise apartments may not have access to parks due to land scarcity, which is a further disadvantage for biodiversity exposure and may negatively affect wellbeing [12].

A mixed methods study that examined the role that neighbourhood green space played in influencing residents’ self-reported health found that green spaces were important for people to relax in and get away from the noise and busyness of the city. Respondents who perceived nearby green space to be useable were more likely to report better general health than those who did not [14].

Recent work has shown indirectly that individuals in urban environments are at a disadvantage in processing stress compared to those in rural environments [2, 15, 16]. The results of a study identifying and describing eight perceived sensory dimensions in green urban spaces conducted by Grahn and Stigsdotter [17] confirmed the need for urban green spaces to be considered as part of future urban planning in order to mitigate stress and public mental health. In an urban neighbourhood study, stress was found to be a full mediator of the relationship between the quantity of streetscape greenery and mental health, and a partial mediator of self-rated health. Residents with higher amounts of streetscape greenery reported better mental health, less acute health complaints and stronger social cohesion [18]. Similar results have been found in studies conducted in England [19], Denmark [20], and Sweden [21]. Von Hertzen et al. (2015) suggested that the benefits of nature in coping with stress should be better acknowledged, and that this research might contribute to new measures to reverse rising trends in the prevalence of conditions such as chronic inflammatory disease.

3. Benefits of the indoor and outdoor natural environment

Loss of biodiversity impairs many essential ecosystem services including the role of environmental microbiota [13]. There are already trillions of bacteria in high rise buildings, but only a limited number flows in through open windows and air conditioning from the outdoor environment. Most of the bacteria, fungi and viruses come from people who inhabit buildings [3]. The home environment then creates new habitats for numerous microbial communities that may be quite foreign for the human skin to adapt to, and may not be beneficial for health. The biodiversity hypothesis theory states that an environment with diverse microbiota modifies and enriches human microbiota, which is a necessity for the development and maintenance of the human immune function [11, 23].

Beneficial bacteria on indoor plants, and in the soil they are contained in, are an important addition to an apartment, stabilising the ecology of the built synthetic environment. Plant-associated bacteria could help to avoid outbreaks of pathogens.
by enhancing biodiversity, which may enhance the immune system [24]. Indoor plants will also purify the air, reducing the emissions of volatile organic compounds such as formaldehyde [5].

Outdoor plants and soil have an abundance of ecological communities compared to indoor environments, and a higher diversity of microbes, and they therefore increase the numbers of insects, birds and other fauna. Outdoor plants such as trees and shrubs also have a role in high density urban areas by shading buildings and streets and assisting with stormwater runoff and nutrient dispersal [25]. Rooftop community gardens may have social and health benefits as well as providing an ecosystem service. For residents interested in gardening, there are also mental health benefits [26]. Green roofs and living walls are a new concept for Australia, and must be formulated both for Australia’s climate, and for the best ecological systems [27].

4. Preliminary findings from a PhD study in Perth, Western Australia

SF36 health surveys and lifestyle surveys comprising of 150 lifestyle questions were distributed and received over four seasons from high-rise apartment dwellers in the metro area of the city of Perth, Western Australia. The responses were inputted into Qualtrics software for analysis. Not all respondents elected to be part of the broader 12-month study, thus 87 lifestyle surveys and 81 health surveys were received. The 21-item Nature Relatedness (NRS) scale has been shown to differentiate between groups of nature lovers and those who do not participate in nature experiences [22, 30]. The NRS Scale was used within the lifestyle survey in addition to eight questions regarding time spent visiting different types of green space and a question regarding time spent gardening.

The results indicate that many high-rise apartment dwellers agree that they are not separate from nature but are part of it. However, these individuals do not have high nature relatedness scores (Table 1), nor do they visit green spaces frequently (Table 2). However many had preferences for green spaces to be around them, with 89% preferring a balcony garden and 83% indoor plants. Around the apartment building 93% of residents would strongly like a park, 87% street trees, 81% a rooftop community garden and 75% vertical gardens. Respondents in the broader study collectively live in 37 apartment buildings, and of those 37 complexes 24 had no landscaping. Nine complexes had a community garden.

The nature relatedness (NRS) and green space data were analysed using SPSS (Version 25). Collectively the components of the scale measure the affective, cognitive, and experiential relationship with the natural world, with a higher score indicating a stronger orientation towards nature [22, 30]. These scores are a strong predictor for visitation to green spaces [22]. Total scores and descriptive statistics were computed for each of the NRS factors. For the total green space mean and the gardening variable descriptive statistics and a total score were computed by averaging across the items. Spearman’s correlations between variables were calculated and it was found that nature relatedness was not
significantly related to the majority of lifestyle variables.

Tables 1-2 present the descriptive statistics and Cronbach’s alpha reliabilities of the combined key study scale variables.

TABLE 1
Descriptive statistics of the nature relatedness measures of high-rise apartment residents with no plants (n = 68) and plants on balconies (n = 19). Five-point Likert scale ranging from one (disagree strongly) to five (agree strongly).

Respondents with no plants had an aggregated mean score that was below the NRS mean population norm of 3.65 [22],
and though respondents with plants scored higher, when a Mann-Whitney test was applied there was no significant difference (.785). However there was a significant difference between the two groups that showed that respondents with plants visit green spaces more frequently than those without (.036). The limitation for the comparison was the smaller sample size of respondents with plants on their balconies compared to respondents with no plants.

The SF-36 is a short questionnaire with 36 items which measure eight multi-item variables including five items on mental health [31]. Of the 81 study participants who completed a SF36 health questionnaire, 45% stated that they experienced emotional problems that interfered with social activity, and 61% felt worn out at least some of the time. There were no statistically significant differences in the figures for individuals with plants on balconies and those with no plants.

5. Conclusion

Existing evidence shows that being around or viewing nature enhances health for the human population living in high density urban areas in cities around the world. Nature relatedness can vary between individuals and appears to be inherent rather than related to lifestyle. A reasonable case can be made to assume that people living above the third floor in high-rise apartment buildings have a reduced exposure to soil, plants and animals than dwellers in low-rise and single-unit housing.

High-rise dwellers with no plants in their immediate environment appear to be further disconnected from nature than those with plants on their balcony.

Based on this study of the Perth population, people in high-rise apartments with no plants visit green spaces less than people with plants on their balconies. This result may be applicable to other apartment dwellers living in other cities in Australia (and elsewhere). High-rise apartment buildings are increasing as available building space in inner city areas diminishes, and this looks to be the way of the future as the human population increases.

Ecosystem services such as parks, community gardens, rooftop gardens, living walls, green roofs and internal green spaces are critical to human health from both a mental and a physical perspective for high-rise apartment dwellers [9]. Landscape architecture in conjunction with government development policies is paramount to enabling ecological justice and accessibility to nature, as well as providing the right microbial balance for high-rise apartment buildings.

Possible recommendations to help planners move towards a biophilic city are as follows:

1. Green space strategies need to become a focus for developmental planning revisions;
2. Developers need to be made aware of the need to put back a percentage of greening when designing high-rise buildings on small blocks.
3. Ecological justice needs to be taken into account so that greening of suburbs does not escalate real estate...
and push lower socioeconomic people out;
4. Greening of unused blocks of state land in suburbs where there is a shortage of public green spaces will benefit residents;
5. Reuse of unused industrial spaces may make neighbourhoods safer and more welcoming in addition to providing nature benefits;
6. Public transportation may also need to be addressed, in order to facilitate more visits to bushland areas or national parks.

Abstract

Green is beautiful, ecology is smart and horticulture is the past? Two housing projects developed in Grenoble, a French city located in the Alps, offer a unique opportunity for a cohabitation between endemic local plants, with fruits and vegetables, and horticultural bushes and flowers. Both of these projects are telling: we don’t need to choose between ecology and gardening to be sustainable!

The first project is located in Seyssins, a small city in the Grenoble suburbs, between the river Drac and the Vercors mountain foothills. The project includes 55 flats, among which 30 are dedicated to social living, rented flats, comprised mainly of families, and 25 flats sold to individual owners. Overall, there are over 150 adults and children living in this housing project. Together, they share a vegetable garden, an orchard and a collective roof garden. In addition, each family is given a small private garden or a large terrace. The top roof is covered with extensive meadows mainly constituted of the identical plants found growing in the rocky soil of the mountain adjacent the apartments. Rainwater is collected in tanks and used for watering the vegetable garden and the roof garden. The gardeners are themselves the residents, some of them owners, others tenants. All together they manage the vegetable garden with the residents’ association, which also provides and takes care of the gardening amenities (equipment and locale), the citrus trees integrated in the mail box room used as greenhouses, the watering installations and the orchard. Four years after the residents’ arrival in their new flats, this project is a success, putting forward its multilayered biodiversity (an influx of birds and insects) and its social development.

The second project is still under construction in the south of Grenoble, near the city’s main ring road. 150 flats will be built, among which, 20\% are reserved for social housing families, 15\% for student housing and 15\% for retired residents. The housing is organized in terraces from the 4th floor up to the 11\textsuperscript{th} floor. It integrates a large roof garden with a greenhouse, a vegetable garden and a small orchard. The rain water used for watering the roof garden is collected in a succession of extensive roof gardens with dry meadows. A wet forest garden is planted in the heart of the housing project. It is also the final area to collect and infiltrate all
the rainwater, coming from each successive terrace, the water circulating from terrace to terrace, partly hidden in the roof structure, partly left to trickle down in the open.

Both of these projects are resilient in the face of climate change. They participate in mitigating the climate change impact in city housing, for summer comfort, as well as for winter wellbeing, with the added bonus of minimizing flooding risks and protecting the ordinary biodiversity of our cities.

Keywords: climate change resilience; green cohabitation; multilayered biodiversity; wellbeing

Introduction

At a time when sustainable development is at a high, how can we concretely integrate into projects environmental, socio-economic and heritage aims, on one hand, in our daily private practice and, on the other hand, in our confrontation with an educational and teaching practice among students in universities or other. The educational experiences hereafter concern mainly the thoughts and reflections experienced at the Grenoble School of Architecture, Grenoble being the “capital” of the French Alps. And it is particularly on the questions that address biodiversity, stemming from the experience in our planting choices, tested through our agency’s landscape projects, that on this occasion, the Singapore IFLA Congress, we wish to take stock of the reflections on this matter, as a professional and a teacher.

In Europe, wilderness, in the ecological and scientific sense of the term, has almost disappeared. Today, there is almost no territory left anymore where man has not intervened in the last 300 years. There are, however, "some" natural spaces, in the common sense of the words, that we know, are not managed either by man, nor by farmers, forest rangers or gardeners. In France, if these spaces are still relatively numerous on faraway mountainsides or certain islands, agriculture and forestry, more or less intensive, widely dominates our territory.

At the same time, biodiversity has never been so much in danger, including the ordinary urban biodiversity such as insects, birds and small mammals. As an example, in 2018 the Paris Natural History Museum and the French League for the Protection of Birds issued a report revealing that a quarter of all breeding bird species, are today in danger in France, their population decreasing around one third these last fifteen years.

Among the many explanations that are put forward, there is the major decline in insect numbers and the evolution of agricultural practices that are leaning evermore towards intensive or industrial methods. Moreover, Europe in general and France in particular, have observed that the new fauna biodiversity refuge is actually becoming our cities. Foxes, wild boars and other small mammals have become a common sight in our urban spaces, cities adapting to new forms of cohabitation. More recently, a wolf even returned into Berlin.

In this context, every new project comes with newfound responsibility for our society to develop new biodiversity shelter spaces (without losing sight of improvements to agricultural methods). It is also urgent to
change our methods and approaches to the project in matters of landscape design.

We created our landscape agency over ten years ago, and for the equal amount of time we have searched to develop our approaches, and our ambitions for the project, making them continually evolve. Whether in our studies or in project management, each of our projects aim to protect not only the local biodiversity but also aim to develop it further. This also includes any concerns in the preservation of plant substrates and stormwater management.

Our design practices and methods must continue to accompany our environmental ambitions, improving them, especially in matters of spatiality, space ambience, function and use comfort, all in the name of general interest. Throughout our studies and projects, plants and flora in general remain "the raw material" at our disposal. But beyond the preservation of regional endemic flora and fauna, we refuse to have to choose between local flora and horticultural and productive flora.

And so, at our small scale level, we continue to test plant associations, stemming just as much from field observation as from literature research. We proceed to follow their evolution, with fauna and flora considerations, but also in matters of functions, uses and esthetics. There is, for us, a form of filiation with the landscape architects’, Piet Oudolf and Noel Kingsbury, ecological and phytosociological approach.

For now the reality is other. After our projects are completed, the biodiversity established, we, unfortunately, remain unable to set up scientific follow-up protocols, having no internal scientific expertise. We simply wish to participate in the collective ambition to create more sustainable living spaces, with conditions allowing our fellow countrymen to live a more sustainable life in these spaces. This is the type of experience we wish to share with the 2018 Singapore Landscape World Congress and, most especially, through the displaying of two of our recent projects

**Living within a kitchen garden, a co-ownership project in the heart of a garden in Seyssins**

Seyssins is a small municipality in the suburb of Grenoble, itself a metropolis of about 450,000 inhabitants.

The city launched a housing project, comprised of 55 intermediate flats, at the heart of what used to be a large garden, complete with orchard. It was partially constructed on an underground concrete parking structure. The site was previously occupied by community and family oriented allotments and represents a strongly sloping terrain of approximately 8,500 m².

Oriented due west, the project stands at the foot of the Vercors Mountain, a vast calcareous and jagged mountain range. The region benefits from a continental climate, with a high level of exposure to sunlight (approximately 2066 hours/year) with heatwave summers and an average rainfall level (approximately 934 mm/year,
including a few days of snow) stretching out over the entire year, with more intense rain periods in the spring and the fall.

1.1. Architectural and landscaping project

The project is organized around five buildings each arranged perpendicularly over a shared underground parking (see ground plane, fig.1 and section, fig.2). Among the 55 flats, 30 are dedicated to social housing and the 25 others were meant to be sold to individual owners. The social real estate developer, after construction, kept on managing 30 social housing flats and sold the others, social housing in France needing to be overseen by appointed public bodies. In this case, the city of Grenoble named “Grenoble Habitat” as developer and administrator.

Each flat has a direct access (as would a house, even though this housing building is known as “intermediate housing”) to a large terrace or a private garden, while smaller flats have access to bigger collective terraces.

The building constructions are organized in a staircase profile that allows grand viewpoints on the three mountain ranges surrounding Grenoble.

The architectural and landscape design was developed in association with GTB Architects, a Grenoble architectural firm. Their design was drawn in a way so that all tenants and inhabitants could share and manage collective spaces such as vegetable patches, fruit trees (including citrus trees), the gardening tool shack and rainwater tanks (see technical cross section fig. 3) as well as a fully equipped common open air space with tables, benches, playgrounds, bicycle storage and a parking lot.

Gardens are located either on the concrete structure or on the original topsoil (the former topsoil being reused after careful storage while construction was underway).
All the rainwater is stored in 4 tanks for summer use and specially directed to the kitchen gardens and the collective terrace (see hydraulic principle, fig.4). The excess water is collected in a wide ditch located on the property limit.

*Fig.4. Stormwater management*

The project also hosts about ten birdhouses for common birds and three bat houses (pipistrelles, see photos, fig. 5 and 6).

![Birdhouse](image5.png)

*Fig.5. Birdhouse*

![Bat houses](image6.png)

*Fig.6. Bat houses*

The project is situated near a tramway station that puts the inhabitants at a 25 minute ride from the city center. There is also a shared vehicle in the car park.

The housing complex is itself at the junction between the city and a vast urban park, a natural urban reserve, the Green Alley of Seyssins. Pedestrian’s and bike’s access to the different buildings is situated along the park pathway.

The public limit is itself put at a fair distance by small vegetable patches and terraces.

The project’s design spanned from 2011 till 2013. The construction itself started end of 2013 was completed in the spring of 2015, as the plantations were done.

1.2. *Plant selection*

The project proposes various plant selections, ranging from endemic dry meadows of the Vercors plateau, the mountain range closest to Grenoble, to the
more classic horticultural selections for vegetable plots of land.
We planted, from the top roof to ground level, the following plants selection:
- On the invisible technical top roof, an extensive vegetation of sedum.
- On the collective roof garden we developed a traditional intensive roof garden, of various melliferous perennials, of bulbs and small shrubs. This terrace garden is cultivated upon 60cm of quality topsoil and a drip irrigation system connected to one of the water tanks (see photo, fig.7).

![Fig.7. Collective roof garden](image)

- In continuity with the flats’ wooden terraces, a semi intensive vegetation of dry meadow is planted on a 25cm substratum (70% volcanic rock, 30% compost) and limestone mulching. The plant selection (46 species of perennials, annual flowers, bulbs and grasses) was chosen among floral lists of the Vercors natural protected zones, in a 3 or 4 km radius (see photos, fig. 8 and 9). Each terrace of the housing itself integrates a large pre-vegetated planter containing aromatic herbs and vines planted next to the sun shades architecturally positioned and designed for better climbing.

![Fig.8. Extensive green roof just after planting](image)

- The main terrace, inserted between the buildings and slotted over the parking, is also a roof garden. There is at least 1m20 of topsoil reused from the site. This terrace garden is made up as a normal everyday garden complete with orchard trees. (see photo, fig.10).
Fig. 10. Hedges and private gardens

- Planters as well as the carpark walls, east of the residences, are planted with shrub trees and vines, on at least 80cm of topsoil. (see sectional drawing before).

Fig. 11. The carpark “green wall”

- The low level terraces, propose vegetable gardens managed by the residents. The surrounding hedges are planted with small flowering shrubs and fruits (currants and blackcurrant mainly).

- Small landings and immediate surroundings in access to the homes, in the drier and sunnier environments, are planted with Mediterranean plant species and fruit trees.

- The wide ditch collecting rainwater is planted with shrubs, grasses and perennials, supporting vast amplitudes of humidity, from temporary submersion to temporary drought (see photo, fig. 12).

Fig. 12. Wide planted gap separating private domain and the public path rainwater ditch.

- Prior to the residents’ incoming, the vegetable plots of land, awaiting the future gardeners, were sowed with a “green fertilizer” (Synapis arvensis and Phacelia tanacetifolia).

- The mailbox rooms have also been designed as unheated greenhouses, each of which is planted with a variety of citrus tree.

Counting trees, shrubs, climbing plants, perennials, bulbs and grasses, about 212 different species were planted. Amongst them 19 different tree species and 15 fruit tree varieties.

1.3. First feedbacks

The Seyssins project reflects, on the one hand, the research and the observations in regards to a typical plant project and, on the other hand, the experience in regards to a social project. It was the object of intense public consulting and inquiry beforehand, a request strongly driven by the municipality
Biophilic Cities

and the real estate developer. The aim was double.

The first goal to achieve was to allow future residents, homeowners and leaseholders, with low income, to get to know each other before having to share common spaces in the same building. Several information meetings were then organized in order to present the project as well as a visit, in situ, during construction.

The second goal aimed to further implicate future residents in the green space management. Indeed, the real estate developer was investing on large amounts of plants (over 14,000) that would become each and everyone’s responsibility whether caring for or only watering them. The challenge was won and the residents up to par. Around 150 people took the gardening project in hand, terraces and gardens alike, even going to the extent of adding new species.

According to all, numerous insects have invested the gardens and the first birds, and even some bats, have also started to call Seyssins home. It is necessary to note that certain residents seemed cautious in the beginning, maybe even frightened, at the idea of cohabitating with bats.

We estimate today that approximately 70% of this initial biodiversity is still present on site, and this, nearly 3 years after having planted. In order to paint a full picture, we must also state that ruderals (notably the Docus carota) have slowly started to dominate rooftop intensive plants.

The more shaded areas (northern face) have had greater difficulties developing to maturity. Certain plant replacements were made, introducing, at the same time, various new varieties.

The garden management in general has been put into the hands of a non-profit association comprised of a group of residents (homeowners and leaseholders). This association is the privileged speaking partner with the residents for all site management questions. Every aspect of management is maintained without any chemical products (see Fig 13).

Fig.13. Vegetable patches, plots

2. A garden building

The second project is in Echirolles, a southern suburb of Grenoble. The building construction only just started in September of 2017. The
project provides for 150 flats, partly designed for low income social housing, homeownership, housing for seniors and student housing, and was the brainchild of the SCAU Architects agency. The Safilaf was the developer.

2.1. Architectural and landscaping project

The housing project took on a triangular shape, a green grass space, complete with fruit trees, allowing for picnics and calm relaxation. (Fig 14 through 17).

An intermediate terrace acts as a liaison area, linking the upper functional parking terrace to the street level interior garden. From the 11th level down to the 5th level, the flats open up to the South onto large rooftop terraces, terraces extended further by semi extensive dry meadows. The rainwater collected from these terraces cascade down from storey to storey. It is then recovered into cisterns in two gardener’s sheds, each of which are located on the parking roof’s extremities. (Fig 18 and 19).

2.2. The landscape design

This project is the logical follow-up to the previously cited Seyssins project. It draws lessons from Seyssins, all the while introducing new methods of experimentation or testing.

One can then see, from the ground up:
- Dry meadows on impoverished substrates planted on semi-extensive green roofs. Contrary to the previous project, the more vivacious ruderals were entirely eliminated from plant lists.

- A garden roof atop the parking facilities, both horticultural and productive. It is the future playground and resident gardening area (Fig.20 and 21).

Fig.20. 3D view of the community collective terrace

Fig.21. Section illustrating the terrace orchard

- The intermediate terrace is made up of potted multi-trunk trees, ground covering plants but also climbing plants on the parking wall. This terrace has the distinctive feature of leading overhead rainwater from summit terraces to the interior central garden below.

- An interior central garden was imagined as «a small piece of wilderness »: a number of trees, green spaces, typical forest undergrowth (a collection of different ferns).

Accumulated, there are more than 13 500 plants, from more than 65 different species.

Conclusion

We have researched varied sources, studied many works, all in order to verify if any information existed concerning horticultural plants that would attract less wildlife in general, and insects in particular, than endemic plants. There are notably several studies on green roofs and green walls, which prove that a flora offering food, in particular flower or fruit nectar, indeed attracted fauna, and that insects and birds that are dependent to a unique species of plant were rather rare. Our own project feedbacks seem to confirm these studies. Floral diversity, including horticultural species, favoring melliferous and/or fruit species, is the key. Sterile horticultural species without nectar, which would disorientate some insects, in particular bees, have been eliminated from all our floral assortments/palettes. It is also necessary to note, that in these urban environments, more or less windy, strongly allergenic plants were avoided.

So, whether it be the Seyssins project, where regular visits allow us continued observation
on the evolution of plant diversity, or the Echirolles project, soon to be constructed, or any other future agency projects for that matter, we realize more and more that we are but at the beginning of our comprehension and mastering of these complex living environments.

This is also the reason that makes our profession so enthralling and captivating.

Abstract

Decision-makers around the world are grappling with the implications of rapidly growing cities and are seeking to foster healthier living amongst sedentary populations with chronic ‘lifestyle’ diseases and an increasingly aging population. Design solutions that address these concerns have the potential to improve standard of living, reduce public or insurance health spending and enhance ecosystem health. The field of biophilic design offers strategies for addressing these concerns while also delivering health, lifestyle and ecosystem benefits.

The theory and related design principles of biophilic design span more than three decades of action research over a variety of geo-political, built environment and climatic contexts. Over the last five years, Conrad Gargett has participated in a multi-faceted action-research partnership seeking to deepen understanding and better integrate biophilic elements towards healthy cities and citizens. Collaborative research has included several projects investigating healing gardens integrated into a Queensland hospital, including an evaluation of garden-visitor experiences (reflective journals and surveys), a review of the design journey (archival analysis and interviews), and evaluation of micro-climate conditions of the gardens (monitoring).

This paper will draw on these projects to identify key roles and influencers necessary to successfully implement biophilic urbanism projects, suggesting strategies for biophilic design to tackle complex 21\textsuperscript{st} Century challenges within a rapidly changing built environment. It will provide an insight into strategically embedding ‘biophilic services’ to address public and environmental health, and climate change impacts. It highlights the need to commit to social responsibility and critical design thinking to nurture human and environmental health, reflecting our innate human need to connect with nature.

We conclude that landscape architecture has a significant role in influencing the design of resilient cities, as leaders in embedding ‘biophilic services’ through systems thinking and interdisciplinary collaboration. In particular, Landscape Architects can ensure that ‘functional biophilic design’ is an integral part of the city’s fabric, contributing to designing spaces for people that feel intrinsically familiar, towards aesthetic, intellectual, cognitive and spiritual satisfaction. Finally we highlight the need for capacity building in the landscape architecture community, to embed biophilic services within projects.

Keywords: Landscape architecture; Biophilic Cities; Health and Wellbeing
1. Observing the critical role of Landscape Architects

Decision-makers around the world are grappling with the implications of rapidly growing cities and increasingly sedentary and aging populations with chronic ‘lifestyle’ diseases such as type 2 diabetes, cardiovascular disease, and obesity (Willet et al, 2006; WHO, 2003; WHO, 2005). They are concurrently grappling with climate change related impacts including increasing temperatures and frequency of extreme weather events, the spread of certain tropical diseases, and sea level rise (IPCC, 2014).

As cities continue to develop and densify and develop around the planet, it is imperative that design solutions address these social and environmental concerns. Indeed prompted by these concerns we can go beyond ‘survival’ to ‘thrive’ (Cooper-Marcus, 2016), collectively improve standards of living, reduce insurance health spending, enhance ecosystem health, and foster built environments that are resilient to the impacts of climate change. We propose the strategic integration of nature into urban environments as being a critical component of such efforts. Amongst global calls to action, we highlight the call for landscape architecture leadership by the Hon Hilary Benn, Secretary of State for the Environment, Food and Rural Affairs, U.K.:

“…you bring together the skills, knowledge and passion that we need for the 21st century in the way that engineering shaped the 19th century. We need you in the fight against climate change. You can show people how it can be done. Your Institute has established a record to be proud of – whether greening gardens or greening the 2012 Olympics, from being leaders in the design of cleaner, greener neighbourhoods to pioneers of green energy and green infrastructure projects.”

Within this paper we use our collective lived experiences over the last five years to highlight the social and environmental responsibilities of landscape architects to improve public health and urban resilience to climate change impacts, towards nature-loving – i.e. biophilic (Beatley, 2000) – outcomes. We propose that landscape architects can champion the integration of what we call ‘biophilic services’, defined as, “the benefits yielded from intentional interventions in the built environment, providing conditions and processes through which one or more biophilic elements yield direct or indirect, implicit or explicit, quantitative or qualitative enhanced well-being” (el Baghdadi and Desha, 2016).

Over the last five years, Conrad Gargett has participated in a multi-faceted action-research partnership with Griffith University, Queensland University of Technology, University of Queensland and Queensland Health, to explore the role of biophilic design in city health, and to better integrate biophilic elements to positively impact cities and citizens. Collaborative research has included several projects using the healing gardens at the Queensland Lady Cilento Children’s Hospital as a case study to better understand the social and environmental impact of biophilic design, particularly within a sub-tropical hospital context. This included an evaluation of end-
user experience (reflective journals and surveys), a review of the design journey (archival analysis and interviews), and evaluation of micro-climate conditions of green space (monitoring).

Drawing on this collaborative journey and the concept of delivering ‘biophilic services’, in this paper we discuss leadership roles landscape architects can take towards delivering healthy and resilient cities. This includes embedding a holistic approach to development from concept through to project delivery. It also includes effectively using spatial data information to design purposeful and effective biophilic cities. We conclude with a discussion of the implications for design and master planning projects, and for professional practice, and several immediate actions to create more resilient cities through biophilic design.

2. The role of Landscape Architects in delivering biophilic outcomes

The design and development of urban spaces and infrastructure is typically a multi-disciplinary process involving planners, urban designers, engineers, financiers, architects, landscape architects and the construction industry – among others. There has been growing recognition of the value of integrated, collaborative approaches that bring together these professions and key stakeholders early in the design and decision-making stages to achieve more holistic, sustainable outcomes.

In order to deliver biophilic services as an integral component of urban design and development, we propose that the role of landscape architects in such collaborations needs to be elevated, to ensure the preconditions are achieved to deliver thriving natural features; and to ensure biophilic design principles inform the broader urban design. More specifically, the disciplinary training and experience of landscape architects support a central role for this profession in the following ways:

- Ensuring the overall design of the urban space or infrastructure is 'conducive to life' in a way that optimises the long-term viability and function of the vegetated and other natural features, including that they receive good light, air circulation, and water.
- Ensuring vegetated areas are well integrated into the rest of the design in a way that supports way-finding, use and maximises the value of those vegetated features. In this regard, the vegetated features are elevated to a central design consideration, rather than an afterthought.
- Integrating broader 'biophilic design' principles into the design of the space of infrastructure, including moving beyond 'nature in the space' (natural features), to also ensure ‘nature analogues’ (natural patterns, forms and materials) and ‘nature of the space’ (nature based design-induced experiences that promote positive emotions) are achieved in the design.

In this section we outline the role of landscape architects in addressing these identified issues, or pain points in the urban environment. From concept design through to handover – landscape architects can champion the integration of biophilic
services through the city as means of fostering improved urban design and ecosystem health, which lends itself as fittingly complimentary to urban related professions that are also contributing to sustainable urban design. Landscape architects play a crucial contributing role in improving urban ecosystem health due to their knowledge of landscape integration in the built environment.

Previous research led by the first author has discussed the myriad of biophilic services that are capable of improving liveability in our cities, through social, environmental and economic improvements (el Baghdadi, 2016):

1. **Social improvements:** Human beings are physically, neurologically and emotionally responsive to cues in their surrounding environment (Ulrich, 1984; Kaplan and Kaplan, 1989; Kellert, Heerwagon and Mador, 2008). This further points to the prominent role of architectural and landscape design, which play a role in the sympathetic (and alternatively the parasympathetic) nervous system (Bengtsson, 2015) influencing people’s health and well-being. Dating back more than 20 years, seminal work in this field has found that higher stress levels reduce the body’s healing processes (Ulrich, 1984; Ulrich et al, 1991), this identifies the significance of designing spaces that make people feel better.

2. **Environment impact:** This method of planning is capable of providing local, state, and national governments with options to mitigate climate change (Newman, Beatley and Boyer, 2009), alleviate UHI effect (Nieuwolt, 1966; Roth, 2002), integrated water cycle management (Xiao and McPherson, 2006), and promote healthy environments for increased biodiversity (Alvey, 2006).

3. **Economic impact:** Various studies have also presented the economic impact of integrating nature into the built environment. Some of which include: reduce absenteeism (Elzeyadi, 2011; Romm and Browning, 1994), increase productivity (Bergs, 2002), reduce building energy demand (Graffin, 2005), increase food security (City of Sydney, 2014; Smit, Nasr and Ratta, 1996), roof longevity (Banting et al, 2005), infrastructure longevity (McPherson et al, 1997), increase property value (Laverne and Winson-Geideman, 2003; Benson et al, 1998), tourism (Chiesura, 2004), catalyse economic development (Terrapin Bright Green, 2012; Skyrise Greenery, n.d.), reduce traffic incidences (Dixon and Wolf, 2007), reduce healthcare cost (Thayer et al, 2010; Bedimo-Rung, 2005), and increase employment (De Sousa, 2003).

With this in mind, Table 1 highlights key challenges within the built environment, benefits of biophilia, and the role landscape architects can play as champions in addressing these within the design of cities.
Table 1. Identified challenges and opportunities for the profession to contribute to solutions

[Insert Table 1 here]

3. Undertake holistic design for biophilic services

In this section we discuss the opportunity to go beyond including incidental green spaces in and around buildings, neighbourhoods and cities, to undertaking holistic design that nurtures human and environmental health reflecting the innate human need to connect with nature. In particular, we argue the importance of locally optimised solutions that are inspired by local context and with a view of delivering biophilic services to achieve optimal project outcomes.

The theory and related design principles of biophilic design span more than three decades of action research over a variety of geo-political, built environment and climatic contexts. Biophilic design or biophilic urbanism continues to evolve as a concept to offer more intentional solutions to urban-related issues (el Baghdadi and Desha, 2016), with landscape playing a prominent role in serving as a framework indicating where to urbanise and to not urbanise, as well as how to urbanise (el-Baghdadi, 2016). Biophilic urbanism represents the idea of integration of urban nature into cities and proffers a design principle to inform intentional and functional use of biophilic elements, such as city and pocket parks, linear green space, and green roofs and walls in the built environment (Beatley, 2000).

Landscape architects through their professional training, collaborative approach and trans-disciplinary working are well equipped to take a leadership role in this arena. True collaboration requires dense interdependent connections, a high level of trust and frequent communication. Negotiated shared goals are driven by mutual self-interest and an appetite for innovative design solutions demonstrating social responsibility. There is a commitment and accountability to network with the community and stakeholders. The commitment is long-term, often high risk with opportunity for high reward and product innovation. Figure 1 illustrates how collaboration works within the landscape architecture field; whereas, Figure 2 demonstrates the collaboration cycle.

[Insert Fig. 1 here]

Fig 1. The cycle of collaboration

[Insert Fig. 2 here]

Fig 1. How collaboration works

Noting the need for a more strategic collaboration process that contributes to effective biophilic design, we propose a more rigorous process which can ensure externalities are carefully identified, solutions have been presented and projects goals are met. Responding to the need for trans-disciplinary teams to understand and apply this knowledge, we have developed an emergent process (see Fig. 3) to demonstrate the role landscape architects can take in
contributing to biophilic design within the urban environment.

[Insert Fig. 3 here]

**Fig 3. Strategic collaboration process to inform biophilic design**

As shown in Fig. 3, the landscape architecture profession needs a more integrated strategy to ensure spatial data is used suitably within the design processes to deliver a project that not only addresses the project brief but also strategically contributes to the built environment. We argue that an impetus to formally integrate ecology into decision making may be needed to encourage a deviation from the ad hoc and aesthetically driven implementation of landscape design and biophilic elements. The research of biophilic elements and their corresponding services (el Baghdadi, 2016) identified that demonstrating net public good from investment in a biophilic element was found to be possible using a number of approaches that range from a value driven analysis to an externality analysis as well as an ecosystem services analysis. This means that linking externalities with the corresponding biophilic service responsible for addressing this externality provides landscape architects with the necessary guidelines/scope to complete projects, whilst simultaneously address climate change consequences.

The three main components from Figure 3 are discussed below:

**IDEA: Project Concept Design Using Spatial Information Technology**

Spatial information technology offers opportunities to increase the visibility and appreciation of the urgency of the challenges facing cities by highlighting the deficit of current approach to urban developments. Utilising spatial information to identify externalities across the built environment provides impetus for recognising the systematic use of biophilic services throughout the city, or for a particular project, to help facilitate sustainable development. Ensuring landscape architects use spatial information appropriately during the project concept design stage creates opportunities to stimulate change in cities by converting an implicit recognition of externalities to an explicit conversation.

**PLAN: Project Design Development Using Biophilic Services**

Figure 3 highlights that an understanding of the taxonomy of biophilic elements along with their corresponding services offers opportunities to facilitate its effective use in the project concept design process for landscape architects. This is because this strengthens the project proposal by offering a menu of options tailored to address identified externalities, through spatial information technology, allowing landscape architects to consider this through the project design development stage.

**ACTION & OUTCOME: Strategic and effective communication**

Communicating findings clearly to the client and relevant stakeholder groups may inform and drive an agenda for change.
In comparing the current situation regarding ad hoc or aesthetically driven implementation of landscape integration, it is apparent that there is an opportunity to employ spatial information technology for communicating the role of biophilic services to encourage clients to accept a project proposal that not only addresses the project brief, but also contributes to climate change adaptation. Additionally, incorporating spatial information and biophilic services into the design process assists in communication in ways that are meaningful across disciplines which becomes important for effective collaboration across teams.

4. Implications for projects and professional practice

As climate change is now strongly influencing policy matters worldwide, landscape architecture should actively participate in the narrative to suggest strategies for sustainable design to tackle 21st Century related challenges due to ineffectual resource use and urban design. In this section we conclude with a discussion of the implications for design, and for professional practice, and several immediate actions.

Immediate action is required to demonstrate the interconnectedness of human actions, climate change and mitigating design solutions. Looking to nature for design solutions, adapting ecosystem services to the urban context and utilising nature’s ability to adapt to a changing environment should be clues to the way forward. These design solutions have to be evidence based, economical and require the support of local and world communities to be effective. In addition to technical knowledge, advocacy and leadership are required to inspire individuals, communities, industry and government to show social responsibility and take immediate responsible actions to support human and planetary health. It is clear that professional practice has much technical knowhow to contribute and has a responsibility to lead the discussion and the development of holistic design solutions.

Avoiding the potential for biophilic design to be regarded as no more than incidental green spaces in and around buildings, neighbourhoods and cities, landscape architects must intentionally consider the unique climate, landscape, and context, and design within this scope of natural elements as biophilic services to help address identified pain points in a city. This requires collaborative practice with architects, landscape architects, designers, engineers and other built environment professionals working together, accessing academic contribution to underpin evidence-based decision-making.

Abstract

Around the world, management and maintenance budgets for public infrastructure including parklands are steadily eroding with the increasingly expenditure on clean-up and restoration following extreme weather events. Without intervention, this trajectory of diminishing budgets has significant implications on the provision of community services and facilities. Community impacts of living with degraded and weather-impacted community-infrastructure, public open-space, and nature-reserves within our built environment call for a fresh approach. To combat these 21st Century challenges, innovative design approaches and design solutions are required. The authors propose the critical need for multidisciplinary teams producing transdisciplinary solutions, focusing on integrating biophilic design.

The paper draws on the authors’ lived experiences and workshops with more than 150 industry, government and academic colleagues in the biophilic urbanism field (2016, 2017) to discuss emerging consensus on how to move forward. This includes overcoming existing barriers to mainstreaming living infrastructure, and overcoming emergent barriers associated with diminishing budgets and changing risk profiles of public open space in our cities and surrounds.

The paper findings have immediate implications for advocating for management and maintenance budgets to prioritise restoration and rehabilitation projects that address future climate forecasts. The findings also have implications for clarifying the role for landscape architects to be working with engineers, public health and healthcare professionals, to ensure that design solutions meet structural (e.g. water inundation), epidemiological (e.g. water-borne illness), and psychological (e.g. mental wellbeing) performance requirements in this rapidly changing climate. The authors intend that the paper also sparks dialogue about effective spending on resilient infrastructure.
Keywords: resilience; biophilic cities; health and wellbeing

1. Introduction

Climate change is a game-changer and a risk multiplier. Cyclones and other extreme weather events are becoming more severe and both recovery costs and times are escalating for communities [1]. It follows then that increasingly limited funds will need to be used strategically to ensure future healthy and liveable cities of the future. Dzau et al [2] aptly refer to the saying ‘Never let a serious crisis go to waste’ when describing the opportunities created by disasters to plan for what we want our communities to look like as they recover, where forethought and development of a shared vision can capitalise on rebuilding opportunities towards resilience in our built environments.

Indeed the built environment – where people live, work and play – presents a crucial setting in which to focus our efforts to build resilience in the face of more severe weather associated with climate change. Greening our cities and incorporating restorative landscapes into urban design is becoming a well-recognised strategy being espoused and adopted to varying degrees worldwide. This is not a new concept but rather renewed in vigour, in the face of climate change impacts.

In the 1800s Fredrick Olmsdead, the father of American landscape architecture, long advocated for green spaces where people could recover from pollution, co-designing many well-known parks including New York’s Central Park. The intuitive rationale for urban greening is quite straightforward. Such landscapes provide a buffer to the ubiquitous biophysical and socio-economic stressors in highly urbanised environments such as higher temperatures, air and noise pollution, congestion, social isolation, multi-media bombardment and busy, stressful lifestyles [3,4,5].

Moreover, access to green and blue space in urban environments has been associated with a wide range of health benefits through measurement and quantification [6,7], and several systematic reviews, including a comprehensive summary of the available evidence by the World Health Organisation in 2016. These health benefits include improved mental health, reduced cardiovascular morbidity and mortality, obesity and risk of type two diabetes, and improved pregnancy outcomes (World Health Organisation, 2016). Current research has clearly moved beyond observing associations, with a greater focus on elucidating their nuances and the mechanisms through which these benefits are derived by different sub-populations in different contexts [8,9].

The benefits of urban greening are attracting the attention of professionals from a wide range of fields, including landscape architecture. These professionals often present with quite different paradigms, perspectives, priorities, foci and depths of inquiry. Furthermore, for a multitude of reasons, each professional discipline tends to talk to audiences from similar backgrounds, values, and perspectives, using familiar jargon and referring to their profession’s dominant paradigm. Silos between professional disciplines have limited the potential benefits of sharing insights between different disciplinary backgrounds [10,11]. In the case of city design, this has led to the default situation of piecemeal and rather disconnected urban design/redesign programs and the inefficient use of limited resources [12].
Within this context, this paper discusses the experience in using biophilic urbanism, which refers to the use of natural elements as purposeful design features in urban landscapes, to reach across multiple disciplines to address climate change issues in rapidly growing economies [13]. The authors present lived experiences in building resilience, through fostering communities of practice that work across professional disciplines to foster ‘nature and nurture’ outcomes in constructed spaces. In the following sections we summarise three events in Australia (2016, 2017) that brought together more than 120 industry, government and academic colleagues to discuss emergent challenges and opportunities for greening cities and fostering healthy, sustainable communities.

2. A Summary of Three Convergent Journeys

In this section we summarise three convergent Australian journeys of the paper’s authors, spanning public health and green infrastructure. Although event participants did not overlap, there are significant reinforcing messages apparent in each of the communities of practice. The three event organisers became known to each other through a common colleague (Dr Dominic Hes, Director THRIVE Research Hub, University of Melbourne) over the course of 2016, and only began collectively discussing the barriers and enablers to mainstreaming green infrastructure in cities in late 2017. In the following section we highlight the insights gained from considering the three events together.

2.1. Healthy Places, Healthy Communities International Symposium

In November 2016, this one day International Symposium held was organised by the second author of this paper (Dr Roiko), with a team of four academics from different schools within the Health group at Griffith University on the Gold Coast who had fortuitously discovered a mutual interest in this transdisciplinary space. With the theme of ‘Cultivating Healthy, Sustainable Communities through Environmental Connections’, the symposium explored two main themes: Linking climate, environment and human health: Case studies to big data and Designing healthy, restorative environments.

Four internationally-renowned keynote speakers from diverse backgrounds shared their experience and insights: Prof. Michael DePledge (European Centre for Environment & Human Health, Exeter University); Professor Pierre Horwitz (Centre for Ecosystem Management at Edith Cowan University); Dr. Chinmoy Sarkar (HKUrbanLab, University of Hong Kong) and Dr. Shaneen Fantin (People Oriented Design, Cairns) They showcased exemplars of new ways of working that can produce major shifts in our knowledge about complex and multi-scalar health responses to the environment.

With the aim of initiating and building a broader network of professionals interested in building healthier, more resilient communities through connections with nature, this event was aimed at and attracted a diverse audience of around 70 academics,

The symposium featured breakout sessions, panel discussions and, importantly, time for mingling and networking. The symposium also provided the stimulus for more intensive workshop discussions with a smaller, invited group of approximately 25 participants from government and academia over the following two days.

Over the three days, individuals from diverse backgrounds worked in small groups to explore themes introduced by the keynote speakers and their ideas were then shared with the larger group and recorded. Groups were also tasked with articulating a key research problem with two research questions and approaches to addressing them. Space precludes a discussion of this rich dialogue but several key findings that are directly relevant to the focus of this paper are as follows:

- We need to be cognisant of past, present and emerging challenges at the environment-health nexus and it is vital to bring indigenous knowledge and different world views and paradigms to the table.
- Everything is connected yet developing collective understandings and being funded to work together to solve problems is made difficult by fragmented organisational structures and discipline-focused funding models.
- Researchers need to acknowledge communities and listen, employ mixed-methods of research and learn how to...
communicate complex issues in effective ways that influence people.

- We need to be leaky at the boundaries, recognising that solutions and strategies come from many disciplinary perspectives.

2.2. Biophilic Urbanism in the Tropics Symposium (BUTS)

In March 2017, driven through direct requests from colleagues around Australia and emerging healing gardens research agenda (Nieberler-Walker, 2015, 2017, a national Biophilic Urbanism in the Tropics Symposium was convened in Brisbane (Queensland, Australia) to share what has been, and what could be in future. Organised by the first, third and fourth authors of this paper (Desha, Nieberler-Walker, el Baghdadi), the one-day event was hosted at the Griffith University Eco-Centre. The profile of the 39 participants is summarised in Table 2 by sector, and in Figure 2 by professional discipline.

Figure 2. Disciplinary background of participants (Biophilic Urbanism in the Tropics Symposium)

Of interest to the authors is the relative lack of landscape architects attending the event, despite the snowball (word-of-mouth referral) approach to inviting participants to attend. Participants were predominantly from science, business and engineering backgrounds, who then provided reflections on the importance of all professions including landscape architecture.

Discussions spanned hearing about key activities in Australia and globally, and interactive sessions to discuss priorities going forward. With a facilitated panel on ‘Industry in Action’ followed by an interactive session on ‘Linking Biomimicry with Biophilic Urbanism in the Tropics’, the event was used to launch the Queensland chapter of the national Biomimicry Network Hub. The event also included an acknowledgement of the life and contribution of Professor Stephen Kellert (1957-2016), who over the course of his career inspired several of the attendees to take on leadership roles within the biophilic urbanism community of practice in Australia.

During the final session on ‘Looking Ahead – Vision for the Future’, participants distilled the ideas of the day into several key
actions going forward, related to embedding nature within urban design towards biophilic outcomes:

- To catalyse health and wellbeing in our interconnected living and physical systems
- To advocate that a resilient and thriving future is possible
- To leverage ecological intelligence and influence socio-ecological potential in cities.
- To bring the national community of biophilic urbanism practitioners together for the first time

2.3. Designing Cities that LOVE Nature – Community Event (DCLN)

In July 2017, Tim Beatley, (a colleague of Professor Kellert, fellow pioneer in biophilic design and author of *Biophilic Cities*), visited Perth, Western Australia. He offered to speak at a community event on the topic – *Designing cites that LOVE nature*. The fifth author of this paper (Söderlund) organised the event with sponsorship by the Australian Institute of Architecture (AIA) and Regional Development Australia Perth (RDA).

Although with a very short lead in time, and limited advertising, the event still attracted 71 attendees on a stormy winter’s night, signifying the interest in the integration of nature in cities. The attendees included architects, landscape architects, academics, local government, non-government organisations (NGOs), interest groups, activists and interested citizens, as shown in Table 3.

</tr>
</tbody>
</table>

![Figure 3. Disciplinary background of participants (Designing Cities that LOVE Nature)](image)

The prime concern which emerged was the rapid loss of nature through infill and frustration was expressed both by local government and community about the lack of regulations, particularly regarding tree loss. Although participants had attended the event due to their interest, the passionate depth of concern and desire to retain and increase nature in the city was compelling.
Beatley suggested the formation of a Biophilic Perth group and there was immediate positive response with many hands going up followed by 52 people signing to the group and a steering committee of ten being formed.

The key learnings that can be summarised by the experience of this event are as follows:

- People from diverse disciplines can be united through a common goal and participate in constructive conversation.
- Across diverse disciplines there is a strong and passionate recognition of the necessity to urgently retain and increase nature in cities for liveability, particularly with rapidly changing climatic parameters.
- More cross-disciplinary collaborative conversations are needed, facilitated by supportive organisational structures and funding.
- Professional, government and research disciplines need access to community conversation in forums that acknowledge ‘the wisdom of the masses’ while communicating the complex issues.

There was a significant practical outcome from this event in the formation of Biophilic Perth as a branch of the global Biophilic Cities network. Represented within the committee is academia, local government, landscape architects, industry and NGOs, all in senior roles and/or with major businesses. The group has met regularly and held well attended events. A presentation and discussion event held in Fremantle, Western Australia in 2017 included senior academics and the Mayor. Since this event, the City of Fremantle joined the global Biophilic City network by signing a pledge committing to biophilic initiatives (April 2018). They are the first Australian city to become a member.

3. Emergent lessons, challenges and opportunities

Looking across the events described above, the authors have independently reflected on and collectively discussed the connections and similarities across the professions’ consideration of urban greening. The first challenge in these discussions was to overcome professional-language barriers, where a variety of theoretical constructs have been used to discuss the role of nature in built environments. For example, addressing the distinguishing features of what it means to have successful ‘green space’, ‘public open space’, ‘recreation space’ etc, occurs differently for landscape architects, engineers, planners, designers, and health professionals.

In the following sections we discuss the variety of theoretical contexts observed during the three events, which span a number of key theories. This has helped to understand and connect language and concepts. We also describe three principles for professional practice that have emerged from discussions, towards fostering healthy and resilient outcomes in planning and design.

3.1. Relationships between theoretical contexts

Reflecting on dialogue at the three events described above over several online and teleconference sessions (August 2017 – March 2018), the authors have synthesised a map of key theories informing research and practice for resilient and healthy cities over the last 20 years, shown in Table 3. In this
case the ‘Built Design’ profession refers to professionals involved in the creation or modification of infrastructure spanning buildings, parks, services delivery (such as energy, water, and waste) and transportation systems. The ‘Public Health’ profession refers to professionals involved in protecting the safety and improving the health of communities, spanning education, policy making and research for disease and injury prevention.

3.2. Emergent principles for professional practice

From these learnings, three organisational principles are proposed for greening cities towards healthy and resilient outcomes, as described in the following paragraphs. These are intended to bring together the learnings from the built environment and health professional disciplines, to create and evaluate transdisciplinary solutions with urban greening outcomes that are technically feasible, economically viable, safe and conducive to wellbeing.

1. Leadership in multi-disciplinary work environments

This principle is concerned with the importance of leadership in walking the talk of collaborative work environments, including clarity around the intent of the planning or design, who should be involved, and processes to be used. Teams with representatives from multiple professions, and spanning industry and academia, with co-location, considering design as an iterative process. Leadership is critical in for example defining the extent of community engagement, the extent of plastic versus real plants, the boundaries of a whole of life analysis versus short term benefits, key elements of garden design, and the need for data capture including clinical analysis of patient responses to green infrastructure.

2. Collaborative enquiry enabled by technology

This principle is concerned with the importance of using technology to model, visualise and communicate opportunities for urban greening, helping to maximise efficiency and reduce costs. For example, using parametric design in curvilinear high-rise buildings, using drones for vertical
green wall maintenance, optimising irrigation systems in green walls taking into consideration the need of each plant in unique conditions for design, using algorithms to inform green infrastructure design, like data informs the strength of the building pillars and foundations, and using geospatial information to run place-based scenarios to guide decision-making.

3. Systems thinking towards transdisciplinary solutions

This principle is concerned with the importance of systems thinking, considering the world as interconnected and interdependent systems that create conditions conducive to life. As described by Acoroglu [31], this includes social systems (rules and structures such as education), industrial systems (manufactured and man-made components), and ecosystems (natural services such as air, water and food). An example of a solution informed by such thinking includes the Blue Health International Project [32], Healing Gardens [33, 34, 35], and normalcy [36].

4. Conclusions

There is an urgent need to overcome existing barriers to mainstreaming green – otherwise known as living – infrastructure, and overcome emergent barriers associated with diminishing budgets and changing risk profiles of public open space in our cities and surrounds. The three principles presented can guide strategic and adaptive actions to green our cities towards nature-loving – or biophilic - outcomes, including the adoption of nurturing ‘design for wellness’ – or salutogenic – approaches to design. Sustained multidisciplinary dialogue, a systems-based approach and collaborative planning and design are critical to such success.

This vision for salutogenic solutions has implications for the way we design our built environment to accommodate unpredictable future impacts including catastrophic weather events. Design inspired by natural systems and their approach to resilience and recovery can lead the way. Our city designers and builders must collectively ask, ‘How can we use natural systems and adapt elements of these natural systems to protect physical assets and provide us with an environment that helps us recover mentally and psychologically?’

The paper findings have immediate implications for design professional bodies in advocating for management and maintenance budgets to prioritise restoration and rehabilitation projects that address future climate forecasts and population growth. For decision-makers in government, there are urgent implications in removing existing barriers to mainstreaming living infrastructure, and overcoming emergent barriers associated with diminishing budgets and changing risk profiles of public open space in our cities and surrounds.

For industry professionals, the obvious challenge is about optimising design for green outcomes, through evidence-based design. The knowledge required to design these integrated systems is complex and relies on interdisciplinary collaborations. This provides an opportunity for transdisciplinary professionals such as landscape architects to take a leading role. This leadership requires technical and practical knowledge and the ability to inspire others to work together.
The findings also have implications for industry in clarifying the role for landscape architects in urban planning, design and construction projects, working with engineers and healthcare professionals, to ensure that design solutions meet structural (e.g., water inundation), epidemiological (e.g., water-borne illness), and psychological (e.g., mental wellbeing) performance requirements; building healthy and resilient communities in this rapidly changing climate.

Acknowledgments

The authors acknowledge the support of the Griffith University EcoCentre in hosting the 2017 Biophilic Urbanism in the Tropics Symposium, and the catering sponsorship of Conrad Gargett. We acknowledge funding provided for the 2016 Health Places Healthy Communities International Symposium by the Menzies Health Institute Queensland, the Cities Research Institute, the Griffith University Climate Change Response Program and the School of Medicine; and the efforts of the coordinating team, including Professor Elizabeth Kendall, Dr Jennifer Boddy, and Professor Scott Baum. We also acknowledge funding provided for the 2017 Perth Biophilic Cities events, in particular Curtin University and Professor Peter Newman. Finally, the authors thank Dr Dominique Hes for her continued insights into interdisciplinary learnings, which inspired the dialogue between organisers across these three Australian events.

Research on the Influence of Green Space Intervention Affecting Depression Recovery: Effective establishment of a virtual scene model

Yang Yu* Xindi Wanga Xueling Ma b Wenqiang Xiang b

*a Harbin Institute of Technology, No.66, West straight street, Nangang District, Harbin, 150060, China

b Harbin Medical University, No. 157, Health Road, Nangang District, Harbin, 150060, China

Abstract

With the booming of society, the tense pace of life has made people's tremendous mental pressure, which triggered many mental health diseases. Depression is not only a common psychological disease in the general population, but also a complication in the healing process of some diseases. At present, green space has been proved to play a crucial role in improving mental health through contacting, viewing and other activities. Therefore, the intervention of green space is potentially useful to cure depression. Using the patients with depressive tendency during the recovery from stroke as the experimental subjects, we study the spatial preference through depression scale and spatial scale in the first early stage. The design elements with the most influential and well-defined factors in green space design are finally determined for the rehabilitation of depressed patients. The results show that patients reject busy space subjectively, while are fond of tranquil space, which has significantly therapeutic effects on depression. Through data and literature, the research puts forward constructive elements and key points of designing effective virtual reality scene model. An evaluation is made of the ability of the information presented in landscape visualization model to meet criteria of credibility, salience and legitimacy when communicating with stake-holders and responding users. These focus on the need for applications of 3D visualization models to be more systematically evaluated, ideally as part of landscape planning exercises where the benefits of particular models for different purposes and audiences are examined across all stages of the decision-making process.

1. Introduction

According to the latest data from the World Health Organization, the global incidence of depression is 3.1% [1]. According to incomp
more attention to their own mental health. At present, a plenty of studies have confirmed that long-term exposure to green spaces imposes a positive effect on depression³. Therefore, actively improving urban green space plays a decisive role in promoting urban livability as well as public mental health. As Barton said: “Environment that promotes healthy activities is the highest ideal of environmental design⁴.”

Research on depression and green space at home and abroad mainly revolves two main aspects. On one hand, it clearly confirms the correlation between depression and green space. Judging from the quality of space environment alone, there is a significant correlation between the daily exposure of young people and the daily mood⁵. There is a potential protective effect of green space on adult depression⁶. At the same time, the poor housing environment and lack of green space are all related to the generation of depression⁷. Mark S. Taylor et al. studied the relationship between tree density in the streets of London and the prescription rate of antidepressants. For each additional kilometer of street trees, 1.18 prescriptions were reduced for each additional unit of trees, confirming that green space has the effect of slowing down depression⁸. The incidence of depression in people living in regions with higher NDVI is lower⁹. In a study in the state of Washington, USA, it illustrates that the larger the urban green area, the fewer the number of consultations on anxiety and depression symptoms¹⁰. On the other hand, based on the recovery of green space, the researchers explore the relationship between physical activity and depression in the green space and try to use it as a new means of treating mild depression. The study indicates that although watching green for a short period of time has the effect of restoring depression, more effective plans need to be prepared through regular physical activities¹¹.

Research on the relationship between depression and green space is currently focused on a qualitative level, clearly confirming that green space can improve people's depression, and long-term exposure to green space is able to reduce the prevalence of depression¹²-¹³. In the past decade, many quantitative studies on space design and planning have adopted landscape visualization technologies, including photographs, paintings, and virtual reality models. One of the main advantages of using visualization research is that it provides a "common language" that all parties can communicate with¹⁴. Stephen establishes landscape basic elements including terrain, vegetation, and water visual representation techniques through digital landscape models to solve abstract problems¹⁵. Neuenschwand-er puts green space type maps and pattern designs into a parametric modeling and visualization chain, realizing the 3D visualization of the green space model as well as exploring the relationship with the ecosystem indicators¹⁶. Leiqing Xu and others use VR scene to experience the influence of building interface and green virtual rate on the streets¹⁷.

From the arguments of the above article, we can find that the overall research results show that the urban environment has a measurable connection with depression. At the same time, the visual scene model is a necessary method for further research in the future. While there are still many problems to be solved in the study of green space with the
recovery of depression as the core: 1) The characteristics of spatial elements in existing green space are inconsistent and cannot be directly used as test scenes, making quantitative research unable to control variables and embodying key influences of elements. 2) Relying solely on photos or videos, the subject’s actual experience is weak. The size and distance of the space do affect the emotions of the participants. Single visual experiences cannot change people's emotions and feelings apparently. Therefore, it is necessary to establish a virtual reality scene model according to the corresponding purpose of research in order to do researches deeply.

2. Methods

2.1. Procedure

The study first selected suitable subjects. Subjects are needed to have depression or obvious depression. Then, through the space scale and in-depth interviews, the necessary components in the scene model are identified. Because some of the questions in the space scale are more abstract and professional, it is necessary to add reference pictures. In the process of in-depth interviews, interviewing the interviewees about each image he has selected is to further explore the information while also ensure the authenticity of the scale. Use the literature to support the metrics that need to be quantified in the scene and give a reference range. The organizational principles of the model are proposed to provide a basis for the same research model of the scene, so that the follow-up can be continuously improved (Figure 1).

2.2. Choosing respondents

This study uses the authoritative Hamilton scale in the medical field to determine the degree of depression of patients based on scores\[18\]. Then, in-depth interviews are conducted on patients with more severe depression as well as a spatial scale is used to determine spatial features that positively affected the patient's depression. As in the field of landscape architecture, spatial elements will change with the specific research purposes. So there is no space scale that fully meets the objectives of this study. Therefore, based on the necessary factors in the design of green space, the study focuses on the design of a spatial scale from the aspects of spatial characteristics investigation and the influence of spatial factors on the

---

![Diagram of Procedure Sequence](image_url)
effects of depression. Through the data collected, the reliability test and in-depth analysis are performed. Factor analysis is used to determine the design factors in the design of a quiet environment that can promote the recovery of depressed patients with the greatest influence.

In the course of the experiment, a total of 11 patients with scores of 8 points or more are screened through the Hamilton scale, and all patients are post-stroke depressive patients. Six of these patients scored 20 points or more and are diagnosed with severe depression. In the process of conducting in-depth interviews with them, focusing on their preference for spatial characteristics due to the fact that their results are representative.

3. Results

3.1. Research data

For the characteristics of spatial features, we investigated the type which is regarded as recreational space frequently and enjoyed by depressed patients. Nine individuals choose the green space in the community, while only one person like to go to the park since he is a photographer. The distance to the green space is within walking distance. The type of activity in the space is only walking. Occasional meeting with acquaintances will have conversation activities, but they will not take the initiative to chat with strangers. There are two persons spending less than twenty minutes in activities. Six interviewees spend twenty to forty minutes and two people take forty to sixty minutes on physical activities. Good-looking flowers or trees of landscapes are viewed outside the landscape and will not be entered. In the choice of the walking path, 60% of people like the deep path, and 40% of people tend to choose straightforward and clear road. For the waterscape type, 80% of people think that watching static water will relax themselves, and 20% of them feel relieved by watching flowing water (such as fountains and stacked water).

In terms of the spatial type preferences, ten subjects choose a tranquil space, and the research finds that they refuse lively spaces through interviews. If they run into this type of space in their lives accidentally, they will deliberately avoid it, otherwise they will feel distraught. For the description of the characteristics of tranquil space, 71% of respondents suppose that there should be sufficient lighting. 57% of people think that there ought to be a static waterscape and a large range of lawns. Everyone thinks that the space needs to be open and the line of sight is not obstructed.

3.2. Spatial features and characteristics

In the initial in-depth interviews and experiments in the space scale, we obtain more valuable results. The spatial preferences of depressive patients are measured more comprehensively, and the consistency in the selection of spatial features is demonstrated. Necessary factors in the green space include vegetation, roads, water features and activity venues. The characteristics of these types of spatial elements are clarified in the process of questionnaire surveys and in-depth interviews and are used to construct scene models. See Table 1.

4. Discussion

4.1. Key points of model construction

Through the determined spatial feature survey and detailed emotional experience interviews, the spatial model's pertinence and comprehensiveness can be better balanced. Different from ordinary standard spatial model design, interviews based on people's preferences and real emotions are more likely to make the model closer to the ideal experimental scene, which results that researchers can more accurately test the effect of the depressive healing of the designed green space. For the above spatial elements, the following points must be noted during the construction of the scene model:

1) For the design of vegetation within the spatial model, the planting layers must be focused. In the actual scene, many green space plants are designed to meet the standard green land coverage index and a large number of unapproachable ground cover plants are used in space. These ground cover plants are usually not seen. They are also completely incapable of healing the green plants. According to a study by Jiang Bin, the tree cover density ranged from 24% to 34% has obvious stress and emotional recovery effects\(^\text{[25]}\). Meantime, the study presents that depressed patients like to watch outside the vegetation, rarely enter it. Therefore, in the model, in line with the above indicators, it is necessary to cleverly and rationally collaborate with the plant hierarchy to make it visible as far as possible.

2) When plants are used to surround the space, according to the results of the questionnaire, depressed patients prefer to enjoy flowers and lawns to make their mood pleasant. In the scene model, the proportion of flowers and lawns can be appropriately increased. The scale of the lawn should be within 200 meters of the side, that is, the ratio of the width of the lawn to the height of the surrounding trees should not exceed ten. In this case, the vertical viewing angle of people will be more comfortable\(^\text{[26]}\). When the height of the enclosing wall in the space is equal to the ratio of the distance between the man and the enclosure is 1:1, and the horizontal line of sight and the angle between the eaves are 45 degrees, a good sense of closure can be generated at this time\(^\text{[27]}\). Thus, the plant height of the enclosing space is suggested to refer to this standard.

3) Combining the result that most depressed patients would like to enjoy a tranquil atmosphere, we are designing a virtual reality scene that can appropriately add birds, water features and music to reduce the noise made by humans. According to Germán’s study, natural sounds can increase people's mood, especially the sound of water\(^\text{[28]}\). Therefore, it is possible to mix slowly flowing waterscapes at appropriate locations. In addition, the roads in the space should be mostly open and semi-open. The path length should be 30m-50m, the width ought to be 0.9m-1.2m. What’s more, the number of road turns should be 4-6 times to achieve the goal of tranquil atmosphere\(^\text{[29]}\).

4) The number and size of scenes in the model need to be considered. In the in-depth interviews, patients with severe depression are more likely to have large fluctuations in mood. Therefore, the experiment needs to be completed as soon as possible. Most patients will choose to relax in a small green space within 10 minutes of the house or downstairs. As a result, the designed model scene should not be too large and need to meet the green space specifications in the community appropriately. Professor Zhu Junzhen defines a garden space of less than 700 square meters as a small garden space in the Miniature Garden\(^\text{[30]}\). According to the urban road greening planning and design specifications,
the width of residential green space should be greater than twenty meters\[^1\]\[^{31}\]. In the book *<External Space Design>* , Ashihara Shinyi points out that the most comfortable external space size is 20m\(^2\)*20m or 20m\(^2\)*25m\[^{32}\]. The size of the model scene can refer to the above specifications.

4.2. Application and improvement of scene model

The virtual reality scene model obtained in the research can be used to explore the value and function of green space health services. In the process of experiencing the model, the participants' actions and movements in the real scene can achieve almost the same results. Through interviewing patients with severe depression, Sims-Gould finds that patients with emotional disorders need to formulate physical activity plans based on potential preferences in the green or blue space, which contributes to the recovery of the condition\[^{33}\]. Therefore, this model can be used not only to verify the healing effect of this spatial interventional therapy but also to explore the influence of physical activity on depression. The spatial elements and characteristics in the study are selected according to the preference of the subjects with more obvious and serious depression, which are more targeted. In the later period of study, while increasing the sample, it is also crucial to add a person with normal mood or depressed mood as a contrast group to explore whether there is a significant difference in terms of spatial perception and spatial preference. Adjusting the scene model according to the research results makes the study more comprehensive and rigorous.

Although this research establishes a virtual reality scene model for environmental experience through experimental data, it can determine the basic features of the functional space for depression healing. However, as a preliminary study of a small sample, the current research still has some problems. The quantitative evaluation of the research still requires more rigorous experimental control and full-sample experiments. 1) Since there are too many elements in the environment, and each element is depressive emotional influences. Therefore, follow-up research should focus on a single factor, exclude other factors from interference, clarifying the role of each kind of spatial element in depressive emotions as well as making future designs have accurate reference. 2) Some clear quantitative criteria for spatial elements need to be given. For example, green coverage is an important indicator of green space, but the traditional norms do not consider the healing function of plants, which leads to that existing indicators cannot be used directly. We need to re-explore what extent of green in the experiment is most helpful for people's depression.

5. Conclusion

On the one hand, the research grasps the basic spatial features that should be possessed by the green space with depression healing function, and define which spatial features can attract depression patients to relax. On the other hand, according to the results of the questionnaire and the literature, the main points of constructing the virtual reality scene model are put forward. The scene model can enable the depressed emotional patients to truly experience the space for further follow-up research.

The virtual reality scene model in the future research can be combined with technologies such as geographic information collaboration platform to create an overall outdoor design experience system while enhancing the realism of the scene. Researchers use GIS to simulate the lighting and pedestrian dynamics in real scenes, so as
to provide a better quantitative reference for planning and design.

Study on Ecological Sustainability of Rainwater Garden Oriented by Soil Health

Lusi Zhang, Xin Jiang, Yang Yu

School of Architecture, Harbin Institute of Technology, Harbin 150006, China

*Corresponding Author, E-mail address: yuyang88@hit.edu.cn

Abstract

Soil health is an important property of the rainwater garden ecologically sustainable. And it is one of the important factors that determine the quality of rainwater garden. However, there are many problems in soil research, such as the multidisciplinary nature of soil research, the richness of soil health assessment methods, and the diversity of soil itself. As a result, our understanding of soil health is inadequate and there is a lack of quantitative criteria for soil health indicators. In this paper, we summarize the following aspects of research on the soil health of rain garden. The first is the effect of soil health in rain garden; the second is the influence factors of soil health in rain garden; the third is the assessment and management of soil health in rain garden. The study found that the efficacy of soil health in rain garden is reflected in five aspects: soil water permeability, water holding capacity, net water resistance, erosion resistance, and soil nutrients. The quantification criteria of soil health indicators are determined by the soil site conditions and the nature of the soil itself. In addition, the soil health index is not only an important factor in the ecological sustainability of the rain garden, but also plays an important role in the ecological sustainability of other disciplines such as urban planning, green buildings, and urban agriculture.

Keywords: Landscape Architecture; Rainwater Garden; Soil Health; Ecological Sustainability; Soil Health Index

Fund Items: National Natural Science Foundation of China (No. 51578173); National Natural Science Foundation of China (No. 51678180)
1. Introduction

The rapid growth of the population in the modern world has caused a shortage of water resources. At the same time, urban rainwater flooding and water pollution have caused huge environmental pressure on cities. In order to cope with urban stormwater problems, various countries have put forward relevant policies, such as the United States’ Best Management Practices (BMPs) and Low Impact Development (LID), New York State's “Zero Water Inundated City” Program (ADC), and UK Sustainable Drainage System (SUDS), etc. China vigorously promotes the construction of sponge cities. Due to the large geographical area of China, the construction of sponge cities will involve different site types, scales and environmental conditions, etc. Therefore, the construction of sponge cities will provide rainwater management and policies for other countries and regions. Formulation plays a role as a reference.

Green infrastructures such as rain garden, grass-grass groves, and biological retention ponds act as small “sponges” that use plant, microbial, and soil properties to remove contaminants from surface runoff and supplement groundwater. China vigorously promotes the construction of sponge cities. Due to the beautiful appearance of the rain garden, it is widely used in various countries and regions. The ecological effects of Rainwater Garden have been widely proven, but the construction of rain garden in recent years has raised the problems of high maintenance costs, poor ecological benefits, and low pollutant removal efficiency. Therefore, related designers and managers are paying more and more attention to their ecologically sustainable construction and management issues. Nature-based solutions NBS (Nature Based Solutions) are now encouraged to improve the sustainability of rainwater storage systems by promoting ideal soil and landscape functions. The purpose of soil is to improve soil health and its ecological function. The landscape is mainly connected through the landscape, increasing soil moisture and reducing soil erosion, thus achieving sustainability.

Soil carries many ecological functions such as water seepage in rain garden, reduction of runoff pollution, and reduction of surface runoff. If it is not maintained, a series of management measures must be adopted to restore and improve the soil function, which will inevitably increase the investment in rainwater garden production, and it will also pollute and destroy part of the rainwater garden ecosystem and environment. In order to effectively manage and use the soil health of rain garden, reduce investment, and maintain their ecological sustainability, it is necessary to analyze the ecological efficacy and influencing factors of soil health. In order to take correct soil management measures and maintain the ecological sustainability of rain garden.
2. Rainwater garden and soil health research process and hot spots

2.1. Research methods and data sources

This article uses CiteSpace and Vosviewer analysis software, based on the Web of Science database, Rain Garden OR Bioretention and Soil Health as a search keyword. A total of 696 related documents, through analysis, objectively summed up the study of soil health in the rain garden area hot spots.

2.2. Year of publication and subject research direction

From the perspective of the number of issued documents (Fig.1), the related research in the garden of rainwater and soil health started in 1990. And it has continued to grow substantially since 2015. Major research disciplines include Environmental Sciences, Ecology, Engineering, Water Resources, Architecture, Agriculture, and Plant Sciences (Fig.2).

2.3. Regional and research hotspots

From the analysis of the national time zone analysis chart (Fig.3). The U.S. has a leading academic role in the field of research on rain garden and soil health. And its achievements are significant and widely used. Followed by China, Australia, Germany, and the United Kingdom. From the perspective of keyword clustering analysis (Fig.4). The research hotspots at various time periods in the research area of rainwater garden and soil health involve Tree species, Bioretention Cell Design, Bioretention System Research, and Sustainability Comparison, etc. There are obvious cross-cutting phenomena in related research.

2.4. The analysis of research frontier

Through the topic relationship diagram (Fig.5). The findings of the study focused on low-impact development, stormwater management and performance, which involved different manifestations (Rainwater garden, Bio-retention facilities, Green roofs, etc.); different influencing factors (Scale, Surface runoff, Soil, etc.); different effects (Rain collection, Adsorption, Water quality improvement, etc.).
Fig. 3. National Time Zone Analysis of Rain Garden and Soil Health Sources

Fig. 5. Rainwater Garden Soil Health Research Frontier Thematic Diagram

Fig. 6. Rainwater Garden Soil Health Study Cluster View

Discovered by the keywords clustering view (Fig.6). The frontier areas of Rainwater garden and soil health research can be summarized in the following three aspects: 1) The research on the efficacy of soil health in rainwater garden includes Retention, Adsorption, Pollutant Removal, Phosphorus, and Heavy Metals. 2) The factors of the impact of rainwater garden on soil health include Land-use, Vegetation, Species Richness. 3) The hotspots of research on sustainable management measures for rainwater garden based on soil health include Stormwater Management, Low Impact Development, Green Infrastructure, etc.

3. Soil Health and Sustainability of Rain Garden

3.1. concept of soil health in rainwater garden

Soil health and soil quality are closely linked and both have similar meanings[14-15]. Carter[16] believe that soil health can describe the dynamic state of the soil in a short period of time. Therefore, soil health mainly refers to the physical, chemical, and biological properties of the soil. To date, there is no unified standard for soil health[17]. Broadly defined soil health refers to the ability of soil as a living system to maintain biological productivity, promote
environmental quality, and maintain animal and plant health and human health. In this sense, soil health and ecological sustainability are synonymous\cite{18-20}. In general, healthy soil should have the following characteristics: soil layer with sufficient thickness for plant growth, adequate but not excessive amounts of nutrients, excellent drainage, and certain resistance to adverse environments\cite{17}, etc.

For the soil health of the rain garden, it is not exactly the same as the green soil type of healthy soil. It focuses more on the ecological efficiency of rain garden and on the sustainability and sustainability of the soil. It not only provides plants with space for growth and nutrition, maintains diverse biological communities, but also meets rainwater garden to store rainwater and reduce surface runoff. Purification of runoff pollution and other ecological effects\cite{9}. Maintaining the soil health of rain garden has important implications for maintaining the ecological sustainability of rain garden.

3.2. Ecological efficiency and influencing factors of soil health in rain garden

1) Soil permeability in rainwater garden and its influencing factors

Rainwater Garden can significantly reduce storm runoff. The merits of soil permeability directly determine the construction area and operating performance of Rainwater Garden\cite{21}. Therefore, determining soil permeability is the key to planning and maintaining the sustainability of rainwater garden\cite{22}. The soil permeability is affected by many factors, and the plant roots obviously help to increase the permeability of the soil and facilitate its self-recovery\cite{23}. Soil properties such as soil organic matter, bulk density and agglomerate size also affect soil infiltration characteristics\cite{24-25}. It can be seen that the permeability of rainwater garden soil not only depends on the structural properties of the soil itself, but also depends on its joint action with the rain garden plants, including root density, plant species, planting patterns, vegetation coverage\cite{26}[56], etc.

2) Soil Scour Resistance and Its Influencing Factors in Rain Garden

The rainwater garden can reduce the surface runoff velocity, and the erosion resistance of the soil can reduce the erosion of the rainwater on the soil and plants. Thereby realizing the process of natural penetration and natural purification of the rainwater garden\cite{35}. In terms of soil erosion resistance, soil use, planting methods, soil cover width and slope all have an impact on soil erosion\cite{27-28}. Precipitation and basic soil properties are the main predictors of runoff coefficients and sediment yields\cite{29}. For the rainwater treatment facility's soil, the slope of the terrain, the width of the cover layer of the soil, and its own properties all play a major role in combating the erosion of rainwater. But in terms of the interaction of the soil and the plant, with the increase of the plant root biomass, the soil Erosion resistance also increases\cite{30}.

3) Soil Water Purification and Its Influencing Factors in Rain Garden

Rainwater Garden can reduce runoff pollution and achieve natural purification of urban rainwater. Soil, as an important component of rainwater garden, can effectively purify rainwater quality\cite{31-32}. The purification of pollutants in the soil mainly depends on the plant roots, and the
developed root system can enhance the removal of pollutants from the soil. Rainwater garden in terms of rainwater runoff purification, soil purification measures can be cut from the source, controlled in the middle, and processed by the terminal. This part is inseparable from the plant root system. Heavy metal, flooding, waterlogging, and other contaminated rainwater runoff will have an impact on plant growth and soil properties. The plant roots can act as a pollutant adsorbent, filter, and retain. This in turn protects the stability of the soil properties. For some stormwater runoffs with relatively low concentrations of pollution, they are directly purified through the soil or mixed with other sand, pebbles, and peat to enhance the ability to remove pollutants.

4) Soil Water Holding Capacity and Its Influencing Factors in Rain Garden

Rainwater garden can retain and save rainwater. Soil water retention capacity is an important indicator of soil moisture and plant growth. It affects the dissolution and transfer of nutrients in soil. The soil porosity and the average weight diameter of the soil aggregates are the main factors affecting the soil water holding capacity. Soil biochar produced at higher temperatures has higher water holding capacity. In terms of water retention in rain garden, the nature of the soil is a direct factor, and rainfall, topographic gradients, and underground biomass are also closely related to soil water retention. The catchment area has a steeper slope, a thicker soil thickness, and a stronger soil water holding capacity.

5) Soil nutrient and its influencing factors in rain garden

Soil nutrients provide nutrient elements for plant growth and microbial survival in rainwater garden. And the ecological effects of the plant root system and its own function in rain garden have a direct impact on the clean water properties, water permeability, and erosion resistance of rainwater garden. Therefore, soil nutrients are important factors for ecological sustainability of rain garden. The soil nutrient in the rain garden is not only closely related to the nature of the soil itself, but the runoff of the rainwater also causes the loss of soil nutrients, which is significantly related to the rainfall and rainfall height. In addition, the number of animals and plants on the site will also have an impact on soil nutrients. The distribution pattern of plant roots in the soil profile is the determinant of plant nutrient acquisition.

In general, soil is used as a rainwater infiltration channel for rainwater treatment facilities such as rain garden. Soil health is generally reflected in five aspects: soil permeability, erosion resistance, detergency, water holding capacity, and soil nutrients. Its performance is not only dependent on the structural nature of the soil itself, but also the interaction between the soil and the plants on the site, the slope of the terrain, rainfall and other conditions have important influence on the ecological efficiency of the rainwater treatment facilities.

3.3. Sustainable Rain Garden Soil Health Evaluation and Management

1) Soil health assessment status
The Cornell Soil Health Assessment evaluates traits, functions, and conditions of farmland soils\(^{50-51}\). The existing two sets of landscape performance evaluation systems, LPS (landscape performance series) mainly focus on the water distribution, permeability, soil loss and erosion reduction of landscape soils\(^{52-53}\). SITES (Susetable Sites Initiative -ve) pays attention to the environmental evaluation of landscape soil, including site selection, planning, design, construction, maintenance, etc.\(^{54}\). From the standpoint of ecosystem flexibility.

2) Soil Health Assessment of Sustainable Rain Garden

Based on the existing soil evaluation system, the evaluation index is particularly important for the evaluation of sustainable soil health in rain garden. The selection of indicators often depends on the ecological effects of soil, and the degree of ecological sustainability that the effect reflects. The quantification method of the indicator is also very important. If the method is not suitable, the result will be misleading. Since the health of the soil depends on the interactions of land use patterns, vegetation types, and soil structure, it cannot be directly measured. At present, the health status of the soil is evaluated mainly through indicators related to the nature of the soil\(^{55}\). The soil health evaluation indicators of the rain garden can be divided into two parts: soil conditions and soil properties\(^{56-58}\). (Table 1)

3) Sustainable Soil Management of Rain Garden

Soil health management plays an important role in protecting the ecological efficiency of the soil. And it maintains the ecological sustainability of the rain garden. Su Changhong proposed a soil management strategy based on the underlying mechanisms and processes of soil, including analysis of soil structure and properties\(^{59}\). Soil organic matter has a certain influence on soil carbon and land management\(^{60}\). And frequent plant
-ing of carbon inputs is the main driving force for soil health changes[61]. The research sho
-ws that the effect of artificial soil treatment is better than that of natural soil[62]. And soil amendment can optimize the permeability and water purification of soil[63-64].

Based on existing soil management measures, the identification of soil health in rain garden can be tested, evaluated, modeled, and mapped. Based on these methods, the management of soil health in rain garden should be comprehensively considered from both the external environment of the soil and the nature of the soil itself, including slope, soil microbes and soil amendments.

4. Conclusions and Outlooks

4.1. Discussions and Conclusions

From the study of this paper, soil health not only helps to achieve the ecological effects of rain garden, but also plays an ecological role and maintains its sustainability in rainwater treatment facilities such as grass-growing ditch, sunken green land, and biological retention ponds. When designing and maintaining the relevant stormwater treatment facilities, in addition to satisfying their aesthetics, the elements related to soil health should be considered in detail: 1) Focus on the site conditions of storm water treatment facilities, especially the terrain gradient, species richness and vegetation coverage, which have a greater impact on soil health. 2) If soil conditions on the rainwater installation site are not good, soil amendments can be used to optimize the soil or replace the soil. 3) Soil health indicators can be used to quickly estimate and predict soil data through scene simulations, software calculations, etc. However, due to insufficient data accuracy[52], soil-related indicators can be tested in the laboratory. The relevant indicators to ensure the scientific accuracy of the data.

After countries such as the United States, Australia, and Germany successively proposed policies for rainwater management, China proposed a guide for the construction of sponge cities in 2014. Currently, the construction of sponge cities has been piloted in 30 cities, and the estimated annual investment cost exceeds 400 billion[65]. So its importance is self-evident. The construction of the sponge city has alleviated most of the urban internal pollution and water environment pollution. In the existing related management policies and performance evaluation, relevant requirements have been put forward for water ecology, runoff control rate, and rainwater utilization rate[66]. However, there is no specific content for the soil. Therefore, based on the results of this study, it is suggested that the special content of soil should be added to the relevant management policies and performance evaluation systems for stormwater treatment in sponge cities, which can be considered from both the external environment of the soil and the nature of the soil itself. The external environment of the soil includes rainfall, slope, land use, species richness, vegetation coverage, etc. The nature of the soil includes the soil moisture content, agglomerate stability and other physical properties, soil
pH, available phosphorus, available nitrogen, etc. Chemical properties, soil microbial content, organic matter and other biological properties.

4.2. Research Prospects

In the future research, in order to better achieve urban stormwater management. And to meet the ecological sustainability of rainwater treatment facilities such as rain garden, ecological retention pools, and roof greening. The landscape architecture must cooperate with disciplines such as ecology, botany, soil science, architecture, and urban planning. Pay attention to the relevant researches on the health of the rainwater treatment facilities. Focusing on the influencing factors of soil health, the quantification methods of soil health indicators, the floating range and changing trends, and the management measures of soil health. These concerns about soil health will inevitably make up for the weaknesses in the design and construction of rainwater treatment facilities.

In terms of research content, ecological sustainability guided by soil health not only plays an important role in rainwater treatment facilities such as rain garden and grass-grooves, but also in urban planning\(^{[67]}\), green building\(^{[68-69]}\), urban agriculture\(^{[70-71]}\). Other aspects are also important influencing factors. Designers and managers need new understandings and creations from the functions and impacts that soil health assumes and the people they serve.

Abstract

For a long time, a unidirectional linear food system between urban and rural areas is exposing various shortcomings: the soil in rural is being eroded by the city, the transportation of food has been increasing carbon footprint etc. The proposal of urban agriculture has provided new ideas for urban planning and development. It promotes a sustainable, self-circulating food system to make urban development more flexible by conducting agricultural activities inside or on the edge of the city. Based on the research result of urban agriculture at home and abroad, being at a community level, the paper proposes growing vegetable by internet, a community construction pattern of urban agriculture under the “Internet+” era in China. And it also conducts questionnaire surveys as to this pattern with accepted by most respondents in the survey for self-satisfaction. Then we discussed the feasibility of the pattern according to the survey results, with a view to more evidences for explanation of the prospects and feasibility of studying urban agricultural community construction pattern in the context of the Internet.

Keywords: Urban agriculture, Community planting pattern, Internet, Participatory, Fruit and vegetable cultivation

1. Introduction

1.1 Background
In 1977, the word “Urban Agriculture (UA)” was formally proposed by an American agricultural economist Allennis (Zhu et al. 2008). And Mougeot defines urban agriculture as: an industry, located in or on the edge of urban areas, recycling natural resources while making full use of human resources and products within or around the city to produce or sell a variety of foods, non-food products, services for the city (Mougeot, 2000).

During a long time, a one-way linear food system has been formed between urban and rural areas. However, with the rapid urban sprawl, the demand for agricultural production makes soil fertility decline and the food transport distance increase. In addition, as people's living standard gradually increases, they pay more attention on food with being eager to return to rural life for self-sufficient duo to more and more food safety problems. For above reasons, UA has been carried out globally (Biel, 2016; Drescher, Holmer et al., 2006), and supported and advocated by many actors from local community organizations and supranational institutions. The benefits attributed to UA practices, such as sustainable livelihoods, food security, reclaiming and self-management of the city, development of local identity and community empowerment (Barriga Valencia et al. 2011; Biel, 2016; Cantor, 2010; Certomà, 2011; Drescher et al., 2006; Ernwein, 2014; Gómez Rodríguez, 2014; Purcell et al. 2015; Turner et al. 2011) as well as promoting neighbourhood friendship, caring for vulnerable groups, etc. (Eva Schwab, et al. 2017)

1.2 States of Urban Agricultural Community Patterns at Home and Abroad

Since the 1960s and 1970s, more and more countries have adopted the bottom-up approach, which has further developed urban agriculture. Furthermore, people try to regain social connections through common production practices of food crops, and the popularity of network technology also makes this phenomenon become more popular (Sylvie et al. 2015). UA can make full use of various types of open green space, like horizontal space and even vertical space in cities, to exert its multiple functions as an ecological infrastructure.

As a country with less resource per capita, China’s needs for UA are becoming more urgent. And there has been some practice in UA in China, but it is not in line with international standards. First of all, the boom of the agricultural suburbs around the city and the establishment of eco-agricultural parks are all only as leisure items to allow people to visit as spectators without reaching the community level and getting involved in people's daily lives. Secondly, the development of internet technology has led to the boom of a virtual public life and pushed people’s lifestyles to change gradually. As various fresh fruits, vegetables with three-kilometre delivery service, it has established a new type of UA in production and sales for people who become accustomed to online shopping because of convenience.

The purpose of this paper is to verify the possibilities of building urban farming communities with "internet +", to find the construction pattern and development strategies, to bring food back to the city. The final goal is to reconnect people with the
local food system to achieve regional community autonomy for agriculture, to promote a healthier lifestyle. It also makes sense for bringing a valuable pattern for the current community planning, transformation of old communities, and construction of ecological communities. (Liu, 2017)

2. Strategy design of UA "online to offline" community planting pattern

2.1. Concept

The community here refers not only to a community with a certain geographical relationship, but to a community with common interests and interests in a certain area. Exactly speaking, community gardens are defined as any land that can be planted by respondents. (Fig.1)

This paper starts from the community planting and proposes the concept of community planting using the combining styles of online and offline. On the one hand, the online recruit volunteers to participate in the study and training of relevant knowledge, and residents and volunteers can be arranged to practice planting off the line. On the other hand, the fruits and vegetables planted off the line can be used to attract customers online to purchase the goods nearby and own it until the harvest to its mature. Through this pattern, unused land is used to reintroduce agriculture into urban life and to form a self-recycling food system.

2.2. Steps of pattern design

2.2.1. Investigation and interview

The research on UA potential is carried out for idle vacant lots in cities. UA can be developed in open spaces, public spaces, private roofs and private courtyards etc.

Interviews with local residents and volunteers, taking into full consideration of various needs, will provide reference for future work.

2.2.2. Establishing a self-circulating community system

Online pattern: The development of Internet technology has boomed a virtual public life, and this plan can use Internet technology to establish a network sharing platform to connect the entire communities in cities.

Offline pattern: It can combine schools, laboratories, public welfare organizations, etc., not only residents but also professionals, students or volunteers can be trained to join it, it can be used as extracurricular projects or life experience projects to grow edible plants and harvest the gains after harvest, the gained edible plants can be donated to public welfare institutions or used for online and offline sales.

Business cycle: Residents can sell their own fruits and vegetables online or offline, and they also can get fresh agricultural products from urban agricultural land in the first place. (Gao, et al. 2014)
Public welfare cycle: Constructing links with public welfare organizations, setting up “care farms” for institutions, so that they can be involved in the process of community building, caring for vulnerable groups, helping the elderly and the sick in the community, and raising funds. The raised a certain funds can be used to maintain the system's operation. By doing these it can mobilize people's subjective initiative for joining.

2.2.3. Establishing a self-circulating community system

Different from the traditional community where material and energy are transmitted in a single line, the self-circulating agricultural community system has a complete material circulation and metabolism system through technical and spatial means such as agricultural planting, water reuse, rainwater collection, and biogas production and utilization. As a result, substance consumption and waste output are reduced to release the community's ecological pressure on the environment.

1) Online mode: The development of Internet technology has boomed a virtual public life, and this plan can use cloud technology to establish a network sharing platform and create “cloud-based dishes” to connect the entire community to cities through the Internet.

2) Offline mode: It can combine schools, laboratories, public welfare organizations, etc., not only residents but also professionals, students or volunteers can be trained to join it, it can be used as extra-curricular projects or life experience projects to grow edible plants and harvest the gains after harvest, the gained edible plants can be donated to public welfare institutions or used for online and offline sales.

Business cycle: After meeting their own needs, residents can choose to sell online or offline as urban agricultural activities have become a platform for communication between agricultural producers and consumers. Both sides can engage in online and offline contacts for consumers can either purchase suitable agricultural products from fields and workshops or even their own roofs at the first time to enjoy direct supply of fresh food from fields at home.

Public welfare cycle: Constructing links with public welfare organizations, setting up “care farms” for institutions such as welfare homes, health care centres, and so on, so that they can be involved in the process of community planting, caring for vulnerable groups, helping the elderly and the sick in the community, and raising funds. The raised a certain funds can be used to maintain the system's operation. By doing these it can mobilize respondents' subjective initiative for joining.

In response to this idea, related questionnaires are designed and a total of 402 questionnaires are distributed by way of online questionnaires. After excluding 50 invalid questionnaires, 352 valid questionnaires are accepted and the recovery rate was 86%.
3. Questionnaire results and analysis

In the investigation and research of the UA "online to offline" community planting pattern, we finally find that 53.13% of respondents are willing to take part in this pattern, and 37.22% are willing to but have no time, and the rest of respondents are unwilling to or unconcerned.

3.1. Basic analysis

In general, respondents are willing to participate in community planting. Most of the men and women are willing to participate it (Fig. 2a)

3.1.2. Place of residence:

More than a half of the respondents are willing to accept this pattern wherever they live in urban areas, rural areas or suburban areas (Fig. 2b).

3.1.3. Age

In the group of respondents over the age of 50, all of them choose "willing" or "willing but not having time". Their
3.1.4. Occupation

More than half of all categories of respondents are willing to participate in it, especially for retirees and other members of the society. At the same time, a large proportion of respondents are willing to participate in it but they have no time, and this situation is more common among students, office workers, and self-employed. (Fig. 2d)

3.2. Analysis of respondents' willingness

3.2.1. Analysis of respondents who are unwilling to participate in the pattern

Among those who are unwilling to participate, the reasons for most of them are as follows: “not interested in it”, “do not like to engage in farm work”, “prefer to buy fruits and vegetables directly in the market”, etc, and a few respondents worries about that it is “unhealthy to eat fruits and vegetables planting in the city”, “do not even understand agricultural knowledge”, “worry that they cannot harvest after planting “and” there is no time”. (Fig. 3a) It is generally believed that UA will have “hygiene problems”, “food safety issues”, “worried about being picked at random”. And hygiene problems are the most noticeable. (Fig. 3b) In the case of solving these problems, there are 35.29% of respondents willing to participate, and this part of the respondents is a potential participant in the pattern.

3.2.2. Analysis of respondents who are willing to participate in the pattern

Among the respondents who are willing to participate in, the preference of community planting patterns is: community garden> roof garden> vertical farm> underground

---

(a. Community planting mode selection)

(b. Choice of preferred plant)

(c. Choice of food to deal with)
farm> others (Fig. 4a), the preference of plants are: vegetables> flowers> fruit trees> ornamental trees> herbs (Fig. 4b). After satisfying their own needs and having more than enough money, most respondents are more willing to choose to give as a present to relatives and friends. The remaining small charities sell online or sell on the ground. (Fig. 4c)

3.3. Impact caused by the understanding of traditional agricultural knowledge and different food safety concerns

The degree of understanding of traditional agricultural knowledge is related to the degree of the acceptance of planting in the vacant land in cities (Fig. 5a).

The degree of understanding of traditional agricultural knowledge is significantly correlated with the choice of distance to buy vegetables (P=0.036, P<0.05)(Table 1). And the more understanding of traditional agricultural knowledge is, the more likely for respondents who do not care about the distance to buy vegetables. And vice versa.

Most respondents have paid much attention to food safety, in particular, respondents over 50 years old are more concerned about food safety and pay more attention to their health. (Fig. 5b)

3.3. Impact caused by the understanding of traditional agricultural knowledge and different food safety concerns

The degree of understanding of traditional agricultural knowledge is related
3.4. Analysis of other factors

3.4.1. Factors that affect the whereabouts of food

In the case of meeting respondents’ own needs, 78.48% of them chose to give to relatives and friends. Most respondents admit to it that promoting neighbourhood friendship, caring for vulnerable groups; changing lifestyles; eco-friendly, shortening the food transport chain; giving residents certain rights to use land; food safety; reapplying and self-managing cities; reducing food expenditure (Barriga Valencia and Leal Celis, 2011; Biel, 2016; Cantor, 2010; Certomà, 2011; Drescher et al., 2006; Ernwein, 2014; Gómez Rodríguez, 2014; Purcell and Tyman, 2015; Turner, Henryks, & Pearson, 2011).

3.4.2 Factors affecting sales

The reasons that affect most respondents to buy fruits and vegetables are as following: freshness, safety, price, distance from home, taste, etc. Many respondents think that there are many factors, especially freshness. As for the purchase methods, most respondents are willing to choose to buy food in the market rather than buy food online for the reason is that they can more intuitively judge the freshness and quality of fruits and vegetables.

3.5. Importance evaluation

Aiming at the “online to offline” community planting pattern, five-point evaluations are carried out from the aspects of edibleness, participatory, innovation, design, and extensibility. In general, respondents are most concerned about the freshness of fruits and vegetables in community planting, followed by the cultivation design of fruits and vegetables. (Table 2.)

1) Edibleness: it is generally believed that edibleness is great importance. And most respondents think that the freshness of fruits and vegetables is important, even 64.77% think it is very important. Respondents is also paying attention to the use of chemical fertilizers and pesticides, especially the former.

2) Participation: “Organization management”, “sustainability “are all above 4 points, indicating that everyone is more concerned about actual benefits rather than entertainment benefits.

3) Innovation: “the instant feedback from the Internet's”, shows the latest agricultural achievements in technology”, “making friends according habits”, and “fun games”, scoring 3.99, 3.9, 3.73, and 3.4 points respectively, so it seems that most respondents think the freshness of fruits and vegetables is more important than them.

4) Design: The planning and design of the garden, the cultivation and design of the crop, and the average design score for the community activity of the plot are relatively high, indicating that we all care more about the interest and sense of design in practical farming.

5) Ductility: The scientific popularization of agricultural knowledge and the introduction of edible plantings scored 3.98 and 4.04, respectively, people considered they are important. (Table 2.)
4. Discussion

UA is a kind of transforming movement. And it also sprouted as a response to slow food movements and greener lifestyles.

In terms of the effects of age, middle-aged and aged people are more likely to accept this pattern because they have more discretionary time and are lack of leisure life. People who understanding more about traditional agricultural knowledge, are more likely to pursuing higher quality of vegetables and less care about the distance to buy vegetables. This group is more likely to become potential customers of this pattern. Most people take much count of food safety. For this purpose, community could regularly push some food safety knowledge to ensure that traditional agricultural knowledge will not be lost quickly, and it will also stimulate public participation in urban agriculture.

4.1. The role of the Internet

The Internet's involvement allows more respondents to have access to eat edible

</table>
plants grown in the community. According to our investigation, a large number of respondents are concerned about the freshness of vegetables. To some extent, the way of online distribution can shorten the distance and the time of delivering. After building their communities, a lot of respondents are more willing to share their fruits and vegetables to their relatives and friends instead of selling them after satisfying their own needs. The intention of privatization is obvious, and it indicates that most respondents choosing to create a community are not for living. Although it will greatly affect the construction of community networks, not all kinds of agricultural products need to enter the circulation chain in the pattern which is carried out under the condition of satisfying the residents' own needs as much as possible. However, with the development of technology and society, the increase in production and the promotion of public welfare will lead to the emergence of business cycles and public interest cycles. Based on a potentially viable business pattern, the development of the “online” is a means to achieve the sustainable developments of sustaining livelihoods and organizing structures. It makes people who have no time to plant but still are interested in and are willing to buy the community fruits and vegetables participate online in this “unique” way, and it also maintain and promote the development of community-building activities.

4.2. Promoting the healthy development of community

From the perspective of social benefits, UA is not only related to the healthy growth of food crops, it is more about the healthy development of community society. Some respondents said: "... we prefer to see a green garden in a once being deserted area near our home, which will let us feel more secure, "which proves that the community planting can create a sense of security and this arrangement leads to a high degree of security and long-term engagement that also meets individual needs. Most people who are willing to participate in the community planting pattern have chosen to give fruits and vegetables to their friends and relatives. This will promote friendship among neighbours, change their lifestyle, and enhance their well-being. In addition, UA has the functions of promotion, education and demonstration. By means of “online” line, the rapid spread of the Internet can expand the affected, lead low-carbon lifestyle, and restore the bond between modern respondents and nature, pay attention to vulnerable groups and care for public welfare.

5. Conclusion

UA community planting pattern of "online to offline" has been accepted by most respondents. A central idea created by this pattern is to encourage collective practice and community planting. This pattern is not a complete replacement for the local industrial food system, but a supplement to it, to provide alternative
forms of lower carbon, green, and more harmonious neighbourhoods. The meaning is not just planting and gaining edible plants in discarded areas, but more on the effects on social, public welfare, environmental, and time-effective effects.

Residents’ wide participation and universal support are continuous motives with combining agricultural production with health and social services. The humanistic care in the community has extended to the online through the pattern. It not only realizes the integration of urban and rural psychology and culture, but also in public welfare. As most respondents are willing to help and subsidize public welfare organizations, the forms will not only be food donations, they can also form the “care farms” in this way, which will be set up in the future to protect the physical and mental health of vulnerable groups such as children and the elderly, to form community interactions and community care, so as to promote the sustainable development of the community.

Exploration of Biophilic System
From Unnatural to Natural

WEN Nian, Vinien

Hong Kong Polytechnic University, Hong Kong 100078, China HKSAR

Abstract

Biophilic refers to the things related to nature and it is a eco word. City is the human habitats and most of them is designed on purpose, for the need or desire. It is the human-centered ego word. City itself is unnatural and because of the population increase, the urban sprawl, the resources development these unnatural urban systems are created more and more which occupied the existed natural landscape. The tendency of biophilic city just likes a kind of return in some extent. Human build the artificial environment while nature contain the ecosystem. With the city development the urban environment would become relatively closed, urban landscape is the intermedia for other creature in the urban system and it should be floating, dynamic and changeable space. The article would analyze the present urban landscape system in Hong Kong with the green ratio of 70% and public space of 85% but more than seven million population. Propose the landscape as the ecological island which would have the specific function like agriculture, commercial or even resident. As a result, the city would develop the new landscape system, the planned but natural free growth.

Keywords: artificial, ecosystem, landscape urbanism, urban farms, vertical landscape

1. Introduction

Bio-, as the geek words βίος, means life which covers every creature in the city. Wilson famously defines biophilia as “the innately emotional affiliation of human beings to other living organisms[1]. Biophilic system is the system attracts people into the natural context. Biophilic city refers to that the artificial urban system contains the things related to nature. However, the city is planned of the human being’s will. The trees are planned along the street as the belt and cannot self-grow like the trees in the forest. The community parks are built to serve the nearby residents and unlike the natural pound which can attract birds and different kinds of fish. The present urban ecological system is the unnatural one because our human as the clients designed it and make the system dominantly serves for us, which makes the biophilic scenario separated from the city. The metropolis is in this side while the nature is in the other side and between them has no connection. The biophilic system tries to
break the present urban system and set up the connection which should be the self-growth urban landscape attach the surface of the city between the natural system and the urban ecology.

Choose the specific Asian city Hong Kong as the site to analyze. Compared with Singapore, the two cities are all island with restriction and potential development. With more population, Hong Kong Special Administrative Region of the People's Republic of China as has the more complex urban planning. Most of the green space in Hong Kong is undeveloped mood and under the protection of the law. With the burden of the high density, these natural reserve or country park are distributed near the territory, the periphery part of Hong Kong. The center of Hong Kong is occupied by the busiest commercial urban activity. The infrastructure networks cut the skin of geological surface and the activity networks narrow the urban landscape space. The Figure 1 displayed the population density within the green space. A biophilic city is a city abundant with nature, a city that looks for opportunities to repair and restore and creatively insert nature wherever it can. Based on the definition of the biophilic city, Citizens no need to build another structure and can utilize the nature as the pop-up space, like the space under the trees can be the emergency space or the space inside the grass can be the dump space. Apparently, Hong Kong is not a biophilic city so far.

This paper would focus on the present urban ecology system in Hong Kong, zoom in several specific urban green spaces, diagnose the reason why the landscape system is not fix the urban system and propose the future of biophilic Hong Kong.

2. The Present Green Space System in Hong Kong

Hong Kong consists of three parts, the Hong Kong island, the Kowloon island and the New Territory. Government sort the land open space into the urban areas, rural areas and countryside and coastal areas. Based on the Hong Kong planning standards and guidelines, the green space is defined as one type of open space for conservation function as the figure 2 showed. The prime function of this space is for conservation of the natural environment and for amenity and visual purposes. It is not countable towards the open space standard of provision. The green space covering a total area of 443
square kilometres is classified as country park, coastal protection area, site of special scientific interest, green belt and conversation area. The planners separate the green space from the urban system in the beginning and the start point of the planning idea is still always the desire to control, control the development, control the growth. The following plots would find those different kinds of green space and explore the possibility of inserting biophilic system to them.

![Diagram of Hong Kong open space]

**Fig. 2.** The structure of Hong Kong open space

### 2.1 Country Park

Different kinds of mountains consist the Hong Kong hilly landscape and the country parks are always designated because of the mountains. The location of the country park is always on the boundary of the city as the main purpose of country park is shorten the distance for visitors to feel the rural and natural atmosphere. In 1976 the Country and Marine Parks Board, be cited as the Country Parks Ordinance, was established to manage the leased land more easily and to provide a legal framework for the designation. There are totally 24 country parks in Hong Kong, 4 of them are in the Hong Kong Island and the rest are in the new territory. The country parks are very popular with different hierarchy of the society. Spending the whole day in the parks is always a good choice for the citizens. About 11.2 million visitors were recorded in 2014 and most visitors engaged in leisure walking, fitness exercises, hiking, barbecuing, family picnics and camping. The figure 3 showed the visitors of country park. With the increasing affluence of the population and the desire for better facilities for informal "countryside" activities and more effective management of the hill areas was required. Furthermore, the country parks take the responsibility of the education to encourage the public enjoyment of the green space. However, actually 22 of the country parks are created for the nature conservation which make a restriction the human activity. For now, the planning department prompt the trail program as the main target is minimising the human activity influence.
Take Ma On Shan Country Park as an example. This park is located in the eastern of the New Territory covering an area of 2,880 hectares. As the urban landscape point, first this country park is in the metro line which connect several sleeping towns attracting more visitors. Second, the government has developed the space surrounding the park into the public housing area. With the human settlement developing, the park may focus on natural platform provision for more nearby residents by adding the new programs and cooperating with neighbour facilities. For park itself the hiking is the main function, which close the distance between human and nature also reduce the disturbance of wildlife. However, the single activity cannot fit the diverse residents, the old need the flat path to walk while the kids need some amusing elements. The community park, the sport centre and other supporting facilities aim to the issue of user diversity.

What if the country park itself can fix the diversity of the visitors and balance the need between urban and nature? What if divide the country park into the vertical layers to achieve the different functions? Moving the temporary residential area to the bottom layers of the park and the top layers could still be the reserve area. The middle layers can be the outdoors sports area, hiking path, rest pavilion and so on.

2.2 Marine parks

As Hong Kong is surrounded by the sea, the marine parks always located beside the country parks. The natural coastline provides the platform for the citizens to contact with the water. Hong Kong planning department puts this kind of parks into the category of coastal protection area of which the main aim
is to protect the natural area and the nearby developing area against the effects of coastal erosion. The method of managing the marine parks is the zoning plan to divide the park to the different part and achieve the multiple function. The mooring site is the anchor function, to allow the ship to park in the and decrease the damage of coral. The core area and the inboard vessels prohibited zone are all the conserve function, to protect the marine lives and prohibit the fishing. The mechanised vessels prohibited zone is the diving function, to protect the divers and snorkelers by preventing the mechanised vessels entry. There are 5 marine parks which the total area is 3,380 hectares and the space for the human activity is around 700 hectares. The present planning is reasonable that the visitors may spend more time to arrive the marine parks so most of the visitors have strong purpose to do such activity.

Pick Hoi Ha Wan Marine Park as the urban landscape point. The site is almost in the boundary of Hong Kong, designated in July 1996 as the first batch of marine parks. The marine park of Hoi Ha Wan is situated at the entrance to the deep estuarine embayment of Tolo Harbour and because of the discharge of the Hoi Ha stream at its head the mangrove stand here is also in estuarine waters [6]. Based on the planning policy is divided into four parts and visitors are permitted in the specific space doing specific activity. Although the large part of the waterfront is distributed for the boat and natural coral, coral communities at Hoi Ha Wan are still under threat of increased sediment loading, discarded fishing nets and cages, and hypoxic events [7]. However, the sea is the public space shared by all different kinds of species. What if apply the vertical thinking to the marine park? Aggregate the mooring site, develop the surface layer into the hydrophilic space and the undersea layers belong to the marine life.

2.3 The Green Belt

The ‘Green Belt’ (GB) zoning is not restricted to the rural area. It can be found in the new towns and urban planning area. This green belt policy is like designating a buffer zone to retain a large undeveloped area surrounding by the urban space, such as the parks mentioned above. The original purpose of green belt is creating an invisible border to prevent the improper urban sprawl and expand the scope of wildlife activity. Though there has never been any attempt to designate a continuous green belt zone to encircle any urban settlement or new town, green belt zoning of pockets of land is found in almost every statutory town plan wherever there are hills. For now, the green belt draws the boundary of the natural space and divides the natural space from the urban system, which drive the conflict between the green belt system with the rapid growth of urban population. Hong Kong government tries to
transform the green belt into the public housing to cover the conflict.

3. The Proposal Biophilic System in Hong Kong

Focusing in the definition of the proposal Hong Kong biophilic system, this part would push forward the details. As the above analyzed, the parks, the green belt and other kind of the green space is separate from city’s daily life because of the location or the policy. Landscape should be the intermedia connecting the rural area, the nature and the urban area, the artificial, like the figure 7 propose the city. Moving the city into the nature, let the landscape grow freely in the city and let the city develop freely in the nature.

3.1 The Boundary of the System

The Hong Kong has its physical boundary which divides itself from the other cities. Actually, inside Hong Kong there is another boundary which divides the city from the conservation area. The boundary protected Sai Kung part and Lantau south part from urban sprawl. As applying the biophilic system the first step is breaking the limitation. Hong Kong should be taken as the whole body. Thus, the general boundary of the system should be the city boundary and inside the city every different function in each district would form the fence naturally. Considering the present situation, the green belt space can be used as the dividing line, which could cooperate the surrounding area. The residential function can be surrounded by the urban farm green belt, the financial function can be surrounded by the outdoors resting green belt and the education function can be surrounded by the interaction garden green belt.
3.2 The Internal Process of the System

The process of the biophilic system drives urban ecosystem from the controlled, the planned level to more sustainable and self-organization level. Like the electric circuit in the transition of this point to other point, need go through the different node, different wire and press different button. For the urban to achieve the aim from unnatural to natural and sustain the internal process, the various parts of the city would be evolved. Obviously, the key policy directive would be those special nodes in the system.

Natural resource, playing the provider role in the ecosystem, is the first and foundation key to zoom in. Up to the sky, down to the earth, everything we can use is the resources. The food we eat, the air we breathe and the land we live are all from nature. City is a type of morphology for collective natural resources. The present policy of Hong Kong protects as much natural resource as possible, but the designation of the country or marine parks is based on the artificial ecology, which is the way created to see the world. In the proposed biophilic system the internal boundary is disappeared, the urban pattern would be reformed, and natural resource can be self-exchanged between the urban nodes. Nature is not only known as the provider but also as the urban space.

Human settlement including the working place, sleeping town and other function site, is for the individual sustainability. Doxiadis had proposed the human settlement is the system of natural, social and man-made elements which can be seen in many ways - nature, man, society, shells, and network or economic, social, political, technological, and cultural [8]. Based on the science of human settlement, the principle of human settlement in this proposed biophilic system is maximization of the connection with the nature, minimization of the influence by the artificial works and optimization of the emergency space inside the natural environment.

Connect policy is the linkage between the above two key elements. The most common urban connection is the road, the highway, all the infrastructure the citizens can rely on. In the biophilic system the things which drive the citizens move the place to another place can all be considered as the connect. In this way urban landscape has the potential to be the intermedia that provide the access to the housing land, the farm land and working part. With such connect the Hong Kong belong to all citizens as well as the city itself.

3.3 The Elements of the System

Generally speaking, the elements can be classified into the provider and consumer. Consumer is the urban elements and the consumer absolutely is the natural elements. The present city consumer the resource and nature always one-way supply. Breaking the environment into the fragments, the biophilic system reprograms these elements and drags the provider and consumer into the same level and create the platform, such as urban farm or vertical green wall for the exchange.
4. Conclusion

Discourse of the biophilic city provide the new way to understand the city. Erase the fixed internal boundary. Create the new form origination like divide the vertical layers or insert the city into the natural space. Explore the possibility of transformation. The present role of each elements can be transformed even to the opposite side. Applying the biophilic system into the way of seeing Hong Kong can find more potential developing direction, city is the part of the system and can be break up into the nature and can be combined with reprogramming the nature.

Acknowledgement

Thanks to Prof. Timothy Jachna teaching me the system thinking, Prof. Laurent Gutierrez of the mapping methods to understand the world and Prof. Peter Hasdell of the urban flotsam. The special thanks are given to my parents for giving me the chance to live in this wonderful world. Wish this paper is the start point of my academic career. Cheers for the future.

Urban Connector - Corridor landscape Planning of Benyamin Suaeb Street in the Centre of Jakarta through the circulations and social spaces

Afra Donata Nimia Makalew\textsuperscript{a}, Dewi Rezalini Anwar\textsuperscript{b}\textsuperscript{*}

\textsuperscript{a}Afra Donata Nimia Makalew, Dewi Rezalini Anwar, Dewi kunthi street 56, Bogor 16152, Indonesia

Abstract

Corridor Landscape could develop into many functions. In the urban areas, the corridor landscape could enhance the quality of urban green spaces. Kota Baru Bandar Kemayoran (KBBK) is in the Central Jakarta area that developed as an environmentally friendly international trading city and has the potential to improve the quality of green open space in Central Jakarta. Urban green open spaces planning requires the existence of corridor landscape that has many benefits to improve the quality of urban landscapes, both in aesthetic and functional terms. Benyamin Suaeb Street is one of corridor that located in KBBK, Central Jakarta that consists of three parts, which are pedestrian way, vehicle way, and the median. Base on the history this street was Jakarta’s big airport and have many potency to be developed. Now days, government already built the corridor but it was built without appropriate planning and give many problems in Kemayoran area. It is need to have study to solve many problems in this corridor. The purpose of this study is to planning the corridor landscape of Benyamin Suaeb. Methodologies that used are site survey, literature study, interview, and questioner base on the method of Booth (1983). The replanning formed by physical-biophysical, ecological and social aspect. All data from these aspects will be analyzed sensitively and can be used to do synthesize that produce a concept. The concept is Urban Connector, that connecting human and environment in sustainable urban space. The Benyamin Suaeb corridor landscape is connected by circulation pattern and social space that create an active corridor with more ecological aspects and a natural atmosphere for urban peoples.

Keywords: Planning, Landscape corridor, urban space
1. Introduction

The city of Jakarta as the Capital of the State of Indonesia experienced a very rapid development. This development process raises various problems, especially due to development without planning, therefore development should be balanced with a nature planning area. This planning of integrated with various aspects is done in order to create a functional and aesthetic sustainable environment. Planning as a process of detailing a planning idea must be accompanied by a maintenance plan as a guarantee of the site is sustainable.

Kemayoran is one area in Jakarta city which continues to grow. This area continues to be active in fixing the environment. Bandar Kemayoran area was once an airport area of DKI Jakarta Province. This area has an area of approximately 454 Ha, with the use of land that has changed from its origin, from an airport to various land use, include dense residential areas, high-rise apartments, star hotels to jasmine classes, markets, offices and business centers.

With the large number of residential and accommodation facilities in this area is inhabited by people from their own background. According to data from the Central Bureau of Statistics Kemayoran area has a population of 242,610 people with a population density of 33,463 inhabitants / km². With such a population, this region must be supported by adequate facilities and infrastructures so as to have a good influence on various aspect, especially social, physical and ecological aspects by plan the landscape Corridor of the area.

Construction of physical facilities and infrastructure can be planned in open space areas that have the potential to be developed in Bandar Kemayoran, one of which is on the green corridor of H. Benyamin Suaeb road. The green corridor that forms the landscape corridor has a length of 3.5 km and the width of each green corridor is 30 m, and the road median width is 4 m. The location is very strategic because it is in the middle of the area. Therefore the arrangement of this area will be carried out which begins with the planning process of landscape corridor equipped with green laying plan that exist in this corridor. This arrangement is expected to be useful for improving the ecological, social, ecological quality as well as supporting the functional and esthetic region image.

2. Objectives

The objectives of this study are as follows:
1. Implement sustainable work based on the Master Plan of Benyamin Sueb Street Landscape (North-South).
2. Obtain development plan and program of open space and green corridor gradually and continuously
3. Obtain the concept of arrangement of the green path landscape of Benyamin Suaeb Street and Working drawing which is in line with the vision and mission of Kota Kemayoran new town development

3. Research method

3.1. Research setting and time

This study was conducted activities conducted in Central Jakarta Kemayoran area with total area of 454 Ha on Jalan Kemayoran which is the main road in the area. The orientation map of the research
setting can be seen in the following Figure 1.

![Fig. 1 Research setting](Source: http://google.maps.com)

### 3.2. Research Method

The methods used in this study were as follows:

1. **Inventory**, is a direct observation or observation of the site at a certain time with different conditions. This activity aims to determine the general conditions directly on the site. Aspects that are inventoried are physical, biophysical, and social.

2. **Analysis and synthesis**, the data obtained through the inventory will be analyzed based on the potential and constraints according to the development that will be done on the site, using descriptive analysis method and spatial analysis, including: physical, biophysical, and social aspects to generate the arrangement of zoning and the concepts.

3. **Concepts**, to be developed were basic concepts, planning concepts and development concepts. The concepts had been made into a reference in making the planning development. Developments concepts are vegetation concepts, circulation concepts, spatial concept, activity concepts and ecological concept. The end result of this stage was the block plan of the concepts concatenation that had been made.

### 4. Planning Process

This stage is an advanced stage of the development concept. At this stage the concept of development is made in more detail by adding aspects of hardscape and soft scape created in the form of site plan.

#### 4. Findings and discussion

**4.1. General Condition**

Benyamin Suaeb Street is divided into two lanes with a median road 4 m wide with an overall area of 1259.96 meters². It has a median road with length from north to south, which is 3.3 kilometers divided by traffic island with a diameter of 22 meters at each intersection. On the east and west of the road there is a green line with a width of 30 meters where on the edge of the green line there is a small and large drainage channels. The total area of 185,346.49 meter² green line, so the total area of planning is an area of 197,445.45 m². In general Kemayoran area is in relatively flat topography with slope of 1% and is at an altitude of 2.0-3.0 from sea level. The relatively flat topography condition allows the region to be developed. Types of soil located in Kemayoran area in general are Alluvial and Gray Hydromorf.

Based on meteorology and climate bureau data in 2015 the average temperature condition Kemayoran area that is equal to
28.15 °C, with average humidity equal to 73.8%. The average rainfall of Kemayoran area is 333.4 mm/month. Reservoirs in the Kemayoran area are artificial water bodies that are partly filled from main drain or main channels around the area that drains the water channel around Kemayoran area. The reservoir is located in the eastern part of the area which aims to control the flood controlled assisted with the help of pump houses and water gates that regulate the exit of water in Kemayoran area. The drainage channels on the tread are divided into open drainage channels and closed drainage channels. In this area is open drainage channel and closed drainage channel. The condition of drainage channel is quite good with no puddles on the road. There are several sizes of drainage channels in the area that is 3 to 7 meters wide.

The dominant vegetation on the green corridor is the sengon tree (Albizia chinensis). Vegetation on the site is grouped by species. The large number of existing plants and with a high enough density, making this tread as green open space is expected to ameliorate climate in the area and also provides other functions, such as the value of education and aesthetics on the site. The existence of these animals certainly provides an ecological value to the tread because the existence of these animals gives a natural impression and creates a natural food chain on the site. The presence of birds can also help in the process of plant pollination. Other animals such as snakes, lizards, and mice must be aware of its existence because it can affect the safety and comfort of users.

In the general condition of the facilities contained in the area is less well maintained. Here are some of the facilities that are located in the area of the Trans Jakarta shuttles, street lights, garden lights on the median and green corridors, billboards, bins, security posts, guardrails and jogging tracks on the green corridor. Existing utilities include electrical substations, electrical panels, sluices, power grids, communications networks, water networks, inland ground gas networks, and drainage channels. The condition of the facility is poorly maintained so that many facilities are not working.

On each side of the North - South Road Green corridor has different visual conditions, ranging from golf courses, settlements, shops, apartments and hotels to swampy swamp forest. In general, the visual aspect of the northern part of the northern-southern part of the road is poor, this can be seen from the irregular vegetation at some point and also the dense vegetation density. The visual condition of the four traffic island is less well maintained, the existing plants have many dead, lots of weeds, and also a lot of vandalism in the planter box in this area. At the side of the road there is a ditch that has a bad visual condition, with the amount of garbage in the ditch and the black water. The visual condition of green path vegetation, median roads, and fences are bad.

This area is very strategic and easy to visit because the location is located in Central Jakarta, close to commuter line station, and often passed by public transportation such as Trans Jakarta, taxi, angkot, bajaj, and motorcycle taxi. Distance of this area from
Jakarta Kota station is 7.3 km and can be reached by about 10 minutes. The condition of road located in Kemayoran area, especially Benyamin Suaeb Street, is still good with asphalt material and can be passed by motor vehicle either two wheel or four wheel vehicle. The circulation located in Benyamin Suaeb Street consists of motor vehicle circulation, bicycle circulation, and pedestrian circulation.

4.2 Social Aspect

According to data from the Central Bureau of Statistics Kemayoran has a population of 242,610 people with a population density of 33,463 inhabitants / km². In general, the population of Kemayoran Complex consists of middle to lower class society and upper middle class. Overall Kemayoran area is managed by PPKK (Kemayoran Complex Management Center). Kemayoran area consists of several blocks, which at the moment several blocks are used for the construction of hotels, apartments, and shopping centers. Some of the blocks that have been built or under construction are self-managed by their respective stakeholders. Activities that can be seen during the survey in this area include jogging, cycling, and selling in the morning. During the day activities that take place are relaxing, just traversing, and used by traders to sell and homeless to rest.

The majority of site users were office workers. There were also street vendors selling around the site. The site was adjacent to two stations so that the site had the potential to become a new place in the center of the city. In addition, there were also routine activities held every week; it was car free day. In regard to that matter, the site was very potential to facilitate the activity. Based on the results of interviews with some users of the site in which the majority of them were the office workers, it was expected that the planning of the park on Sudirman Street was not only a decorative park but also can facilitate the users of the surrounding site.

5. Analysis and synthesis

Physical and Biophysical Aspects

Location and Boundary Site

Location of the north-south green corridor Benyamin Suaeb Road has length of 3.4 km, width 30 m on the left and right sides and area of 8 Ha, which is a very large site for a green corridor. The north-south green corridor road located in a very strategic location as in the center of KBBK and connects the center of community activities, also connects KBBK with its surrounding areas. With these conditions, the site has many potential to serve as the main attraction for KBBK and supporting community activities and its function for improving the microclimate for the site and surrounding areas. The conditions of site which is border on appartement and hotels makes the site support the exiting activities around that.

Topography and Land

The green corridor of Benyamen Suaeb Road has the same slope of land and topography, that is flat. The different level of the site caused by different height between road and green corridor, road median, and drainage line. The different of the height was made for differentiate
between paths and also their usage. Drainage line which is in the green corridor (the big drainage line) has depth of about 1-15 m. The explanation of topography and land can be seen in the following Figure 2.

![Fig. 2 Explanation of topography and land image](image)

**Climate**

Based on BMKG data in 2015, the average temperature condition in Kemayoran area is 28.15 °C, with relative humidity of 73.8%. Based on the equation is known THI value of area of 26.7 which makes Kemayoran area is uncomfortable condition. On Benyamin Suaeb Road microclimate modification is necessary to obtain atmosphere for users.

**Hydrology**

The use of water around Benyamin Suaeb Road is mostly obtained through ground water. The channels on Benyamin Suaeb Road consist of open drainage channels and closed channels. Most of the channels on the green corridor side are open channels with widths varying from 3-7 meters. The widest drainage channel is in the north. With a width of 7 meters in the western part of the road from the south. The condition of the drainage channel is not maintained. Waste accumulation occurs in the drainage channel especially at the point of transition of the intersection. Type of waste that many found inorganic waste that require special handling for cleaning.

**Vegetations**

Vegetation on the tread appears to be dominated by trees with tree species namely sengon (Albizia chinensis). Planting vegetation on a site tends to be grouped by species, this is indicated by the number of similar trees planted in a similar and adjacent area. The vegetation conditions on the green corridor are not entirely in good condition. Many of the vegetation is not feasible to be planted in the area with the condition of vegetation that has been damaged and even died of disease. The large number of old trees with a very large diameter of trees that is about 70 cm -90 cm with a very close spacing of about 2.5 m - 3.5 m makes the area under the tree becomes moist and less sunlight. This requires intensive attention to this vegetation, especially for plants that harm the user by relocating.

6. **Concept**

**Basic Concept**

The basic concept of designing this green line is the urban connector. Urban connector is a green open space concept that can connect all aspects of urban life while maintaining a major focus on sustainable urban space. The urban connector is an integrated space concept with a multifunctional circulation pathway, implemented on the use of circulation paths for several functions such as pedestrian, bicycle, and jogging track in a single circulation corridor.
Design Concept

Based on the concept, the applied design pattern is organic where the spatial pattern follows the groove of the existing tree, thus minimizing the intervention of the site. This design concept also describes motion and movement that characterize a vibrant urban society.

Development Concept

Based on the basic concept of urban connector will apply some space that can accommodate user activities / users. Space that will be formed based on this concept that is like social space, conservation space, and circulation path. Social space in which there is interaction space, space gathering and educational space. Conservation space within which there are various plants existing collection of trees that have been divided into several groups and can be an area of support for urban activities both within and around utilized. Utilization of this collection is called urban arboretum, with this space is expected user/user can get education about plants located along the green corridor.

1. Circulation Concept

The circulation Concept to be used is referring to the basic concept of the tread is multifunctional circulation. This multifunctional circulation is integrated in the utilization of the circulation path for some functions. In addition, in this concept will also include a special path of reflection that is expected to accommodate the needs of the community / user.

The formation of circulation to be made that refers to the concept of design in the form of organic patterns or motion / movement that describes the dynamic Jakarta community. It can be seen in Figure 3.

![Fig.3 Circulation Concept](image)

2. Space Concept

Based on the basic concept of urban connector will apply some space that can accommodate user activities / users. Space that will be formed based on this concept that is like social space, conservation space, and circulation path. Social space in which there is interaction space, space gathering and educational space. Conservation space within which there are various plants existing collection of trees that have been divided into several groups and can be an area of support for urban activities both within and around utilized. Utilization of this collection is called urban arboretum, with this space is expected user / user can get education about the plants located along the green corridor.

3. Vegetation Concept

The concept of vegetation to be used on the site refers to the existence of existing plants to be conserved. The diversity of vegetation species located on the site, especially the trees, causes no need for efforts to add shade vegetation, this is because the condition of the tread is quite well shaded. The addition
of vegetation will be maximized in the social areas that will be formed. Type of vegetation to be added to the area is aesthetic vegetation where to add a beautiful impression on the site. The addition of vegetation will also be done to replace the iron fence into a live fence. The addition of vegetation is done to reduce the rigid impression on the site and to make the barrier from the tread to the circulation of motor vehicles (Main Street). Vegetation to be used on the barrier is the type of thorny bush and ground cover where they will be combined so as to create an esthetic composition.

The next vegetation concept is in a certain segment a mini arboretum will be created. This mini arboretum contains a collection of tree plants that already exist on the site. Mini arboretum concept has a purpose that is to provide educational benefits to the community/user. Mini arboretum will be equipped with interpretation boards, making it easier for the community/user to know the types of plants collection.

4. Activity Concept
The concept of activities to be developed on the site is very diverse. Based on the results of the inventory and analysis of the activities of the users of this area, some of the activities that must be accommodated are walking, jogging, cycling, sitting, watching birds, interpretation of vegetation collection, sports, and others. These activities will be accommodated by the arrangement of facilities in some areas of this green channel. These activities are expected to accommodate the social activities of the community and are expected to reduce the level of individualism and social gaps that occur in the site.

5. Ecological Concept
Ecological concepts are raised to have a better long-term impact on the environment. Viewed based on the analysis of site conditions is very potential for the application of ecological concepts. Ecological concept to be applied that is by minimizing the intervention on the site. Form of such concepts as bird watching, bioswale, 3R (Reduce, Reuse, Recycle). This bioswale concept is applied to add better water absorption areas. The bioswale illustration can be seen in Figure 81. The 3R concept is also applied in utilization.

7. Site Plan
The site plan has a length of ± 3.4 km, width ± 30 m on the left and right sides and an area of ± 8 ha with a relatively flat surface area. The Green corridor landscape constituent elements consist of circulation paths and spatial elements supporting spatial circulation activity activities. The circular path of organic pattern divides the tread from north to south on each side integrated with the existing circulation path in several parts. The existing circulation path that has been built and managed by the partners is maintained in the new siting design and integrated in the site plan with the pattern adjustment at the points of the circulation path. The activity spaces connected by the circulation path are arranged on several sections in each segment with repeatable placement patterns at a certain distance interval. This is done to provide a uniform social space on each segment. Segaligus can be functioned as a rest area for users of the circulation path for both, walking, jogging
and cycling activities. Site plan can be seen in Figure 4.

Fig. 4 Site Plan

8. Conclusions and suggestions

Conclusion

The Benyain Suaeb street as corridor landscape is connected by circulation pattern and social space that create an active corridor with more ecological aspects and a natural atmosphere for urban peoples.

Suggestions

Urban connector is a good concept to create an active social space in the Jakarta urban area. So, it could be a good model that can be implanted in another part of Jakarta city.

Biophilic Cities

ARRECIFE. THE CAPITAL OF THE BIOSPHERE RESERVE.

Juan Palop Casado
LPA - Lab for Planning and Architecture, Luis Doreste Silva 18B, 1º, Las Palmas de Gran Canaria 35017, Spain

Abstract

Biosphere Reserves, the program launched by UNESCO in the seventies with the aim of fostering an organic relationship between human beings and Nature, have generally been very successful in promoting organic relationships in natural and rural areas, but rather less when it comes to urban environments.

This fact is very clearly demonstrated in Arrecife, the capital of the island of Lanzarote, one of the pioneering Biosphere Reserves in the world.

This paper describes the first attempts taken by the Biosphere Reserve of Lanzarote to improve this situation by implementing its biophilic agenda into the urban regeneration of Arrecife. Biophilic Urban Planning; Biosphere Reserves; Arid Cities.

1. Introduction

1.1. Lanzarote

The Island of Lanzarote is part of the Canary Islands, a subtropical archipelago of eight islands situated off the east coast of Africa. The island presents a dry landscape which was the result of multiple volcanic eruptions between 1730 and 1736, which were preceded by a small episode in 1824. These eruptions covered most of the fertile areas of the island with ash, making the island even more arid (fig.1).

This arid climate has brief spells of rain during the year with increased overnight humidity. Water scarcity has been one of the main issues in the history of the development of the island with water recollection, accumulation and saving encouraging the emergence of site-specific ways of water engineering in rural and urban environments.

In fact, some of the most attractive landscape configurations of the island came from a water efficient way of planting wine, called La Geria. It is an indigenous way of cultivating wine adapted for this arid and hostile ground consisting of funnel-shaped hollows filled with porous volcanic soil that
Biophilic Cities

retains the water from night-time humidity which then feeds the plants. The system is topped by a low semi-circular wall that protects from the constant, drying wind (fig. 3).

La Geria is a very good example of the postulates promoted by the Biosphere Reserve in its promotion of creative ways of living and working in harmony with nature. The landscape of La Geria has become part of the landscape identity of the island and its hydrologic intelligence.

This water culture and the ingenuity it requires, dates back to the beginning of the 60’s when the first water desalination plant was built. The massive access to fresh water was a turning point in the history of the island as access to water will no longer be a problem.

This change made the development of mass tourism over the following decades possible, becoming the main economic activity of the island, with almost 3 million visitors a year. This development brought an exponential increase in the population and a much in demand tourism-focused work force that had to be accommodated in the capital. Since then, Arrecife has not been comprehensively planned, playing the role of a back yard; being a sort of dystopia with respect to the excellent landscape of the rest of the island (fig. 2).

1.2 Reserve of the Biosphere

The Biosphere Reserves are part of a UNESCO program entitled Man and Biosphere. Established in 1971, the main aim of this program is to explore innovative solutions where people will live and work in harmony with nature.

A biophilic ambition announced almost 50 years before reconnecting nature and living processes became the agenda of the century. Since its foundation, more than 600 territories in the world have been declared a Biosphere Reserve.

The island of Lanzarote was declared a Biosphere Reserve in 1993 and has since counted on massive social support. It was not only one of the pioneering Biosphere Reserves, but the first to integrate the whole territory; the natural, the rural and the urban environment. The whole island was declared a reserve and therefore subjected to the biophilic ambitions of the program.

Since its founding, the Biosphere Reserve has developed an intensified action that protects and values the natural condition of the island. It includes issues such as the protection of biodiversity, sustainable development policies, campaigns against plastics and, more recently, the development of renewable sources of energy and light modes of mobility.

Next year the island will celebrate its twenty-fifth anniversary as a Biosphere Reserve. Despite its uncontested success in preserving the natural environment of the island and promoting new methods of human-nature integration, one can argue that incorporating the whole island into a reserve, including its urban environments, has not been addressed at all.
Faced with this ontological contradiction that may distinguish between the “biosphere” and the “urbanphere”, the team that run the Biosphere Reserve has decided to focus on the urban part of the island and, specifically, onto its capital, Arrecife.

2. The Objective

The challenge is now to transform the city of Arrecife into a true reserve capital, putting Lanzarote again as a leading member of the UNESCO program by coining and developing the term “Capital of the Biosphere Reserve.”

In order to achieve this, the Biosphere Reserve plans to test a new kind of city planning and design that will work by putting nature and living system dynamics as driving forces of its urban renovation; a truly biophilic approach. A new perception of (urban) reality, understood as a complex system in a dynamic equilibrium, coming from the constant interchange of energy, matter and information with its natural and social environment.

3. The Project

Arrecife has been the capital of the island since 1852. It is located in the centre of the eastern side of the island, at the foothill of a system of soft mountains that runs down the middle of the Island, from north to south. The city has a very unique waterfront made of reefs that define the city’s identity and give it its name (Arrecife means ‘reef’) (fig.2).

The city has developed like most coastal cities by first following the coastline, then, from the 70’s along two bypass roads in the form of two semi-circles. These have brought about the colonization of the hinterland, structuring the districts and the social classes according to their distance from the waterfront.

Arrecife contrasts sharply with the tourism paradise that the island has become. With poor urban planning, the city has become an exception to the ecological legacy prescribed by Cesar Manrique. It can be said that Arrecife remains isolated from the biophilic sophistication that has raised the prestige of Lanzarote as a natural reserve.

This situation was reported in a national newspaper which ranked Arrecife as one of the most deteriorated cities in Spain. The absence of a proper planning guide and the poor planning of most of the modest housing areas of the city have compounded this situation. To confront these antecedents, the Biosphere Reserve’s leaders have decided to intervene with an alternative approach to the dominant planning visions of the city by implementing biophilic principles to its urban planning and design. It is time to introduce the values and principles of the Biosphere Reserve into an urban space.

3.1 Principles and Methodology

At first, steps were taken to define a set of principles and a work methodology. The principles include a vision of the city as a living organism: managing urban flow will dictate how the city looks; what people feel
will prevail over expert intuition; bottom-up street-level surveys will replace top-down office-based approaches; and local patterns will be restored in place of ‘imported’ solutions. The first part of the methodology, the diagnosis, was done by an extensive walk of the entire city; including eight-hour sessions that were at times carried out alone and at other times accompanied by local residents and experts.

3.2 Los Caminos del Agua

The methodology of walking and talking raised the issue of the constant floods that the city periodically experiences. These are especially intense on the northern edges of the city, where poorer districts are located, as these are at the foot of the mountains off which water runs on its way to the coast.

This situation was not a problem for the ‘pre-desalinisation’ generation because they were educated to take advantage of this situation. As a result, the city has an impressive heritage of tanks and ponds that are strategically situated for collecting this water. Although this infrastructure is visible today, it is unused and the ravines are buried under an urban lay out that does not respect the topography of rain water.

The intelligence of the landscape of La Geria serves as a reference. We have to be ambitious for the city and with the intelligence applied to the urban areas, intelligence which is part of the genetics of the island. We only have to value it again (fig.4).

The walking tours showed that even though most of the ravines have been built over, there are still some fragments in parks and empty plots; places which have remained unseen to the clumsiness of poor urbanization. They offered a clear diagnosis: we have to re-integrate the three elements of the city: its territory; its natural environment; and its hydrology. This is even more urgent given the increased intensity of rainfall brought about by climate change situation. The project focused, then, on the reconstruction of these former hydrologic pathways.

The first phase of this reconstruction draws on the existing fragments and historical cartography. The network of tanks and ponds helped to map out the system which depended on them, with old maps and digital topography also playing a valuable role. Discussions with elderly residents who remembered when the water used to run within these channels shored up our findings (fig.7).

The result of reconstructing these fragments together with the introduction of new parts, in those places where the ravine had disappeared, was four waterways. These transverse the city; starting in the hinterland and ending logically at the beaches, constructed as sediment accumulated over time. The resulting lay out is a ‘Frankinstien’ sum of still existing water pathways and new eco-engineered parts. At the top, a set of retention parks connects the system with the rest of the territory and provide a communal open space in the most run-down districts (fig.6).
The idea is that these four ravines will work as a water infrastructure, both on a city and a district scale. They will channel the run-off and the storm water, incorporating small plazas and parks that connect the waterway with the residential districts. These plazas serve as an intermediate infrastructure for water harvesting and storm water storage preventing blockage in cases of heavy rain. They can also serve as natural grey water purification plants, where old tanks and ponds are ear-marked for restoration before being integrated into the system and put into service (fig.8).

The resulting waterway expand and contract to adapt to the limitation of working in an existing urban environment. The wider hydrological and infrastructural function has integrated pedestrian pathways and a cycle trail, along with vegetation and trees that provide shade and gathering spaces to form an urban landscape that performs infrastructural, ecological and social functions.

These four waterways called Los Caminos del Agua each extend for around 12 kilometres, forming a brand new lay out of the city that provides a new way of navigating the city apart from motor traffic flows. This new structure connects all districts and ensures they are all have convenient access to the coast. Reduced to only forty-five-minute walk, the beaches now become part of the new park, and not only a domain of the ‘first line’ residents. Nature imposes an alternative order to that imposed by the real-state.

4. The Model

Los Caminos del Agua is a critical part of the first vision of the city submitted by the Biosphere Reserve. This new system of water and walking is intentionally combined with the two existing motorways. The intersection of the two systems accommodates mobility interchange nodes, with car parks and bus routes allowing easy and convenient connections with the four Paseos. The system finalizes with a program of transforming each neighbourhood into an eco-district with accompanying small scale actions at street level(fig.5).

In December 2016 this city vision was presented to the local government where most of the political, social and professional stakeholders were represented. Unanimously, the board gave the overall project the green light. Since then the Reserve office has been working on the feasibility plan of the first of Los Caminos del Agua. The design development of the first phase is expected to be submitted during the first semester of 2019.

5. Conclusions

Although this is a project still in progress, some lessons can be taken from this initiative on different scales and dimensions.

5.1 The outside from the discipline view.

Sometimes it is easier to promote biophilic approaches to a city from institutions not directly involved in the official urban planning of that city. The case of the Biosphere Reserve of Lanzarote is not
only useful to other reserves that want to project their biophilic agenda onto urban environments, but also to any institution which wants to incorporate nature to a greater degree into their community life.

5.2 Landscape as Infrastructure.

Restoring storm water system is an opportunity not only to intensify the ecological and hydrologic performance of the city, but to integrate in a new urban landscape social, environmental, infrastructural and urban spaces.

5.3 Water approach at Arid Cities.

Paradoxically, it makes sense to have a hydrologic approach in areas where water is scarce. This places are going to have more frequent and more intense spells of rain as a result of climate change. Moreover, arid cities, like any other city, process the water consumed every day that could be filtered and used at the city scale without having to deliver it to the sea.

5.4 Interdisciplinarity.

A biophilic approach demands the participation of many experts that will contribute to production of synthetic proposals that integrate ecological, infrastructural, landscape and social demands into the project.

Acknowledgments

I would like to thank the Biosphere Reserve team and, in particular, to Ana and Quino for their commitment to the sustainable development of Lanzarote and their support and collaboration during the production of this work.

Abstract

The migration crisis is a worldwide phenomenon, at where social conflicts, natural disasters and the rise of the sea levels are some of the reasons of this process. In Brazil, there are 8,863 recognized refugees. From 2010 to 2015, this number suffered a 2,868% increase.¹ The We Are All Immigrants (WAAI) Project is based on an initiative developed by the non-governmental agency Orientavida. Based in Potim, São Paulo, Brazil, in an area of 8,000 square meters the undertaking intends to: create an assistance model to the refugees; develop a model which can be used in different regions; strengthen partnerships with other NGOs and other supporters of the cause. The Project, conceived by the David Ito Arquitetura office forecasts the construction of 32 houses and a community center. It scopes to shelter families (4 people average), guaranteeing legal assistance and aiding the immigrants in cultural insertion processes. With an estimated permanence of 6 months per family, within a period of 10 years, the project aims to attend 15,000 people. The Landscape Architecture Project, developed by the landscape architect Marcelo Vassalo, proposes Nature as the top priority of the design of both free and constructed spaces, adressing a better environmental quality and the creation of “affective bonds between people and the place or physical environment”.²

1. Introduction

The migration crisis is a worldwide phenomenon, at where social conflicts, natural disasters and the rise of the sea levels are some of the reasons of this process. In Brazil, there are 8,863 recognized refugees. From 2010 to 2015, this number suffered a 2,868% increase.¹

The We Are All Immigrants (WAAI) Project is based on an initiative developed by the non-governmental agency Orientavida. Based in Potim, São Paulo, Brazil, in an area of 8,000 square meters the undertaking intends to:

- create an assistance model to the refugees;
- develop a model which can be used in different regions;
- strengthen partnerships with other NGOs and other supporters of the cause.

The Project conceived by the David Ito Arquitetura Office forecasts the construction of 32 houses and a community center. It scopes to shelter families (04 people average), guaranteeing legal assistance and aiding the immigrants in cultural insertion processes. With an estimated permanence of 06 months per family, within a period of 10 years, the project aims to attend 15,000 people.

The Landscape Architecture Project developed by the landscape architect Marcelo Vassalo, proposes Nature as the top priority of the design of both free and constructed spaces, addressing a better environmental quality and the creation of “affective bonds between people and the place or physical environment”². The urban dimensions proposed in WWAI in the following, some of the key concepts of the project are shown below.

2. Biophilic city: solutions based on nature

- Nature as a priority on the design of the project;
- Multi-functional usage of the vegetation: insolation protection, food production, bird fauna attraction and local Biodiversity increment;
- Vegetable garden and orchard areas, providing contact with the ground (connection, belonging);
- “The existing processes and cycles of the Nature”³ present in the design of the external areas; differentiated Implementation, providing coexistence and contact with the Nature.

3. Smart nation | technology: green infrastructure system

- ICF Constructive System (Insulated Concrete Forms) guaranteeing better quality to the internal environment;
- simulation performed with Design Builder Program, evaluating the quality of the built environment;
- project adopted as Pilot Project by GBC (Green Building Council Brasil) program certification Referential Condominium, and Leed NC (New Construction) for the community center;
- network involving supporting NGOs;
- Green Infrastructure System, using high-performance landscaping-related technologies, such as biovalves, rain gardens, green ceilings, etc.
4. Future resilience: living with nature

- a Project to serve the ecosystems;
- rain water exploitation and reuse of grey water;
- prepared environment to tackle social phenomena;
- urban forest and restoration of the hydrological cycle;
- recycling and composting structures for the organic residues;
- environment sharing and exchange of experiences;
- natural draining systems, contributing to an increase in the quality of the infiltrated water;
- efficient planning, providing better environmental quality with the same cost and occupied area of conventional projects;
- creation of dynamic systems and use of efficient solutions, promoting a reduction in 30% of the consumption of electricity, 40% of the waste of potable water and 100% of the waste water for non-drinkable purposes.

5. Final considerations

- The WAAI residential project is in the development phase of projects and is scheduled to start in 2019

- The project aims, demonstrates that it is possible to build residential habitats where nature-based solutions are part of the concept and program in landscape design and promote the benefits of being integrated with nature.

- The Project demonstrates that it can be applied in federal and state housing programs, since it has the same urban characteristics as those provided for in the legislation.

- New fronts of migration are currently occurring, for example with Venezuela, where the concept of WAAI residences could be used by adapted tents or "containers", demonstrating that through a differentiated deployment, we built environments where integration between the natural and constructed elements occur with more harmony and meaning.

- The Project uses a process of Planning and Integrated Project, where all the disciplines act interdisciplinarily in the making of decisions and in the definition of the projects. Systems are chosen according to their cycles, trying to transform waste into products and guarantee vital resources, such as water, abundant in the enterprise.

- Taking into account the architecture of the vegetation we can predict the benefits that the landscape has to offer us. The multifunctional use of vegetation deserves to be highlighted by the amount of benefits it offers.

- Simulation performed with Design Builder Program, evaluating the
quality of the built environment. A creation of dynamic systems and use of efficient solutions, promoting a reduction in 30% of the consumption of electricity, 40% of the waste of potable water and 100% of the waste water for non-drinkable purposes.
