Abstract

Under the trend of national physical fitness in China, what the large-scale sport architecture represent is no longer just the region image. With the theories of regionalism, humanism, green ecological building spreading and development, architects begin to rethink, as the important public buildings, if the large-scale sport architecture should take on the greater social mission. Meanwhile, the urbanization process causes the city density increasing day by day, making the problem of environment and the shortage of construction land become the main contradiction nowadays. Under the situation above, green ecological is becoming the main stream consciousness. Architecture, landscape and environment will become increasingly integrated and creating landscape through architectures will become an inevitable trend. In this context, in view of the characteristics of large span, large volume and large interface of sports architecture, this paper analyzes the feasibility of the sinking mode in the design of sports architecture, summarizes two kinds of sinking patterns, and puts forward the landform sports architecture design based on the sinking mode, through which the sports architecture can minimize the oppression to the environment and become the creators of urban landscape. According to the particularity of sports architecture, this paper analyzes the disadvantages of sinking mode, and puts forward the applicable reference. For the disadvantages, combined with the actual cases, this paper summarizes the coping strategies in natural lighting and ventilation, traffic streamline and disaster prevention, aiming at to lead the sport architecture design on the road of ecological and contribute to the creation of the sustainable development of eco-economical city from the perspective of sports architecture design.

Keywords: Sport Architecture, Landform Design, Sinking Mode, Sustainable Development

Fund Items: National Natural Science Foundation of China (No. 51578173); National Natural Science Foundation of China (No. 51678180)
1. Introduction

With the large volume, sports architecture always occupy a large area, which inevitably affect the urban environment. Since 21st Century, the urbanization process in China has led to shortage of construction land and environmental problems. With the popularization of the "national fitness" in China, the construction of sports venues has entered the peak period, causing the contradiction between the environment and the shortage of construction land. Under this background, the sinking mode is becoming one of the sports architecture patterns and showing the trend of landform so as to maximize the optimization to urban space. But the sinking mode can also lead to many disadvantages, such as energy saving, streamline organization and so on. Therefore, how to rationalize the multiple criterions of sports architecture has become an unavoidable problem in the development of the sinking mode.

This paper analyzes the applicability of sinking mode in sports architecture, summarizes the advantages and disadvantages of this pattern, and points out coping strategies with actual cases, aiming at pointing out the essentials of the sinking mode and guiding landscape become the new direction of sports architecture, thus promoting the harmonious between architecture and urban environment, the efficient use of urban land and the innovation of sports architecture.

2. Early sports architecture base on the sinking mode

The origin of sports architecture is based on the sinking mode.

In the first ancient Olympic Games in 776 B.C., in order to save time and effort, people use the natural terrain and put the main field in the flat canyon through the hills and set up the bleachers along the hillside[1]. The way of embedded design makes the site hidden and shows the harmonious between people, nature and architecture (Fig.1).

Fig. 1. A caption is positioned left-justified below the figure or scheme.
The 1896 Athens Olympic marble stadium (its predecessor is the ancient Greek arena), which was built in 330 BC, was rebuilt in 1895. It was also built according to the terrain. The 47 rows of bleachers were arranged along the hillside, as if they were broken out from the earth (Fig.2). The 1936 Berlin Olympic stadium was built in 1913. As the ancient Greek arena, the whole site seemed to grow out of the land and merged into the surrounding landscape (Fig.3). Similar to the above, the University Stadium in 1968 Mexico City Olympic Games, which was built in 1953, also inserted the seat to the earth, hardly used any concrete, gracefully integrated into the environment (Fig.4).

Actually, there are similar works of Chinese early sports venues. The Nanjing Central Sports Conference, which was designed by Guan Songsheng and Yang Tingbao in 1931, contained a number of outdoor venues. In order to save time and money, the whole plan was on the hillside. Some of the bleachers were built based on the slope, and the national sports field and basketball court were laid out based on the original terrain. The whole site was embedded in the earth, and the construction only spent 6 months (Fig.5-6).

3. The feasibility of the sinking model in the current sports architecture

3.1. The problems of sports architecture in China

Firstly, in the past sports building construction, for the major events, it is customary to use high standard construction to create landmark and pursue visual effects.
With the smooth curve and form, the Tokyo new national arena designed by Zaha Hadid Architects shows the sense of future, while it has been questioned as a result of the negative impact on the environment so that eventually replaced by Kengo Kuma and Associates. Besides the high cost, the environmental concept reflected is worth thinking (Fig.7).

Secondly, the urbanization process leads to the increasing tension in urban land. The 2016 China National Land Resources Bulletin shows that the area of urban construction land has fallen year by year since 2013 (Fig.8) The sixth bulletin of China sports field census data shows that the average sports area is only 1.46 m² in 2014, which is much lower than developed countries. Besides, China's State Council "on accelerating the development of sports industry to promote sports consumption" proposed that in 2025, the area of per capita sports field in China should reach 2 m². Therefore, the reduction of urban construction land has prevented the increase of sports area and become another major contradiction.

3.2. Feasibility analysis of the sinking mode

The above two contradictions are mainly reflected in the conflict between the growing sports venues demand and the shortage of land and urban environment, which can be alleviated through the sinking mode. Firstly, the sinking mode can reduce the volume of sports architecture and abate the pressure on the urban environment. The Wukesong gymnasium in Beijing is located in old Beijing. The court is sank to 10 m underground, and the ultimate height fell to...
27.4 m², reducing the impact on the environment. The application of wood composite material in the facade also expresses the rare affinity in sports architectures (Fig.9).

Secondly, for the contradiction between the land and the area, the underground space can be used for stacked layout and increase the area[3]. The sports center of Beijing Forestry University is limited to the shortage of campus land. In the planning, we suggest excavated down the existing stadium in the campus and layout the gymnasium, natatorium and training hall in the underground and then arrange the stadium above them. Finally, the stadiums are sank to 10 meters underground and the new stadium is 5 meters on the ground, and the the new sports center is realized without extra occupation of campus land (Fig.10).

3.3. Classification of sinking mode

Thus the sinking mode is not mited to the site in contemporary, but also often uses the underground space to meet other functions, which can be divided into the court sinking and space sinking (Tab.1).

3.3.1 Court sinking

Court sinking refers to the playing area and its related main rooms. This model is often used, mainly for single venues, can effectively reduce the volume create a harmonious external space environment, which is more suitable for outdoor stadiums or large indoor gymnasium.

3.3.2 Space sinking

The space sinking refers to the singking of the venues or ancillary facilities and then layout of the sports venues above. The common underground spaces include sports function, parking function or ancillary function. This mode is applicable to the construction of venues that are contradictory to the land supply and the area.

4. The landscape design strategy of the sinking mode sports buildings

The large-scale of sports architectures makes it appear in the high-density cities in face of many contradictions. However, from the perspective of landscape architecture, the unique volume and space of sports architecture conforms to the architectural requirements of the landscape architecture. Therefore, it is more conducive to create a harmonious environment by combining the
landscape and the sinking mode of sports architecture. In the landscape design, there are three common strategies for sports architecture: Form metaphor, vegetation loading and ecological materials.

### 4.1. Form metaphor

In the process of seeking a harmonious coexistence with the natural environment, the morphological constitute is one of the most common points for architects. Starting from the morphological constitute, reducting the volume of buildings, optimizing the architectural form and trying to weaken the artificial traces, so that the architecture is no longer to appearance as a conqueror.

For example, Berlin Olympic Racing Museum and natatoria, Germany, are located in a park, to avoid destroying the original environment, the idea is to simulate the entire roof as a lake surrounded by surrounding trees. The design sinks 17m underground so that people can only see a metal roof as if a lake on the ground, which contributes to the landscape in the city (Fig.11). In the design of the sports center of Beijing Forestry University, the sinking landscape courtyard is built on the east. One side of the wall is carved artificially. The bottom of the wall is introduced into the pool and vegetation, and the metaphor of Chinese traditional landscape are finally expressed (Fig.12).

![Fig.11 Berlin Olympic Racing Museum and natatoria, Germany](image_url)
4.2. Vegetation loading

Vegetation loading is using the characteristic of large interface of sports architecture to reproduce vegetation, which gives green back to urban and also effectively improves the city surrounding micro-climate.

The central gymnasium of Osaka is located in the city park. The concept of "harmony with nature" is put forward in the design, and the sinking mode is adopted. The diameter of the main arena roof is about 110 meters and above the roof architects built a green artificial hills, planting a variety of plants and flowers, and setting the ring walking path onto the roof to create a miniature park for the city. As a result, the nature environment is preserved above the building, creating a new landscape for the city. According to the measurement, the planting roof not only contributes to the improvement of climate, but also contributes to indoor thermal stability. The sinking mode makes the building take full advantage of the underground constant temperature and thermal insulation characteristics (Fig.13). The Dalian Shide stadium, designed by the NBBJ architects, sinks the court 6m underground to reduce the volume, while the outer wall of the building loads green plants just like a vertical garden in the city (Fig.14). The height of the Beijing Forestry University stadium is 5 meters on the ground, and the grooves are designed to plant the vine vegetation at the bottom of the field protection fence, where we want to show the green vegetation on the fence (Fig.15).
4.3. Ecological materials

Under the social trend of sustainable development, the selection of environmental low carbon materials has attracted the attention of architects. In the project of Meishan Sports Center, in order to fully integrate the building into the environment, we sink the court 6 meters underground in order to relieve the oppression. In the facades and the peripheral structures, the wood composite material is used to echo the local bamboo culture. The roof form is derived from the traditional Chinese folk, absorbing the design idea of the harmony between heaven and man in the ancient Chinese architecture, and finally realizing the harmonious dialogue between architecture and environment (Fig.16).

5. The applicable and coping strategy of sinking mode

5.1. Application situation

It is worth noting that there are many challenges in the investment, ventilation, lighting, evacuation, and disaster prevention in the sinking mode sports architecture. It should be considered whether to adopt the sinking mode, and several factors should be taken into consideration such as the urban planning, the surrounding environment, building scale, the geological strip and the investment and so on (Tab.2).

5.2. Coping strategy

Aiming at the potential challenges of sinking mode sports architecture, we should meet three principles of ecological conservation, streamline unimpeded and disaster prevention. The following will combine with the plan of Beijing Forestry University sports center to explore.

5.2.1 Natural lighting and ventilation

In the design of the sports center of Beijing Forestry University, because the upper of the gymnasium is a stadium, so the...
The roof can not be lighted and ventilated. The solution is to expand the courtyard on the east and indirectly realize the natural lighting. Through the opening of the window, the air is circulated in the three Gymnasiums (Fig.17-18).

Besides, for other sinking mode sports architectures, natural lighting and ventilation can be done through the top interface and the side interface generally (Tab.3).

5.2.2 Streamline organization

The underground gymnasium, training hall and natatorium of Beijing Forestry University have taken an independent and parallel layout, compared with the integral-style, reducing the evacuation distance in the horizontal direction. In the vertical direction, each level of elevation is connected through the platform to realize the evacuation. Through technical measures, it can ensure that there is no fire and smoke in the outdoor platform and underground courtyard at the time of the fire, where it would be a safe region people can be evacuated and wait for rescue. In the fire fighting, the underground fire line is

6. Conclusion

In the past, large sports architectures in China have always pursued spectacular and magnificent visual effects based on the high investment, in order to highlight the prosperity of political and economy achievements, thus actively repel the sinking mode[4]. At present, the contradiction between urban development and sports architectures is becoming increasingly prominent. Sinking mode is conducive to
solve the contradiction between sports architectures and environment and land supply. At the same time, using the morphological features of the large interface of sports architectures to make a landscape design on the basis of rational structure, thus relieving the sense of oppression and ritual of the sports buildings, will undoubtedly be a new trend of sports architecture in the sustainable development nowadays. Therefore, the "sinking mode" is an attitude that reflecting the attention to the urban environment from all sectors of society. "Landform" is an idea that reflecting the progress of ideology and the sublimation of social aesthetics.

However, the sinking mode of sports architecture does face many technical challenges. This paper advocates that architects should choose the sinking mode reasonably according to the characteristics of the environment and the project itself, and at the same time should also meet the design criteria of ecological conservation and streamline unimpeded. At present, the research on the design strategy of the sinking mode sports architecture is relatively deficient. This paper hopes to attract more attention to the sinking mode sports architecture, so as to provide new references from the perspective of sustainable development.

Abstract

Urbanisation has become the norm for human settlement on this planet. Increasingly, world population are moving to live in urban area either for convenient, jobs opportunities or other reason even though it is not an ideal environment for human. It is the time we need to re-think how we build our cities that could still nurture environment.

The conflicting factors while developing a city is the build-up area versus greenery. To deal with this, emerging trend of the new buildings is to integrate greenery on the roof. While it is a noble idea, there are questions of how to make these greenery sustainable for the long future.

Ideas of growing a forest on the roof were explored on 2 projects in completely different scale in the hope to find a solution for sustainable green roof in urban area. One is a business park of 35,000 site area and another one is a private house in city area.

Mapletree Business City II, Singapore

The site that this project stood on was once occupied with warehouse covering the entire site with concrete surface. However, this new development give us opportunity to reclaim back the greenery. A ‘Forest Ecosystem’ is created on top of car park podium and on sky roofs of the stacking tower with average soil depth at 1.5 meter to ensure forest future growth. 70% of the site area is covering with greenery.

Varying tree’s size from sapling to mature trees are randomly placed to form a true forest composition. Variety of flowering and fruit baring trees and shrubs species help enhancing the created forest as habitat for butterflies, dragon flies, bird and other wild animal to maintain biodiversity at large.

Series of mounds are created to deal with storm water management with bio-swale at the foot of each mound to effectively regulate drainage pattern while allow the run-off to slowly filter
through the sandy layers. Eventually, the pre-filtered rain water is collected at the lowest point and leads into the rain water harvesting tank, treated and recycled for irrigation. The tank size is calculated to hold 7 days of irrigation water. Incorporated with rain censor system, which will save irrigation water during rainy days, the amount of irrigation water saved in the tank will be sufficient for the relatively wet island of Singapore.

*Forested House, Bangkok, Thailand*

For a private house, a more simple strategy to create forest is employed. Varieties of young trees of around 1 year old are selected to ensure that it can adjust to the 1 meter depth planter depth condition. All dry leaves, are not treated as garbage but instead return back to the soil ground to become natural fertilizer as in the real forest. Within 10 months after planting, the trees grow to double the height providing natural shading reducing heat into the house greatly.

We hope this 2 projects will demonstrate how to integrate a sustainable greenery into city of the future – a Biophilic Cities.

---

**1. Introduction**

Urbanisation has been a major global trend since 1950s and UN’s statistic predicts that 66% of world population will be urban by 2050. City as a product of capitalism has to perform to mainly sustain the economy which results in a typical compact hi-density living coupled with well-connected transportation system. This model might work well economically, though, it creates much stress to ‘Nature’ as it is not in the equation from the start. Some cities introduces Public Park to provide greenery to offset the harshness of the built-up area. However, proportionally, buildings both in commercial and residential area still occupy much of the space in the cities.

There are many problems arises from lacking nature in the cities including urban heat island, flooding, poor air quality, less social interaction, and unhealthy lifestyle. To introduce greenery back to the cities while still maintaining density of build-up area, many cities starts to look into the integration of greenery on roofscape of these buildings.

Advance construction technique which solves waterproofing and loading issue, certainly allow us to integrate greenery on the roof. Though, long term maintenance of these green roof require a lot of resources to ensure moisture and fertilizer content is optimal for plants’ growth as the condition is still different from true ground planting where moisture and fertilizer can be exchange naturally. Many green roof that were built without considering maintenance factor has ended up with removal of plants altogether.
In search of a sustainable way to execute a green roof, we have explored how to create a condition as close to nature as possible so that the plants can survive without having to provide too much resources.

2. Can we grow forest on the roof?

Idea of growing forest on the roof were explored on 2 projects in a completely different scale. One is a business park of 35,000 sqm. site area and another one is a compact private house in city area.

2.1. Mapletree Business City II

This project is situated in Singapore amidst the nearby Nature Reserve and Parks; Labrador Park, Hort Park and Kent Ridge Park. The main concept is to create a forest to extend ecological corridor from these nearby parks into the site. The main challenge is the fact that most of planning area is on a vast car park’s podium roof designed as a new ground floor to connect seamlessly to adjacent buildings and main public transportation.

Various consideration were taken into account in order to achieve a sustainable forest on the roof.

2.1.1. Soil Depth & Space Creation

Due to the limitation on ceiling height of the car park below, average soil depth initially achieved is only 800 mm. which is not sufficient to grow big trees. To deal with this, series of mounds is created throughout the roof. The highest point of each mounds is set at 1 metre high, thus, 1.8 metre soil depth is achieved at the highest point. The mounds in natural form, varies in size, becomes a 3 dimensional elements in the landscape shaping various spaces mimicking deep forest experience.
Network of pedestrian walkways in different width cuts through the mounds creating a natural movement of people wandering/commuting through the greenery. Some of the mound is integrated with private sitting area on the top of the mound surrounded with lush vegetation.

2.1.2. Water Management

Over a large expand of roof area, flat surface of greenery usually induce water clogging problems. Therefore, the mounds are not only designed to solve the soil depth issue, but they also utilised as main device to regulate the surface water run-off pattern efficiently.

Bio-swale is integrated at the foot of each mound to slow down the downpour and at the same time filtering dirt and toxin that come along with the rain water through sandy layer. Unlike concrete gutter system, bio-swale retain some moisture in the ground after the rain making depend less on the irrigation watering.

Eventually, the pre-filtered rain water is collected at the lowest point and leads into the rain water harvesting tank, treated and recycles for irrigation. The tank size is calculated to hold 7 days of irrigation water.
Incorporated with rain censor system, which will save irrigation water during rainy days, the amount of irrigation water saved in the tank will be sufficient for the relatively wet island of Singapore.

2.1.3. Mixed Indigenous Planting Species

In order to create a forest habitat, over 65 indigenous species of trees, shrubs, ground cover, and water plants mostly found at nearby Nature Reserved were specified.

Another good property of the mound is that it provide greater surface to plant more number of trees as and shrubs as compare to flat ground of the same outline. Varying tree’s size from sapling of 0.5-1 metre high to young trees at 2-3 metres high to mature trees at 6-8 metres high are randomly placed to form a true forest composition. Feature trees of more than 8 metres high is only used at area where instant shaded is needed.

Majority of the trees planted are the younger trees which have better growth rate as compared to an older specimen. Average spacing of each trees is around 2-4 meters to achieve dense foliage which allow less sunlight to reach the ground

Variety of evergreen, flowering and fruit baring trees and shrubs species help enhancing the forest as habitat for butterflies, dragon flies, bird and other wild animal to maintain healthy biodiversity at large.

Tropical Forest Tree Species:
Fagraea fragrans, Michelia champaca, Bucida moleneti, Dalbergia cochichinensis, Calophyllum inophyllum, Chrysophyllum cainito, Elaeocarpus hainanensis, Pouteria obovata, Lagerstroemia floribunda, Eugenia polyantha, Dillenia philippinensis, Melaleuca cajuput, Garcinia subelliptica, Dillenia indica, Pometia pinnata, Brownea grandiceps, Millingtonia hortensis, Shorea leprosula, Xanthostemon chrysanthus, Khaya senegalensis, Sterculia parvifolia, Barringtonia acutangula, Tecoma rosea, Ficus lyrata, Barringtonia asiatica, Crescentia cujete

Tropical Forest Shrub Species:
Jatropha integerrima, Crinum amabile, Alocasia macrorrhiza, Asplenium nidus,
Philodendron burgundy “green”, Neomarica longifolia, Heterocentron elegans, Justicia gendarussa, Belacanda chinensis, Ophiopogon jaburan, Calathea loesseneri, Philodendron scandens, Hymenocallis littoralis, Sphagneticola trilobata,

Water Plant: Thalia geniculata, Nymphaea, Pontederia cordata, Typha angustifolia

2.1.4 Activities

Even though it is designed as dense forested roof, full ranges of activities including small/large gathering area, seats, natural ponds, green amphitheatre and various sport courts are also inserted to encourage a healthy lifestyle for all users.

The forested roof is destined to be a vibrant communal nodal point for both human city life as well as urban wild life.

Green Amphitheatre

Main corridor where part of the forest extended underneath the building footprint

Sport Court and Fitness Station

Private sitting area on top of the mound surrounded with lush forest species
Main passage with the experience of crossing the stream and forest
2.2. Forested House

Another project is a private house situated in a low density residential district adjacent to rail line mass transit station in Bangkok city. Typical home in this area built during 1970s’ usually contains sizable front garden with the home at the back. This allow big trees to grow at the street level providing shade and greenery for the neighbourhood. As a result of good vicinity to rail line mass transit, price of land has risen up considerably, so it’s understandable that new homes built to replace the older one in the last few years often maximise the plot area as much as what the regulation allow. Though, this trend is worrisome because it leaves no space to plant any trees anymore.

This project is also following this trend. New bigger home was to be built to replace the existing smaller one to cater for extended family. Though, its also the vision to still integrate greenery as much as possible into the house utilising various roof surfaces.

Few strategies were considered from the beginning of design stage to ensure that planting location and method is ideal for tree growth and require less maintenance for house owner.

2.2.1. Make Room for Trees

To deal with the rectangular plot of 12x24 metres, the layout of the house is segmented to 3 sections to allow 2 courtyards in between. This is not only encourage good wind flow to reach every room in the house but also allow space to plant trees at the courtyards.

On second floor, planter is integrated in front of the house to provide privacy for the bedroom facing the local street. Another planter is also added at the courtyard to allow connection to the bedroom.

On third floor, where the roof is, the planter of 1 meter high, double up as railing, occupied around half of the total area leaving flat surface for other functional use such as, dining table, urban farm, and cloth drying area.

Altogether trees will be grown on every floor from ground up to the roof.
Roof Plan

Elevation showing Tree’s location from ground up to the roof

Location for tree planting both on ground and on planters
2.2.2. Forest in the box

The average planter height is around 1 to 1.5-meter-deep with limited size of around 2 * 4 metre. Only young trees of 1-2 year old with 1 inch trunk diameter were selected to be planted because the young root system still have a higher chance to adapt to the limited soil condition. The whole planter box is filled with high nutrition topsoil help to provide enough food for the roots. To increase number of trees to be planted on the small planter size, only columnar shaped trees were specified.

Indigenous tree species typically found in mixed deciduous forest were used as they demand less watering to save the resource. More than 20 species of Evergreen, Flowering, Fruit Barring, and Edible trees creates a much more biodiversity for urban area.

It is a design process to allow nature to success through the years rather than to create an instant thick forest look which might not last long. Within 10 months after completion, trees are grown up to twice the height of the original size when first planted.
2.2.3. Urban Farm

Roof surface is an ideal place to have an urban farm as there plenty of sun that herbs and vegetable needs. Thus, another important function of the forested roof is to produce fresh, organic food for the family.

Thai fruit tree such as Star Apple, Rose Apple, and Star Gooseberry were randomly mixed into other forest trees to lessen the chance of getting attack from the insect. Variety of Thai traditional herbs is planted in series of planter boxed of 400mm depth.
2.2.3. Sustainable Forest

As this is a private house, simple maintenance were planned from the beginning to ensure that the forest grow well in the long run without too much resource. Following are few important points.

Water Irrigation

Slow release drip irrigation at the root is chosen to save water. Perforated micro poes tube run through the top soil layer releasing minimum water throughout the day maintaining sufficient humidity at the root of each tree. In this way, lost of excess water is less than sprinkler system.

Encourage Natural Composting Process

Underneath the trees, shrubs and ground cover were not planted to leave bare soil for fallen leaf to cover. All dry leaves are collected not to throw away, but to fill the forest floor. Over the times, natural degradation process from microorganism turn the leaves into natural nutrient-rich fertilizer producing food back for the trees. Each tree species consume and produce different kind of nutrient. Variety of trees help to balance the nutrient distribution.

Irrigation Diagram

Natural Composting Process Diagram and Photo
Selective Pruning

Because of limited space, over the time when each tree grow at different speed, branches may crash effecting growing rate of the slower trees. Quarterly, selective pruning of the branch may be required to give way to the slower tree to grow.

2.2.3. Species List

Fragrance Flowering Tree:
Fagraea fragrans, Michelia champaca, Calophyllum inophyllum, Millingtonia hortensis, Shorea roxburghii G.Don, Citharexylum spinosum, Melodorum fruticosum

Fruit Bearing Tree:
Star Fruit, Star Gooseberry, Jack Fruit, Rose Apple

Distinctive Flowering Tree:
Mayodendron igneum, Jacaranda obtusifolia, Spathodea campanulata, Lagerstroemia floribunda, Lagerstroemia speciosa, Lagerstroemia floribunda, Cassia grandis, Cassia 'Siam White', Shorea robusta, Gardenia sooteptensis Hutch

Distinctive Flowering Tree:
Jacaranda obtusifolia

Thai Herbs and Vegetable:
Basil, Sweet Basil, Hairy Basil, Stevia Grass, Pepper Mint, Spear Mint, Lemon Grass, Lime, Chilli Padi, Butterfly Pea, Passion Fruit, Cucumber, Climbing Wattle, Yellow-Berried Nightshade, Mulberry
Biophilic Cities

months after completion
3. Conclusion

Both Mapletree Business City II and Forested House show the potential of how to integrate greenery sustainably into dense urban fabric of many cities without having to sacrifice build-up area usage.

Many more possibility could open up if ‘Forested Roof’ is applied throughout the city. It might become a new ground for recreation, commuting, food production, education, etc., that also help to mitigate the impact of many challenges cities are facing today such as, urban heat island, absorb rain water to prevent flash flood, produce oxygen, generate social interaction, and promote healthy lifestyle. Biophilic Cities could become true.

Abstract

With the increasing number of dense and green building typologies in Singapore comes a paradigm shift in the perception of greenery as part of the built environment. This shift on the side of authorities has produced firm legislation-driven guidelines to achieve Singapore’s vision of being “a city in a garden”. Despite this motivation and the fact that having greenery in buildings has many benefits has generally been acknowledged, such typologies are still not often pursued by building industry professionals. This study was carried out to determine the current perception of industry pioneers and relevant recommended schemes promoted by the Singapore Government. For the investigation, seven industry pioneers (four architects and three landscape architects) who have designed and realised award-winning dense and green buildings, were chosen. In order to understand the impact and challenges that lead to individual perceptions, they were probed through a detailed analysis of interview transcripts. Information was collected using structured open-ended interviews, and the results were qualitatively analysed on NVivo. The qualitative study revealed that while there is a significant appreciation of the legislation leading to such typologies, there is also a consensus on improving such legislation to avoid pertinent issues. These legislations and relevant issues are identified and discussed in the paper. The study shows that the pioneers generally agreed on the advantages and benefits of dense and green building typologies. However, there was a disagreement among architects and landscape architects on the designed aspects that lead to usage and maintenance of greenery in buildings. Also, the study shows that there is ambiguity among the pioneers on the interpretation of existing legislation and its corresponding impact, which may or may not lead to flexibility in designing such typologies. The paper seeks to stage a two-way conversation among the industry professionals, to highlight and improve the gaps in perception while discussing existing policies, programs and incentives, aiming to enhance understanding of dense and green buildings in Singapore.

Keywords: building legislation, landscape urbanism, maintenance, greenery
1. Introduction

With the increasing number of dense and green building typologies in Singapore comes a paradigm shift in the built environment. It produces strong legislation-driven guidelines to remain committed to “City in a Garden” concept even into its heights. Nearly half the size of metropolitan London, Singapore has transformed modern metropolis with diversified economy in a short span of 50 years. In the wake of rapid urbanization, Singapore’s unique circumstances and land scarcity demand the need to find innovative ways to optimize “Garden City Ambience” with the limited land area. In the year 2001, Prime Minister Goh stated that ‘going vertical’ in the form of roof deck gardens, sky terraces, landscaped balconies and planter boxes could be one amongst few other strategies. He also highlighted the need to generate awareness of the benefits of high-rise greenery so that building owners and designers would incorporate such greenery in their building designs. [1]

The benefits of skyrise greenery have since then been well documented. Among them are environmental benefits such as storm water retention, improvement of air quality, economic benefits such as energy resource savings, and socio-economic benefits that include recreational opportunities in dense urban environment [2]. Much of the greening efforts in Singapore are put into action through governance and schemes that promote greenery in dense urban environments.

1.1. Skyrise Greenery Incentive Scheme (SGIS) by National Parks Board (N Parks)

The Skyrise Greenery Incentive Scheme was introduced in the year 2009 to increase greenery provision in Singapore by funding up to 50% of installation costs of rooftop greeneries and vertical greenery. Singapore to date has a total of 182 projects and 80.5 hectares of rooftop greenery. Skyrise greeneries in Singapore is set to increase with the Sustainable Singapore Blueprint (SSB) target envisioning 200 hectares of rooftop greeneries by 2030. [3,4]

1.2. Landscaping for Urban Space and High-rises (LUSH) by Urban Redevelopment Authority (URA)

Introduced also in the year 2009 complementing the Skyrise Greenery Incentive Scheme is LUSH where new developments and redevelopments can be eligible for incentives in the form of additional Gross Floor Area (GFA) for incorporating rooftop greeneries. Over the years, the LUSH Programme [5] has evolved to include co-located greeneries and roof top solar panels, rooftop urban farming to name a few.
Fig. 1. LUSH Programme details by Urban Redevelopment Authority explaining different areas of building with greenery provision

1.3. GreenMark Scheme by Building & Construction Authority (BCA)

The BCA Green Mark Scheme was launched in January 2005 as an initiative to drive Singapore’s construction industry towards more environment-friendly buildings. In the year 2010, with the release of V4.0 Green Mark Scheme started to recognise and award points for Green Plot Ratio (GnPR) which is calculated by considering the 3D volume covered by plants using the prescribed Leaf Area Index (LAI). [6]

1.4. Landscape Excellence Assessment Framework (LEAF) by National Parks Board (NParks)

Introduced also in the year 2013, the Landscape Excellence Assessment Framework, or LEAF for short, is a certification scheme to recognize development projects with outstanding greenery. This is the first scheme in Singapore that is solely dedicated to the provision and management of greenery. With LEAF, NParks aims to encourage more greenery in Singapore’s urban landscape. [7]

Despite the motivation in the form of legislation and the fact that greenery in buildings have many benefits, the dense and green building typologies are still not often pursued by building professionals. [8] Hence, it may be appropriate to ascertain whether the assumed benefits of skyscraper greenery are perceived to be true among the professionals in the building industry. If they were indeed deemed to be true, it would raise the question of why greening of urbanscapes are not as widely adopted as they should be and what obstacles there are to their development. A qualitative perception study of built environment professionals such as architects and landscape architects would aid in removing the inherent barriers in adoption of greenery in dense urban environments.

The objective of this study therefore to conduct qualitative interviews with industry pioneers to understand perception of the following:

1. Dense and green building typologies
2. Role of Legislative frameworks such as SGIS, LUSH, LEAF and others and their contribution to the design process
3. Challenges of integration of greenery into different building functions
4. Suggesting measures to overcome challenges and existing legislation, if any

2. The Study

2.1. Respondents

The objective of conducting face to face interviews for this study is to determine the inherent benefits and barriers of deploying dense and green building typologies that industry pioneers perceive to be true. Another aim of the interview is to analyse any disparity in views between the different disciplines. The participants in the part of the study reported here consisted of seven respondents who are industry pioneers in Singapore. The interviews were conducted among two target disciplines, namely Decision Makers/Design Lead from the
architectural firms registered under the Singapore Institute of Architects (SIA), landscape architectural firms recognized by Singapore Institute of Landscape Architects (SILA). [10,11] These two target disciplines also enable to study perception that influences design thinking and thus adoption of dense and green building typologies.

The respondents have completed several noteworthy and award-winning projects across Singapore with varying functions such as The Interlace, Skyville@Dawson, Punggol Waterway Terraces I, Oasia Downtown, Khoo Teck Puat Hospital and Solaris. These projects are each distinct in nature and embrace incorporating greenery into dense urban environments in their own unique ways. The interviews were taken during a period of March 2017 till July 2017.

2.2. Survey Questionnaire

A comprehensive questionnaire was developed with consultations not only from architects, academics and urban designers but also from researcher/s specializing in cognition, perception and behaviour in urban environments. The interdisciplinary consultation allowed to frame the questions in a manner which was neutral, unbiased and open-ended in nature. The interviewee responses were therefore not constrained to certain categories as provided by the interviewer but consist of whatever answer they wish to give. By using such a strategy, it is expected that the open-ended questions will provide replies that better reflect a person's own perception. All the respondents are asked the same questions in the order in which design thinking is progressed namely, concept, design development and post occupancy, only 4 most relevant of the 26 questions asked to have been included in this study. This structured strategy was a way of increasing the comparability of responses and ensure responses to all questions for every interviewee. Furthermore, this approach provides a 'natural' basis of organization for analysis of data from design to construction and handover to post-occupancy.

Question 1: How do you define dense and green building typologies?

Question 2: Could you please explain the role of LEAF (Nparks), Green Mark (BCA) and Replacement Greenery (URA) programs and how does it contribute to the design process and architectural configuration?

Question 3: What are the challenges (direct and indirect) for the integration of greenery into buildings?

Question 4: What more could be done to improve incentive schemes from the Government, please highlight with an example of the completed project?

2.3. Analysis

The interview data were transcribed, typed into word files. For the selected questions, only selected quotes were analysed using NVivo. NVivo usage was kept limited to helped with categorization and classification of the interview data. NVivo allows qualitative data to be easily managed, cross-referenced, organized and analysed. Purpose built for qualitative and mixed-methods research NVivo enabled visualization of results to brainstorm and map ideas and explore connections between project items. [12]
Fig. 2. Visual of NVivo tool used for categorization and classification of the interview transcripts.
3.0 Defining Dense and Green Building Typologies

Architects

RH: "Particularly tied to the amount of architecture in your field of view, and that's where we think planting can be very helpful to make density bearable."

MH: "When it comes to dense typology, you need to think about the void, and then what is in the void? The green."

SY: "Traditional understanding is that, greenery is lost, because the building replaces the green. But, if we can lift that site, or find a way to replace it within that building development, then we can try to balance both greenery and built environment."

SC: “With buildings, if you green it, whether is it on the ground plane or up on the elevated plane, or even on the elevation, it would be green.”

Landscape Architects

FP: “Architecture is not just about buildings. It’s always about the relationship to the external. Always in connection with the greenery. ”

HS: "If you have a suburban road, does not have any trees in it because it’s so narrow, you are over-dense. But if you got enough space to plant a row of trees on that road, it becomes greener. So, density and green tend to come together, it’s a kind of push-pull arrangement depending on how your planning is done."

SM: “I am interested in landscape spaces having a function. I am more interested in that leading into design, rather than a proportion of space that is ‘green’."

It is clear from the transcripts that both architects and landscape architects agreed that greenery is a powerful tool to reduce the perceived development density. While the weightage in architects’ perception are inclined towards a balance of form and visual relief, the landscape architects perceive greenery in relation to the surroundings. Although one landscape architect highlighted quantum of greenery should not be seen in isolation with its function.

4.0 Governance and Schemes Promoting Greenery

Architects

RH: “It helps in getting the whole industry talking about greenery. It means there is a sort of eco-system of specialist landscape companies who can supply green solutions. These programs are creating statistically significant increases in green all over the city."

MH: “At the beginning we try to free from all these regulations. And also, we always try to get a bit of freedom on these rules and regulations and see how we can expand. Sometimes I feel it is a bit too framed, too rigid."

SY: “I think these policies are very useful. Without the policy, sometimes obstacles are from the client. The client may
not subscribe to the same philosophy and look at the return on investment only, therefore policies help to balance that consideration for the decision making of the architect.”

SC: “Frankly, it’s a hassle because it provides that challenge for designers, to really critically think about how to encompass or accommodate all these requirements. And that is good intention.”

Landscape Architects

FP: “The government should not have to define how to deal with handicapped people, and elderly people, etc., practises have an obligation to think holistically about design. Same applies to greening”

HS: “Limitations with LEAF and Green Mark are that LEAF certification may be harder to achieve where product of architecture is building focussed and Green Mark’s green plot ratio is heavily dependent on plant species and growth assumptions of green cover. LUSH must be used for the purpose of replacement of usable space in a green environment anywhere on your building. I’m a great fan of landscape replacement, I sell it everywhere, including overseas.”

SM: “I think there is a kind of fundamental difference, that we see as design. We don’t approach projects, or clients or situations from a policy point of view. You approach it from a design expression or functional point of view.”

Architects and landscape architects have varied views in relation to governance and schemes promoting greenery. The architects’ have mixed opinion about role of governance, some find it rigid, challenging and framed, whilst others see it a way to integrate industry, create new ecosystems and also support architects to push the agenda of greenery to the clients. Two of the landscape architects agreed that greenery is part of holistic approach to design and need not be policy driven. Although one landscape architect highlighted challenges in achieving specific schemes.

5.0 Challenges in Integrating Greenery with the Buildings

Architects

RH: “Technical spatial challenges such as soil depth, complicated drainage runs and blockages, irrigation, accessibility for maintenance, wind and anchoring large trees.”

MH: “Cost of high rise structures with respect to additional structural weight for trees and maintenance issues sometimes limits the exploration.”

SY: “Without the policies behind it, developers would be concerned about the capital investment and maintenance aspect. Singapore has actually been quite successful in building our system that allow this amount of urban greenery to thrive, to happen.”

SC: “Not just complying with 100% replacement greenery but also costs of implementing this compound the challenge.”

Landscape Architects

FP: “I think, one of the major challenges is to have developers understand that we
should come into the project much sooner than later. Usually we get the project after it’s already been approved for planning.”

HS: “There is a lot of complexity across all the disciplines, with everybody dealing with everything: from structural loading to drain discharges.”

SM: “We can have all the ideas and principles we want, but fundamentally we are working for someone who has a commercial agenda, the client. And government authorities also have an agenda, there is no fixity to design that makes our job much more difficult in terms of coordinating these external aspects, while focusing on installation and maintenance.”

There is a general consensus between architects and landscape architects about the capital investment cost and maintenance issues that need to be resolved. One architect highlighted that because of policies and early adoption Singapore has developed an ecosystem that allows for greenery to thrive. On the other hand, a landscape architect highlighted the need for early involvement in design that can help mitigate some of the challenges that may arise.

6.0 Potential Improvements

Architects

RH: “One of the significant improvement was when URA made sky garden free of GFA. I think they are a little rigid with the 45-degree rule. If the vertical greenery U-value, shading coefficient calculation would be accepted, then it would potentially be adopted at much higher rate than it is now. Would be interesting if NParks would have an integrated greenery masterplan with actual requirements that your vertical greenery must connect to the canopy of the street trees for instance, to provide routes for squirrels to reach more part of the gardens. Categorisation of garden and more studies to have a complex understanding of the various roles and nature performance rather than just seeing as a decorative manicured garden, I would really like to see the research on how can we retain all the benefits of this but do it in a way that people can really make sensible decisions about the level of cost in maintaining the gardens, and manpower.”

MH: “Definitely GFA relation, how can we give some more bonus with GFA, when it comes to greenery. Then I think the regulations should be in a way more flexible to push more the specificity of each project. Because of rigidity with 45-degree rule, developers do not negotiate with architects.”

SY: “Feedbacks from my clients, is that the current incentives balance the investment they put in. It’s equivalent to GFA given, so if we want to intensify further, it’s always about economic incentives. Perhaps to provide incentives for maintenance and operational subsidies. A multi-agency collaboration to promote greenery in buildings as opposed to existing individual schemes.”

SC: “I would say, maybe, not so much in terms of implementation but in terms of built environment industry education. Also, the upcoming improvements to be implemented in a staged manner for the industry to adapt along the way.”

Landscape Architects
FP: “In a quantum leap, not very much. Because everything takes a step by step process. And can we get to a point where we can fully integrate, buildings layers and everything? It will take a lot of effort, and probably new mind-set, new thinking, are we there yet? We are getting, as a city, in 50 years, doing what it has done. It’s phenomenal. And the grand experiment can continue in Singapore, I think, it’s the only city in the world where something like this can be done.”

HS: “My view is that it should not be dollars and cents. The incentives which give more GFA for doing certain things are good. The government wants to have an environmental gain, but it hasn’t found a mechanism to do it, that allows flexibility on the GFA issue.”

SM: “An individual designer come and do-little component parts rather than having more of a significant say on some other broad issue. One needs to understand landscape should be thought about as a series of connected spaces, and purpose that they have. So, where landscape is accessible, and let’s widen the term, accessible to mean functional as purpose, it got amenities. And all sorts of characteristics, if we could make those arguments and then stitch those into those planning frameworks instead of just replace like-for-like 100% of the site with green.”

The need to integrate greenery on buildings with the larger networks of city and research on areas such as biodiversity, urban heat island mitigation, ecosystem services to help designers and policy makers frame future policies with a holistic view. Architects specifically thought the GFA exemption with 45-degree rule must be flexible to relate with specificity of each project and should not be applied to all projects as a standard rule.

7.0 Discussion

Although the transcripts are elaborate, only selected quotes have been used for this paper. The discussion takes into account complete answers for these four questions. The amount of skyrise greenery in Singapore has grown from 61ha in 2013 to 72ha in 2015, which far exceeded the target of 50ha the Government had hoped to hit by 2030. The new target is now 200 ha of building greenery by the year 2030. [2] A qualitative and research-based approach on functionality, ecological performance and post occupancy maintenance should be considered as opposed to only quantifying greenery and landscape areas. Each government agency has its own targets when it comes to greenery and its adaptation in built environment with different greening programs. There is an emerging need for an inter-agency collaboration to harmonise the commonalities and qualitatively review different legislations and schemes against the set goals. Most architects and landscape architects were of the view that the existing regulations and schemes need to be flexible for a case by case adaptation. The author identifies the need for conducting an industry wide survey and developing key categories for flexibility in existing legislations and scheme to provide the designers with more innovative freedom.

It is imperative that the industry pioneers strongly perceive that for clients to pursue dense and green building typologies economic incentives play a significant role. Existing economic incentives balance the investment but need to be intensified. For instance, an incentive for maintenance of
existing skyline greenery and awards/recognitions to the same will help the greening agenda. With high rise built environment, maintenance came out as the biggest challenge and needs to be reviewed holistically. With visionary goals for “vertical kampung” the industry also needs to work in an interdisciplinary collaboration towards greening Singapore.

Acknowledgements

The authors wish to express special thanks to all the interviewees for sparing their valuable time and sharing their knowledge and thoughts. Also, the authors wish to thank their team Panos Mavros, Kristina Jazuk, Thibault Pilsudski and Emek Erdolu of Future Cities Laboratory, Singapore ETH-Centre, Singapore.

Abstract

From ‘garden city’ to ‘vertical kampung’, the urban evolution of Singapore to its current dense and green morphology has long been influenced by some form of biophilia. It is commonly claimed that urban greenery can cool localities but few studies have analysed the surface temperature differences between greenery and artificial materials across multiple building developments. We conducted an observational field investigation to quantify the thermal performances of exposed and shaded surfaces, including greenery and artificial materials, in five case studies of green infrastructure in Singapore. We then assessed the results against expectations about urban cooling strategies from existing literature. The difference in mean surface temperature between greenery and various artificial materials, namely masonry materials, plastic and rubber, ranged from 4.82°C–23.5°C. The effect of shading on mean surface temperature was a reduction of up to 6.37°C. For every 1°C rise in air temperature within the recorded range, the difference in surface temperature between greenery and artificial materials increased by 0.88°C–5.17°C while the surface temperature reduction from shading increased by 0.50°C. Owing to differences in context and methodologies among studies, it is difficult to directly and fairly compare the effect sizes we detected with those from existing literature. Nonetheless, our results validate that the substitution of conventional artificial surfaces with greenery and the introduction of shade are plausible strategies for localized cooling in dense tropical cities.

Keywords: surface temperature, material type, shading, green infrastructure, ecosystem services
1. Introduction

1.1. The City in a Garden — Biophilic urbanism in Singapore

Biophilia—the desire to have and experience nature—is well rooted in Singapore’s urban evolution. Since the early days of independence, the nation’s first Prime Minister, Lee Kuan Yew, had the vision to grow Singapore into a ‘garden city’ and through the ‘Clean and Green’ campaign, managed greenery sprouted in the spaces between buildings all over the city [1,2]. In 2012 and onwards, the vision for green Singapore has shifted to the concept of a ‘city in a garden’ which emphasizes making environmental sustainability part of the city’s DNA [3]. At the same time, innovations in greening technologies and policies such as the Sky Rise Greening Initiative have facilitated the sprouting of greenery on building facades and rooftops [2]. From an aerial view of the entire of Singapore in Google Maps, it is evident that the city has grown to be dense and green.

In Singapore and the wider tropics, the implementation of urban greenery is not only motivated by biophilia but also by people’s valuation of their functional benefits. These benefits range from environmental and ecological ones such as mitigation of the urban heat island (UHI) effect [4], supporting urban biodiversity [5,6] and noise reduction [7], to socio-economic ones such as provision of visual relief [8], being a destination for leisure and recreation [8] as well as increasing the value of properties [9].

1.2. Dense and Green! But too hot? — Biophilic urbanism for a cooler Singapore

With urban development and global warming continuing largely unabated, there have been concerns about the health consequences of the increasing intensity of UHI in cities across the world. This is because the phenomenon directly exacerbates the risk of heat-related stress, injury and mortality for city dwellers, particularly during extremely hot spells and heatwaves which are expected to increase in severity and frequency in the future [10–12]. For tropical cities with high relative humidity like Singapore, UHI is more pressing as the threshold temperature above which conditions become lethal is considerably lower than cities with drier climate, e.g. at 20% relative humidity, temperatures typically become deadly only when above 40°C whereas at 80% relative humidity, temperatures above 30°C can already kill [13]. High relative humidity makes it more difficult for the human body to dissipate heat through sweat evaporation.

Often overlooked but also of concern is the impact of high temperatures on the health of the other living residents in the city—the urban flora and fauna. For instance, high temperatures have caused multiple mortality events of urban bats [14]. As recently as January 2018, more than 200 flying foxes in the city of Campbelltown, Sydney, succumbed to heat stroke as temperatures reached 47°C [15]. In November 2014, up to 5000 flying foxes in Casino, northern New South Wales, were killed by a heatwave sporting temperatures of 44°C [16].

To mitigate the UHI effect, one of the many strategies proposed is to increase the extent of urban greenery [17,18]. The cooling effect of urban greenery has been quantified by many studies spread over a wide geographical context. An investigation of the cooling effect of shade trees in a park in Taiwan revealed that air temperatures underneath tree canopies can be up to 2.5°C lower than the air temperatures in adjacent unshaded spaces [19]. A study of an extensive green roof in Hong Kong stated that greenery lowered the daily maximum floor surface temperature by 5.2°C, and the
air temperature 10cm above the ground by 0.7°C [20]. A green wall in Beijing was monitored and reported to be, on average, 4.5°C cooler than its bare counterpart [21] while an experiment at Reading, United Kingdom, illustrated that between vegetated walls and exposed brick walls, the difference in adjacent air temperatures and surface temperatures reached 3.0°C and 9.9°C respectively [22].

Numerous relevant studies have been done in Singapore. At a rooftop garden, Wong et al [23] found that the maximum floor surface temperature measured under a shrub was about 30°C cooler than that of an adjacent floor without plants. The same study also reported a maximum difference of 4.2°C in air temperatures, measured at a height of 300mm above the ground, between areas with and without plants. In terms of vertical greenery, Tan et al [24] showed that a concrete wall could be 6.9°C cooler when clad in a layer of greenery. There are also studies investigating what factors account for greenery’s cooling effect. Using data from three plots of rooftop greenery, Tan et al [25] produced a prediction model linking plant evapotranspiration rate and shrub albedo with the mean radiant temperature above the greenery. At a reference mean radiant temperature of 50°C, the model predicts that greenery with an evapotranspiration rate of 0.030mm per minute and a shrub albedo of 0.30 will lower the mean radiant temperature by 16.5%.

There is general consensus that urban greenery can cool localities by 1) intercepting solar radiation and preventing the warming of surfaces and air in its shade, 2) acting as a heat sink by having surfaces that are cooler than artificial materials or the air temperature, and 3) evapotranspiration which converts sensible heat to latent heat and consequently, reduce the energy available to increase ambient temperatures [26].

When exposed to the same amount of solar radiation, the surface temperatures of plants are likely to rise to a lesser degree than conventional artificial materials such as concrete and asphalt because 1) plants have the ability to self-shade, with the lower layers of leaves and stems receiving less solar radiation, 2) the biotic morphologies of plants often result in there being pockets of insulative still air between and within layers of leaves and stems, and 3) some of the heat energy absorbed by the plants is diverted to fuel biological processes, particularly photosynthesis and evapotranspiration. As such, we hypothesized that greenery tend to have low heat admittance and accumulate less heat over time. With greenery being less responsive to the temperature of its surroundings as compared to artificial materials, we expect that the surface temperature difference between the two will widen at higher ambient temperatures.

Our main research question was “What are the thermal performances of exposed and shaded surfaces of greenery and artificial materials in green infrastructures in Singapore, and do they align to expectations from existing literature?” To answer this question, we quantified the surface temperature differences between greenery and several artificial materials across shaded and unshaded conditions. In contrast to previous studies, which typically collected data from a single landscape feature repeatedly over time or in an experimental setting, we recorded field observations of five post-occupied buildings which embrace greenery in their design and have greenery on and around them. This serves to most directly assess and compare, on a building development scale, the actual thermal performances of the different surfaces in those existing infrastructures.
2. Methods

2.1. Data collection and image classification

The five case studies investigated are Punggol Waterway Terraces I, SkyVille @ Dawson, Khoo Teck Puat Hospital, SOLARIS and Oasia Hotel Downtown. Snapshots of surface temperatures were measured and recorded in the form of thermal images using a FLIR E8 infrared camera (FLIR Systems, Wilsonville, Oregon, United States). The camera has a reported accuracy of ±2°C and a thermal sensitivity of <0.06°C, and was calibrated to an emissivity of 0.93 to compromise for the emissivity of concrete (0.92), rubber (0.95), plastic (0.93), wood (0.90) and that of plants (0.94-0.98) [22,27–29]. At each building, we surveyed the surface temperatures of the range of materials and plants present on-site by taking 30 thermal images of various spaces with greenery, including ground gardens, landscaped deck, elevated gardens and vertical greenery. The thermal images were taken on two non-rainy days per case study, between 14:00 to 18:00. Ambient weather conditions, namely air temperature, humidity, wind speed and solar radiation, were recorded during the survey periods using an Ambient Weather Ws-1001-WiFi OBSERVER weather station (Ambient Weather, Chandler, Arizona, United States) set up at a height of 1500mm above the ground. The surveys were carried out between 21st August 2017 and 20th March 2018.

We set the infrared camera to capture a digital image of the same resolution and field of view whenever a thermal image was taken. The surfaces in the digital images were categorized by surface type, consisting of eight categories—water body, shrubs and trees, turf, metal, masonry materials, wood, plastic and rubber, as well as a binomial shading condition (shaded or unshaded). This is accomplished through a semi-automated, two-step image classification process which involved manual demarcation and color range selection in Adobe Photoshop, followed by K-means clustering using the raster package [30] in the R software environment. Subsequently, the thermal images were overlaid onto the corresponding categorized digital images and the mean temperatures for the shaded and unshaded surface types in every pair of images were determined (Fig. 1).

2.2. Statistical analysis

All statistical analyses were performed in R version 3.4.1 [31]. Using the lme4 and lmerTest packages [32,33], we generated a global linear mixed-effect model based on the mean temperatures of shaded and unshaded surfaces in all the analysed images. In this model, the response variable was mean surface temperature. The fixed explanatory variables were surface type, shading condition, air temperature, relative humidity, wind speed, solar radiation, as well as the first-order interactions between surface type, shading and air temperature. Collinearity between the explanatory variables, excluding interactions, was assessed using the vif.mer function and the variance inflation factors calculated were all less than 2.15. Two nested random intercept variables were also included to account for the spatial and temporal variability between the thermal images. These random effects were the identity of the thermal image, nested within the identity of the case study, and the time at which the thermal image was taken, nested within date. Subsequently, we used the “dredge” function from the MuMIn package [34] to propose multiple candidate models and ranked them according to the Akaike information criterion. The best model had a weight of 0.79, thus we deemed model averaging unnecessary. The model matched our hypothesis that surface type, shading and air temperature had synergistic effects on surface temperature.
3. Results

3.1. Surface type

In our model, the reference category for surface type was shrubs and trees. Under unshaded conditions, and at the average recorded air temperature of 31.0°C, there was no significant difference between the mean surface temperature of shrubs and trees, and that of water body, turf, metal or wood. However, shrubs and trees were expected to be 4.82°C cooler than masonry materials, 8.35°C cooler than plastic and 12.9°C cooler than rubber (Table 1). These differences became more prominent at higher air temperatures. When air temperature reached 33.4°C, the maximum recorded, shrubs and trees were predicted to be 7.05°C cooler than masonry materials, 12.4°C cooler than plastic and 23.5°C cooler than rubber.

3.2. Shading

Shading was more significant for artificial materials than greenery, with the cooling effect on the particular surface types increasing in the order of masonry materials, wood, plastic and rubber (Table 1 and Fig. 2). At the mean air temperature of 31.0°C, shading was estimated to lower the mean surface temperature of masonry materials by 3.09°C, the mean surface temperature of wood by 4.25°C, that of plastic by 4.52°C, and that of rubber by 5.16°C. This stands in contrast with the surface temperature decrease experienced by shrubs and trees which is 0.98°C. With the air at a maximum of 33.4°C, the surface temperature reduction caused by shade on these artificial materials increased by a magnitude of 1.22°C each, to 4.31°C (masonry materials), 5.47°C (wood), 5.74°C (plastic) and 6.37°C (rubber).
Table 1. Coefficients of the best model explaining the effects of surface type, shading, air temperature and their first-order interactions on mean surface temperature.

Fig. 2. Predicted mean surface temperature (± confidence interval) of the various surface types under shaded and unshaded conditions

3.3. Air temperature

For every 1°C increase in air temperature, the difference between the surface temperature of shrubs and trees and that of masonry materials, wood, plastic and rubber increased by 1.04°C, 0.88°C, 1.93°C and 5.17°C respectively (Table 1). Similarly, the surface temperature reduction owing to shading increased by 0.50°C per 1°C rise in air temperature.

4. Discussion

4.1. Thermal performances of greenery and artificial materials

The results of this study match the general understanding established by previous research that greenery is mostly cooler than conventional artificial materials, and support our hypothesis that plants have low heat admittance (Fig. 2). Under exposure to solar...
radiation, the differences in surface temperature between greenery and artificial materials that were detected ranged from 4.82°C–23.5°C, depending on surface type and air temperature. Some parallels can be drawn with comparable studies. For instance, the estimated 4.82°C difference between shrubs and trees and masonry materials supports Di and Wang’s finding that the average temperature of leaves on a green wall was 4.5°C cooler than that of an exposed brick wall in Beijing at summer time [21].

It is, however, difficult to directly compare our results with those from existing literature because many previous studies were conducted in different environmental conditions. For example, a study in Phoenix, Arizona, detected a 10.6°C difference in mean surface temperature between concrete and turf which is larger than what we reported [37]. The is possibly because the data was collected from open plots in a hot desert climate [39], whereas our measurements were taken within green building developments situated in an equatorial humid climate [39]. This highlights the importance of recording and reporting the range of contextual variables such as air temperature and relative humidity which affect local surface temperatures.

In addition, studies often employed different methodologies which makes it difficult to fairly compare their results. Most investigations about the cooling effect of greenery on building envelopes compared the temperatures of artificial surfaces when exposed to solar radiation versus when underneath greenery [20,22,23,35]. This is as opposed to a comparison of the former against the canopy or leaf surface temperature as we had done. In contrast to the variety of artificial materials we studied, the majority of previous studies focused only on the temperature difference of greenery with concrete and asphalt [20,35–38], the most common artificial surfaces in urban areas.

Irrespective of shading, the hotter artificial materials seen on-site were invariably masonry materials, plastic and rubber, with masonry materials having the lowest mean surface temperature among these materials, and rubber the highest. The thermal performances of these materials were largely attributed to their thermophysical properties, specifically 1) albedo, which affects the amount of incident solar radiation absorbed and reflected, 2) emissivity, thermal conductivity and diffusivity, which influence how fast heat is absorbed, transferred and released, as well as 3) volumetric heat capacity which concerns the amount of heat required for the material’s temperature to rise [39]. By enhancing these properties, a material can have cooler surfaces and likewise, materials with low values for these properties have a greater capacity to absorb and store heat [39]. Many of the rubber and plastic surfaces we surveyed were dark colored, e.g. black and brown, and rough textured, suggesting that they had low albedo. Also, the high surface temperatures of these materials can be explained by their low thermal conductivity and diffusivity [40]. Conversely, the cooler artificial materials were water body, metal and wood. This is likely accounted by the relatively higher heat capacities of water and wood, and the characteristically high albedo and thermal diffusivity of polished metal [40].

Regarding greenery, we found that shrubs and trees had similar mean surface temperatures as turf. Any biological variations inherent to the plant forms, which might have affected their surface temperatures, were likely concealed by the unintended consequence of urban design in determining their microclimates. As a case in point, the difference in evapotranspiration
rates between shrubs and grasses might not be a significant factor in the light that turf is often relegated to open areas receiving direct solar radiation, whereas shrubs are more likely to be incorporated into shaded scenarios. Furthermore, we did not measure the evapotranspiration of greenery during our surveys, such as conducted by Shashua-Bar et al [41], and hence we cannot conclude whether evapotranspiration differed significantly between the plant forms or how this phenomenon relates to the observed surface temperatures.

4.2. The effect of shade on the thermal performances of greenery and artificial materials

As expected, surfaces were cooler when shaded because shading is essentially a form of solar radiation protection that reduces the amount of heat energy reaching the shaded surfaces. Since air temperature can be a proxy for solar radiation, it follows that the cooling effect of shade becomes more significant at higher air temperatures. However, this cooling effect was not equal across surface types. At the mean air temperature of 31.0°C, the surface temperature reduction of shrubs and trees by shade was less than 33% that experienced by the hotter artificial materials, including masonry materials, wood, plastic and rubber. The lower variability of surface temperatures in greenery was also remarked by Wong et al [23] and Köhler et al [42]. This might be because of the plants’ low heat admittance and their ability to actively regulate their temperatures as part of homeostasis which the artificial materials lack.

Interestingly, the greater the material’s potential to get hotter, the bigger the difference in its surface temperature under shaded and unshaded conditions (Fig. 2). We deduced that since shading virtually blocks out solar radiation, its effect on lowering surface temperature should be directly proportional to the materials’ ability to accumulate heat from solar radiation. As such, shading is more effective on materials that can attain higher surface temperatures. One such material from the case studies would be rubber which was recorded to exceed 70°C when unshaded. Rubber was predominantly used as the flooring for play areas, some of which were located on roofs and highly exposed to the sun. It would be highly efficient to shade these play areas to improve the thermal comfort of the people using said space.

4.3. Recommendations

Replacing various conventional artificial materials in unshaded spaces with greenery, or placing greenery on shading structures creates an offset of solar radiation interception, whereby the shading structure receives the solar radiation instead of the surface below it. This can effectively reduce the UHI effect. Greenery implemented in the case studies lowered surface temperatures by a maximum of 23.5°C.

Based on potential surface temperature reductions, shading should be prioritized on artificial materials rather than on greenery, and particularly on those materials that can attain high surface temperatures such as rubber and plastic with low albedo and low thermal diffusivity. Shading of artificial materials was found to decrease surface temperatures by up to 6.37°C. This could be a viable strategy for localized cooling in tropical cities.

Since the magnitude of the surface temperature reduction by greenery and shading increased with air temperature, more impactful cooling can be achieved by implementing landscaping and shading structures on buildings or spaces anticipated to experience the hottest microclimates.
Further research should investigate the relationship between the duration of shade and how that interacts with different species or functional groups of plants. In a high-density urban environment, different shading conditions are common. To green the city most efficiently, it may not be necessary to pick specialist species that have high thermal performances in particular shading scenarios, e.g. fully shaded spaces.

5. Conclusion

This study presented the thermal performances of exposed and shaded greenery and artificial materials in five green infrastructures in Singapore. Our results support the general understanding established by previous research regarding the potential of greenery and shading for cooling urban localities. It is difficult to directly and fairly compare the effect sizes we detected with those from existing literature because of differences in context and methodologies. Nevertheless, the reported surface temperature differences between greenery and the various artificial materials, as well as the surface temperature reduction by shade validate the effectiveness of cooling strategies utilizing greenery and shading when applied to the context of the case studies in particular, and to dense tropical cities in general.

Abstract

In Chinese traditional culture, living plant’s smell is an important aesthetic object. Smellscape is an organic part of Chinese traditional gardens. Jiangnan gardens in Ming-Qing Dynasty (1368 A.D.-1912 A.D.) paid much attention to smellscape design and formed a unique design wisdom from long-term gardening practice. Through studying historical literatures about gardening and garden living, such as Yuan Ye, Zun Sheng Ba Jian, Zhang Wu Zhi and Xian Qing Ou Ji, this paper firstly summarizes 102 species of aromatic plants used in Jiangnan gardens in Ming-Qing Dynasty, and points out 22 species of them are the typical ones. Secondly, it presents the design methods of smellscape by using aromatic plants: land planting, pot planting and vase planting, and reveals the key points of these design methods. Thirdly, it concludes the aesthetic characteristics of smellscape: seasonality, metaphoricity and philosophy, and analyzes how they benefit to well-being. Although smellscape design wisdom of Jiangnan gardens in Ming-Qing Dynasty cannot be simplified as an accurate plan to be directly grasped, it should be an enlightenment to modern high-quality living environment and healing garden practice.

Keywords: smellscape; aromatic plant; Chinese traditional garden; design method; aesthetic characteristics; well-being

1. Introduction

Living plant’s smell is an important aesthetic object in Chinese traditional culture. Its sensibility and indescribability make it fascinating. Smellscape is an organic part of Chinese traditional gardens. Jiangnan gardens\textsuperscript{c} in Ming-Qing Dynasty (1368 A.D.-1912 A.D.) paid much attention to smellscape design and formed a unique design wisdom from long-term gardening practice.

In the historical literatures about gardening and garden life, we can find that Jiangnan gardens used a large number of aromatic plants to design smellscape by different methods which were integrated with the ancients’ aesthetics. It can be seen from some views and their names\textsuperscript{d}, such as “Bamboo Fragrance Pavilion” (Zhu Xiang Zhai),

\textsuperscript{c}“Jiangnan” means the lower Yangtze region which is in east central China. It includes many cities such as Suzhou, Shanghai, Changzhou, Hangzhou, Jiaxing, Huzhou, Nanjing, Zhenjiang, Yangzhou, Shaoxing and Ningbo. “Jiangnan gardens” means the gardens built in the above cities.

\textsuperscript{d}In Chinese traditional garden, a view usually is named by the most significant feature of the surrounding landscape.
“Lotus Fragrance Pavilion” (Ou Xiang Xie) and “Smelling Osmanthus Fragrance Pavilion” (Wen Mu Xi Xiang Xuan). This is one of the unique artistic characteristics of Chinese traditional gardens.

Against this background, this article focuses on three key questions:

- What aromatic plants are used in Jiangnan gardens?
- How to design smellscape by using the above aromatic plants?
- What are the aesthetic characteristics of this smellscape?

The following paper is organized in 5 parts. Section 2 – 4 solve each of above questions respectively. The last part concludes.

2. Aromatic plants in Jiangnan gardens

In order to summary the aromatic plants in Jiangnan gardens, a unique database was established. This database included 10 historical books and 500 garden notes. More specifically, these 10 books included Yuan Ye, Zunsheng Bajian, Kaopan Yushi, Zhangwu Zhi, Xiangqing Ouij, Guang Qunfeng Pu, Huamu Xiaozi, Ruan Pushi, Xuepu Zashu and Hua Jing [1-10], which are the important historical literatures about gardening and garden living. In addition, 500 garden notes are also the important historical literatures to investigate aromatic plants in Jiangnan gardens, they were collected by Chen Congzhou, Wang Jiaju, Gu Yiping, Chen Yifu, et al [11-14].

Based on this unique database, there are 102 species of aromatic plants mentioned in Jiangnan gardens, wherein 22 species are the typical ones (Tab. 1.), as their fragrances were the most frequently described.

3. Design methods of smellscape

Smellscape is constructed by planting aromatic plants in garden. Through studying the historical literatures and surveying the garden heritages, design methods of smellscape could be summarized as following: land planting, pot planting and vase planting.

3.1. Land planting

Land planting is the most common design methods of smellscape. The design methods
include two dimensions. First, the aromatic plants were usually planted in land by varied forms, such as isolated, symmetric, multiple and group. Second, these plants are combined with other garden elements like rockery, water, building, corridor, pergola and fence.

Different aromatic plant has its relative stable land planting form to create typical smellscape, which is usually depended on the plant’s ecological habits, ornamental characteristics (posture, color, smell, sound, etc.), cultural connotations, utilitarian functions, as well as the surrounding conditions. The typical land plantings are as following.

Pulm blossom’s fragrance is light, its branches are sparse and thin, and its character was considered as pure and lofty. Therefore, it usually was planted individually beside the study house or water, and this could create an imperceptible aroma environment.

In addition, the white pulm blossoms which were considered better than the red ones, usually were planted in group covered a rockery and surrounded a pavilion or living room, this created the so-called “Aromatic Snow Sea” smellscape (Xiang Xue Hai, Fig. 1.), because the white color looks like snow and the view of large group looks like sea.

Magnolia is another aromatic plant which was loved by its white flowers and light fragrance. In Chinese traditional culture, magnolia has a laudatory name called “Jade Tree”, because when flowers are in full bloom, all the tree is white like pure jade. Jade Tree has been given an elegant connotation, and it usually was planted in front of a hall (the highest class of residence building) in a solemn way: symmetric planting.

Unlike pulm blossom and magnolia’s light fragrance, wintersweet’s scent is strong, sweet, cold and very easy to be perceived but not vulgar, so it was deeply loved by the ancient literati. They called it “surprising aroma”, and considered it was the indispensable smell in winter. So wintersweets always were planted with well-designed rocks in the courtyard of a quiet area (Fig. 2., Fig. 3.).

Bamboo was one of the most important plants in Jiangnan garden. A large number of bamboos usually were planted along waterside, cover artificial mound, around pavilion or study house, and to create a clear realm. And bamboos’ smell is the key element to lead to the clear realm.
Bamboo’s smell which is sent forth by leaves and trunk is different from flowers’ fragrance, it’s very light and hardly to be perceived. But it fits for the ancient literati’s olfactory aesthetic. In Chinese traditional culture, bamboo’s smell is considered as “thin delicate fragrance”. And there were so many buildings in Jiangnan gardens named by bamboo’s smell, “Bamboo Fragrance Pavilion” (Zhu Xiang Zhai) in Lvjing Garden was a typical one.

Lotus is another aromatic plant which was very common in Jiangnan garden. As aquatic plant, lotuses were usually planted in pond around the pavilion which was located in the middle of pond or at the edge of pond. In order to smell lotus flowers and leaves, the pavilion’s elevation was kept open to let the wind come in with lotuses’ fragrance (Fig. 4), just like Chen Haozi (1612A.D.-?) said:

Open room that suit for long summer residence should be close to water, and its windows should be taken away, Chinese parasols should be planted in the front of it and bamboos should be at the back of it, pond with lotuses should be kept around and closed to it, water pavilion should beside of it, so that it could be resistant to sunlight and let the aromatic wind pass through. [10]

Except the aforementioned aromatic plants, other typical species such as orange, osmanthus, gardenia, peony, daphne, roses and rice were also usually planted in land in Jiangnan gardens in Ming-Qing Dynasty.

3.2. Pot planting

Pot planting is another design mothed of smellscape. As well known, bonsai is an excellent Chinese traditional art. Bonsai is a fashion in Jiangnan in Ming-Qing Dynasty. The Jiangnan literati especially liked cultivating plants in pots (sometimes with stone or many other decorations) to make them to be artworks and putting them indoors to enjoy them.

Most of bonsais were made by aromatic plants and their smells attracted the literati which can be discovered in historical literatures:

Wintersweet which height is more or less 35cm but posture is old and flowers have strong fragrance, suit for desk in study room to make attractive scene for enjoying. [15]

The characteristics of daffodil and orchid are leisurely, they fit for porcelain bucket and beautiful stone, should be settled under windows of bedroom, so that their fragrances could be enjoyed in everyday life. [10]

These phenomena are also showed in Ming-Qing paintings (Fig. 5., Fig. 6.).
In short, the typical aromatic plants under pot planting in Ming-Qing Dynasty’s Jiangnan gardens were as follows: Plum blossom, wintersweet, peony, daphne, jasmine, orchid, daffodil, plantain lilies, chrysanthemum, lily, tawny day lily and lotus.

3.3. Vase planting

Flower arrangement is another excellent art in ancient China. The aromatic flowers which were cut to plant in vase is another effective way to create smell environment. From the most important flower arrangement related books in Ming-Qing Dynasty: Pinghua Pu and Ping Shi \cite{16}, we can see that so many typical aromatic flowers were the popular cut flowers, they are plum blossom, magnolia, osmanthus, wintersweet, gardenia, peony, daphne, jasmine, roses, orchid, daffodil, plantain lilies, chrysanthemum, lily, tawny day lily, lotus and bamboo.

Vase planting followed certain rules. For example, peony’s flower is big, colorful and aromatic, it was well known as “national beauty and heavenly fragrance”, so it fitted to big and gorgeous vase in high class of residence building like hall (Fig. 7.). Plum blossom’s flower is tiny and its fragrance is hidden, so it fitted to small and elegant vase in bedroom or study room (Fig. 8).

4. Aesthetic characteristics of smellscape

In Chinese traditional garden culture, smellscape is not only an olfactory environment, but also an aesthetic object. Therefore, it has some important aesthetic characteristics such as seasonality, metaphoricity and philosophy.

4.1. Seasonality

Aromatic plants are living organisms, they have different characteristics in the four seasons, and their florescence are not the same (Tab. 1.). The ideas of “the garden which is considered to be excellent should has flowers in four seasons and has fragrances all year round” is a common design pursuit in Jiangnan gardens.

For example, the Humble Administrator's Garden (Zhuo Zheng Garden) would be filled with fragrances of peony, magnolia, michelia, orange, roses, pulm blossom and bamboo in spring; in summer, it would be full of scents of lotus and gardenia; in autumn, it would be pervaded with aroma of osmanthus; and in winter, it would be filled with wintersweets’ fragrance (Fig. 9.).
The smellscape in four seasons contains the message of nature, just like the famous poet Lu You (1125A.D.-1210A.D.) said: “The flower’s fragrance attacks could know the weather suddenly turn warm”. The ancient Chinese literati got physical and mental pleasure and happiness in feeling the rhythm of nature by enjoying different smellscape in four seasons.

4.2. Metaphoricity

In Chinese traditional culture, the fragrances of plants are endowed with profound connotations, giving smellscape certain metaphor and symbolism. For example, lotus aroma is a symbol of refusing to be contaminated by an evil influence. So, the garden owners usually created lotus smellscape and gave it a name, such as “Far Fragrance Hall”, to express their personality thoughts of nobleness and the principle of living.

The rice scent which is quite different from flower sweet is a symbol of reclusive live. Withdrawing from society, cultivating rice and vegetables to live self-sufficiently is an idea life to the ancient Chinese literati. It was originated from Tao Yuanming (352A.D.-427A.D.) and became an idealistic concept in garden design. The above picture (Fig. 10.) shows rice smellscape in Lejiao Garden, it expressed the owner’s idea that was free from vulgarity and his pursuit of seclusion life.

4.3. Philosophy

Philosophy is another aesthetic characteristic of smellscape in Jiangnan garden, it was usually emerged in the name of view.

“Smelling Osmanthus Fragrance Pavilion” (Fig. 11., Fig. 12.) is a famous view in the Lingering Garden (Liu Garden). The name of this view is an allusion to the zen book of Wu Deng Hui Yuan. It enlightens people getting out of the existing knowledges and appreciating the universe noumenon from every nature things like osmanthus fragrance floating in the air.
“Listening Fragrance” (Ting Xiang) is another name of view which was common used in Jiangnan garden. As is known to all, five senses have their own specialization, fragrance can only be perceived by smelling, but not by listening. However, why the ancients constantly emphasized “Listening fragrance” and even embedded this idea into the garden design? The ancient literati said: From the perspective of spirit, nose and ear are the same. \[17\]

Listening is not through the ear, but the spirit. \[18\]

These prove that the experience of “listening fragrance” is not a perception of physical sense, on the contrary, it means closing all the physical senses and getting rid of rational logic, using spirit to feel the five senses interdepend and interconnect. This is an otherworldly experience and highest aesthetic realm. In this ream, the soul attained clear, bright and absolutely free, and the mental life was settled down.

5. Conclusions

In summary, smellscape is an important and organic part of Jiangnan gardens in Ming-Qing Dynasty. There are 102 species of aromatic plants used in Jiangnan gardens, and 22 species of them are the typical ones. These aromatic plants are planted in different way such as land planting, pot planting and vase planting to design smellscape. It depends on the plant’s ecological habits, ornamental characteristics (posture, color, smell, sound, etc.), cultural connotations, utilitarian functions, as well as the surrounding conditions (rockery, water, building, corridor, pergola, fence, etc.).

In Jiangnan garden, smellscape is not just olfactory environment, it’s an aesthetic object. Seasonality, metaphoricity and philosophy are the important aesthetic characteristics of smellscape, and they benefit to well-being.

Although smellscape design wisdom of Jiangnan gardens in Ming-Qing Dynasty cannot be simplified as an accurate plan to be directly grasped, it should be an enlightenment to modern high-quality living environment and healing garden practice.

Study on the Mode of Regeneration of Urban Abandoned Quarry —a Case of Fenghuang Lake Park in Nansha, Guangzhou

Yicheng Weng¹,²*, Yuanyuan Li¹

¹South China University of Technology, No. 381 Wushan Road, Tianhe District, Guangzhou, 510640, China
²State Key Laboratory of Subtropical Building Science, Guangzhou, 510640, China

Abstract

With the rapid development of urban construction, the ecological problems of abandoned quarry have become urgent problems in the construction of biophilic city. Nowadays, the mode of regeneration of mine abandoned land has changed from the initial single ecological rehabilitation to the integration of ecological rehabilitation and landscape function, and the pits have become part of the urban green infrastructure. Taking the design of Fenghuang Lake Park in Nansha, Guangzhou as an example, on the basis of ecological rehabilitation, this paper studies how to better play its functions of flood control and drainage, recreation and popular science education. And ponder several issues after the completion of the park, with a view to providing new ideas for the design of regeneration of urban abandoned quarry in the future.

Keywords: ecological rehabilitation; mode of regeneration; abandoned quarry; Fenghuang Lake Park
1. Introduction

With the development of the world economy, urbanization, industrialization, and resource development have led to the ecological destruction of the drainage basin and the deterioration of the urban living environment. The situation of the urban ecological environment has become increasingly severe. As the economic structure of developed countries shifts ahead of the developing countries, the problem of urban industrial abandonment caused by the arrival of the post-industrial era appears earlier. As early as the end of the 19th century, there have been renovations of industrial abandoned sites. Successful redevelopment can turn abandoned land into retail commercial land, residential land, office land, non-polluting industrial parks, parks, plazas, exhibition halls, etc., embodying the reusable recycling of land fully\(^1\).

From the early transformation, we can see that the designer retained the picturesque part of the scene and tried to use traditional aesthetics and design ideas to transform the fragmented landscape. Art began to intervene in the transformation of industrial wasteland, mostly abandoned quarries\(^2\). With the introduction of ecological thought, major changes have taken place in the methods for the reuse of urban abandoned land. The respect for the site's ecological development process, the recycling of the material and energy, the advocating of the self-sustainability of the site and the advocacy of sustainable treatment technologies reflect the strong ecological concepts. These concepts have been fully reflected in the landscape design after the industry\(^3\).

Similarly, in order to reduce the input, quarry adopts vertical mining methods which leaves vertical quarreling surface behind. Abandoned quarry as a type of industrial waste, still looks like a piece of messy “patch” even after the quarry is closed, seriously destroying the surrounding natural landscape\(^4\). Abandoned quarry can be used as land for various purposes after reasonable ecological restoration. The sunken ore pit is a scar on the earth, but its special topography is also the origin of wonderful design ideas. With years of development, there have been many cases of the design of utilization of abandoned quarry pits at home and abroad (see Table 1).

In a word, the regeneration mode of urban abandoned stone-pit has experienced continuous development in aesthetic design, ecological environment restoration, etc. Now it is not only necessary to realize ecological restoration, but also to change from a single ecological restoration to ecological restoration and fusion of landscape functions. Based on the ecological restoration and integrating various landscape functions, the abandoned quarry plays a more ecological, social and economic role.
2. Project Practice

2.1. Project Overview

Guangzhou Nansha Fenghuang Lake is located in the central area of the Jiaomen River in Guangzhou, which was originally a six-large-stone pit left over from the south foot of the Nansha Dashanna Mountain. The stone-pit has a wide area and its depth is as high as more than 50 meters. The wall of the pit is steep, which has a great impact on the surrounding environment, and there are great safety risks. The construction goal of this park is to connect the six large quarry pits as a whole. Then connect water from rivers and lakes to divert water from the Jiaomen waterway, drill the valleys to connect the water in the mountain ponds, and excavate the lake to form artificial lakes.

Construct the embankment and supporting waterfront, else. The park would become a comprehensive pit park with multiple functions, such as improving the landscape of the area, rainwater storage as the main function, and improving the ecological environment, displaying the humanities and history, and providing recreational tourism sites etc.

This article focuses on the construction of the completed Nansha Fenghuang 2nd Lake. The total area of the lake is 143862m². This area is the middle construction area of the central of the Jiaomen River recently. The lake is combined with the exhibition hall key project for development and construction, which meets the priority construction conditions. It will help improve

2.2. Flood control and drainage

Nansha New District is located in the subtropical monsoon climate zone, with mild and humid climate, warm and rainy. The Fenghuang Lake Project has formed 6 lakes by integrating the original 9 quarry pits, and is connected with the downstream of the Jiaomen village River and Guiheng River, which forms the "Fenghuang Lake" of the Jiaomen River with a water surface area of 54.3hm² and a total length of 6.59km along the lakeshore. In the surrounding area of the lake, interception ditch will be set up to increase the area of rain collection in the lake, increase the natural runoff, create a clear spring water landscape in the dry season, and intercept mountain floods during the flood season. The landscape water level in the lake is maintained at about 5m by culvert sluice scheduling. Strengthen the vertical landscape convergence, improve the connectivity and accessibility of the lake range, and explore its recreational value\(^5\) (see Fig.2).

(Fig.1. Aerial view of Phase 1 of Fenghuang Lake construction project in Nansha)

(Fig.2. Replenishment water transfer schematic)

The main function of the 2\(^{nd}\) artificial lake is drainage, and the design standard adopts the regional drainage standards—the rainstorm in 24 hours in 50 years is not a disaster. Through the calculation of the characteristic parameters of the entire lake district of Fenghuang lake, the 2\(^{nd}\) lake is connected to the Jiaomen Village River through the connecting section. The landscape water level is same as the one of the Jiaomen Village River and Jiaomen Rivers, which is 4.7-5.3m. The maximum water level for the drainage is 5.74m, the maximum storage capacity is 1.79 million m\(^3\), and storage capacity is 85000 m\(^3\). The height of the lowest point of the surrounding land and road is about 6.3m. The lake bottom elevation of the Southern half part of the 2\(^{nd}\) Lake Construction Project is basically determined according to the status of the pit, with a maximum depth of about 50m and a minimum elevation of -27.5m. When torrential rain occurs, if the flood level H is
bigger than landscape low level which is 4.7m, and the flood level H is smaller than the outer river level H, the floodgate cannot self-discharge. Then the pump station needs to be turned on. This time, the direction of the water flow is the direction of the center of Jiaomen River to the direction of each pump station. And the direction of the water flow is multidirectional.

2.3. Viewing and recreation

As the lake area was originally a quarry pit, the water depth was deeper. For security reasons, the 2nd lake area was unable to set up a cruise ship for people to play. What’s more, the wall of the pit is relatively steep, and the ornamental green design along the edge of the pit has become the design focus (see Fig.3).

From the recreation point of view, this design combined with the current terrain, lays out as a circular overall structure in the plane, which combined slow traffic and node recreation. The overall layout of the plane is dug and filled to form a "gourd" shape, which takes the “blessing” and “wishful” meaning of traditional Chinese culture. On the side of Liuyuan Road, the water trestle shall be constructed under the premise of ensuring safety, to avoid excessive lengthening of the section of the road with the sidewalk, and to solve the problem of lack of slow traffic problem on the lakeside of Liuyuan Road. In order to enhance the accessibility of the park, a high-level viewing platform with close contact with the sidewalks, will play a role in
enriching the spatial level of the lake and providing a diverse view of the lake, together with the hydrophilic platform and the water plank road. At the same time, a landscape corridor bridge is added to the mid-lake island. The landscape corridor bridge is designed with the concept of "Phoenix Spreading Wings and Walking in the Woods". It spans the middle of the park and connects park courier station, mid-lake island and east entrance plaza into a whole, which is an important landscape node of the 2nd Lake Park. In order to maximize the protection of the island's ecological environment, the landscape corridor bridge adopts an overhead form, with the terrain varying and ups and downs and forming a viewing platform. It is like a phoenix wing that rises above the lake island and is set amidst the forests of the lake island, which enrich the spatial level of the park greatly (see Fig. 4).

(Fig. 4. Rendering of the landscape corridor)

The Fenghuang Lake Park bicycle path and trails are set along the lake and connected with the city's green road. Its entrances and other important nodes near the river bank are magnified into landscape plazas to facilitate the gathering of tourists. Along the main road, as far as possible, the original ecological pattern was maintained, and the polyline trails were partially embellished, which is interspersed with greening and is rich in change. Cleverly set up a viewing platform to form a platform for picking up feet, choose a relatively smooth position on the shoreline, and walk through the steps down to the hydrophilic platform to give visitors the opportunity to get close to the water while ensuring safety.

From the viewing point, around the landscape walks set up along the lake, shrubs and flowers form a multi-layered landscape that covers the shores of the lake. Waterscapes, vegetation, and leisure trails echo each other. The greening of the lake adopts the form of planting troughs along the coast. Because the slope of the lake bank is very large, and almost no soil is available for plant growth, concrete planting troughs are set up along the banks, and the greening plants are potted in the planting troughs, as the greening of the lake (see Fig. 5).

(Fig. 5. Trestle standard section)

The artificial floating island technology can be adopted at the lake center far away from the lake shore. The functions of the artificial floating island include the prevention of embankment erosion and protection of the coastline, providing habitat for wildlife, landscaping, water purification and filtration, and biological disinfection six aspects. The use of artificial floating island technology, on the one hand, will increase the green coverage of the park and enhance the overall landscape effect of the park.
park. On the other hand, improve the overall water quality environment of Fenghuang Lake by the use of floating islands, to purify water bodies and achieve the effect of water purification and water beautification. By using the wet-framed ecological floating island, aquatic plants with strong resistance and a certain purifying effect on water quality are selected as the first-choice species, such as Acorus calamus, Thalia dealbata, Iris, Canna generalis, Arundo donax var versicolor, HornLian, Zizania aquatica, etc. At the same time, in order to imitate the vegetation greening effect of natural tidal flats, plants of different heights are selected to form three levels of high, middle and low level plant effects.

2.4. Science education

The stone-pit is unique urban landscape left behind by human activities. Its ecological and educational significance is also an important part of the cultural connotation of the area. The original fish ponds on the side of Fenghuang Avenue will be resources and facilitate ecological protection, improve water quality, and enhance the ecological character of 2nd Lake. The layout of wetlands and trestle bridges take example by the flat pattern of mulberry fish pond in the south of the Five Ridges, forming a series of shoaled waters of varying sizes and shapes, with grouped plants of taxodium distichum and various types of aquatic plants. And water plank roads that shuttle between them to provide close contact with the water environment. opportunity. Plant the background forest along the top of the lake road, face the wetland with a gentle slope lawn to form the high spot of the site, and adorn the ornamental trees locally, along with the sloping stone benches. The view is wide, and the panoramic view of the wetland is visible. Markers and science cards are set up to show the history of quarry pits, lake water purification, and conservation of native plants and animals.

From the perspective of historical culture, the ruins of the Jiaomen battery on the northeast side of 2nd Lake are mainly protected in design. Keep the original terrain and text stele, and set the retaining wall according to the change of the actual terrain. In the ruins of the side, increase the entrance and set up the steps. Through the text and structure design, show the history and culture of Jiaomen battery. The fort sites can enhance the cultural connotation of the 2nd lake. Because of the higher position, there is also a good view point. (see Fig.6).

3. Think

This article have expounded the restoration and utilization of Fenghuang Lake Park in Nansha, Guangzhou from three aspects: flood control and drainage, viewing and recreation, and science education. After the park was built, it was discovered that
there are still several issues to be considered by the park’s post-evaluation:

3.1. How to better consider the use of mine pits in upper level planning

Because the distance between the red line of the urban planning road and the Fenghuang Lake pit is too close in the upper planning of the area surrounding the Fenghuang Lake, there are many congenitally deficient issues for the planning and construction of the Fenghuang Lake. For example, there is not enough space for park recreation, especially on the east side of the park. Due to being close to the main road Fenghuang Avenue, park roads can only overhang the cliffs of the pits, which greatly increases the difficulty and cost of the project; There is a lack of green transition between the surrounding high-rise residential buildings and the park, and the viewing experience in the park is more depressing; The municipal bridge on the west side of the park pass over the lake surface of the park. The mass of the municipal bridge divides the lake into two parts, which is incongruous with the park landscape. The upper-level plan does not adequately take into account the use of the pit park, which has a great impact on the subsequent planning and construction of the park.

3.2. How to coordinate security and landscape issues

The particularity of the stone-pit terrain makes its safety issues need to be carefully considered in design. For example, after the project was completed and used, it was found that there was a security problem in the park’s gently sloped grass near the lake and the greening of the road adjacent to the main road. So a green wire mesh fence was temporarily added. Although the addition of these two places guarantees certain safety, the landscape effect is poor. Therefore, how to satisfy the needs of landscape visual effects and safety at the same time is a problem, which needs to be emphatically considered in landscape design.

3.3. How to better reflect the pit site characteristics

The stone-pit has a steep rock wall and generally has a large depth. In the current scheme, the connectivity of the water system has completely hidden the stone-pit, and the part of the mountain body exposed on the lake surface has been cleared. The special site characteristics of the stone-pit have not been reflected. How to use and display the unique topography and landform of stone-pit more rationally is a key research issue for the future planning and design of pit parks.

Tactical Rural Planning in China ‘Beautiful Country’
Rural Renewal Planning Project

Zehao Hu,\textsuperscript{a} Xiaoshan Fang,\textsuperscript{a}`

\textsuperscript{a}South China University of Technology, No.381, Wushan, Tianhe, Guangzhou, 510641, China

Abstract

This paper contends that country public engagement and participatory of villagers in rural renewal planning project in China. It based on a rural regeneration project called ‘Beautiful Country’, This policy focus on the regeneration of poor condition and environment of rural China. The author argues that all of people who work for ‘Beautiful Country’ should familiarize themselves with strategies and tactics focus on effective, low-cost and long term changes in countries, especially for those rural public spaces out of management. Those public spaces were the keys for rural regeneration and it was an efficient way to create a popular and active open space, for people who have a desire to change and reconfigure their country. This paper chooses the regeneration plan for Bangzhuang country in Guangdong Province, China, with the strategies used by Tactical Urbanism, but in the rural China, it could be called as Tactical rural planning. Those actions (happened in Bangzhuang regeneration plan) include: community gardening, stimulate space rebuild, water canal cleaning and system rebuild, natural play, abandoned building reuse and more. These plans insight on the poor rural environment which designers and planners are ignored and it makes an effort to achieve more flexible spaces for people who live in the rural. It also tries to find solutions to the problem that ‘Beautiful Country’ faces: The regeneration of country and the people participation. Many of the efforts have been done before Bangzhuang, but lacking of participation of stakeholders leads ‘Beautiful Country’ works limited. The town planning and design need professional skills but the deep understanding of the rural China could be reflected by public participation, especially in the community gardening building, reuse of abandon spaces by locals and the processes for the rebuilding. The tactical rural planning gives Bangzhuang country the potential to move with the participation of stakeholders. This illustrated through the analysis of standards of ‘Beautiful country’ goals and it could be an effective way to doing the rural renewal planning.

Keywords: Tactical Rural Planning, Rural Renewal, Beautiful Country, Natural Play, Chinese village.
1. Introduction

A rural renewal planning project called ‘Beautiful Country’ was set up in rural China from 2013. The policy and strategies for this project will focus on 5 areas: agricultural development, life quality, rural civilization, cleanliness of countries and management democracy. Many researchers for problem of rural China are agreed with the policy. Many researches in macroscopic have been done before the thousands of designers and architects go to the countries for doing the rural planning and regeneration.

It is a difficult and huge rural regeneration project never happened in the history of China. In the Traditional Chinese Villages Catalog (TCVC,2012-2014), it shows that the number of traditional Chinese village is 4153, but the whole number of them is 662,238 (2016). It means that only 0.627% of villages are included in the catalog. Villages in the catalog have the priority for the design plan, special funding and more policy support. Architects and planners also will take those seriously, spend much time in this kind of village and do the design after a series of field research. With this policy and special funding support, the regeneration of villages in the catalog going quite well and the it succeeded (Fig.1). Designers keep the traditional buildings, roads and other infrastructures, design with natural elements which are really important to these traditional villages. The policy supports the development of the traditional villages. Most of them found the right track on their development method, such as traditional travel, characteristic agricultural products, characteristic crafts, natural education, etc.

As it mentioned before, only 0.627% of the villages in China are in the TCVC, it means 658085 villages which out of TCVC will not get enough technical and financial support. This illustrates the outcome of regeneration of these villages will be unsatisfactory as that in TCVC.

2. The disadvantages of rural renewal method in some villages of China

With the limited time and funding, the architects and planners who work for ‘Beautiful Country’ have to do the design in a simple but efficient way, although it might not be a good choice. They dismantle almost all the old buildings, except those in the listed buildings. Dismantle an old building and build a new one will cost much less time or funding than repair it. They usually have several templates which from urban building, but called ‘beautiful village housing’. Most of them look the almost the same, even in the same size (Fig.2). All the buildings located regularly as what we could see in
many modern cities of China (Fig.3). For those villages which are generous for their land, architects and planners will find a new land which near the original one, then they build a new village and suggest villagers to move in. This could be seen as the lowest cost plan without any cost to dismantle. It seems that the villagers abandon the original village and move to a new village which looks like the city. This kind of regeneration effect not good as those villages of TCVC.

As what happened in many villages of China, designers set oversize squares which are not matching the need and population for villagers. Those squares are rarely used because it is not friendly, popular or active enough. It really costs a lot of funding but with a low return. No matter in the view of environment update or public space regeneration (Fig.4).

Some of designers and decision makers lacking the consideration of budget and they prefer to put the money into some memorial archways or monuments in the entrance of village (Fig.5). Those high-priced monuments are not the primary task for village regeneration, they could not update the living condition, either.

To decrease the time of construction, local materials are rarely used in the villages regeneration project. Concrete, cement, tile, brick and quartzite are the suitable choices for designers. Another reason is that designers and decision makers believe these materials will contribute to making a clean

![Fig. 2. A New Chinese village, most the buildings designed by from same template.](image1)

![Fig. 3. Villas in Zhengzhou, Henan province, China.](image2)

![Fig. 4. Square in a village of Huian county, Fujian province, China.](image3)

![Fig. 5. Memorial archways of Datian and Jingnan, Fujian province, China.](image4)
and tiny village environment. However, this thinking will change the landscape style of village. It will change the texture and the fabric before which lead to a destruction to local characteristic. What is more, the frequently use of cement flag pavement is also waste and environmental-unfriendly. Earth, local plants and water, these nature elements is also a part of village, it is no need to avoid them (Fig. 6, Fig.7).

Above all, for some villages which are out of TCVC, the ‘Beautiful Country’ rural renewal planning project partly could be seen as ‘Constructive destruction’. The rural housing made by same template, oversize squares, useless but expensive memorial archways and overuse of cement, their disadvantages are obvious. All of those method of rural renewal should be reviewed and correct before it leads to a greater destruction to Chinese villages (Yu, 2006).

3. The potential methods

For those villages out of TCVC, the funding of village renewal is limited. Road system, drainage system and garbage disposal, which are usually the main problems villages face at the moment. Improving those infrastructures should be the first task. It will cost a huge part of the funding but it is essential and worthy. Those improvements will contribute to the village landscape, cleanliness and life quality of villagers at the same time. Then the second task of rural renewal could be focus on the public spaces. Those public spaces were the keys for rural regeneration and it was an efficient way to create a popular and active open space, especially for villagers who have a desire to change and reconfigure their village. In a Chinese village, villagers usually have a blood relationship with others and they will have temple fair, village traditional event quite often. It means the public space could be a link between villagers, this is particularly important: to keep the public space open and active. So the decision makers and designers need to consider the event and the things could be happened among villagers which close association with existing public spaces and the updating projects might be done. The strategies used by Tactical Urbanism might be a potential solution to activate the public space, it could be called as Tactical Rural Planning. The tactical rural planning is to

Fig. 6. Cement covered the earth and grass under a ficus microcarpa, Dongshan, Fujian province, China.

Fig. 7. Cement barriers of the river, Huian, Fujian province, China.
use effective, low-cost interventions for local rural areas benefit (Elrahman, 2017). It could be a simple or short-term revisions to use public space during the time out of the traditional events, to change the existing public spaces structure (Fayoumi, 2017). With the rich landscape of rural areas, water, mountain, forests, grassland and agriculture land could be the elements of tactical rural planning, villagers familiar with these and revisions could be done and run by themselves. As it mentioned before, tactical rural planning could be done after the infrastructure, it could be seen as a method to close the connection of villagers. This benefits the rural civilization and rural management, it also meets the rest demand of ‘Beautiful Country’.

4. Bangzhuang Country and Tactical Rural Planning

4.1 Bangzhuang Country

Bangzhuang country is a small country in the Longjiang town, Jieyang city, Guangdong Province, China. It located in the south of Guangzhou, 5km to the South sea. Bangzhuang consists with 3 villages, there are Bangzhuang village, Xiangzi village and Lintai village. The total population of Bangzhuang Country is 4015, 2161 of them live in Bangzhuang village, 1104 live in Xiangzi village and 1013 live in Lintai village.

It has rich landscape resources, only 5km Southward is the South Sea, a river called Longjiang River passes through the Bangzhuang Country, three villages surrounded by agriculture land, parts of them covered by forests and there are some lakes in the villages. It also has historical human resources, with several temples of Buddhism, temples for village god, ancestral halls and some ancient trees identified as the protection god of villages.

The problems of Bangzhuang are still obvious. Except those problems faced by other villages, the bad quality and too narrow road (Wu, 2014), incomplete drainage system and poor village environment, Bangzhuang suffered with other two main problems. The one is that it has a week land drainage. villages did have drain pipes, which were only for those drainage from indoor to outdoor. In village, sewers still need updated, this will be covered by infrastructure improvement. However, the land drainage between villagers was poor, ponding area is huge during the rainy days, especially in a wet climate of Guangdong province. Ponding may be harmful to some crops in Bangzhuang. It also makes the decrease of agriculture land. What is more, the open drainage canal covered with water hyacinth, a kind of aquatic weed, this dramatically slow down the speed of water flow (Fig. 8). Villagers are dissatisfied with this and it also become breeding grounds for the mosquitoes. The other problem Bangzhuang faced is the low quality of public space. There are some public spaces in villages, but it is not attractive enough (Fig. 9). However,
It could not be successful without the participation of stakeholders. Decision makers and designers could consider the opinions from villagers before making the decision. It also plays a key role in the rural regeneration.

4.2 Tactical Rural Planning

Those tactical rural planning actions could include: community gardening, stimulate spaces rebuild, water canal cleaning and system rebuild, natural play, abandoned building reuse and more. It could start from the gap space filling by local, like community garden or crop plot. The existing public spaces could hold traditional event as the local drama show, village god’s birthday celebration and so on. Then the water canal cleaning could be activities for children and villagers, they could clean the water hyacinth by physical and biological way. This could be an activity for school, also could be seen as a natural class. For those abandon old building near the lake of village, the village management could have recreational activities or cultural movement. Some of old building also could be reuse for activity rooms for children, elders or women.

4.2.1 Community garden

Villagers in Bangzhuang wish to improving their living conditions, especially in the new village area. A lot of new buildings have been set there. It could not change the building style and the building patterns in the new building area. Nevertheless, it still could change the gardens, the gap between buildings and the line spaces along the roads. In the new building area, land have been separate into many blocks and every block has it owner. At this moment, there are some blocks still the empty. Maybe villagers could use that empty block and the gap between building to make a community garden. Just some chairs and table, surrounded by plants which villager like. Trees could be planted in the planter so that they could be remove easily. After this, a good place for relax and community communication will be done (Fig 10). This community garden might be short-term, with the development of village, the community garden could be replaced by a new house or garage. However, villagers will have the long-term benefits for their relationship with neighbors. There are a lot of water pump in Bangzhuang, this could be used for watering the community garden.

Fig. 9. Children play in a public space with a bad environment in Lintai village

Fig. 10. Community garden between buildings
Everyone could help their neighbor and villagers water the plants anytime. The road in Bangzhuang is quite straight but narrow, the local material could be used for construct a pergola. This will totally change the façade of buildings and contribute to a better street landscape. Every family could have their opinion to choose the plants they like, flowers, vine, bamboo even vegetables are suitable for this line community garden (Fig. 11). The community garden boost the landscape of building area of Bangzhuang. Moreover, the social goals are achieved and the environmental benefits the whole village. This is will contribute to the regeneration of the village and meet the demand of village management.

4.2.2 Public spaces rebuild

Ponds, squares of the temple, spaces under the trees and agriculture land close to the village, those existing public spaces are potential for the village. For tactical rural planning, those spaces are close to buildings, the surroundings might be used for the background to support the events psychologically. People could change the spaces by short-term structures. Fishing and catching the fish by hands are well liked by everyone. Ponds could be classified by different depth of water for safe. Decks might be good but it is not necessary. A good option is to keep the ponds and the natural elements as original after safety check. Water, mud, water plant and the topography could be beneficial for children who play (Fig 12). Those are parts for nature and they could not be insulated in the development of children. The only thing designers could do might be keep them safe and try to create more possibility. Villagers will use those renewal spaces with limited interference. The trees in the village also could be used. A tree in the entrance of Lintai village is quite popular to children, it is only 10m to the next building. Designers could change level of the ground for a flexible way to play. Facilities for children play could activate these places after school. Some soft material as plastic papers, pipe and mirror paper could be freely used by villagers to create a colorful and attractive places (Fig 13). Those small changes might contribute to the public space renewal in village, more elders will refer to go to this place with their
grandchildren. The boundaries between building areas and public spaces will be flexible, this will make people come outdoor. During the time of traditional event, the play facilities could be replaced by show field by slightly changes. All of these methods used in the public spaces might be an efficient way for rebuilding the spatial pattern of the village (Bayat, 2016).

4.2.3 water canal cleaning

Land drainage is the main drainage way of Bangzhuang village. Most of the water canals were covered with water hyacinth. One way to solve this problem is to renew the water canals with concrete as other villages did. However, it might not be a good choice, it is not ecological, cost much and it will have negative impact to local ecology. The water hyacinth could be remove by villagers cleaning. This might be seen as a play activity for children. Some recreation facilities could be used for this, such as mini excavator, mini crane or hay mower (Fig. 14). Children will enjoy the time of playing and the water hyacinth will be removed in the same time. The cleaning time could be set according to the growth cycle of water hyacinth and other water plants. Another way is to increase the grade to make sure the speed of drainage flow rate, this will slow down the grow speed of water hyacinth. What is more, the walking paths between agriculture land and villages could be redesign. This will lead to a better walking system for villagers who do the farm work. Designers could set some terrestrial plant which negative to the growth of water hyacinth, such as lantana, along the walking paths. The fallen leaves of lantana into the water have inhibitory effect to the growth and development of water hyacinth (Yi, 2006). It could be seen as a biological, low cost and ecological way to deal with the existing water canal problem.

4.2.4 abandoned building reuse

The amount of old buildings in Bangzhuang is more than 50. Those old buildings are not used or less used, some of them are abandoned. Some old buildings are located in front of the Fengshui pond, it is potential to be a popular public space for villagers. People who play in this space will build the sense of their own community. Those old buildings are always with a strong traditional features, even could be seen as
the landmark for Bangzhuang. It could be renovated and switch to a public building such as library, junior or senior activity center and center of traditional event. Designers and decision makers could evaluate the quality of those old buildings first, then they decide which could be the most valuable for villagers to renew. It is no need for them to renovate all the buildings, they could make the process of the renovation freely. The stakeholders could participate in the whole process, even could DIY the building to what they wish to be (Fig. 15). Villagers have the talent with handicraft, traditional music could show these to others. The wall of the building, could be the background for the activities, or people could do some sketching, painting, doodling or writing in the suitable place. This could be a potential way for reusing the abandoned building (Sargın, 2012) and it could activate the community in the building area of Bangzhuang.

5. Conclusion

The difficulty of ‘Beautiful Country’ rural renewal planning project is more serious than we thought. Those villages out of TCVC faced the problems above and they could be lead to constructive destructions if we ignore the problems made by decision makers and designers. From the discussion above, Tactical Rural Planning may be a potential method for doing the rural renewal planning after the construction of infrastructure. Those participation of stakeholders, activities and the freedom decision makers and designers offer could contribute to the improvement of public spaces in Bangzhuang village. What is more, this will make the villagers have a strong sense for build a better village for themselves. Tactical rural planning may not solve all the problems, but it really responds to the problems we faced in ‘Beautiful Country’ project and it made us realize the challenges we have in follow. The method we try in Bangzhuang could be an example to show how it improve the environment and how public participation could be in the way of rural renewal project. With the public participation through the whole process, it could be an effective and potential way to do the rural renewal planning.

Abstract

Based on the idea of system, over all planning the Rain systems、the Natural systems and the LID systems in city, work together, to form water system belong to the city park green space in the specific climate and geographical environment, that work on permeate water、retain water、water Purification、water Drainage、Use water, for landscape ecological environment design is very important. The LID system is an effective complement to urban Rain system rather than an alternative to the water environment problem of urban park green space. On the one hand, the city park green space is naturally more permeable soil, natural vegetation water storage power, producing runoff speed slow, when heavy rain and floods, the park green space is the key unit to the city to regulate the rain water. On the other hand, due to the ground surface of road and paving in modern park is obstruct with the impervious surface, urban ground water recharge is insufficient, the rainwater resources by rainwater pipe network quickly go, city park green space caused by drought, water shortage which will affect the park microclimate environment and greening plant growth. Through two case of city park green space landscape design practice, from China Xuzhou, discusses the landscape LID technology application and effect, in the city park green space, and the thinking process, summed up six LID strategy about city park green space landscape. Main research contents include: research of Xuzhou city hydrology and rainfall conditions, the field into a natural savings, natural purification, natural irrigation and rain refinement using intensive green space, using both the construction garbage and surrounding demolition road waste materials as cavity packing, at the same time for real-time monitoring of field ground water environment and the use and management of collecting rainwater.

Keywords:City park, Green space, Landscape design, LID technology;

1. Introduction

The precipitation distribution in nature has its special law: there is a certain correlation between natural geography and precipitation, and this correlation has a significant difference in the gradient of precipitation in geography.

*Email: 230129032@seu.edu.cn
blocked by mountains and far from the sea, is vulnerable to summer monsoon rains. Area more than 1600 mm annual rainfall, is mostly in the southeast coastal area, precipitation in most places of Taiwan, an average annual rainfall of 6489 mm; 800mm and other rainfall lines pass through Qin MOUNTAIN -- Huai River to the southeast edge of the Tibet plateau; 400mm and other rainfall lines are mostly through the Daxing 'an ridge, Hohhot, Lanzhou, Lhasa to the eastern edge of the Himalayas; More than 200 millimeters are concentrated in the northwestern hinterland. The driest and driest place is Tokelson, west of the Turpan basin, with an average annual precipitation of just 5.9mm. (Fig.1)

Precipitation gradually from the south to the north of Jiangsu province, south of Wuxi, Changzou, such as more than 1200 mm, annual average rainfall in northern areas such as Xuzhou, Lianyungang, annual average precipitation is 600-800 - mm, only the more significant difference between the north and the south. (Fig.2)

2. RESEARCH PROBLEM

In the process of urbanization, changes in the underlying surface bring about changes in the water environment. The surface of the city is mostly "impervious", which has the characteristics of large runoff coefficient, high yield and fast convergence. The occurrence of short duration of heavy rainfall, easy to cause waterlogging disaster, seriously threaten the safety of life and property of citizens. Urban roads bear the brunt of the flooding, becoming the most dangerous. In 2012, 77 people were killed in the July 21 heavy rain in Beijing, 11 of them drowned on the road. [1] At the same time, because the city ground "impervious underlying surface, as well as traditional to" row "give priority to the municipal drainage design patterns, pipes rainwater resources to be concentrated, platoon walk quickly, causing the deterioration of underground water level, ground subsidence, an acute shortage of water in urban soil, greening custody cost is high. The problem of urban water environment is mainly reflected in "urban waterlogging" and "urban water shortage". Urban Water Shortage and Waterlogging polarization has become an important factor restricting the sustainable development of cities. (Fig.3)

2.1. Urban water shortage in CHINA

According to 2015 China statistical yearbook, China now has 12 provinces (or municipalities directly under the central government) per capita water resources quantity under severe water shortages line, including nine districts (Beijing, Tianjin, Hebei, Shanxi, Liaoning, Shanghai, Shandong, Henan, Ningxia) water resources per capita is lower than 500 cubic meters, to extreme water shortage area. [2] In addition to Shanghai and Jiangsu, other areas of water shortage are in the north, mainly in north and northwest China. (Fig.4)

In order to ensure the normal growth of vegetation, a large amount of water is consumed every year. If city park green space per square meter every year green irrigation water 2tons of calculation, get rid of natural rainfall, Nanjing city park green irrigation water alone each year to 32 million tons,
urban greening irrigation water use is high, brings great pressure to the city water. According to statistics, in 2012, Beijing's urban green water consumption reached 686 million tons, accounting for 19.0% of the total water consumption. [3]

2.2. Urban waterlogging in CHINA

According to China's ministry of housing and urban-rural development of 32 provinces in 351 cities in 2010 waterlogging situation survey, from 2008 to 2010, our country has 213 cities had different degrees of water waterlogging, accounting for 62% of the cities studied, waterlogging disaster city is more than 3 times a year has 137, accounts for more than 40%.

Through data analysis, urban waterlogging is common in both the southern and northern regions. According to incomplete statistics, Beijing, Jinan, Changchun and other cities in the northern region, as well as Wuhan, Changsha, Nanjing, Guangzhou and other cities in the south have suffered serious waterlogging disasters. It has universality and frequency. The urban waterlogging in the northern regions mainly occurred between June and August, and the southern cities were concentrated in May and September. The time of occurrence is relatively concentrated. (Fig.5)

The expansion of urban construction, make originally which has the function of natural water, flood peak depression, mountain pool, lake, reservoir damaged by artificially filling or filled with, for it greatly reduces the storage and distribution function of the city. The increase of the urban hardening area and the decrease of green space area resulted in the gradual reduction of the seepage surface of the city, the increase of the surface runoff and the acceleration of the confluence, thus increasing the risk of urban waterlogging disaster. At the same time, it greatly reduced the water storage function of the underside of the city, resulting in water shortage in the city. (Fig.6) (Fig.7)

3. LID TECHNOLOGY RESEARCH

3.1. Characteristics of urban green space water environment:

As a sponge body, urban green space has strong infiltration capacity and water storage capacity. Its runoff coefficient is generally 5% to 15%, and the slope of green space drainage is generally 0.5-1%. Urban green space drainage is given priority to with surface drainage (i.e., use of green space of undulating terrain slope to make rainwater collection by oneself, again through the ditch, valley, mountain stream to organizations such as the guidance, into nearby bodies of water or to the nearest urban rainwater pipe), at the same time combining ditch drainage and drainage pipe as the supplementary means; The capacity of urban green space for rainwater is affected by soil properties, soil water characteristics, saturated conductivity, rainfall characteristics, etc. [4] The larger the soil permeability, the smaller the runoff. Vegetation can intercept rainfall, the strength of the degree of the intercept and vegetation types and climate types, plant species, plant canopy structure, closely related to rainfall intensity, etc.

*Email: 230129032@seu.edu.cn
3.2. Urban green space LID strategy:

Urban green space LID strategy:
1. Protect the original green spaces, such as forests and grasslands in and around the city;
2. Enhance the urban green space and urban water system and surrounding ecological base, build the network and scale of urban green space system structure, strengthen the rain flood regulation function of green space;
3. Through the catchment and storage means, strengthen the entrapment of green space and the surrounding land runoff rainwater and storage, and slow release into the soil around it;
4. Consider vertical design of green space landscape and drainage, guide the green catchment and collection of water;
5. Choose the sponge facilities, given the runoff from itself and the surrounding through the overflow emission system and the urban storm sewer drainage system and rain runoff discharge system fully cohesion;
6. Choose plants combined with moisture conditions, appropriate chooses resistance to salt, submergence tolerance, carrying capacity emphasize native plants. (Fig.8)

4. Xuzhou city park LID practice

LID development technology is also called "sponge urban construction" in China, with the same research object and the construction goal, in the technology has been developing rapidly in China, won the strong support of the Chinese government. Xuzhou San Huan west road greening "sponge city" pilot project: including Xiang Wang road node and Han Shan road node.

4.1. Park green space -- design of the sponge green space of Xiang Wang road in Xuzhou city.

Xiang Wang road node sponge green space is located in the northwest of Xuzhou city, Xiang Wang road and San Huan west road. The total area of this project is 12545m². Considering the Xuzhou hydrology and rainfall conditions, the field into a natural savings, natural purification, natural irrigation and rain refinement using intensive green sponge, using both the construction waste venue and surrounding roads demolition and construction waste materials as cavernous cavity packing, at the same time for real-time monitoring of field ground water environment and collecting rainwater refines the use and management. (Fig.9) (Fig.10)

4.2. Park green space -- design of the green space of Han Shan road in Xuzhou city.

According to the vertical situation of the site, the site should be designed as a seasonal rainwater garden, and the rainwater retention and purification process can be realized. On a vertical processing, be natural rainwater collection in the field in central low-lying areas, through vegetation, sand and gravel, tectonic structure, such as natural sponge cavity filling will collect, purification, precipitation, rain after purification of water through the soil natural penetration, so as to achieve the water retention, accumulation, purification, and covering the role of groundwater. (Fig.11) (Fig.12) (Fig.13)

*Email: 230129032@seu.edu.cn
5. APPLICATION AND DISCUSSION

5.1. LID design philosophy 1: System Optimization

According to City waterlogging and green Water shortage problem, promote to build the Integrated Water Management System in specific climate geographical environment of the City (" Water Collection - Water Utilization" Integrated Rainwater Management System), cut the surface runoff and accumulated Rainwater Utilization fully organic combination, forming an effective Rainwater Collection processing, centralized distribution, transfer, purification, rain slow-release function such as irrigation System, to effectively solve the City waterlogging and greening Water shortage, Achieve more urban rain Water, Landscape, ecological Design target of the coupling (Achieve the Multiple Design Targets of Integrating of Rainwater, Landscape and Ecology in City Road). [5]

5.2. LID design philosophy 2: Adjusting Measures to Local Conditions

Significant difference exists among Different Location of the city (There are Obvious Differences among Cities with company's Geographical Location), for urban sponge system design, such as rainfall, soil properties, the terrain and the surrounding water system is the precondition of sponge system, management mode at the same time, also need to take into account such factors as aesthetic habits. In the current domestic under the urban green space application more recessed green technology as an example, the recessed green space with supplementary groundwater, regulating runoff, flood detention and reduce runoff pollutants, and other functions, but also is affected by the underground water level, easy to assemble pavement has less waste, green, soil matrix is difficult to replace such limitations. Therefore, how to construct urban road sponge system in high water level non-permafrost regions must be adapted to local conditions.

5.3. LID design philosophy 3: Taking Advantage of Nature

The outstanding part of city waterlogging problem is due to the traditional drainage design focus too runoff to deal with the conflict is centralized, and uses the “源头分散 、化整为零” (Source Dispersion and Break Up the Whole Into Parts) of the design can achieve twice the result with half the effort, to part not only alleviate the urban road drainage pressure, but also solve the urban road green belts pressure, but also solve the problem of the urban green are arid, restored the natural water cycle process of the city. [6]

5.4. design philosophy 4: Qualitative Research

The whole process of system construction and research is based on quantitative research, using GIS and SWMM software to comprehensively analyze urban road vertical and water environment; Through quantitative research, scientific design pavement, rainwater transmission and storage system; The real-time transmission system of automatic monitoring devices such as sensors and Internet of things; Write special computer program and mobile APP, and monitor system operation through intelligent
terminal equipment. Quantitative research to support the analysis and evaluation of water environment of urban roads, and scale and design facilities, sponge, sponge system and performance evaluation, etc., and improve the objectivity of sponge of city construction, scientific and accurate, quantitative research is of great significance for the urban construction of the sponge. (Fig.14)

6. CONCLUSION

Precipitation, underlying surface conditions, differences between different cities, urban water environment is different, city water problem is obviously not a strategy, the model can solve, sponge city construction must be for day, adjust measures to local conditions, based on the system architecture, the global understanding of sponge city essence collection of ooze water, drainage, water storage, water purification and water into an organic whole, solve the problem of urban water environment as a whole.

ACKNOWLEDGMENTS

Thank you to all the team worker of paying their time and effort in this study. And we appreciate the support from the landscape digital research laboratory of Southeast University.

Nanyang Technological University of Singapore – Biophilic Campus in the Making

Lee Fei Chong, Alfred
STX Landscape Architects, Singapore
51 Bras Basah Rd #03-05/06 Singapore 189554, Email: alfredlee@stxla.com

Abstract

Formed in the year 1991, Nanyang Technological University of Singapore (NTU) was sitting on the old campus ground of former Nanyang University built in 1956. The 200 Hectares Yunnan Garden Campus is the largest (by land sizes) and oldest university campus in Singapore with rich cultural and heritage value as well as generous natural parkland-like landscape. One of the most memorable and distinctive features of Yunnan Garden Campus is its abundant and varied landscape. These include avenues of shade trees beside streets, large open spaces, primary forest along the northern and western edges of the campus, the meticulously designed environment of the iconic Yunnan Garden, and informal planting that surrounds Nanyang Lake. This diverse collection of original landscape is neither substantially integrated nor well connected. Over time, the original continuous landscape has been fragmented by the construction of roadways, buildings, pathways, and other infrastructures. The ecology of these isolated landscape patches was further degraded by a limited variety of plant species, the prevalence of introduced plant species, and the disruption of the original groundwater and surface water patterns. The proposed master plan in 2010 is driven by the key strategy to address ecological fragmentation by stitching the natural system back together, based on modal of “patches, corridors, and matrices. Blue and green landscape corridors were introduced as part of the essential framework of the campus masterplan connecting the scattered greeneries around the Campus. The idea was first tested in the Pioneer and Crescent Hall Project in year 2012. The project was completed in year 2015 and had brought biophilic living to reality.

Keywords: Ecological fragmentation; Natural System; Patches Corridor Matrix; Biophilic
1. NTU Yunnan Campus Masterplan 2010

The 2010 Campus Masterplan values the significance of the natural environment of the Yunnan Garden campus. One of the key objectives of the masterplan is to enhance and reinforce the university’s identity as an eco-friendly and biophilic campus. Based on an ecological theory of 'patches, corridors, and matrix' developed by Richard Forman, the master plan outlines a long-term strategy to re-connect the fragmented patches of the landscape into a sustainable whole that will enhance the biodiversity of the campus. This approach includes the creation of an integrated network of green and blue corridors thru parks and green infrastructures for an environmentally sustainable and integrated landscape.

By adopting the ABC Water programs initiated by the Public Utilities Board of Singapore (PUB). The collection, treatment and conveyance of rainwater run-off and water conservation will complement the development of these integrated blue and green landscape corridors. This will require new and existing detention ponds, retention ponds, and other water bodies to collect surface water runoff for recycling and re-use. The ponds and water bodies will also enhance ground water recharge, and provide a habitat for birds and other wildlife. The masterplan had recommended for all existing and future proposed stormwater drains and drainage channels to be designed with the ABC Waters guideline in mind whenever feasible, to create naturalised water ways, minimising the quantity of impermeable concrete drains on campus.

Fig. 1. NTU Yunnan Garden Campus Masterplan 2010
1.1 Patches, Corridors, Matrix

Patches, Corridors, Matrix is a landscape and ecology theory developed by Richard Forman in Land Mosaics: the Ecology of Landscape and Regions (1995). It classified the natural environment in term of three basic spatial element, referred to as patches, corridors, and matrix.

There are several isolated landscape patches within the campus and surrounding environment. To connect these typically isolated patches, several landscaped corridors are proposed. For example, one of the proposed landscape corridor will link Clean Tech at the east of the NTU Yunnan Garden Campus to the parkland in the North Hill precinct, create a natural corridor adjacent to Nanyang Avenue and provide a continuous landscape connection leading from the new east west entry road southwards to Yunnan Garden. The proposed corridor will also add extensive natural linkages at the campus periphery, expanding the size of the original ecosystem.

The reconnection of isolated patches will improve the health and fitness of both the patches and the landscape corridors. Both the corridors and the patches will be planted with native plant species to increase biodiversity. Wherever feasible, landscape corridors will extend across, above or below existing roadways, pathways and other barriers allow animals an uninterrupted movement. Boardwalks and pathways along the landscape corridors will create opportunities for interpretive nature walks. Pavilions and decks accessed from the boardwalks and pathways will provide further informal social gathering spaces, outdoor classrooms, and lookouts.

Fig. 2. Landscape Masterplan framework based on patches, corridors, and matrix theory. The corridors allow unimpeded flora and fauna movement between patches.
1.2 Habitat Corridor

Habitat corridors are land or water connections that permit uninterrupted, safe movement of animal across roads, walkways or other barriers. Habitat corridor will be a significant element in encouraging biodiversity by maintaining the health and fitness of plant and animal species. Movement within the broader natural systems will also lead to a more diverse and vibrant natural environment, better able to sustain itself. Habitat corridor was identified as one of the essential components in enhancing the natural system of the Yunnan Garden campus. Whenever feasible, the existing and new development with the university should bear in mind the importance of creating an uninterrupted ecosystem and shall promote the enhancement of the biodiversity around the campus by taking into consideration the ecological aspect during the planning stage of the development.

Fig. 3. Illustrative plan: The site’s natural system provides a foundation for the Master plan’s proposal. The ecological framework of the campus help determines the future development possibility. The corridors allow unimpeded flora and fauna movement between patches.
1.3 Naturalized Waterways, Retention Ponds & Detention Ponds

The original surface water and ground water routes of Yunnan Garden Campus have been altered by several hardscape areas. These drain into some impermeable reinforced concrete storm water, roadside and building drain. While this drainage system are generally very efficient, it has a number of adverse environmental effects.

Existing and proposed new drainage system should be designed and adopt the “ABC Waters Design Guidelines”, to create a more sustainable drainage strategy. This will involve, where feasible, the creation of naturalised waterways and vegetated drainage swales.

The ABC Water Programme was started in the year 2006 by the Public Utilities Board of Singapore (PUB). It is the Singapore’s version of Water Sensitive Urban Design (WSUD) program aiming at transforming all water bodies in Singapore into clean, beautiful and functional landscapes where the water could eventually be retained, harvest and reused for the water scarce country.

A number of new detention and retention ponds for the recycling and reuse of rainwater runoff will be created. All campus water bodies, including naturalised waterways, retention ponds, detention ponds and lakes will form a continuous integrated network of water elements. The naturalised drainage system has several benefits. These include habitat for native flora and fauna and the creation of social, recreation, and interpretive learning opportunities. The natural cleansing and filtering by water plants through biological uptakes will not only capture sediments and reduce the passage of pollutants, it reduces heavy metal and contaminants in the water system and cleaner water will be discharged.
1.4 Planting & Hardscape Strategy

The Master Plan's planting strategy is based on the re-creation of a native landscape of lowland rainforest species sustainable within this endemic environment. Fostering native flora and fauna will increase the landscape's biodiversity. A native landscape is also easier to maintain and will give the campus a distinctive character and sense of place.

Within the naturalised waterways and the retention and detention ponds, wetland plants known for their water cleansing and filtration properties, as well as for their slope stabilising properties should be used. These plants should also provide habitat for native animals and birds. The goal of the planting selection and design is to mimic a natural littoral edge.

Minimizing hard surfaces should also involve the transformation of exposed concrete roof surfaces and terraces using green roof systems. The impact of hard surfaces can also be reduced at ground level where new road paving, parking lots, pathways and plazas should be constructed, wherever possible, with permeable and porous paving materials.

1.5 Implementation of the Masterplan

The substantially integrated blue and green landscape corridor is an ambitious program of landscape program for the university. It will form a physical network as the backbone of proposed new built form on the university campus. It will be the fundamental principle and landscaping roadmap to follow through and implemented over the next 15 to 20 years.
2. Pilot Project – **Pioneer and Crescent Hall @ NTU**

2.1 Project Overview

The integration of a blue and green network was first tested in 2012. The landscape design of the Pioneer and Crescent Hall at Nanyang Crescent is a combination of the naturalised waterway, wetland and ponds surrounded by a native landscape that is sensitively integrated to create a dynamic equilibrium of nature and man-made. Inspired by the big idea behind the masterplan, the six residential towers designed by the architect sprawling over a 3.5 Hectare of land is making an analogy of the stilt roots of the mangrove tree sitting over the pool of natural water body.

An underlying principle of the landscape design is the landscape/ecological theory of ‘Patches, Corridors, Matrix developed by Richard Forman (1995). The deep topography depression of the site presents a unique opportunity for integrating ‘Active, Beautiful, Clean Waters’ features in the landscape design (ABC Waters Program). Existing concrete drains, stagnant water bodies and an isolated lily pond, are transformed and connected by a green and blue landscape ‘Corridor’ of natural stream and water cascade, to new ‘Patches’ of the cleansing biotope, retention and recreational ponds, rain gardens, and marshland.

The naturalised drainage system provides...
a habitat for native flora and fauna, increasing the landscape’s biodiversity. The natural cleansing and filtering by water growing plants capture sediments and reduce the passage of pollutants. The continuous network of water elements established through the site provided a natural setting for a variety of spaces such as seating decks, gazebos, boardwalks, amphitheatre and outdoor classrooms, creating social, recreation and interpretive learning opportunities.

The fusion of landscape and architecture intermingling creates a spatial symbiosis between man and nature, resulting in a nurturing holistic environment that strikes the perfect equilibrium between study and play, rest and rejuvenation.

Fig. 7. Overall Site Plan of Pioneer & Crescent Hall at Nanyang Technological University, Singapore, Yunnan Garden Campus.
2.2 Key Observations of the Existing Site

**Existing Lily Pond:-**
The existing lily pond is a shallow pool of water with a depth of 500mm. There is no sign of algal bloom due to insubstantial Nutrients discharged through the inlet culvert and well-adapted water plants within the pond that are effective in removing nutrients from the incoming runoff.

**Existing Open Earth Drain:-**
Stagnant and muddy condition observed in downstream water body – the open earth drain. There are forming of algal bloom found near to the pipe culvert, and the majority of the water body is stagnant. The muddy water is a result of a shallow water body with an unlined bed.

**Existing Concrete Cascading Drain:-**
Signs of erosion were observed at some parts of the shallow water body. This indicated that the existing water body might have experienced fast flows in the past. The fast flowing condition could be even more pronounced due to fast flow for incoming cascading drains and the absence of energy dissipater.

Fig. 8. Diagram illustrating key observations of the site.
The Impact of the Proposed Student Housing Development:-

a. Runoff incoming into the water body is associated with the higher nutrient level and suspended solids compared to current grassed/vegetated surfaces.
b. Water quality within the existing water body may deteriorate further, especially within those shallow water bodies downstream of the lily pond. This is because these shallow water bodies do not have settling capacity as well as limited phytoremediation taking place within them. Coupled with its stagnant condition, the risk of algal bloom is expected to increase.
c. Water level fluctuation within the existing water body is supposed to be higher when more runoff is discharged from the new development.
d. More erosion is expected to take place at the banks of the water bodies as more runoff is discharged from the new development.

2.3 Design Approach and Objectives

To minimise the impact of the development and to ensure proper water quality within the water bodies surrounding the development, the following approaches were adopted:-

a. Water quality sampling and analysis were carried out to identify nutrient levels from the incoming culvert and drain. This enables a better design of ABC Waters Design Features.
b. The current shallow water body was re-configured in term of their bed profile and shape to achieve the following:
   - Better settling capacity of the water body;
   - More shallow marsh, deep marsh or submerged marsh to be introduced around the water body as a buffer to reduce sediment from being discharged into the water body; as well as to promote nutrient removal by plants;
   - Better flushing by introducing cascading streams;
   - Separation of a large water body into various smaller water bodies, where each of them was designed as different ABC Waters Design Features, aiming to promote treatment train;
   - Energy dissipater (in the form of natural rocks) was introduced to dissipate energy for incoming drain so that to minimise soil erosion.

The ensure that the goal of the project will be achieved, the design team had outlined the following objectives:-

a. To remove pollutants/nutrients from existing/new development before discharging into the water body.
b. Encourage stormwater harvesting and reuse.
c. Re-configuration of existing water body to enhance self-cleansing capability and encourage phytoremediation processes.
d. The utilisation of water body as a lifestyle.
2.4 Key Design Considerations

Flood Control
a. Proper by-pass system from ABC Waters design features must be provided and connected to the storm drain so that the surrounding area will not be flooded. As a result, an emergency spillway was proposed as a flow bypass of downstream wetland for events up to the 10-year ARI event.
b. Minimum engineering requirements for surface water drainage must be met.

Performance Targets
a. ABC waters features to be designed to meet the stormwater quality objectives
b. Removal of 80% for TSS, 45% for TN and 45% of TP (for 90% of all storm events)

Erosion and Sediment Control
a. Prevent sediments from flowing into drains during rain events. Proper slope gradient were considered during the design process.
b. Employing soil stabilisation techniques such as bioengineering

Mosquito Control
a. Prevent mosquito breeding

2.5 Design Implementation – The Living Water bodies

Based on the site topography, site characteristics and design intention, the following treatment train of ABC Waters Features is proposed to achieve sustainable stormwater management:

a. Sedimentation Basin
b. Linear Wetland
c. Bioretention Basins (Rain Gardens)
d. Cleansing Biotope
e. Pond

Fig. 9. Diagram showing the design principles and idea.
Fig. 10. Treatment train diagram illustrating the stormwater system designed for the landscape area. It explained how water was being collected, treated and conveyed.
Cont. from Point 2.5

Sedimentation Basin (@ RL+117.0)

Reducing sediment loads is an important way to improve stormwater quality. Sedimentation basins can form an integral component of a stormwater treatment train and are specifically employed to remove (by settling) coarse to medium-sized sediments from the water column. As such, the existing lily pond furthest and highest in terms of topography is proposed to be converted into a Sedimentation Basin, which will retain any coarse sediment before discharging runoff into a Linear Wetland.

Linear Wetland (@ RL+116.0)

The Wetland is a shallow extensively vegetated water body using enhanced sedimentation, fine filtration and pollutant uptake processes to remove pollutants from stormwater. Water levels rise during rainfall events and outlets are configured to slowly release flows, typically over three days, back to dry weather water levels. The relationship between detention time, wetland volume and the hydrologic effectiveness of the system were optimize to maximise treatment given the wetland volume site constraint. Plant material was carefully selected to ensure proper nutrient uptake.

Bioretention Basins/ Rain Gardens (@ RL+117.0)

The two Bioretention Basins/ Rain Gardens will pre-treat runoff from impervious surfaces of the new development and the rainwater discharge from the roof of the residential towers before discharging it into the Wetland and Pond.

The basins were densely planted with surface vegetation as a means of pre-treatment before they infiltrate/percolate through a prescribed filter media. During percolation, pollutants are retained through fine filtration, adsorption and allowing some biological uptake.

The Cleansing Biotope (@ RL+116.0)

The Cleansing Biotope, a form of artificially constructed wetland, consisting of nutrient-poor substrates that are planted with wetland plants which are known for their water cleansing capacity, is proposed in the eastern part of the project site. The water runoff is filtered through the substrate layers, collected by the underneath perforation pipes, which finally discharge the treated runoff out from the biotope system. The biotope is designed to provide higher treatment to the sites runoff by recirculating water from the pond to the cleansing biotope and – after further treatment – discharging back into the pond thru mechanical system (Water Pumps).

Pond (@ RL+115.0)

The central pond adjacent to the canteen represents the predominant water body of the development due to its proximity to the new residential halls and gathering places. It is for that reason that the water quality present in this pond is of upmost importance and can only be achieved by a series of pre-treatment and re-circulation.

The introduced re-circulation between pond and the top of the wetland will not only improve the treatment of stormwater and therefore the water quality of the pond but only avoid any stagnant water by creating a continuous moving water body.
Fig. 11. Schematic section through the Sedimentation Basin, Wetland and the Pond. Breakout spaces and boardwalk were added as amenities to the dwellers.
Fig. 12. Sedimentation basin transformed from isolated lily pond as part of the "Active, Beautiful, Clean Waters" feature designs, contributing to sustainable water management system and increasing the landscape's bio-diversity.

Fig. 14. Outdoor seating deck and Gazebo with view of pond and cascading stream.

Fig. 15. A glimpse of the introduced natural system from the student hostel above. The integration of nature and built form was carried out with the aim of creating a biophilic living environment for the staff and student.
3. Conclusion

The master plan in 2010 had outlined the key strategy to address ecological fragmentation by stitching the natural system back together, based on modal of “patches, corridors, and matrix. As a result, integrated blue and green landscape networks were introduced as part of the essential framework.

The sensible design strategy represents a unique opportunity to create a cohesive, inclusive and high-quality private realm which complements the University campus and existing context, creating a peaceful oasis within the vibrant campus compounds. In between, what oneself did not realise is that the integration between nature and the existing/new built form had slowly turned the university into a biophilic campus.

The pioneer and crescent hall project have laid down a good foundation and earmark as a successful precedent for similar projects in the future. This had given a boost of confidence to the campus community in believing that the key landscape principle is the one to live by.

More projects of similar nature of different scale will be implemented campus-wide over the next few years as part of the Masterplan's recommendation. For instance, the up and coming Yunnan Garden and Nanyang Lake Upgrading Project which schedules to complete by the year 2020. With the strong momentum and continuous efforts, coupled with careful implementation, a biophilic NTU Yunnan Garden Campus is not far from being a reality.

Living in Sculptured Nature
A Case-Study of Three Private Residential Development

Yeo Seow Nan, Sherman Stave, Helen Smith-Yeo
STX Landscape Architects, Singapore

Abstract

The landscape design of outdoor communal spaces within private high-density residential developments (condominiums) is not known to the public at large, as they are private spaces, only known and used by the residents of the developments. But this space contributes to around 40-60% of the footprint of each development, and that amounts to a substantial area where the landscape enhances the residents’ experiences with and connections to nature, and also makes a contribution to the environment.

The immediate experience of the communal landscape space is visual, auditory and tactile. Outdoor amenities such as swimming pools, children’s playgrounds, gardens, and seating areas are usually integrated into the landscape design. When the design of such spaces takes on forms, textures and materials derived from nature or natural elements, the result is the creation of spaces that strengthen users’ connections with nature.

The visual experience of the landscape is from near and also from a bird’s eye view, as the high-density developments have residential units on high floors with views down to the landscape space below. The use of sinuous, organic forms in the design of landscape elements mimic forms found in nature, such as curved lines of rivers, waves, branches or leaves, enhancing the visual experience both from near and afar. Overall patterns of these curved lines weaving across the built landscape, intersecting with each other, giving rise to spaces in-between the curves that are bursting with colours of blue and green, provide arresting images reminiscent of nature. At times, the straight lines of the architecture or of a landscape element such as a walkway cut across the curves and organic forms, creating contrasts that heighten the sensory experience of the landscape.

The auditory experience is contributed by features in the built landscape that create sounds of nature, such as a waterfall, a bubbling creek, a water spring. Other sounds of nature are borrowed from fauna such as birds and insects that are attracted to the natural plant elements in the landscape design.

The tactile experience of the landscape comes from the use of natural elements or materials. Colours of blue and green are formed by the natural elements of water in the pools and planting that surround the outdoor amenities and spaces. The use of natural materials such as granite and timber, add to the tactile experience of the users.

Keywords: High Density; Urban; Landscape Design
1. Case Study No. 1 – The Panorama

In the Panorama project at Ang Mo Kio, the design and layout for the landscape gardens was conceived as a lush tropical garden environment that corresponds to the site. Inspired by the naturalistic contours of the site, the genesis of the concept is an abstraction and manipulation of the notion of contours, the landscape design has ‘ribbons’ of walkways and decks weaving across the central open space between the residential blocks, in both horizontal and vertical dimensions, creating a multi-layered and pluralistic environment, linking together different amenity zones.

The planning of the building blocks around the perimeter of the site, surrounding a large central landscape space, provided the opportunity for aerial views of the overall landscape from the residential units at various levels and also from the roof terraces of each block.

The sinuous lines of the landscape weave across the site like ribbons, gradually flowing up and down along and across the center of the open space. The lines take on a 3-dimensional form, with a tree-top wall sweeping across the landscape, over pools, walkways, a playground, and lush planting beds, providing a varied experience of walking across these elements at different heights. The spaces between the lines are filled with a soothing composition of colours from natural elements of water (blue), planting (green), timber deck (brown), granite stones (yellow and gray), offering a rich visual experience.
Fig 4. Lines take on a 3-dimensional form – a tree-top walk sweeps across, over a playground. Photo by Author; Yeo Seow Nan.

Fig 5. Organic forms expressed at an intimate level, with curved benches rising out of the floor. Photo by Author; Yeo Seow Nan.

The organic forms derived from nature are also expressed at a more intimate level, in a lookout deck with a stretched canopy, a mesh walkway that weaves between trees in a curvilinear form, down to even smaller details such as the curved benches that rises out of the floor at the roof terrace.

Fig 6. A mesh walkway weaves between trees in curvilinear form. Photo by Takeo Sugamata; SWITCH

The gentle bubbling of extensive pools in the central landscape space provides a calming auditory experience. A curved waterwall cascading from the ground level down the basement drop-off area creates soothing waterfall sounds that mask vehicular noises. Quiet reflective pools surround the drop-off area.

The tactile experience is crafted with a careful choice of materials. The lightness of the mesh railing of the treetop walk allowed users to feel close to the surrounding elements, and at the same time, fulfill authority–specified safety requirements. The detail of the mesh selected, weaving of metal in ribbon form, is consistent with the overall landscape form. Natural timber was selected for the main pool deck areas, outdoor dining spaces, lookout decks at the ground level and roof terraces, to provide a softer tactile experience as these are activity spaces where users spend more time, compared to circulation spaces finished with the harder granite material.
The landscape area within the development is extensive, covering 75% of the site area. Half of this landscape area is green, where a large variety of plant species (around 25 different trees species, and 70 shrub species) were used to increase the biodiversity of the site.

2. Case Study No. 2 – Helios Residences

The landscape design for the Helios Residences is composed of a series of garden terraces with water elements that negotiate the vast level differences of the site. Each of the garden terraces has different water elements to create a unique spatial character and provide a soothing auditory experience throughout the landscape.

Amorphous shapes suggestive of natural forms, are used in landscape elements at the different terraces, as planters, timber decks, skylights in an overhead pool and a large reflective pool in the middle of the drop-off plaza.

Nature seemed to take over the architecture in this development, where climber plants scale up the façade of the building, cling on to and wrap around columns at the 1st storey terrace, transform an entrance wall to soft green and turn into a thick green hedge wall around the tennis court.
2.1. Central Waterwall and Urban Forest of trees

The overall organization and composition of the landscape is based on a central waterwall along Cairnhill Circle road. The dramatic 6m high waterwall has water gently rippling down its surface and it drops to 9m and subsequently 12m as the site levels drop. Water from the waterwall flows down into a continuous base reflecting pool, which wraps around the entire length of the ground storey lobby and landscape terrace.

The water level is the same as the lobby floor level, making the pathways and lift lobbies appear to be floating on the surrounding water body.

Amorphous-shaped planters are located in the reflecting pool, and repeated in the timber deck areas, creating various pockets of spaces for activity, linked by a sinuous pathway and the surrounding water body.

Overhead, an amorphous-shaped skylight hovers from the pool above the terrace. The terrace links to the Multi-Function Room Terrace at a lower level. At the Multi-
Function Room level, there is a balcony overlooking a reflecting pool and surrounded by waterwalls.

There is a flight of stairs leading down to an open-to-sky timber deck, which serve as a BBQ area. A green mesh wall with *Thunbergia grandiflora* climbers terminates the axis of the central water wall. Beyond this green wall is the tennis court.

**Fig 13.** An urban forest of trees reaches out from the 1st storey landscape terrace to the cantilevered pool overhead. An amorphous-shaped skylight frames a piece of the sky. Photo by John Gollings; John Gollings Photography

**Fig 14.** Nature takes over architecture, with creeper plants cascading down a high wall on one side and creeper plants forming a thick green wall around the tennis court. Photo by John Gollings; John Gollings Photography

### 2.2. Cairnhill Road Entrance

At Cairnhill Road, small side gate entrance is framed by walls fully covered by the *Ficus pumila* climber, like an entrance to a secret garden. After the green wall is a still reflecting pool framed by green hedges. A path leads across the reflecting pool, through a green veil of vines planted on vertical cables, into the lift lobby.

The waterfeature at this level symbolically connects to the central waterwall and reflecting pools at the ground storey.

**Fig 15.** Entrance to a secret garden - climber plants cover a low entrance wall. Photo by Author; Sherman Stave
2.3. Cairnhill Circle Main Entrance
Waterwall

The main entrance is approached along Cairnhill Circle road. Along the main approach drive is a long waterwall and reflecting pool with a row of bubbling water jets, which provides a backdrop for the entrance signage, which is placed in front of it. A row of palms run parallel to the waterwall.

Fig 16. A still reflective pool is framed by hedges and a green veil of climber plants. Photo by John Gollings; John Gollings Photography

2.4. Green Trellis at Main Entrance

The green trellis is similar in character to the vertical vine cables forming the green skirt of the buildings. It is composed of a series of 4.5m high steel fins along the boundary wall. The steel tension cables span across the driveway and are spaced at 500mm apart. The trellis provides a veil of greenery yet maintains a sense of openness with the sky.

Fig 17. A green trellis provides a veil yet maintains a sense of openness with the sky. Photo by John Gollings; John Gollings Photography

2.5. Drop-off Plaza

There is a large amorphous shaped reflecting pool in the center of the drop-off plaza. The pool has similar amorphous shaped planters within it. These amorphous shaped planters are a repeated pattern in the reflecting pool under the towers.

Fig 18. An amorphous-shaped reflecting pool with amorphous-shaped planters marks the drop-off plaza. Photo by John Gollings; John Gollings Photography

The pool cascades down a 1.3m water wall along the driveway ramp leading up from the
basement. At the lower level driveway drop off lobby, the space is defined by a waterwall that serves to terminate the axis of approach from the main entrance.

2.6. Sky Terrace Landscape

At the 4th storey Sky Terrace, pockets of deck spaces below the building overhand are wrapped around with a green veil, providing cool spaces for various activities – children’s playground, children’s pool and seating spaces. Waterwalls, water veils and bubbling waterfeatures animate these spaces.

The intimate pocket decks lead on to an infinity swimming pool that opens up to vast views of the surrounding skyline.

Fig 19. An infinity pool opens up to the vast views of the surrounding skyline. Photo by John Gollings; John Gollings Photography

3. Case Study No. 2 – Belle Vue Residences

The Belle Vue Residences is based on an archipelago concept where buildings and islands of amenities ‘float’ in a water lagoon.

The landscape of the Belle Vue Residences is a contemporary and exclusive setting for living in an urban forest. The unique landscape feature is its seamless fusion of nature and managed water to create a central “lagoon” around which the buildings metaphorically branch out. Units at ground floor enjoy water and planting just outside their living rooms or bedrooms. Reflecting images of nature and sky on the water surface create a calm, idyllic setting.

The lagoon consists of several separate water bodies that appear visually as one main water element. The water bodies making up the “lagoon” are: a 30m lap swimming pool, Jacuzzi area, aquatic pond and mirror reflecting pools.

Fig 20. Overview of the landscape at Belle Vue Residences, based on an archipelago concept. Photo by John Gollings; John Gollings Photography

Fig 21. Communal landscape appears as extension of private enclosed spaces, with natural planting or water edges. Photo by John Gollings; John Gollings Photography

Naturalistic forms flow through the central landscape space, with amorphous-shaped islands scattered on the “lagoon” and have planting that drapes over the water
edges to enhance the naturalistic impressions. The largest island contains the children’s pool and playground.

The strong relationship of indoor & outdoor spaces for the units are reinforced in the form of private enclosed spaces and communal landscape islands which appear as extensions of indoor spaces with natural planting / water edges. The strong indoor & outdoor relationship is also reflected in the clubhouse design, where amenities and landscape are seamlessly integrated within a tropical garden setting.

Pedestrian pathways are formed by broad sweeping arcs that correspond to the flow of the architecture. The paths connect major spaces such as drop-offs, common lift lobbies and activity areas. Where the arcs intersect, they form punctuations in the landscape addressed by specimen plantings.

![Fig 22. Naturalistic forms flow through the central landscape space, with amorphous-shaped islands, scattered on the water “lagoon”. Photo by John Gollings; John Gollings Photography](image)

Fig 22. Naturalistic forms flow through the central landscape space, with amorphous-shaped islands, scattered on the water “lagoon”. Photo by John Gollings; John Gollings Photography

The landscape area of the site is extensive and covered around 65% of the site, including both hardscape and softscape elements. Around 30% of the site area is green and planted with a large variety of plants. In consideration of several shady pockets in the development, a wide variety of lush, shade-tolerant plants were selected that can thrive in such an environment and provide sufficient screening between public and private spaces.

![Fig 23. A wide variety of lush, shape-tolerant plants provide screening between public and private spaces. Photo by John Gollings; John Gollings Photography.](image)

Fig 23. A wide variety of lush, shape-tolerant plants provide screening between public and private spaces. Photo by John Gollings; John Gollings Photography.

In all, the 3 selected projects have different characters and all sought to engage the human senses to nature, with a range of visual, auditory or tactile experiences. The presence of water, the use of biomorphic forms and patterns, a dialogue of complexity and order, come together to create a sense of Living in Sculptured Nature.
Intertwined Human Settlements and Natural Environment—A case study of reclamation and creation of Wanqingsha Island

Tian Mengxiao a,∗

∗The Kong

Abstract

Land reclamation is a major way remaking nature. Following the urbanized advancement, large-scale reclamation projects are carried out in land-scarce coastal nation and city to create new land for urban construction from the sea in a short time, including Hong Kong and other large cities in the Pearl River Delta (PRD). However, the quick acting of reclamation mode has also been controversial for the negative environmental impact. Meanwhile, there still existed another mode of long and slow reclamation activities in PRD for rural settlements, which seems more environmentally friendly and create a diversity of landscape. By choosing Wanqingsha island (万顷沙) as case, this paper will observe and analyze the 200-year history of shaping the island and tries to reveal how the reclamation activities transformed the natural environment and what kinds of settlements and landscapes they created.

Wanqingsha island that located between the Jiaomen waterway (蕉门) and Hongqili waterway (洪奇沥) at the estuary of the PRD now belongs to Nansha District of Guangzhou as an important agricultural production base and popular wetland tourism destination. With continuously reclamation activities taken by different groups of people, it gradually grew from the small and natural sandy shoal at Pearl River estuary in Qing Dynasty into the presently coastal town. The paper combines field research with literature review and constructs a historical narrative through three levels: social, ecology and morphology. It shows that the interventions of human not only produced linear settlements which related to the reclamation methods but also formed a mosaic of diverse landscapes including farmlands, fish ponds as well as wetlands. It also illuminates that during different stages of producing reclaimed land, the residents shifting the livelihood to respond to the changing natural environment.

Based on the case of Wanqingsha island, the paper argues that during the long and slow reclamation, the human settlements and the natural sand island intertwined together to grow and differentiate over time, like a life entity. The superposition of human and natural energy identified distinctive time periods which projected spatially and formed the patchy, time-varying diverse landscape. By doing so, the paper not only makes it significant to rethinking the relationship between human beings with the natural world but also sheds new light on the future urban design and reclamation projects.

TIAN Mengxiao, Architecture Department, The University of Hong Kong.
1. Introduction

Under the influence of both natural geographical changes and reclamation activities, the Pearl River Delta (PRD) which was originally limited to the river mouth has continued to grow since the seventeenth century, extending into the ocean and forming new islands. (Fig. 1).

Fig. 1 Map of Guangdong Province in 1692 (Thirty-first year of Emperor Kangxi in the Qing Dynasty). There were lots of islands on the Pearl River Estuary at that time. Source: Zhongguo di yi li shi dang an (China First Historical Archives), Guangdong Li Shi Di Tu Jing Cui (China: Zhongguo da bai ke quan shu chu ban she, 2003), p24-25.
Unlike the contemporary large-scale reclamation projects which create new land for urban construction from the sea in a short time, the historical reclamation of land for agricultural production and rural settlements on the Pearl River Estuary was a long slow processes. Over this long period of time with great dependency on natural reclamation, residents adjusted their means of livelihood to respond to the changing natural environment during the different stages of land reclamation. Apart from its effects on the natural environment, the slow mode of reclamation also influenced the society and the formation of the settlements. This intertwined relationship between

Fig. 2. Map of Pearl River Estuary. It shows the Wanqingsha Island is located in the middle of Shenzhen, Dongguan, Zhongshan and Guangzhou, which are important cities of the PRD.

human beings and the natural environment is represented clearly by the evolution of Wanqingsha island.

Located between the Jiaomen Waterway and the Hongqili waterway at the estuary of the Pearl River and now forming part of the Nansha District of Guangzhou, Wanqingsha is an island with flat topography and complex hydrology, including twenty-one parallel waterways and two towns. Continuous reclamation activities created the island from an original small and natural sandy shoal in the ocean at the end of seventeenth century into the presently coastal town settlement (Fig. 2). During these 200 years of development, the pattern of growth indicates a similarity in the reclamation process conducted by different groups of people. Furthermore, in the process from the initially formed land to the area still under development today, various landscapes and production modes have adapted to the different stages of reclamation process, and these have co-existed on the island simultaneously (Fig. 3). This is an excellent opportunity to demonstrate the interaction between nature and human development over diverse historical periods as well as to reveal how the reclamation activities transformed the natural environment and the kinds of settlements and landscapes that were created.

2. The Geographical background and the creation of land

The system of the Pearl River primarily consists of three rivers, the East, the North, and the West, converging into the delta, splintering into a dendritic pattern of estuary.

Fig. 3. Satellite imagery of Pearl River Estuary in 1998. It shows the paralleled waterways, the ongoing reclamation lands and the mosaic-like green landscape of Wanqingsha Island. Source: Dongguan Li Dai Di Tu Xua 东莞历代地图选 (Dongguan: Dongguan shi zhen xie wen shi zi liao wei yuan hui, 2006), p128.
waterways and then emptying into the South China Sea.\(^1\) The alluvium brought down by the rivers filled in the bay and created the upper reaches of the delta at a very slow pace. It was only through human action, dike construction and reclamation, that the increase in size of the Pearl River Delta began to quicken.\(^2\) The courses of the North and the West Rivers changed frequently, and the earliest levees were built precisely in the

---

2. Marks, 32.
areas towards which the changed water courses directed their discharge. After the Song dynasty, the flow of the rivers stabilised with the help of the dike building and sediment settled further downstream which created underwater sandbanks or shallow intertidal mudflats which become the natural foundation for reclamation activities. By the end of the fourteenth century, the sandy sediments had gradually extended to the present Pearl River estuary with dunes continued to emerge including the region of what was later to become Wanqingsha island (Fig. 4).³

The natural environment and the geographical conditions created opportunities that promoted the exploitation of sandy fields in the Wanqingsha area and the reclamation activities were first recorded in chorography at the end of the eighteenth century (Emperor Jiaqing, Qing dynasty). Powerful families from the neighbouring Xiangshan and Dongguan regions rushed to compete for land development in the mid-nineteenth century because of the quick growth of sandy sediment regions. In fact, the name of Wanqingsha region in Chinese means thousands of hectares of sand. In the ten years between 1838 and 1849 years, more than 145 qing⁴ sandy fields were enclosed and reclaimed with an average increase of 12 qing per year.⁵ In 1892, the area of reclaimed land had reached 4000 mu⁶. At that time, Wanqingsha had begun to be recorded frequently in cartography (Fig. 5). In the blank space that originally represented the ocean, the name of Wanqingsha and the emerging shape of the island started to be shown. This shows that

cultivable land and simple settlements might be formed in the area as Wanqingsha was no longer an area of sand which could be seen above the water in the low tide and would be still submerged in the high tide. In spite of the considerable increase in reclamation during the middle and late Qing Dynasty, the reclamation activities based on natural dunes and marshes were still a long-term multi-stage process. In general, the formation of sand fields had five stages depending on the state of sediment and the depth of water. These were known as called as “fish swimming”, “scull-touching bottom”, “crane-standing”, “grass-spaying” and “reclamation”. Only during the “grass-spaying” stages could people cultivate grass to firm the sandbanks and promote the deposit of more sediment. Initially, the first three stages were almost completely dominated by natural shaping forces. However, during the period when vast reclamation took place in Wanqingsha, the passive waiting for the natural formation of sediment had changed to become the active exploitation of the sand which still submerged in the water with the development of reclamation technology. Rocks were sunk into the stretch of foreshore to gather more sediment around the rock foundation and this promoted the appearance of a muddy surface which was suitable for reeds and the planting of grass. Meanwhile, the purpose and technology of dike construction also changed during the Qing dynasty.

In the early stages, levees, mostly built with mud and parallel to the waterways, were used to protect cultivated land from the flood. After the Qing dynasty, dike construction became a means for people to enclose sand and accelerate the deposit of sediment (Fig. 6). The building material improved from the easily destroyed mud into a combination of stones and earth. For the reclamation of Wanqingsha, the use of stone piles to construct the embankments was recorded. In other nearby areas during the same period, there is a record of detailed construction techniques that used rammed

---

7 The ‘fish swimming’ stage, when the depth of water was 2 - 3 m deep at low tide. The ‘scull-touching bottom’ stage, when depth of water was 1 - 2 m. The ‘crane-standing’ stage, when water further deceased to about 0.2 - 0.3 m. The ‘grass-spaying’ stages, when most of the beaches were exposed at low tide and waterweeds start to grow. 8 David Faure, Emperor and Ancestor: State and Lineage in South China (Stanford, Calif: Stanford University Press, 2007), p274.
earth together with stone masonry and grass reinforcement. This improvement in the technical methods made the dikes stronger to maintain the sandy fields during tidal movements and also increased the success rate of reclamation. However, it is expected that although the reliability of the stone-built embankment was much higher than that of mud, the cost of constructing dikes had also increased considerably. Hence, although it was very attractive to create cultivatable land from the natural shoals, the long and slow process of reclamation was still a risky process. Thus, what motivated the developers who dominated the rapid and considerable reclamation of Wanqingsha during the Qing dynasty in spite of the high costs and considerable time required?

3. Power of reclamation and the formation of settlements

By the 1680s, after the disorder related to social and political problems finally came to an end, the gentrified society on the Pearl River Delta returned to normal. In the upper area of Pearl River Delta, the early settled clans reactivated the restoration of peaceful conditions and the revival of the economy supported these big families to expand their power and their property by carrying out land reclamation on the Pearl River estuary including Wanqingsha island. Thus, when discussing the shaping of the new island after the seventeenth century, it can be said that nature was one of the shapers and the magnates from the upper delta were the other.

As mentioned before, from the eighteenth century, the large clans from areas near Wanqingsha, such as Dongguan, Zhongshan

---

Fig. 7. Settlements pattern of villages dominated by clans (left) and settlements of Wanqingsha Island (right).
Source: Illustrated by the Author.

Fig. 8. The formation of linear settlements on Wanqingsha Island.

and Foshan, began intense competition for reclamation. However, with these powerful clans, the newly created lands were more of a means to gather wealth and influence rather than to expand the living spaces. What the magnates needed was the power of control as well as the capital provided by the newly created spaces rather than the actual land to inhabit and cultivate. The most important thing for them was to claim the landholding and tax collection rights. Meanwhile, the increasing reclamation activities meant that the sands moved further away from the villages of the big families. Thus, the lineages who owned the land and had the right to collect the rent hired labour to build dikes, reclaim land, farm and harvest the land. The persons who settled on the sands area were the tenants. These were the weaker villagers as well as the boat people who lost their living space because of the land reclamation and the disappearance of the ocean area. In this situation, the settlements formed at Wanqingsha were unlike the compact villages of the larger clans (Fig 7).

First of all, the settlements on the island did not have focal ancestral halls in the centre because the residents settled on the island did not belong to big clans. Second, since the initial purpose of building residential spaces was largely to facilitate reclamation activities and cultivation, the resulting settlements were scattered with more attention to the servicing of the reclaimed lands and the convenience of transportation. Therefore, most of the buildings faced the waterways because boating was the main means of transportation (Fig. 8). Besides, dikes were the only lands with enough load-bearing capacity for construction until the reclamation finished, so the initial buildings usually rested against the embankments on one side with the other side standing in the water with supporting wooden pillars hammered into the river-bed (Fig. 9).

In Wanqingsha, all these reasons resulted in a linear loosely distributed configuration of settlements along the waterways and dikes. On the other hand, while the high profits and high risks of reclamation required investors familiar with the reclamation mechanism, the participation of large clans somehow ensured the capital for these operations and demonstrated their planning preferences. From the middle of the nineteenth century, Mingluntang from Dongguan dominated the reclamation activities on Wanqingsha island. Even though in the following hundred and fifty years, the control of power changed several times, the majority could always be attributed to a single organization which contributed to the preferable organized reclamation activities. This is expressed by the settlements and landscape fabric of Wanqingsha island that evolved from the first waterway formed during the Qing dynasty to the twenty-first waterway now, with newly created land, and parallel rivers which commenced at the beginning of the reclamation and got caught in the middle of the levees, stretching from northwest to southeast in an orderly manner.

\[\text{Ibid.}\]
\[\text{Guangzhou Shi Dang An Guang, 170.}\]
4. Changing of livelihood and production mode

Since the purpose of reclamation was a struggle for power and land, rather than to

create additional living space, the main feature was to declare dominion by enclosing the sand with stone. Inside the enclosed dike system, the water-rich sandy field slowly drained and changed into farmland while outside the dikes, the Pearl River kept bringing more sediments to form more sandbanks. In comparison with the method of filling the areas with large amounts of rocks, clay and draining the wetlands, the impact on nature by this slow and long-term reclamation mode is less pronounced. The long process provided a buffer for the transformation of nature, and also prompted the residents to develop different production methods based on the condition of the reclaimed land.

In the early stages, the dikes surrounded a salt-water area. Cyperus or reeds would be planted in this area, which increased the stability of the dikes and improved the salinity and alkalinity of the water and the soil. After several rounds of planting grass, the land would be suitable for planting crops. In the early years, due to the food shortages, rice was the primary crop. With the development of agriculture and integrated farming, the dike-pond system with fishpond and mulberry dikes as well as fishpond and sugar cane dikes was developed. Thus, from an early stage in the reclamation process, the enclosed areas were utilised for aquaculture (Fig. 11). This was followed by the setting up of the dike-pond systems. When reclamation reached a certain extent, the partly dewatered wetland could be used for wetland planting with crops such as water chestnut and lotus roots. Eventually, the land would finally have enough load-bearing capacity for the construction of buildings.

The settlements expanded with the land and the population increased. Settlements that originally distributed linearly along one side of the dike first extended to both sides, then expanded outward layer by layer. Previous dikes now became roads in the villages. Since the reclaimed land was lower than the

Biophilic Cities

Dikes, in the villages it can be seen that the roadside buildings have a one-storey height difference from the road, while the waterside buildings are level with the road (Fig. 12). Inhabitants in the waterside houses reclaimed land from the waterway on an individual basis whenever they needed additional living space, and this resulted in many small building foundations. Furthermore, it is recorded that as settlements along the waterway were approaching saturation, some people would separate from the villages and participate in new reclamation activities, most of these being fishermen. New reclamation activities would establish new living spaces and form new settlements (Fig. 13).

This shows how as the state of the reclamation of land changed, the way the people used the land also changed. In this situation, the development of agricultural ecology, the formation of settlements, and the transition to reclaimed land are combined organically. For Wanqingsha island, from the first waterway as the earliest reclamation to the twenty-first waterway as the latest reclamation in time, agricultural production and the network pattern of the waterways reflect the adaptation to the natural condition of the different reclamation stages. In the early reclaimed areas, the area from the first waterway to the sixth has a more dense settlements and serves as the town centre and agricultural trade centre. The middle stage area from the sixth waterway to the eleventh has more agricultural development. The location from the eighteenth waterway to the twenty-first is still in the early stages of reclamation, and

here the residents engaged in the fishing industry (Fig. 14). As a result, the artificial dikes changed the

Fig. 14. Settlements and diverse landscape of Wanqingsha Island. 12-a shows the beginning of reclamation which include the waterways, the wetland and the grass planting. 12-b shows the dike-pond system that the banana trees are planted on the dikes enclosed the fishponds. 12-c shows the papaya plantation on the new created farmland. 12-d shows the rice cultivation on the first reclamation area of Wanqingsha island. 12-d shows the linear distribution of settlements along the waterway and the already formed farmlands on bothsides of the village. Source: 12-a, b, d, e in: Guangzhou Panyu Qu Wen Lian 广州番禺区文联, Wan Qing Sha Tian Wan Juan Hua 万顷沙田万卷画 (Guangzhou: Panyu qu wanjingsha ren min zheng fu), 2004. 12-e: Photograph by the Author.
natural environment, and the original ocean area became islands. Nonetheless, over a long period of reclamation, this change is an adaptation and utilisation of the environment rather than an invasion. Even though the growing island shaped by an organic combination of artefacts and nature changed the marine ecology, it also formed a new wetland environment. As the eighteenth waterway reclamation proceeded, the new wetland attracted wintering birds and finally became a long-term gathering place for them. This kind of island building and reclamation is not free from effects on the environment. However, in comparison with the more rapid reclamation mode, it seems to be more eco-friendly. In contemporary times, an age of rapid urban development and construction and land shortage, can we find a more appropriate way to bring together different modes to combine cities and the environment?

Abstract

In the early 1990s, Taiwan like many core cities in mainland China, the aesthetic of the industrial revolution advertised by mechanization became the powerful impetus to urbanization. At the same time, it aroused some reflection from architects. Huang Shengyuan is one of them. He and his Field Office reflect on the relationship between urban practice and the natural pattern from the perspective of time, thinking about the linkages from the early single living units to today's urban scale and between architecture and man and nature, and hope to practice a Naturally, companion design complying with the law of growth, therefore, he chose Yilan, so that the building back to nature. The backward industrialization and urbanization of Yilan provided a hotbed for the ideal of Huang. The accumulation of more than a decade has led to the city's transformation. However, Huang’s practice also stimulated intense discussion of "Criticism of Pastoralism" and avoided the objective problems at the urban scale. This is a special case. Whatever, the practice of Field Office, in a dystopian position, shows us how cities can grow like mankind over time and this may be a special meaning of the Biophilic City. As a result of the challenges we facing, we need to explore more deeply. This paper is subsidized by NSFC project which is named as <Research on Technical System of “Downtown Factory” Community-oriented Regeneration in Yangtze River Delta Region>. (Grant No.51678412)

Keywords: Growing city; urbanization, time; Criticism of Pastoralism,
1. From the Past to Now-Huang is in Yilan

1.1. Connectivity between City and Nature – Building Map of the Field Office

There are two natural opportunities for connecting Yilan to nature.

One is geographical. From a geographical point of view, we are usually used to see Taiwan as three parts: Taipei, Taichung and Tainan, and Yilan is located in northern Taiwan. However, divided by natural north and south ridges, Taiwan is divided into east and west. The west is a central area of a highly modern city facing the mainland. The eastern part is backed by a mountain ridge. The ocean and nature are isolated from each other. Yilan is the largest and most concentrated one. The land has the typical nature of natural habitat. Judging from the natural location of Yilan itself, it is a triangular area surrounded by two ridge lines and a coastline, naturally blocking the convenience of connecting with the outside world. Yilan has the necessity of connecting with nature.

(Fig.1)

Time is another important opportunity for mutual feedback between nature and Yilan. Huang Shengyuan’s connection to the urban space in the past 20 years has made Yilan an overall harmony. From the results, this is a metaphorical echo of the “urban acupuncture” put forward by Malarias in Barcelona’s urban regeneration strategy in 1982. However, if the “acupuncture city” is a result-oriented urban layout, Huang’s team is a process-oriented free connection. Time is an important starting point to understand Huang Shengyuan's team work. Time is not their enemy but a friend. They almost took root in the land of Yilan. Many of the cases continued for a long time. They covered half-to-none and they had no funds. After many years, when they were about to be forgotten, they found some funds and the construction site moved again. They seem to be playing the next big game in Yilan, step by step to get the whole game. When the energy isn't going to be used, it's time to use the energy on the other side and wait until after some time, the interesting thread of the game is slowly seen. And as the roots of the dense network deepen the cornerstone of Yilan, slowly changing the appearance of Yilan, and self-growth.

How exactly do people realize that they are in a certain domain? Is there a kind of metaphorical border in the modern Yilan built by people who see through certain qualities, which encloses the Yilan’s place, and at the same time continues to radiate outwards while building people's belongings? Urban image theory believes that people's understanding of the city and the formation of the image is achieved through the observation of the city's environment. The various signs of urban form are symbols for people to identify cities, and people form feelings by observing these symbols so as to gradually understand the nature of the city. The more clear the symbols and structures of the urban environment are, the more people can identify cities and bring about psychological stability and ownership. Huang Shengyuan constructed the appearance of Yilan one by one through his
own practice. In the middle of Tian, these symbols are not just buildings.

(Fig.2)

1.2. Landscape-oriented

If you want to seek the connection and connection between things, the bridge is not the best carrier. When we tried to discuss the connection between man and nature, the Jinhai plank road showed a strong contrast and led people to nature in the way of landscape.

(Fig.3)

In the "waiting" scenario we describe, distance is the most central expression. “Bridges allow rivers to go their own way, and at the same time provide roads for people who will eventually die, so that they can travel to and from the two sides of the river... The bridges on the highways are braided as calculated, as long as possible in the length of the traffic network. In addition, the bridges travel back and forth with the rushing or slowing people, making them reach the other side and reaching the other side as a deceased. Heine grid gave the bridge meaning, but now it connects the other side. Bridges have little sense of distance. All forms of transportation have gradually ignored the distance. The way people get to the other side is greatly enriched, and time is infinitely efficient. Nowadays, we can ride on cars and rush on high-speed mixed-energy soil bridge decks. Everything is quick and convenient, and of course, there is no general expectation and miss in the past. The Jinhai Plank Road, on the other hand, restores the road to walking, slows people's pace, and at the same time reconstructs this distance, and introduces natural elements to enrich people's senses. It is silently attached to the side of concrete, filling the void of time and distance with the relationship between nature and human settlement.

The “free connection” of the Jinhai Plank Road has three manifestations: First, it is a confrontation with concrete. The Jinhai Plane Road hangs on the side of the original road, highlighting a binary opposition with a positive attitude. The machines and industries represented by highway bridges provide efficiency and speed while also disregarding the distance of people. The Jinhai Plank Road creates a quiet and private passage for the walkers. The residents around the service station respect the visitors. Perhaps only the pedestrians who are slowing down are the true enjoyment of the Yilan River. Only under the shadow of the bridge will they resist the summer. They will stay on the lawn and listen to the flow of rivers. The second is the scale of the person. “The road is narrower, the talents will meet; the light is dark, and the bird can rest.” In the eyes of Huang Shengyuan, the encounter meets unexpectedly is more talkative than the others, and for this reason, there is no need to deliberately satisfy the needs of the function, but care about the delicate seasoning of various scales, returning people to natural. The third is the echo of construction and nature. The most unforgettable sight of the Jinhai Plank Road is the structural bars that are arranged on the outside and are arranged in rows. They sway in the wind and make up the special metallic silk flowers on the Jinhai plank road. In addition, planting plants are planted on the edge of the whole plank road and introduced
into the climbing vines. The drip irrigation and spray systems involved at the same time can also be used to regulate the microclimate and increase the mood of the wind and clouds. The non-ordered galvanized grille, wood, and weather-resistant steel plate used in the bridge deck are more transparent when approaching the center, giving pedestrians a vague sense of danger and focusing more on the water surface, tending towards nature.

Since then, the Jinhai plank road has been guided by the landscape and has established a “bridge” between man and city and nature. (Fig.4)

1.3. Space Shape (Positive Space - Negative Space)

“Land on the ground” is also returned to the land. The non-architecture mode shows the connection between the field and space.

Luodong Cultural Square is a model of Huang Shengyuan's practice. Before this, various local governments set up cultural centers under the guidance of cultural policies, including auditoriums, libraries, and galleries. However, cultural centers are often a large black box, which is far from the people's lives. In this context, Huang Shengyuan took the lead in breaking this silence in the form of a "shelving." In the case of 90m X 90m and a net height of 18m, the Luodong built a long period of “construction rate.” In this real plane, “Yellow” is a function that is twisted in the air and twisted and combined. The amount of energy that attracts free entry and exit and spontaneous activity makes this original energy that was inherent in the night market and is further stimulated during the day. On the south side of the site, "Huang" uses design contrasts to create a level difference in a flat field, nesting complex, undulating space systems, and the crowds of sports and leisure here, in this dynamic venue. Find out how you exist here.

(Fig.5)

Restitution and utilization are the two core elements of this case that focus on the “ground”. Restitution often metaphorizes a revolt. In today's group of architects who return overseas and have strong ideas for the local community, most of them have some rebellion and confrontation. When the policy is stimulated, there will always be a strategy of stress. However, under the background of individual heroism, this kind of confrontation is often presented in novelty, and under the slogan of Futurism, it preaches a clamor for controversy. Each of them publicized their own "goodwill," and hoped that this "goodwill" could one day be understood and "impressed" around them. In the end, in those voices of advocacy and crusade, they pushed to the cusp and formed an isolated core. What waits for these is the support and criticism of those multi-core and globalization. They refused to return to themselves and saw something outside the building. At the moment, the "useful use" implies a positive intervention, and it is expected that the architects will be able to present themselves when they return to this place.
2. From Now to the Future-Practicing in Urban

2.1. Isolated Architecture

Today's cities are a collection of buildings. (Fig.6)

If we take a look at today’s cities from the standpoint of Yilan, we can quickly understand why Huang Shengyuan is controversial. First of all, it is the degree of development of the city. Although the development of Yilan is based on a moderating, slow-warming approach, most of the inland cities that are isolated from nature, or small cities that are surrounded by cities, bear the brunt of the efficiency of urban development. Whether in the past 90s or today, no one would talk about feelings on the basis of material scarcity. In the following 20 years, when the deterioration of the environment brought about by the rapid expansion of the city and the accelerated way of life have allowed more and more people to reflect on their own circumstances, people are looking around. Huang Shengyuan and his Yilan can enter people's vision.

The second is the scale. We have talked about the city connection of Yilan. In fact, it is a kind of recognition and urban image. People get stability and find their own attribution and value. So, how to construct a modern metropolis image of the city so that people can gain self-identity in it, not self-loss? Kevin Lynch once outlined the five elements of the physical environment in his book: roads, borders, regions, nodes, and markers. However, with the current expansion of the metropolitan scale, it is difficult for us to control the overall situation. Cities are constantly being deconstructed by partitions. We can integrate a certain area and show it on the ground, but when we put together, we will no longer have an overall urban outlook. When we compare the urban fabrics and skylines of Barcelona's new and old cities, Beijing, Shanghai and Paris, we have to conquer the courage and courage of Osman. In an over-scale urban environment, this gradual progress from bottom to top is inevitably one-sided and inefficient, and there is the danger that one day will finally be destroyed by a certain personality.

The third is the relationship. Does the city's space respond to each other and must use architectural methods? If our answer is yes, it is perhaps in cities where the stock is overflowing. The interface of the city is entirely determined by the architecture. However, there is still a gap between buildings and cities. It seems to have become an unclaimed gray space. It is neither a city nor a building. It is a barrier erected by hedgerows and fences, and it rejects the infiltration of the two. When constructing the boundaries of the city's core area, the buildings are always on the sidelines and stand tall and self-possessed. With various gestures and reasons, they shrink their own bodies and carry their own walls. Fortunately, Luodong Cultural Square also showed us the negative answer.

(Fig.7) (Fig.8)
2.2. Landscape and Decoration (and Gardens)

In the practice of Huang Shengyuan's local practice, landscape is a kind of flexible medium that exists in the earth and presents the freehand drawing that distinguishes it from the western thinking based on rational thinking and the oriental "garden".

According to Professor Zhou Yi of Tsinghua University, “Utopia is a set of abstraction that overrides the reality of the real world by thinking and detachment from the real world. It is in conformity with the abstract rules of rational principles, with perfect organizational order and optimal operating efficiency. A highly harmonious and self-contained vision of integrity." With the help of Utopia, Western landscapes tend to exhibit a strong geometric composition, narrating clear logic, and providing a form template and design paradigm. In the oriental gardens, even Japan’s dry landscape courtyards are seeking a spiritual synesthesia and resonance. They don’t care about the form, but they care about an order and the atmosphere in which they live and the perception of the field. (Fig.9)

For Huang Shengyuan, the “being” in the earth is not an abstract speculation in the concept, but a real material world with five senses and physical body. These are closer to the appeal of the oriental gardens, but they emphasize the participation and dynamic changes of the viewers. Furthermore, unlike gardens, the creation of landscapes is often an open environment. It is an open gesture that welcomes the inclusion of all kinds of elements, together influences, and creates a sense of place in this place. Therefore, we see that in the design of the Field Office, the landscape encourages people to perceive the building (non-architecture) subject in a supporting role and extends around to connect with several other cases. When this extension expands again, it will find itself incorporated in a great natural pattern.

2.3. Group People in Taiwan for Urban Innovation

The essence of the city is its concentration. The city is formed by agglomeration and it is also reformed by agglomeration.

In these 20 years, Taiwan has not only Huang Shengyuan. After the great earthquake in 1999, Xie Yingjun came to the disaster area with the spirit of "Utopian Realism" to help residents rebuild. In the first time, he built a temporary resettlement area for the Thao people. The firm also moved to the disaster area and set up next to the resettlement area. He used the same materials to build the team into the disaster area, and later turned the disaster area office into a large base. Develop a set of construction methods that the residents of the group can build on their own. In order to complete their own homes in a collective manner, such a mode of modular design and a simple construction system enables all people to gather together and complete their own modernity.

Over the years, there are still many people who are tangling with the uniqueness
of Yilan. The criticism of Huang Shengyuan cannot be used as a paradigm for urban improvement. However, Yilan has never been given the status of city in fact, but is constantly building its own, ground. From the author's point of view, the greatest value of Yilan lies in its emergence as an Yilan, which presents the characteristics of this place at this time, which can be clearly recognized, identified, and recognized by people. From a historical point of view, compared to classicalism, modernism, or postmodernism, etc., the current era has yet to form a core of convergence. The timeline is uneven, and the leap of development has made everything intertwined. Together, chaotic. We seem to have many groups, but we have never owned a "Texas Mounted Police." We seem to have held many meetings but never built IBA; we seem to be looking for a way out, but we don't clearly distinguish it from Outside of the core of those doctrines, their own situation and pursuit. We have indeed converged and converged over all previous eras, but we have violated the rules and principles of colonialism. Perhaps we need another dimension to guide us.

(Fig.10)

3. Urban Reformation in Passive Way

Another dimension of guiding urban change is urban events. If Huang Shengyuan enters Yilan from the boundary of time, in the 1990s, with the reunification of the two Germanys, the disintegration of the Soviet Union, and the end of the Cold War, all major issues left over from the Second World War have finally stabilized, and the entire world has entered the recovery of the urban development stage. Until the beginning of the 21st century, people used the vast range of science and technology previously used in warfare on the construction of cities. Taking China as an example, Hong Kong and Macao have returned in succession, heralding the initial victory of one country, two systems. In the subsequent development, in 2011, the rate of urbanization in the Chinese mainland exceeded 50% for the first time, reaching 51.3%. This means that China’s urban population exceeds the rural population for the first time, and urbanization in China has entered a critical stage of development. In these 20 years, human beings have gathered all their previous efforts, which have greatly consumed the cost of the earth’s resources and reconstructed cities that were almost disturbed by post-war issues. Huang Shengyuan also took this opportunity to extend a helping hand to the almost defeated Yilan.

American architecture critic Giedion put forward the concept of “time-space-building” at the beginning of the 20th century. It was a sense of time when the speed of maneuvers brought unprecedented shock to mankind. The expression of “events” was “new” and “old”. "Drawing a clear fault between them, if not, there is nothing special to highlight the new era, although there is still a gradual transition between them. When we are looking for a wedge, everything is compressed to the extreme.

(Fig.11)
4. Conclusion

Huang Shengyuan is not an ambitious architect, but like a repairman, he repairs buildings in each cracked area, builds a landscape, and finally connects the city. Every supplement in Yilan has its own imprint on later generations. There are some common attributes and tendencies. Where people's footsteps have been accumulated, the characteristics of human nature here are presented. If we stand at the perspective of Huang Shengyuan, we can describe that there is an essential difference between home and studio, that is, so-called townships and cities have caused substantial differences due to different stocks. This is why Huang Shengyuan has influenced people's thinking about the city but still has to be questioned. It's wise to slow down your own pace. Slowing others down is critical.

In the construction of nature, there is no need to discuss the attributes of "in the ground." Today we discuss “on the ground” because people are in the cities and the cities are in nature, replacing the attributes we have in the region. In fact, we do not have to break through this framework, or establish a system to demolish this "wall." If the scale and the pursuit of humanity are really expressed here, cities can serve as a place where such people can gather, and they can express the relationship and position between nature and human settlements, presenting the “the way that a dead person will exist in the earth.” Human nature cities can grow naturally like humans.

Abstract

This paper addresses landscape-based strategies for urban new town revival in China. Urban new towns have been planned and built in an incredible speed in the last twenty years in China. Suffering the low quality of building design, inadequate infrastructure and taking no count of the value of nature in the planning, design and managing; New Town Renewal is an inevitable challenge for repairing our urban and nature environment in fast growing cities like Shanghai.

This paper examines landscape as a critical framework for New Town Renewal in a Chinese Context. First, the paper will claim New Town Renewal as an emerging crises and opportunity for city design, especially landscape urbanism; a brief review of new town planning evolution will be presented here.

Second, the paper will use a recent urban design practice in Nanqiao New Town near Shanghai as an example, to demonstrate the necessity and leading role of landscape architecture in New Town Renewal practice. In this case, a 32 acres industrial campus built in 2000s is seeking for an urban design framework to be revived from low-end manufacturing upgrading to a mixed-use development, comprising a combination of office and laboratory buildings, that are home to several biotechnology companies, retail areas, rental apartments, and parks and open space. There key strategies are proposed here: First, with landscape and built structure layered overlay, a MULTI-LAYERED spatial structure is provided here, which view the entire campus as a living arena of processes and exchanges over time, allowing new forces and relationships shifting through and across the urban field; Second, the GRID SYSTEM as an effective field operation, is extending the framework for a wide range of flexible and changing development over time, enable people to provisionally stage a site for various and shifting programmatic events; Third, the proposal came to a whole repertoire of “Gateways, Viaducts and Reservoirs”, each finding new expressions making landscape as operative techniques to urban spatial notation.

Last, the paper would further claim that as more and more urban new town facing repairing in the future, landscape architecture have more opportunities and will play an increasing important leading role in improving daily human living quality in urban environment. This paper is supported by NSFC project. (No. 51678412).

Keywords: New Town Renewal; Landscape Urbanism; Built Environment; Multi-layered; Grid System; Gateways
1. Introduction: New Town Renewal in China

Urban new town has been planned and built in an incredible speed in China in the last twenty years. One major commendable achievement is the suburban planning and design. Chinese cities used to be product of Soviet planning practices and aesthetic preferences (Kuan & Rowe, 2004), but the open-door policy and the introduction of market mechanisms was pushing cities to experience the huge physical transformations (Friedmann, 2005; Lu, 2006; Xue, 2006, 2010). This enormous achievement in the last twenty years has created new towns and districts at an accelerated rate unknown before.

On one hand, any urban planners, designers, and scholars must be humble in front of this historic process of urbanization with unprecedented scale in human history. But on the other hand, the simplicity and standardization make those new towns a well-known product, economic to construct and easily accepted by the construction industry (Shane, 2013).

The new town construction in China has followed the Industrial Model, as in the British planner Ebenezer Howard’s Garden Cities of Tomorrow (1898) or in Le Corbusier’s City of Three Million (1922), just like what Lynch (1981) called “the city as a machine”. More often, the newly-built urban district was driven by market force, manufacturing services, housing need, and strong municipality ambitious, and was shaped on where used to be factories, warehouses, villages and farmland, with extremely low relocation cost and in unprecedented speed. With ambitious to show a model city or how city should be shaped in future, they absorbed Perry’s (1990s) conceptualization of the Neighborhood Units and what Lynch proposed Eco-city (1983) in the master plan. However, creating new town from an agricultural base has never been easy as the sprawling city in both European and America demonstrated. Suffering the low quality of building design, inadequate infrastructure and taking no count of the value of nature in the planning, design and managing; New Town Renewal is an inevitable challenge for repairing our urban and nature environment in fast growing cities.

New Town Renewal has been attracted increasing attention recently. Not only in the ghost town like Ordos and Tianji Eco-cities, but also in the rethinking of the revival of metropolitan core. The Lujiazui experiment is a recent research lead by Prof. Cai Yongji in Tongji University, with a team of 11 undergraduates. Lujiazui Pudong exhibits the typical progression of Chinese urbanization from an under-developed area full of warehouses and farmland, into a symbol embracing globalization and modern metropolis with clusters of skyscrapers (Xue, 2011). The vision of today’s Lujiazui was created in the Lujiazui international urban design competition held in 1992. Though it was trying to absorb the latest urban planning idea from western world, this area was shaped as a mono-financial area, which excluded other functions especially daily activities at human scale. The main purpose of the experiment is to supplement the daily function to create a 24-hour’s zone.
Students are trying to insert “complexes” with a height of 24 meter, which included a variety of spaces, theaters, stadiums and living facilities.

Lujiazui Experiment (see Figure 1) is a typical case reflecting the rethinking and exploration from urban planners, designers and scholars, with an Urban Acupuncture approach. This paper would further examine landscape as a critical framework for New Town Renewal in a Chinese Context.

2. Reclaiming Landscape as a Framework for Urban Design

Landscape has played double role in the current urbanization. One significant reason that landscape has gained increased attention is the failures of abovementioned universal and utopian trends in architectural and urban planning and design. Landscape has been a tool to resist homogenization of the environment while also heightening local attributes (Corner, 1999). Another reason is the increasing concern to ecology and environment. Based on the earlier ecological work of Ian McHarg (1969) to contemporary practice of Landscape Urbanism.

A significant difference for landscape urbanism in Western and China is that the massive process of deindustrialization have stressed the new demands of land-use planning and urban design in Western countries, while in China the main challenges comes from the severe situation for repairing nature resource from the fast industrial expansion, the new tech industrial upgrade benefit from the informatization, and the urgent need for high living quality from new citizens. The latter requires an even high flexibility for the future industrial and urban revolution. Best case could be JCFO’s winning proposal for Qianhai Harbor, Shenzhen, which defined the five distinct and sub-districts by “water fingers”- a landscape infrastructure and parkland played the role as innovative framework for the urban construction (Figure 2).

In the last ten years, landscape has been applied as framework to both downtown revival and new town planning. Sasaki’s winning proposal to reshaping Suzhou Creek - historically one of Shanghai’s most vital water routes but later suffered severe pollution and neglect– into an urban and cultural watershed delineated by the recreational waterfront edges and urban frontage (Figure 3). Landscape, served as a dominated framework in the revival process, addresses vast physical and social gaps in the city’s fabric. Similar framework could be traced in JCFO’s master plan for the revival of Seattle Waterfront (2012), Highline in New York City (2003), West 8 for Toronto Central Waterfront (2006).

In the next section, the author will provide a recent urban design practice, which use landscape as framework for repairing new town crisis in Shanghai.
3. Case Study: Nanqiao New Town

3.1. Challenge from Urban Upgrading

Shanghai’s industrial transformation and upgrading have driven the development mode from the former extensive, high-consumption, and high-pollution development to the new development mode of green, low-carbon, safety, and recycling, and build a green, low-carbon, safe, cyclical new model of urban industry. The base industry relies on East Beauty Valley on the west side to form an industrial chain based on beauty and health, and it becomes a bearing space for the development of the beautiful and healthy industry in East Beauty Valley and promotes the clustering and development of beauty health industry clusters in Fengxian District.

The site is located on the east side of Nanqiao New Town, Shanghai, China. The west side relies on East Beauty Valley is the industrial support for the site, while the affordable housing on the north and south sides serve as the consumer base. To avoid the traditional development mode that breaks the space and historical continuity, the design hopes to seek the survival and regeneration of urban space. The site attempts to be a promotion and extension of the landscape of the Tuannan Highway Avenue, which leads to a landscape-oriented design concept (Figure 4-5).

3.2. Landscape Oriented Urban Design

The urban design is landscape-oriented, and all content centers on the landscape design. The status of the site is mainly comprised of old workshops and multi-story office buildings, and a small proportion of them are high-rise buildings. Based on keeping the original road network unchanged, most broken and obsolete buildings can be demolished and rebuilt, and some old buildings with certain values and integrity can be preserved and reconstructed.

Firstly, the spatial organization adopts a sandwich-type structure, where multiple landscapes form a continuous landscape corridor and are sandwiched into building groups (Figure 6). Secondly, the street landscape including the scale and skyline will be also taken into consideration while creating a friendly and favorable atmosphere. Lastly, different types of landscape applied in a spatial sequence can also be experienced through the interpretation of different season themes: such as cherry blossoms in spring, lotus in summer, ginkgo, and beech in autumn, and plum flower in winter.

3.3. Key Strategies:

a) Multi-layered Spatial Structure

A multi-layered spatial structure is constituted like a sandwich including different parallel layers as Rem Koolhaas did in the La Villette Park Competition. Inside the blocks, a series of U-shaped corridors will be embedded to connect ten plots in the base, and a slow-walking aerial trail will be set up for visitors to take a walk, rest and stay. With the sandwich-type planar spatial structure, the city interface which is more rigorous and closed, alternates with the interfaces within the cluster, which is relatively curved and open, and they rely on each other and support each other.
The urban design incorporates a series of functional blocks in a slow corridor, uses landscape-first design techniques, rationally utilizes natural ecological elements, and creates public open spaces around the landscape nodes to improve the overall living environment.

Within each block, there is a valley-shaped space with high middle and low sides. It could guide people and improve the efficiency of space use. It integrates production and living in the valley and combines theme-based cultural activities such as viewing, smelling, and eating, creating a festival-style production, and living atmosphere (Figure 6,8).

b) Grid system
The main building heights are set at 24m, 48m and 80m, and the elevation angle with the centerline of Tuannan Road is about 30°, 45° and 60° respectively, creating a pleasant street space scale (Figure 7,9).

Along the Tuannan Highway facade, mainly multi-story buildings below 24m, accounting for about 50%, have fewer openings and form a flat and unified urban interface. Along the inner street of the group, there are more openings available and accessible for visitors, creating a variety of inward walking spaces and a rich inner spatial experience. The building plan transforms in the 50m*50m module, which is friendly for pedestrians and potential for phased development, different heights showing different architectural forms. The basic modules are combined and coded to form a continuous, rich, and diverse urban space.

c) Gateways, Viaducts and Reservoirs

The landscape is divided into four types: ecological type, participation type, functional type, and water system. Each type contains different types of landscape nodes. Eco-type landscapes include grassy slopes, tree arrays, and green trails, providing activities that are close to nature. Participation landscapes include island-style activity venues, weekend bazaars, interactive sculptures, and other participatory landscapes that provide exchanges and communication for tourists. The functional landscape includes a stadium, an outdoor theater, a tea pavilion, etc. To satisfy visitors' needs for different landscape functions, the water system is the waterfront landscape, which can adjust the microclimate and provide people with a pleasant scale of hydrophilic activity platform, which will become the highlight of the landscape belt. Waterfront landscape can also be used as a low-lying wetland for rainwater collection. It uses the concept of a sponge city to regulate precipitation and delay rainwater. Through the provision of irrigation systems, the collected rainwater from wetlands can also be used for irrigation of landscapes throughout the site (Figure 10-12).

4. Conclusion
As more and more urban new town facing repairing in the future, landscape architecture has more opportunities and will play an increasing important leading role in improving daily human living quality in urban environment. Landscape, as a critical framework, with operational design tactics like layering, grid, gateway etc. could play a
significant impact on disciplinary limits beyond landscape itself, from urban guidelines to environment improvement, which is exactly needed by the new town renewal.

A Comparative Study of Urban Ecological Functions of Flood-storage Landscape Parks - Take Landscape Parks Design in Harbin as Examples

WANG Haoyu, LI Zhenyu

Abstract

The rapid development of Chinese cities has brought many problems to the urban environment, such as the decline of air quality, the pollution of urban water, the decrease of biodiversity and so on. The increase in urban population also places higher demands on urban landscape design, including a more complete urban surface runoff system. The global climate change has brought tremendous pressure on the urban water environment. Urban floods are common in China's coastal areas, although measures have been implemented to avoid disasters. The most common way to mitigate urban drainage pressure is underground piping systems but its disadvantage is expensive cost of constructing and complex maintenance. Urban floodplains are one of the best strategies to deal with the pressures of the city's water environment, both to relieve pressure from floods in urban rivers and to provide high-quality habitats or transit points for fish and migrating birds. More and more urban flood storage landscape parks are under construction in China, which undoubtedly provides a good solution for improving the urban landscape system. The construction of this kind of landscape park will help to enhance the vitality of the urban landscape and the attractiveness of the city, and this will greatly promote the economic development of the city. China's freshwater resources are in short supply. Most Chinese cities are facing a very serious shortage of water resources. Urban landscape design should give full consideration to the issue of water storage. Urban wetlands can assume the role of landscape preservation and rainwater purification, which is like a huge sponge. This article will take Harbin Qunli Wetland Park as an example. The project incorporates a large-scale rain and flood landscape management system with groundwater replenishment and providing rest areas for the citizens. This paper is subsidized by NSFC project which is named as "Research on Technical System of “Downtown Factory” Community-oriented Regeneration in Yangtze River Delta Region". Thankful to the project owner Prof. LI Zhenyu who is the dean of College of Architecture and Urban Planning of Tongji University.

1. Introduction

The phenomenon of large-scale urbanization has caused enormous changes in the pattern of worldwide land use. The rapid growth of population has forced the city to expand, and the city has rapidly expanded its way of encroaching upon grassland, farmland, forest land, and wetlands. The upgrading of population capacity is also changing the original land structure. Land and wetlands, with their unique natural properties, are responsible for absorbing surface runoff in the ecological chain. Changes in land use patterns have shown a sharp decline in the proportion of green land, farmland and wetlands.

The process of urbanization in China is relatively fast on a global scale. In the process of urban construction, the constructors often pursue speed rather than having an overall concept, neglecting the quality of construction, leading to imperfect urban infrastructure.

Hard land and pipeline are relatively common practices in traditional Chinese urban construction. Drainage pipes can alleviate the trouble caused by urban rainwater and floods to a certain extent, but this method is not sustainable. Hard pipelines are less elastic, and when faced with rare storms or floods, the system is easily destroyed. In addition, the hard pipeline system is difficult to maintain, and it is very easy for the pipeline system to accumulate wastes from alluvial surface of the city, resulting in blockage of the pipeline system.

The establishment of flood storage landscape park is one of the important ways to build a sponge city. This method effectively uses the existing urban green space and carries out targeted sustainable landscape reconstruction. The establishment of a flood storage landscape park effectively integrates man-made and natural resources, and deepens the natural self-adjustment capabilities.

2. Overview of City Flood-storage Landscape Park

2.1. Flood storage landscape park and city

Flood storage landscape parks were first produced in the United States in the 1990s and aim to control the runoff caused by impervious pavements in cities through natural self-regulating infiltration. Such landscape parks can effectively buffer the problems caused by the inability of rainwater to infiltrate, become urban sponges, and make adequate use of water resources for buffering. Stormwater stays in landscape parks, alleviating flooding problems in the city and at the same time providing excellent landscape benefits.

In cities with adequate water resources, flood storage landscape parks can rely on the original urban landscape resources, and construction is relatively time- and labor-saving. In areas with relatively scarce water resources, the construction of flood storage landscape parks is mainly in the form of constructed wetlands. The establishment of wetlands often requires a lot of resources and labor, and it is relatively difficult to use and maintain them in the later period. The key to building such a flood storage landscape park is to coordinate the relationship between the various links in the landscape biological chain, so as to construct a complete ecological self-circulation system. The relationship between soil, man-made, vegetation, micro-organisms, animals, etc., needs careful and detailed scrutiny.
2.2. The function of flood storage landscape park

Well-managed wetland landscape parks can effectively regulate the urban micro-climate. Under the background of global urbanization, reinforced concrete is gradually eroding the space of urban landscape green space. The city's large number of artificial thermal energy, buildings, and urban hard paved roads and other high-calorific bodies make the city more temperature-stable, with temperatures significantly higher than those in the surrounding suburbs. When the concentration reaches a certain value, it may affect the human body. The health of your life poses potential threats, such as inducing respiratory diseases, heart diseases.

The reduction of urban green space is one of the main factors that lead to the urban heat island effect. The construction of a flood storage eco-landscape park can effectively absorb solar radiation, and most of the solar radiation energy absorbed by the vegetation is used for the transpiration of plants and is converted to chemical energy in photosynthesis. Therefore, the construction of a flood storage landscape park can effectively reduce the urban heat island effect and reduce the ambient air temperature around it.

In addition, flood storage landscape parks can also effectively increase urban biodiversity. The constructed wetland and vegetation environment of the landscape park provide a unique living environment for microorganisms and small-scale aquatic animals and plants. The wetland animal and plant communities gather here, and humans and nature are able to live in harmony here. The forest area is mainly planted with water-tolerant plants, which are basically composed of trees, shrubs, and land. The wetlands are mainly composed of small trees, shrubs, and herbaceous plants. The shallow water area is mainly planted with emergent plants such as reeds and cattails. These plants can be used to absorb heavy metals in water bodies to purify water bodies. When the flood storage landscape park is well maintained and operated, small mammals and birds also join the entire ecological chain, and the ecosystem is increasingly perfected.

3. Harbin Qunli Wetland Rainfall Park

3.1. Urban Stormwater Resources in Harbin

Harbin City is located in the northeastern part of China and is affiliated to the temperate continental monsoon climate zone.

After the founding of New China, Harbin entered the period of rapid urbanization and the scale and speed of urbanization accelerated. However, in the process of urban development, because the environmental protection issue has not been taken seriously, the environment of wetlands has deteriorated rapidly, and the area of wetlands has dropped sharply, functions have been reduced, and biodiversity has decreased. The ecological environment of urban water resources in Harbin faces great challenges.

Harbin has a total wetland area of 125,000 hectares, including a wetland park in Harbin City. In addition to the Qunli Wetland Park, there are two state-level wetland parks, the Sun Island National Wetland Park and the Baiyupao National Wetland Park. However, unlike these two wetland parks, the surrounding environment of the Qunli wetland park is the built residential community and the main urban roads, while the first two parks are themselves located in the natural environment.
Biophilic Cities

3.2. Geographical Environment of Qunli Wetland Rainstorm Park

Located in Daoli District of Harbin, the Qunli Wetland Rainfall Park was completed in 2010. It is designed and completed by the Beijing Tumen landscape and is a typical urban stormwater park. The park is located in the central part of Qunli New District in Harbin, which covers about 300,000 square meters of ground.

The special feature of Qunli Wetland Park is that the plots are urban wetlands that do not remain much after the rapid development of the city, and are surrounded by urban expressways, large residential areas, and cultural and commercial areas. With the rapid and large-scale construction of Qunli New District, this wetland is indeed facing a great threat. On the other hand, Harbin itself belongs to the cold climate area, and the minimum temperature in winter is below -40°C. Therefore, the Qunli Wetland Park has an icing period of several months from November, and the depth of the water body must meet the requirements for winter for small fish.

3.3. Wetland Park Design

The Turenscape was entrusted by the local government of Harbin to protect this piece of wetland. The designer proposed a design plan for the rain-flood park on the basis of protection. In this program, the original wetland in the city has been effectively protected, and Park can provide excellent urban ecological services for the city.

1. Respond to the impact of cities - Isolation and Communion

The base is surrounded by urban roads. On the one hand, it is necessary to separate the city from the park. This can effectively protect the ecological environment of the park. On the other hand, it also needs to integrate the park into the city and effectively exert the urban ecological function of the park.

First of all, in order to set up a hierarchical relationship between the park and the city, there is a height difference of 2~3m between the venue and the surrounding area of the Park. On the one hand, the elevation difference weakens the direct connection between the park and the city to some extent; on the other hand, this method also makes full use of the ups and downs of the original landscape, effectively reducing the amount of earthwork and reducing the cost of construction. And expenses. From the city to the interior of the wetland park and from the wetland park, two distinct landscapes can be felt.

Second, in order to make the wetland landscape better serve the urban residents, the wetland has a ring-shaped three-dimensional trestle bridge and two observation towers. The trestle bridge is placed on the wetland. The pedestrian streamline does not directly contact the wetland landscape. This approach effectively reduces the area occupied by the wetland, and it can also ensure that the living environment of plants and animals in the wetland is not destroyed. The winding path of the boardwalk provides visitors with more views of the wetland landscape and has become a new tourist hotspot in Qunli New District.

2. Urban stormwater collection

Since ancient times, the effective use of water resources has always been a topic that cannot be disturbed in the process of urban development. China's vast territory and abundant resources, the total freshwater resources ranked sixth in the world, but because of China's large population, per
capita water resources is only 2,300 cubic meters, the world average is about 10,000 cubic meters. Moreover, China belongs to the monsoon climate zone and the country has a vast territory. Therefore, the uneven distribution of water resources in time and space is very serious. Spatially, precipitation decreases from the southeast to the northwest. In time, most of the precipitation is concentrated in the months of May to September each year, and floods often occur. Therefore, China's water supply and demand contradictions are very prominent.

Urban rain-flood park is a sustainable means to deal with the contradiction between supply and demand of water resources. Rainwater harvesting at the Qunli rainstorm Wetland Park in the group comes from two parts. One is the catchment area of about 30 hectares of the wetland park itself, and the other is the rainwater collection of the special construction site in the north of the wetland park. This part of the rainwater includes the northern planning. The cultural and recreational land and the residential land and the collection of road rainwater connected to the park grounds. (Picture) The former integrates rainwater into the park's development area through the height difference of the wetland park itself, while the latter directly connects to the park's wetland bubble through the park's underground circular pipe. The collected rainwater will be directly used in the wetland. Park interior.

3.4. Influence of Qunli Wetland Rainwater Park on Urban Ecosystem

After completion, the Qunli wetland park has apparently begun to have a positive impact on the surrounding urban environment. This article mainly introduces its impact on the biological environment, the influence of the natural geographical environment and the influence of the social environment.

1. Biological environment - enrich species diversity

Qunli Wetland Park formerly known as the black fish bubble wetland, at the beginning of the development of Harbin city, where once a paradise for all kinds of wild animals and plants, has a very complete wetland ecosystem. In the later period of urban development, the amount of water in wetlands has decreased and the ecological environment has begun to deteriorate.

The construction and improvement of wetland parks are of great significance to maintaining ecological diversity, which is mainly reflected in three aspects: biodiversity, plant diversity and animal diversity.

The plant community within the wetland has been dominated by reed ponds, continuing the original vegetation ecosystem. At the same time, there are as many as hundreds of other types of vegetation such as ferns and angiosperms within the wetland. The growth process of aquatic plants absorbs nitrogen, phosphorus, and other elements in water, and synthesizes plant proteins, thereby purifying water quality. Wetland plants have a dominant influence on the ecological environment of the entire storm-water park. The degree of development of the plant ecosystem directly determines whether the entire rain-flood park system can operate normally.

In terms of animal diversity, the Park is also a paradise for many species of creatures to inhabit and breed. On the one hand, Harbin is a must-see route for migration of migratory birds in the Far East. The ecological environment of wetlands can provide a suitable habitat for aquatic birds. On the other hand, micro-enriched wetlands provide a good living environment for fish.
The difference in most wetland ecosystems is that the body of water in the Qunli Wetland Park is self-contained, so the types of fish are relatively small.

2. Geographical Environment - Cycle Configuration of Water Resources

In addition to the natural rainfall received by the park itself, the design plan of Qunli Rain Flood Wetland Park collects rainwater mainly through four urban interfaces such as green areas, permeable pavement, squares, and parking lots to form multiple small-scale rainwater blisters. In the plan, rainwater pipes on the city road will also be connected to the park. The entire design of the water cycle has a strong organic nature. After being purified by aquatic plants, soil, and gravel, the rainwater will reach the standards of landscape water use and green water use and can be used for irrigation of urban vegetation.

However, in the actual use, there are certain problems in the purification and utilization of rainwater. In the initial stage of the park construction, the internal water resources of the park mainly come from groundwater. However, in the later operation process, the groundwater level in the city decreases rapidly, and the source of the water body is mostly supplemented by the Songhua River water system. Supplementary water is piped to the interior of landscape wetlands. However, there is a situation where water resources are not evenly distributed. Some waters have sufficient water and the water quality is relatively high.

3. Social environment - a multi-faceted industrial drive

The completion of the Qunli Wetland Rainfall Park has undoubtedly greatly improved the quality of urban life in the nearby areas. The park has provided a good living environment for the surrounding citizens in terms of ecology, greening, environmental protection, water quality, atmosphere, and transportation. And work environment. At the same time, the construction of wetland parks has also accelerated the speed of urbanization in the surrounding areas. A large number of residential areas have come into being and the quality of residential properties is relatively high.

4. Examples of wetland parks adapted to local conditions

The construction of wetland rain-flood park is a relatively small category of natural destructive activity in human construction activities. Wetland park construction in different regions can basically adapt to local conditions and choose appropriate methods to protect ecological resources.

4.1. Caiyun Lake National Wetland Park

Chongqing is the capital of China's River City and Fog City. The terrain of the city is complex, and as a result unique urban landscapes have emerged. Caiyun Lake National Wetland Park The sanitary ware is located at the junction of Jiulongpo District and Gaoxin District in Chongqing City. It consists of two parts, namely Caiyun Lake and Taohua Stream. It is mainly used to treat the sewage generated in daily life. The wetland park is in a state of high ups and downs, and the height difference is complex. In the design of the park, the designers used the concept of “three-dimensional wetland” and constructed multiple elements such as wetlands, lakes, streams, ponds, and terraces into a rich one. The three-dimensional landscape system.
4.2. Liupanshui Minghu Wetland Park

Liupanshui is located in the Wumeng Mountain area of Guizhou Province in China. Because of the cool climate throughout the year and low UV radiation, it is also known as the cool city of China. In the “West-to-East Power Transmission Project” in China, Liupanshui, as an important node city, left behind a relatively serious problem of coal and steel pollution in the city. Minghu Wetland Park removes existing hard riverbanks by connecting different types of existing water bodies in order to restore the natural ecological functions of the water bodies. At the same time, Minghu Wetland Park has fully utilized the terrace landscape of the current terrain, and established a terraced wetland ecosystem in the elevation zone of the riverfront.

5. Summary

Although the urban rain-flooded wetland park has a great role in restoring the urban ecological environment and protecting water resources, it itself also has the characteristics of vulnerability and sensitivity. In the course of the operation of the ecosystem, the wetland park’s lifespan will be greatly shortened if it is not able to achieve a good balance in all aspects. Therefore, at the level of urban planning and landscape design, careful consideration and careful operation must be made.

Secondly, in the site selection and construction of urban rain-flood wetland parks, local conditions should be a necessary condition. Different urban areas have great differences in historical conditions, climatic conditions, geographical conditions, and biological species. How to distinguish primary and secondary relationships among many conditions, solve the most important problems by solving major problems, and establish a sustainable and ecologically distinctive wetland park will also become an important aspect of the future construction of wetland parks.

In addition, although the Urban Ecological Wetland Park can promote the rapid development of the economy, culture and other aspects of the city to a certain extent and improve the quality of life in the surrounding residential areas, this is not one of the main functions of the urban rain-wet park. Economic and social benefits should be placed in a relatively secondary position or be treated as an additional urban welfare.

Finally, the operation of the wetland rain-flood park should also be given great attention. Although the construction of rain-flooded parks in the city has sprung up and more and more projects have been built, in the long-term perspective, parks that can operate better are not the majority. How to sustainably operate the urban rain-flooded wetland park so that it can serve the urban ecological environment for a long period of time requires the joint efforts of city decision-makers, ecological observers, and city builders.

The Influence of Landscape Urbanism on Urban Development

Qing Mei

College of Architecture and Urban Planning, Tongji University, Siping Road 1239, Shanghai, 200000, China, People’s Republic of

Abstract

Landscape urbanism is to understand the city as an ecological system. By building and improving the landscape infrastructure, the function of the infrastructure and the social and cultural needs of the city can be combined to make the modern city built and extended. James Corner has explained the concept of “Landscape” and “Urbanism” separately in his book.

First of all, the development of landscape infrastructure includes rain flood storage, pollution disposal, habitat construction, ecological corridor improvement etc. On the basis of this landscape ecology, designers provide diverse and recreational places to liberate people from the negative effects of congestion, pollution and noise, and enhance the quality of the city.

Secondly, it is the concept that city is as a landscape itself. This ecological, natural-return and highly open city is the city of landscape. The power of urban growth and transformation is interpreted as the interaction between large scale ecological groups, regional waters and complex biological networks.

In short, landscape is the carrier of various natural processes. These processes support the existence and continuity of life. At the same time, landscape is also a vehicle for building and infrastructure. It provides an interface for integration and exchange between natural environment and infrastructure. Only by attaching importance to the role of nature in the city and the landscape urbanism can we create a city as a Biophilic City soon.

This paper is subsidized by NSFC project (No. 51678412) which is named as “Research on Technical System of “Downtown Factory” Community-oriented Regeneration in Yangtze River Delta Region”.

Keywords: Landscape urbanism; Urban; Improvement; Infrastructure; Public space; Natural process
1. The background and definition of Landscape Urbanism

1.1. The background of the Landscape Urbanism

The middle of the twentieth Century, in the global capital of the city, some European countries’ process of urbanization has increased, coupled with the rapid development of the city brought a series of problems, such as noise pollution, traffic jam, small living space and the environment pollution caused by industrial activities. At the same time, with the development of urban economy, people's sense of leisure demand has also been strengthened. Leisure has become an important part of people's life. The traditional dense urban form has been weary of people. People are eager to live in low density. And it should be suitable for car trip, surrounded by large area of green and public space. Therefore, the emerging theories, such as landscape urbanism, are also born.

1.2. The definition of the Landscape Urbanism

Charles Waldheim is defined as follows in the "Declaration" in reference: Landscape urbanism depicts an approach to the reintegration of the existing order in the process of contemporary cities. In this process, the landscape architecture is the most basic element of urban construction. In many times, the landscape has become a window for the revival of contemporary cities, especially in North America, and an important medium for urban reconstruction. In this context, the practice of landscape urbanism takes a positive and effective analytical framework to deal with the problems of the city. In particular, the landscape urbanism is most applicable when a large number of sites which was abandoned, polluted and left over by the city.

Landscape urbanism focuses on improving the urban blank area with the principles of spatial organization, dynamic interaction, ecological elements and key technologies, enabling the city to exist in a dynamic, healthy, strategic and continuous state. The process it emphasizes can adapt to the development patterns of different stages of the city, thus promoting a more relaxed and flexible natural process. This process is compatible with the complexity of urban development. At the same time, this flow, continuous form of urban development can also provide people with the continuous development and change of public leisure space.

2. The landscape urbanism is beneficial to the improvement of urban infrastructure

2.1. The types and significance of infrastructure construction

Infrastructure construction includes stormwater flood control, pollution treatment, living environment, ecological corridor based on the improvement of landscape ecology. Design staff provide a variety of entertainment to free people from the negative effects of pollution and noise, thus to improve the quality of the city. The utilization and treatment of water resources is an important link in the construction of infrastructure, and is very helpful to the improvement of the urban environment.
2.2. *Potsdam square rainwater utilization*

The famous case is Potsdam square, Germany. It is the most attractive place in Berlin. Its striking buildings include restaurants, shopping centers, theaters and cinemas. It is not only attracting tourists from other places, but also a scenic spot frequented by locals in Berlin. There are about 70 thousand tourists visiting here every day. The water landscape here is especially impressive for tourists. But most tourists may not know that Potsdam square is a model for rainwater utilization. All landscape water is from rainwater collection. ( Fig. 1. )

Because of the shallow groundwater level in Berlin City, commercial area is built not only increase the groundwater recharge, nor increase the emissions of rain. Therefore, developers using the following scheme of rainwater utilization: build the "green roof" to become the green lag of rainwater. On the one hand to prevent rainwater runoff, play a role in flood control. On the other hand, it makes the water’s evaporation become fast to increase air humidity, and improves the microclimate effect. On the construction of roof which are not suitable to become the green space, the remaining rainwater will flow through pipes which has a filtering function into the main building and the total Square underground storage tank. After preliminary filtration and precipititation, and then the water go through the water pump in the control room and the filter. Part of it entering the building's reclaimed water system is used to scour the toilets and irrigate the garden grass on the roof. The other part is sent to the artificial stream on the ground to form a rainwater circulation system and complete the purification and filtration for the second time. And the underground water tank is equipped with the water quality automatic monitoring system. When the water surface is reduced by evaporation, the automatic system will supplement it by the water in the storage tank. ( Fig. 2. )
Four waterscape systems of the north water surface, the water surface of the music square, the main surface of the triangle and the water surface of the south side are completed together. Through the artificial water system, urban life and natural elements will be integrated, not only purify the water, but also add the natural public space for the crowded city. The fountain before the SONY center building is the most popular place. The triangle artificial lake is the center of the square. And “ladder water” in front of the Berlin Film Festival Movie Palace is well-proportioned, and make people feel the nature.

### 3. The landscape urbanism is beneficial to the construction of urban public space

#### 3.1. The necessity of the use of Landscape Urbanism in urban public space

Urban public space is an outdoor, open and public space for public recreational activities in cities. They are important for urban development and construction. Whether the layout of public space in the urban macroscopical scale, or the design of building on the micro scale of the site need a theoretical thought to guide the future planning and design of the city. Since the development of landscape urbanism, so far, we have put forward our own ideas on the basis of absorbing the existing related ideas. The social background and the lack of green and public space faced by today's cities must make them strong adaptability and vitality.

### 3.2. Case studies-- The Millennium Park

The Millennium Park is an excellent example of the landscape urbanism in the construction of urban public space. (Fig. 3.)

Firstly, urban public space can provide citizens with a humane leisure space and high happiness index, making it an important factor to stimulate vitality of the city and ensure the vitality of the urban central area. The idea of landscape urbanism agrees with the vitality of the city, opening up many urban green spaces, and bringing the natural landscape more into the city and revitalize it.

The base of the park was originally a large underground parking lot, providing parking for the city. The original plan was to build a "green parking lot", but with the continuous implementation of the project, a large city park was formed. While realizing
the general function of urban public space, the park also provides 9000 parking spaces for the city, which greatly satisfies the parking demand of the city center. At the same time, it has also increased the vitality of the urban central area and improved the publicness of the urban public space. The park belongs to the whole city, and it belongs to all citizens, and every citizen has the power to enjoy it. The Millennium Park's planning embodies the human centered care. From the perspective of functional zoning, park planning meets the needs of different groups, whether old people, young people or children, can find suitable areas for their activities. From the park facilities, the visible barrier free facilities also allow the disabled to enjoy the construction of the urban public space. From the point of view of staffing, there are both professional staff responsible for daily maintenance and special service for tourists. From the point of view of the park's operation, the rest of the project is almost free, in addition to the parking fee and commercial operation of the commercial network. This plan will attract everyone to enter the park and enjoy the park, so that the Millennium Park can be interpreted as the publicness of the urban public space.

Secondly, the priority of the public space pattern is another important measure for the development of the city. Public space has an irreplaceable role in improving the material, ecology, recreation and landscape of the city. The priority of public space also reflects the guiding ideology of respecting nature in the process of urban construction. It is same as the landscape takes the place of the architecture and becomes the carrier of the city's function in the landscape urbanism. Therefore, the landscape urbanism has a strong connection and mutual assistance with the construction of the urban public space on both the target and the strategy.

The Millennium Park realizes the functions of recreational entertainment and sports fitness through square, footpaths and open lawns, and realizes greening, beautifying, ecological and even popular science functions with its large area of greening and diversity plants. In addition to the park lawn and ornamental trees, there is also a botanical garden. The park covers an area of 5 acres and has 205 kinds of plants including shrubs, 21 species, 130 species perennial flowers, flower bulbs 33, other 21 kinds of plant. These varieties of plant species are planted to meet the green, beautifying and ecological functions of the park, as well as the science popularization of the botanical garden.

4. The landscape urbanism is beneficial to the revival of the natural process of the city

4.1. Landscape urbanism is the catalyst for the base

Landscape urbanism thinks about the city problem from the perspective of landscape, and the ecological strategy is the breakthrough point to solve the problem. It explores the possibility of mediating the differences between the architecture and the landscape, the site and the object, the method and the art. Therefore, in the face of increasingly complex urban environment, the landscape should be given priority. The means of ecological design should also be used as a medium to become the seed and catalyst for the rejuvenation and regeneration of the whole site.
4.2. The natural revival of the fourth middle school in Fangshan

The design of the fourth middle school in Fangshan (Fig. 4.), Beijing embodies the design form of the natural process. Also, after the city was tortured by the negative effects of environmental pollution, the designer reintroduced the positive measures of natural regulation. In the design, agriculture and landscape combine to make agriculture become a landscape, so that the landscape not only has aesthetic function, but also has production functions, and meets the functions of campus learning, culture, leisure and experience of agricultural labor.

The fourth middle school of Fangshan, is located in the center of a new town outside the fifth ring of Southwest Beijing. Creating more open space full of nature is the starting point of the design. This is what the Chinese urban students are in urgent need of today. The spatial constraints of the site have stimulated the design strategy to create multi-layer ground in the vertical direction. The school's functional space is organized into two parts, and the garden is inserted between them. (Fig. 5.) Vertically collocated upper and lower spaces, and their contact, support or connection in different ways in the middle area, are strategies for building space, and also symbolize the relationship between formal and informal teaching space in this new school.
In this huge structure, the main traffic flow line is expanded to create an indoor place for social interaction, like a river, which also contains free-form "islands", which provides a semi private enclosure for small group activities. The roof of the teaching building is designed as an organic farm. It provides 36 experimental fields for 36 classes of students. It not only allows teachers and students to have opportunities to learn and cultivate, but also respects the past that they once used as farmland. These changes in the landscape reflects the dynamic process of landscape. And the school teachers and students participate in the work. This scene also creates a landscape, not only to close the distance between the students and teachers, but also to the students' sense of identity, and more to reflect their participation. The whole landscape has been devoted to the cultural atmosphere of the campus. At the same time, the landscape enriches the campus environment and provides food for people. More close to the relationship between people and the landscape. ( Fig. 6. )

5. Conclusion

So we can find two clues. Firstly, modern landscape science and ecological science have an increasingly deep impact on the construction of human living environment. Secondly is a landscape reading of contemporary urban phenomena. The background of these two clues is the post industrialization, the continuous spread, and the mixed city. In that era, cities showed a lot of new features: high mobility, centralization or no centralization, mixed functions, and so on. Cities can be seen as a horizontal, constantly changing landscape system, in which the concept of city and landscape has become blurred.

Landscape urbanism is under this constantly blurred boundary, which has a multifaceted impact on the urban infrastructure, public space and natural process. The mode of perfection, promotion and revival is the main mode, and the more dominant intervention in buildings and cities is more quickly solving the urban problems and affecting the urban form and experience.

Research of Park Soundscape perception and its Impact factors
Take the ecological square in Shenzhen as a case study

Abstract

Park soundscape perception research is a research branch of park soundscape. Certain research was conducted on the relationship and effects between sound perception and gender, occupation, visual simulation, and landscape characteristic. But there was still a research gap on the relationship between soundscape inventory and its related perceptions, the influencing factors of soundscape perceptions and the relationship between people’s emotions and sound perceptions. This research took soundscape in city parks as a research object. It collected a sound clip for lab study through sound-walking in ecological square in Shenzhen, then applied a dose – response lab test and survey to test the park soundscape perception. This research collected 107 effective samples for data analyzing. Results conclude as: 1) All the natural sounds were acceptable sound, most anthropogenic sound were unacceptable sound. Four high listening frequencies but low acceptance sound were concluded. 2) Certain soundscape perceptions were correlated with other. 3) There was a coupling relationship between people’s emotions and sound perceptions. Which showed the natural sound would aroused the pleasant emotions. 4) The noise sensitivity and water sound perception were correlated with each other. Result implied that, people who were less sensitive with noise would be more attracted by water sound. Based on the above five findings, research discussed corresponding suggestions for park soundscape management, which include soundscape inventory management, noise control methods, the landscape enhancement methods which for the park soundscape perceptions improvement.

Keywords: Soundscape preceptions; Impact factors; Management Strategies

1. Background

Take the soundscape as a research objective, the aim of this research is to reveal people’s different sound perceptions and its impact factors. To identify the acceptable or unacceptable sound inventories, and its acceptance degree. Based on the sound acceptance, this research would continue to find the potential impact factors to soundscape which might include people’s noise sensitivity, park motivation and personalities, and also exam the coupling relationship between sound perception and emotions. Finally, this research will
Biophilic Cities

propose suggestions and strategies for park management. Suggestions will include noise control and specific management and landscape design strategies. TWO hypothesis were proposed for future verification: Hypothesis 1: People’s personality and park motivation were both apply as impact factors to people’s park soundscape perceptions. Hypothesis 2: People’s sound perception has coupling relationship with emotion. This research will validate these two hypotheses through the following analysis.

2. Research Methods

2.1. Data collections

Research applied the sound walking method\(^1\) to collect the sound clip which used as the dose – response listening material. The sound walking was taken at 11:00 o’ clock of April 26\(^{th}\), at the ecological square of OCT, Shenzhen, 2017. The weather was cloudy with slightly rain, the highest temperature for the day is 26 ℃ . More human activities happened at north dining area, while less human activities happened at the hard-paving area of ecological square. The sound walking route (figure 1) was started from the entrance of southwest hard paving square, walking through the square and turned to north dining area, walked along the dinnning street to the jungle area of northeast part of ecological square, went through the jungle and end over at the gate zone of Jinan University Tourist college. The sound walking took six minutes. This research picked a part for the does – response clip.

2.2. Questionnaire and research design

This lab questionnaire contains a dose-response listening tests were given to participants to measure their soundscape perceptions. The 18 questions in the questionnaire could be summarized as four parts. 1) Evaluating the sound clips and writing down their related feelings. 2) Testing the personality, noise sensitivity, gathering the personal information such as gender, age, park visiting frequency, living places etc. 3) Gathering information of park visiting motivations. It would take participants about 35 minutes to finish the questionnaire. The lab survey was conducted in Shenzhen Jinan university tourism college from April 26th to 29th. Participants were randomly recruited from undergraduate students in Jinan tourism college. 107 effective samples were collected during this lab study.

For the sound evaluation question, research implemented a dose–response lab test. The participants were required to wear a noise reducing headphone, and listen to a clip . After listening, participants were provided a sound checklist, and required to click the sound which they heard in the clip, and evaluated their acceptance of the sound based on a nine points Likert Scale (-4 to +4, -4 represents the very annoying, +4 represents very pleasing, see table1). Besides, they were also required to write down their feelings (words or phrases) towards the sound they heard.

The sound checklist includes natural and anthropogenic sound. The natural sound contains sound of wind, water, bird songs, animal, insects. The anthropogenic sound includes sound of aircrafts, shuttle buses, children yelling and shouting, adult yelling and shouting, group talking, eating, etc.

For the second and third part, the questions of Ten items of personality
Biophilic Cities

(abbreviate as TIPI), noise sensitivity, and park motivation were setted for testing the soundscape perception factors, and the relationship among these factors. Ten items of personality scale were based on gosling’s research which has high validity for using. Four groups of laboratories (two as a group) were trained to conduct the lab questionnaire. They were ensured each participant to answer all the questions, to fill all the requirement of the sound checklist and to make sure each participant to listen sound clip carefully.

3. Results and Finding

3.1. Sound source and its acceptability

The percentage of participants in the sound clip listening that heard each of the 30 types of sound included in the sound checklist was calculated and graphed on the Y-axis. The evaluation of the sound clip listening that heard each of the 30 types of sound included in the sound checklist was calculated and graphed on the X-axis, figure 2.

Compared the natural sound types, the anthropogenic sound types were more frequently be heard. The most frequently heard types of sound were list as follows: bird song (93%), people’s voice (74%), group talking (68%), aircraft (64%), walking and running (64%), rain (63%), café (54%), Children, loud or yelling (52%), wind (48%), water (45%), loud yelling (39%), eating (38%), car driving (35%), unknown electronic devices (30%), whispering (30%). The acceptance of the according sounds was: bird song (+1.67), people’s voice (-0.41), group talking (-0.88), aircraft (-0.85), walking and running (0), rain (+0.97), café (-0.05), Children, loud or yelling (-1.32), wind (+0.76), water (+1), loud yelling (-1.55), eating (+0.15), car driving (-0.63), unknown electronic devices (-0.41), whispering (+0.1).

From the descriptive analysis, research conclude that: 1) all the natural sound types were acceptance sound no matter the listening frequency is high or low. The bird song was the sound type with both high listening frequency and acceptance. 2) For the anthropogenic sound, the unacceptance degree of certain sound types were similar, which was between neutral to -1 unacceptance. they were walking and running sound, car driving, electronic devices, tourist guide and tourists talking, tracking car and small business yelling. 3) On the contrary, the singing, eating, whispering and sound mark as the anthropogenic sound, were the acceptable sound.

The experiment showed that, most anthropogenic sounds were negative sound which would bring negative emotions to people. Hence, from the descriptive analysis, we drew conclusion that, in city park environment, the natural sound would be more acceptable than anthropogenic.
sounds. But certain anthropogenic sound, such as car driving sound, electronic sound, tourist and tourist guide sound, by proper controlling strategies and management, would reduce the unacceptance to people’s soundscape perceptions.

3.2. The correlative relationship between different sound types

Through the correlation analysis, research proved that the perceptions of certain sound types were correlated with each other, take significance (P<.05) into count, see table 2. Certain sound perceptions were correlated with each other, results showed that: The sound perceptions of wind and water (P=.192, Sig.=.048), water and insects (P=.382, Sig.=.000), thunder and insects (P=.244, Sig.=.011); animal sound and insects (P=.341, Sig.=.000) were correlated with each other. Ranking as the correlative degree of two sound types were: animal sound and insects, water sounds and insects, wind and water, wind and insects, thunder and insects, wind and water. Hence, from the combination perceptions perspective, the sound combination of thunder and rain, wind and water, animal and insects would easily rouse up people’s soundscape perceptions towards the acoustic environment.

3.3. Sound perceptions and emotions

Through the grounded theory, we counted the word frequency which people used to describe their feelings towards the sound. The words used to describe the natural sound in high frequency (Figure 3) (counted by word times) were: pleasing (33 times), peace (14 times), ease (14 times), relaxation (11 times), comfort (11 times). The results showed most of participants used positive words to describe the natural sound. Wind: pleasing (4 times), peace and comfort (3 times), relaxation and sung (2 times); Water: delight (5 times), relaxation (3 times), peace (2 times). Rain: pleasing (7 times), relaxation (4 times), comfort, peace, enjoy (2 times); Thunder: peace (2 times); Bird songs: Pleasing (14 times), relaxation (6 times), comfort (4 times), peace, delight (2 times); Insects: Pleasing (3 times), peace, comfort (2 times); Animal sound (2 times). Regarding to the four lowest acceptance anthropogenic sounds, the words which used to describe each sound were: Children yelling: irritability (3 times), annoying (3 times), noising (2 times); Café: no sense (5 times), peace (4 times), anxious (3 times); Aircraft: peace (6 times), annoying (3 times), a bit noising (2 times); Group talking: peace (5 times), relaxation (3 times), annoying (2 times).

By comparing the sound quadrant diagram and emotional quadrant diagram, especially anchoring the sound into the emotional quadrant diagram based on the most frequently words which participants to use to describe their feelings, this research found the coupling relationship between the sound perception and emotions. (fig.3) Results showed that the natural sound would bring pleasant, relax, and comfort emotions to people. Hence, the natural sound should be in the yellow and green quadrants of emotional quadrant diagram. On the contrary, the anthropogenic sound would bring annoying, anxious, some bit noisy emotions to people. Hence, the
3.4. Park motivation and noise as sound perception impactors

This research proved the correlative relationship between certain park motivations and personalities, showed as table 3. This research took significance (< .05) as count. It found the reserved and quiet personality was correlated with the park motivation of ‘experiencing the natural quiet and peace’ (P=.413, Sig.=.000), ‘experiencing the nature’ (P=.285, Sig.=000) and ‘Escaping personal/social pressures at home’ (P=.225, Sig.=.021). Also, the personality of ‘Sympathetic, warm’ was correlated with the motivation of ‘learning cultural stories of parks’ (P=.211, Sig=.031), ‘appreciating the scene’ (P=.224, Sig.=.022), and ‘pursuing family leisure and recreation’ (P=.289, Sig.=.003) in parks. Besides, the personality of ‘open to new experiences and complex’ was correlated with ‘inspiration of art’ (P=.196,Sig.=.04) and ‘physical rest’ (P=.212,Sig.=.034). Based on the analysis, we drew the conclusion that, people with special personality may have special park motivations. Overall, people with reserve and quiet personality might seek ‘quiet’ in park. People with personality of sympathetic and warm might seek dynamic activities in parks, such as ‘Learning cultural stories’ and ‘Appreciating the scenic’.

This research also examined the relationship between people’s sound noise sensitivity and perceptions. In the noise sensitivity scale, the item ‘I am sensitive to the noise’ was represented as high noise sensitivity; ‘I get annoyed when my neighbors are noisy’ represented as little noise sensitivity. ‘I get used to most noises without much difficulty’ represented as no noise sensitivity at all.

Through the correlation analysis, we got the conclusion that water sound was correlated to neutral noise sensitivity (table 7), which meant, people who liked the water soundscape might not be too sensitive to noise. Hence, water soundscape was a special sound type, which might not only affect people’s sound perception, but also people’s noise sensitivity.

4. Conclusion and suggestion

Based on the analysis above, four characteristic of sound types were summarized as following aspects:

1) The anthropogenic sounds were more easily to be heard than natural sound. The acceptance degree of certain anthropogenic sounds was similar, and the unacceptable degree was between neutral to less annoying (-1). Differ from other anthropogenic sound, the songs and soundmark were acceptable sounds.

2) The natural sounds were all acceptable sounds, even though certain of them with less hearing frequency than anthropogenic sound.

3) Certain types of soundscape perceptions were correlated with each other, such as the perception of wind and water, perceptions of animal and insects, perceptions of insects and water sound, etc..

4) Four types of anthropogenic sounds with high hearing frequency and unacceptance degree were in the upper left quadrant of soundscape quadrant map, and people who make noise that keeps me from falling asleep or getting work done’ represented as slightly noise sensitivity; ‘I get annoyed when my neighbors are noisy’ represented as little noise sensitivity. ‘I get used to most noises without much difficulty’ represented as no noise sensitivity at all.
needed to pay more attention in the park soundscape management plan.

Regarding to the four points above, research developed soundscape management suggestions for the improvement of park acoustic environment and park soundscape perceptions as following:

1) The park managers need to control the noise of anthropogenic sound, especially pay attention to the four types of high hearing frequency and unacceptance sound in upper left quadrant of sound chart (figure 4). Through the aircraft routes and tourists’ activities management, especially the noise reducing landscape design strategies, the managers can reduce the noise impact to park acoustic environment. The noise decibel would be reduced and anthropogenic acceptance would be increased.

2) Conserve the natural sound, and explore more types of natural sounds by landscape design to enhance people’s sound environment perception. Natural sound can be created through creative landscape design, such as increasing the plant coverage, landform reshaping to create more natural spaces, water landscape restoring, ecological parcels creating for bird and other habitants. and proper use the acceptable anthropogenic sound, such as song singing and sound marks.

For the correlative relationship between sound emotion and perceptions, the manager should create more natural space, such as water fountain, jungle and forest landscape to create more natural soundscape perception chance. It is important for managers to create quiet and meditate places for people with reserve and quiet personalities coming to park for natural quiet seeking. The research implied that people with less noise sensitivity may like water sound. Based on this point, we need to consider the proper usage of water landscape, to avoid excessive noise water landscape, such as huge water fountain, large scale of waterfall and stream, the distance between residential apartment to water landscape.

The role of urban farms in urban renewal: a case study of urban design of the Old Fourth Ward in Atlanta

Zifeng Sheng

1239 Siping Road, Shanghai 200092, China

Abstract

This paper takes Tongji University - Georgia Tech - University of North Carolina at Charlotte three towns in the United States Atlanta mm block city as the theme of urban design as an example, through the study of the US population diet structure, research on the base Analyzing and judging the possibility of urban planting industry, designing strategies to introduce urban farms into the base to meet the needs of people’s healthy living, and introducing the role of urban farms in urban renewal. The article will research and develop the industrial park of production technology through the research on the design, utilize the propaganda of the original downtown area for food production and processing, and hold the strategy of food fairs and exhibitions. Residents and businesses in different communities can showcase their products. Explain the application forms of urban farms in urban public space and residential buildings.

Keywords: Urban farm; Renewal; Downtown Atlanta; Urban design
1. Introduction

This urban design project is located in Atlanta, Georgia. The site is in the Old Fourth Ward near the city center and not far from the Beltline. The core of the design is to improve people's health by improving the way to get fresh vegetables. From this point of view, we design a city farm to meet people's demand of healthy life and to stimulate the vitality of the site.

2. Introduction of the concept of urban farm

2.1. The food desert in Atlanta

There is a serious food desert in Atlanta. The U.S. Department of agriculture defines the food desert as a low-income community, which is more than a mile away from reliable fresh produce and other healthy foods. This map (Fig.1) shows the food desert in downtown Atlanta. The site is located in the yellow area, indicating that it is located in low income neighborhoods, and it is more than half a mile away from the nearest supermarket. In vehicle accessibility analysis (Fig.2), the base is located in the blank area, which represents that the base performed well in access to fresh food. Many residents need to shop in convenience stores, where the prices are higher than those of full-service supermarkets, and the choice is usually limited to processed foods with high-fat, high-salt and high-sugar. The difficulty in obtaining fresh vegetables leads to a high incidence of obesity, and may even lead to diabetes, cardiovascular disease and other related diseases, which reduce the living standards of people.

As Jeffrey P. Koplan, vice president of global health at Emory University, said,” The easy availability of fresh, appetizing local food, especially fruits and vegetables, is an attractive and cost-effective contribution to improving our diet and the health of our population.” This urban design aims to provide Atlanta residents with the access to safe, nutritious and cheap fresh food through the creation of a multi-functional urban farm, and to establish a sustainable local food system to enhance residents’ health and environmental quality. At the same time, it promotes local economic development and establishes links between rural and urban farms.
2.2. The advantages of urban farms

Based on the demand for non-polluting food in Atlanta, we set up a local food production and supply system by setting up the urban farm, shortening the distance of high quality food from the farm to the table, and allowing non-insecticide, antibiotic-free and hormone-free vegetables and fruits to enter the house in a convenient way. This system can effectively improve the current situation of “food desert” in Atlanta. The establishment of the urban farm system will have a profound impact on the city: (1) A good diet structure can be formed. (2) There will be no agricultural failures due to climatic factors, such as drought, flood and pest calamity. (3) Urban stereoscopic farms grow organic crops, and there are no herbicides, pesticides and fertilizers. (4) It can reduce the cost of food transportation, save energy and reduce emission. (5) It can effectively retain the urban green space, retain the functions of the ecosystem, and improve the quality of the urban environment. (6) It can reduce unsound environmental impacts, recycle and utilize sewage, and form a new urban landscape style. (7) It establishes new production and sales system, provide new job opportunities and promote urban economic development. (8) It increases the stability of social structure by introducing agriculture into cities.

Urban farms can bring huge social and economic benefits. For example, one type of urban farm, vertical farm, relies on the organic farming technology of water tillage, without the need of pesticides and synthetic fertilizers, and it does not inject pollutants into the waterway. Vertical farms can efficiently produce food and vegetables. Its irrigation water comes from treated rainwater, which can alleviate the water crisis. At the same time, the vertical farm is located in the center of the city, eliminating the adverse environmental impacts of transportation and related processes. All kinds of crops can get accurate growth conditions through close monitoring, so as to increase output. Besides, indoor planting is not affected by natural disasters such as floods, droughts and hurricanes. Many sustainable technologies have been used synthetically: rainwater will be treated for irrigation, combined with water recovery systems, and unused water is collected by gas culture and hydroponics methods. The production of crops in vertical farms can be carried out all the year round. The yield of indoor acreage of 1 acres, which is equivalent to 4 to 6 acres or even more of outdoor output.

3. Design elements of urban farms

When we design urban farms in our base, we need to consider two important issues: the first is the size and location of the farms. The other is what kinds of crops we need to grow and how to grow more fresh fruits and vegetables. For this reason, we calculated the area required for the farms, and set up the allocation plan of planting crop species.
according to the local climate, environment and resident diet structure.

### 3.1. Location selection of urban farms

Question 1: the area of the farm. According to the existing population density in the base, we can predict the reasonable total population of the base will be stable at around 3,000 people. According to the proportion of 200-500g of fresh fruits and vegetables per person daily, we calculated the proportion of urban farms in the 146,073 square meters of land.

Question 2: how to grow crops better. We explored the necessary factors for the growth of crops: sunlight, soil and water. We guide the design of urban farms through the comparison of sunshine duration and crop sunshine demand in Atlanta. By using the Ecotect software to analyze the height and shelter of the existing buildings (Fig.3), we find the best sunshine area suitable for the growth of crops.

Through the analysis (Fig.4) of urban precipitation and other factors, we find that the annual average rainfall in Atlanta is 49.71 inches, which is 27% higher than the national average. In Atlanta, the rainfall will increase by about 10% per year in the future, and the rainstorm will increase by 50% every year. This means that there is a high possibility of flooding in the urban subsidence area, so it is very important to use the terrain to collect rainwater. We believe that this possible flooding situation can bring new opportunities for the design of urban farms.

We can combine the low-lying land with the storage irrigation system based on the elevation information (Fig.5).
In the case of drought, the urban farm is made to be a park, and the farm is distributed along the irrigation line (Fig.6), so that the necessary irrigation requirements for the growth of the crops are satisfied. Besides, by analyzing the factors such as the original land use and elevation, we finally determined the location of the concept area of the urban farm.

3.2. Analysis on the function of urban farms

As for the function of the urban farm, we do not want it to be a "rural in the city", and we want to give it a variety of functions to meet the needs of modern life and increase the value of land use. We think that urban farms are more arranged in urban public space, so that farms can be used as public places for people to enjoy activities. Urban farms bring people not only food but also a healthy concept of life. This mode can be applied to other parts of Atlanta City, so as to improve the quality of life of the whole city citizens.

Taking the two nodes in the base as an example, we discussed the positive effects of urban farms on urban renewal. The “community farm” is located in the area of the retaining church. The church can gather people for worship, and the “community farm” attracts people to grow vegetables there. In the central square, people can display their own vegetables, and they can also eat foods made from green vegetables in the surrounding restaurants. This harmonious community atmosphere can make people living in fast-paced cities feel the comfort of rural pastoral life. The experimental area we design is 12,100 square meters, covering 60 families, providing 65 urban farm areas, which can generate 5,000 dollars in income. In this “community farm”, we set up a green restaurant, a picnic area and a vegetable display area, which are used to taste green food, have outdoor picnic and show planting results, etc.

For “community farms”, we grow corn, onions and potatoes from April to June, and grow carrots, lettuce and broccoli from July to September, according to plant habits. In addition, the interaction of auxin among plants also promotes the growth of crops. For example, tomatoes, lettuce, and garlic grow better when they are together. The synergistic effect between plants and
animals will also affect crop growth, such as the pollination by bees.

In addition to the “community farm”, in this design project, the reservation of the original Civic Center in the base also provided a good opportunity. We transformed it into a convention and exhibition place. The latest agricultural production technology and achievements are presented here, and some food-related exhibitions will be held. The studio of Civic Center will also broadcasts the knowledge of food production technology and healthy life concept.

3.3. The combination of urban farms and buildings

For the relationship between urban farms and building groups, we have conceived that for large urban public spaces, urban farms could be embedded in the following three forms: (1) Uss public building sites to embed. (2) Transform the layout of existing public buildings, and gradate the layout of cultivation space. (3) Make full use of the large area of roofs of public buildings and arrange crop planting space. For high-rise towers and residential buildings, urban farms can also be involved in it: (1) Embed the site, taking the urban farm as a part of landscape. (2) embed the buildings, introducing the concept of vertical farm, and let crops grow in the buildings (Fig.7).

4. Conclusion

As a way of introducing agriculture into modern urban space, urban farm is mainly to put agricultural links such as agricultural products and livestock breeding into urban public space and buildings which can simulate the growing environment of crops. It can also realize the self-sufficiency of agricultural products through production and processing.

Waterfront industry heritage regeneration for bridging the urban space -- a case study of the London Canary Wharf and the Shanghai Xuhui Riverside

Daren Wang, Zhenyu Li

*Tongji University, No.1239 Siping Road, Shanghai 200092, People’s Republic of China

Abstract

The potential value of the Waterfront Industrial Heritage (WIH) in urban renewal is well recognized. This research emphasizes the renewal process required carefully design in order to increase the value of renewal WIH in bridging the urban space. Comparative analysis has been adopted as the research method to evaluate the two waterfront industrial heritage renewal cases which including the Canary Wharf in London and the Xuhui Riverside in Shanghai. Through this analysis, three disadvantages of Xuhui Riverside have been revealed as oversized scale, discontinuous interface and lack of service facilities. In addition, this research concluded that the spatial integration of waterfront industrial heritage can be divided into three levels: urban area function co-ordination, urban spatial interface continuity, and urban life events reappearance. The three levels of space considering in the process of urban renewal can deal with the problems existing in the renewed waterfront industrial heritage. (This paper is subsidized by NSFC project (No. 51678412) which is named as <Research on Technical System of “Downtown Factory” Community-oriented Regeneration in Yangtze River Delta Region>.)

Keywords: waterfront industrial heritage; urban renewal; bridging; scale; spatial interface

1. Introduction

After entering the post-industrial era, the industrial heritage in the original urban central gradually became the main region for urban renewal. The waterfront industrial heritage, as the production of the development process within the old industrial city, play an important role as the intermediary in the process of bridging urban space. In the beginning of the modern industrialization period, due to the demanding of the shipping goods, the industrial areas usually located near the riverside. Additionally, the industrial areas gradually encircled by the city in the process of urbanization (Tian and Huang, 2008) [1]. Thus the majority formal industrial facilities had becoming the industrial heritages which could be seen as the crucial elements in the urban renewal process.

In recent years, the urban renewal carried out by Shanghai has gradually transformed
the waterfront industrial heritage into a public space. There are several pilot projects along the Huangpu River such as the renovation and construction of the Expo area, Xuhui Riverside, and the recent Yangpu Riverside demonstration section. Although the industrial heritage on both sides of the Huangpu River have undergone a transformation, there are still many aspects for improvement. Furthermore, it is critical to improve the quality of the existing riverside public space which is reconstruction from the waterfront industrial heritage. This paper starts from the analysis of the Canary Wharf in London, and make a comparison with the waterfront space in Shanghai. In addition, proposes three levels of urban space bridging for waterfront industrial heritage.

2. Waterfront Industrial Heritage and Urban Renewal

In the late nineteenth century, Camillo Sitte (1889) emphasized the integrity of urban spatial development in his “City Planning According to Artistic Principles”, and provided a theoretical basis for urban spatial cognitive methods [2]. Kevin Lynch (2001) emphasized the individual's perception and experience of urban space, and made urban users an important part of urban space design [3]. Sun (2012) discusses the dynamic development of public space in the process of urban development from the theory of the coupling of urban public space and architecture, and puts forward five strategies for realizing the integration of urban public space and architecture, and emphasizes activities in the walking space [4]. The research on urban space has implications for the renewal of the waterfront industrial heritage.

The research on the theory of urban renewal has a long history. Yan (2013) pointed out that the narrow sense of urban renewal theory is coping strategies facing the urban recession [5], which proposed from the stander point at the urban level. In the recent theoretical development, Robert and Sykes (2000) also elaborated on the general urban renewal approach, and defined it as a compound and overall development method [6]. Lu and Wang (2016) summarizing the concept of urban renewal in Europe and the United States [7]. Additionally, they put forward the strategy of building pilot characteristic vital areas. Zhu et al. (2015) conducted an in-depth summary of the research methods for urban renewal, pointing out that the current research focused on the renewal of material space while paid insufficient attention to institutional design [8]. This trend emphasis the impotency of carefully designed process.

Among the recent studies industrial heritage has been the hot spot for both urban planning and landscape architecture. In 2001, scholars such as Wang Jianguo and Yu Kongjian conducted research on landscape and urban design in response to regional renovations. For instance, for the study of industrial heritage, Wang (2008), Yu and Pang (2002), and Liu (2012) conducted in-depth research on protective reutilization, repair protection, and evaluation systems, focusing on the discussion and practice of protection strategies [9,10,11]. In contrast, Hospers (2002) pointed out that the tourism value of industrial heritage and the promotion of the regional environment is vital in the industrial heritage renewal [12]. Zuo (2008)
conducted a detailed study on the status quo of the protection and development of Berlin's industrial heritage and summed up a valuable protection and renewal strategy [13]. However, its actual adaptability in China remains to be verified. Liu and Li (2012) introduced the industrial heritage of Shougang as a concrete case and illustrated them from the perspective of conservation planning and renovation design [14]. Li and Sun (2017) put forward a strategy for transformation and renewal in their research on the community-oriented regeneration of “Downtown factory” [15]. Philip Feifan Xie (2015) discusses the rational use of industrial heritage from the perspective of the entire life cycle [16].

In general, the research on industrial heritage has paid more attention to the construction monomer itself, and there is lack of attention to the current situation of the industrial bridging situation after the renewal of the industrial heritage. The role of the renewal of the waterfront industrial heritage in the promotion of urban space has attracted widespread attention in the academic community.

3. The practice of waterfront industrial heritage renewal

This article selected the practice of the renewal of the waterfront industry heritage of two cosmopolitan cities, London and Shanghai, as research cases. The two cities have similar international status. They have irreplaceable status in their respective countries and are recognized internationally as the most competitive cities. Due to their important historical status, the two cities experienced the process of industrialization and several transformations in the modern era, becoming a model city for industrial upgrading.

Additionally, London and Shanghai were crossed by the Thames River and the Huangpu River respectively, and provided the waterway traffic for their e industrial buildings at early period. Therefore, it is of great significance to study the transformation of the waterfront industry heritage in these cities.

Among the two cities, the most significant waterfront industrial heritage transformation is Canary Wharf in London and Xuhui Riverside in Shanghai (Fig. 1). From the three aspects which including the historical background, the extension of urban streets and the level of urban space, it is possible to clearly display the renewal spatial relationship between the waterfront and the city.

![Fig. 1 Urban textures and case locations in London and Shanghai (Source: Adapt from Mapbox)](image)

3.1. London Canary Wharf

Canary Wharf is located in the Dockland area, east of central London and is the largest urban renewal project in London in the late 20th century. The old industrial area on the banks of the River Thames had a glorious past. Along with the Industrial Revolution, the area was known as the most important
port in London at that time, but it gradually became an abandoned industrial area covering 71 hectares (Yang, 2005) [17]. Furthermore, Gordon (2001) pointed out that at the end of the 19th century, the Dockland changed from unplanned development to market-led free development zone [18]. Its renewed initiate by British Conservative government, which began in 1881, which is looking forward to regional integration and overall development through the London Docklands Development Corporation (LDDC).

Although there are general guidelines for urban design in this stage of development, without the spatial master plan, space has been fragmented and disordered (Edward, 1992) [19]. From 1991 to 2001, the Dockland region experienced a second development and renovation, which gradually made Canary Wharf a new financial center in London (Fig. 2).

Moreover, Canary Wharf using structural open space to connect the whole block. The east-west axis penetrates the site while linked open space patch. There are two more axes in the north and south.

The overall plan reflects a combination of geometry and axis. In the three-dimensional space, it presents a complex way of three-dimensional stratification with multiple functions and multiple elevations, providing the city with a rich and pleasant urban space (Fig. 3). The small-scale landscape nodes on the site also become places for traditional activities such as Christmas skating.

Fig. 2 Canary Wharf Scope (Source: Yang Shuo. Social Integration of Urban Space Network and Large-scale Urban Renewal: Inspiration from London Canary Wharf[J]. World Architecture, 2005(11):79-83.)

Fig. 3 Open space at Canary Wharf (Source: Author)

3.2. Shanghai Xuhui Riverside

The formation of Xuhui Riverside is very Different from Canary Wharf. Xuhui Riverside has always been a concentrated area of urban industry in the middle and late 20th century. The major cement factories, paper mills, ceramics and other factories and enterprises used to locate in that area. The
environmental pollution at that time also reached an unprecedented level (Lu and Zhang 2011) [20]. Afterwards, Shanghai’s Xuhui Riverside was an ideal site for the 2010 World Expo. In the contrast, it is a great opportunity for Xuhui Riverside to regeneration. This huge project become an important issue for urban development. Its construction goal was to develop as an ancillary project for the Shanghai World Expo and eventually completed the transformation from an industrial land to a citizen garden (Fig. 4).

Xuhui Riverside is the earliest development area in Shanghai with waterfront landscape oriented as a development concept. Its main area is from Rihui Port to Xupu Bridge. After planning and designing, Xuhui Riverside has three areas: Fenglin Life Science Park, Riverside District, Riverside Business District and Riverside Residential District. In this area, the Xuhui Riverside's landscape belt from Nanpu Station to Dong'an Road plays an important connection function, and the advantages of its waterfront have been fully expressed. In the design of Xuhui Riverside, the theme and event functions were given to each venue. From the northernmost Beipiao terminal tower crane plaza to the dragon art museum to Nanpu station gantry hanging square, the historical memory of the waterfront industrial heritage was anchored in the venue. However, there are also several problems. First, the riverside landscape belt, as a linear park, measures 8.4 kilometers, but the service facilities on both sides are far away. Second, it is separated by a wide road between the waterfront landscape and its business district on the north side, and it did not connect with any subway line which causes the weakness of public accessibility. Third, the spatial interface in the waterfront area is discontinuous and the landscape greening level is relatively simple.

From the above two cases, it can be seen that the waterfront industrial heritage plays an important role in bridging the space during the process of urban renewal. In the case of Canary Wharf in London, the abandoned industrial terminal became a new financial center, and the old waterfront industrial area in Shanghai turned into a supporting area for the Expo and further became a public landscape park. From the cases of these two cities, it can be concluding that the pleasant scales, the vivid interface of street, and the nodes for recreation play an important role in the transformation of the waterfront industrial heritage. Additionally, the renewal waterfront industrial heritage can serve as a medium to bridge the urban space.
4. Three approaches of bridging

In the case of Canary Wharf, it illustrated that there is no overall planning for the early rise, and the development based solely on the economic market will eventually lead to spatial chaos. In the case of Xuhui Riverside in Shanghai, the problem of excessive scale and poor public accessibility led to the fact that the role of the waterfront industrial heritage as a mediator was not fully exploited. In order to deal with these issues, comprehensive considerations can be taken from three levels.

4.1. Functional coordination in urban areas

1. Functional positioning

In order to deal with the problem of space fragmentation in the renewal of the waterfront industrial heritage, we must first think from overall planning of urban areas. From the case of Canary Wharf, the transformation of the abandoned industrial area aims at the old features of the financial facilities in the Old City, positioning the new area in the city's emerging central business district (CBD), which corresponds to the city's overall development. (Fig. 5).

In contrast, Shanghai's Xuhui Riverside, initiate as a supporting area of the World Expo, following as a commercial area for comprehensive development, and mix functions such as comprehensive residential research and development have also been well adapted to the development of the city. The Xuhui Riverside landscape belt actually lacks the corresponding functional supporting facilities and is only constructed through the construction of the basic landscape.

2. Public transportation

The construction of public transportation reflects the accessibility for the citizens.

Fig. 5 Canary Wharf Complex Transportation System (Source: Author)

Fig. 6 Functional Area Map of Canary Wharf (Source: Author)
Compare to London Canary Wharf the Xuhui Riverside has relatively poor accessibility due to the lack of transport facilities. In contrast, and Canary Wharf is directly connected to the city center via the subway and is organized in a complex, multi-layered approach to transportation, with multiple spatial experience (Fig. 6).

The Xuhui Riverside currently requires a 20-minute walk to reach the nearest subway station. Therefore, Xuhui Riverside District's service targets are mostly concentrated with residents in the surrounding areas, or people visiting the nearby Long Museum. It can be seen that there still could been improvement in Shanghai Xuhui Riverside area with in the overall development. It is worth considering how to solve the problem of accessibility between mixed functional areas separated from fast roads.

4.2. Urban space interface

1. Pleasant scale
   In addition to the overall functional orientation, close-up scales need to be taken into account in the renovation of the waterfront industrial heritage. As the traditional industrial zone is a production-oriented design method, the space created is also for industrial production. In the process of urban renewal, it requires a change of thinking, and the design of the scale is based on the scope of appropriate activities. Consider. In the case of Canary Wharf, a scale close to the human body was created by the structures that stretched out over the water and the enclosed space of the building (Fig. 7).

   In the case of Xuhui Riverside, the scale of the landscape belt along the river has not been well controlled (Fig. 8). The riverside space usually lacks a small scale space with a sense of enclose. The space only uses water and greenery as the interface which lacks public service facilities such as public toilet, coffee shop and info station.

Fig. 7 Oversized scale at Xuhui Riverside (Source: Author)

2. Space for Recreation

Fig. 8 Canary Wharf Waterfront Structure and Street (Source: Author)
According to Kevin Lynch’s theory, in the shaping of space, the nodes of space which is the one of the five essential elements have a very important role. In the case of Canary Wharf, the scene shown in Figure 9 is a scene of the public space in Canary Wharf around Christmas.

![Fig. 9 Temporary skating rink in Canary Wharf open space (Source: Author)](image)

The original green space was turned into a temporary skating rink and became a venue for Christmas traditions. In Xuhui Riverside, it is more reflected in the shaping of industrial related landscape sketches (Fig. 10). Landscape structures with traditional industrial heritage elements become attractive recreational nodes on the site of Xuhui Riverside. However, the distribution is linear and the distance between nodes is more than 1.5 kilometer. Additionally, there is a lack of necessary urban furniture in the site.

![Fig. 10 Empery landscape features at Xuhui Riverside (Source: Author)](image)

4.3. Reproduction of Urban Life Events

In discussing the subjectivity of the venues, urban life events are the best basis for testing the space. According to Jan Gehl's theory of interaction, buildings with functions play an important role in shaping the communication space. It is necessary to create spaces that have the possibility of events through the enhancement of enclosing
of space and the implantation of functions. In the Xuhui Riverside area, landscape sketches do not have substantial commercial functions (Figure 11). The activists cannot obtain the necessary services within the venue.

Xuhui Riverside landscape belts should introduce more interfaces for living, such as cafes, sales, bars, and bookstores, or new business models based on experience. In short, relying on simple green area to open space does not create a good waterfront space for the city's riverside. In the summer and winter when the climate is relatively unfavorable, the open riverside space is inactive. In contrast, for the London's Canary Wharf, shopping malls, restaurants, and exhibitions do not appear as a series of individual buildings. Instead, they present a variety of forms that together create a place full of possibilities for life events (Figure 12).

5. Conclusion

Shanghai's waterfront industrial heritage is intensively distributed on both sides of the Huangpu River. The waterfront industrial heritage, as a heterogeneity in the urban space, used to separates the uniform and coherent texture of the traditional city. Its great potential for shaping urban space in the post-industrial era has been emphasized. In the existing transformation process, there are still problems such as the lack of regional coordination, discontinuous interface, and excessive scale. Particularly prominent in the case of Xuhui Riverside, the functional separation, the lack of supporting facilities led to a gap between the quality of space and the use of efficiency.

In order to cope with this problem, the three approach of bridging the urban space should be incorporated into the consideration of urban renewal, and further increase the continuity of the waterfront on the two sides of the Huangpu River. Eventually the urban green space can be shaped into a truly place designed for human through the construction of a human scale and further promote the regional development.

Landscape Mediation in Leftover Spaces of Cities

Fang Wei*

Tsinghua University, Beijing, 100084, China

Abstract

During the rapid urbanization process, urban problems are exposed and city’s rich context is reduced and interfered. Dilapidation, abandonment, and ruins in built environment initiate leftover and residual spaces which are changing the fundamental meaning of urban space. The leftover space, left behind by socio-historical processes and practices, includes back lanes and alleys, yards of dilapidated building, voids between edifices, unbuilt space for lack of finances, and space under the flyover, etc.

To respond to these changes, concepts and theories of urban repair utilizing landscape mediation is put forward, aiming to make the city more flexible, resilient and biophilic from microcosmic angles of landscape urbanism and green infrastructure theories. Instead of other approaches, landscape intervention and mediation is more appropriate and powerful to make full use of leftover spaces and make cities and communities safer and better for living. The idea of landscape mediation is not only to fill the space gap but to unify the entire heterogeneous elements.

With the purpose of looking into different strategies and methods of activating negative space, several special cases in Japan, China, Italy and U.S. are showed and made comparsion to illustrate specific methods, which are introduced to make leftover spaces reclaimed, revitalized, and repurposed into urban parks and even urban agriculture. From the case studies and comparison studies, linear parks, pocket parks, micro facilities, mobile green space, urban farms, water sensitive gardens are imbedded into landscape mediation system, as shown in the examples of 606 Park in Chicago, Austin’s downtown alleys, Zighizaghi garden in Italy, and Lafayette Greens in Detroit, etc. Also, specific cases in this study are illustrated where issues of urban organization are very complicated, and comprehensive ways of arranging green elements are needed, such as Bethlehem SteelStacks Arts and Cultural Campus in Pennsylvania, etc. Accordingly, Poché as joint or transition which is referred to as an “in between” to the adjoining spaces is reconsidered, showing how landscape in urban fabric connects and meshes urban tissues and meanings. By documenting activities such as leisure, urban agriculture, informal communication, and social encounters, this research also addresses landscape micro-tactics for social effects and cognitive benefits besides human sensory connection to nature and physical well-being.
By examining different types and specific tactics of reviving leftover spaces, The framework and toolbox of landscape mediation for leftover and residual spaces in cities are established. It demonstrates how inclusive and biophilic design are applied in reviving negative spaces and transforming the city’s artificial environments by unifying separated parts with green elements, and how important roles landscape plays as catalysts, connections and mediations in post-modern cities.

Keywords: Leftover Space, Landscape Mediation, Biophilic Design, Poché, Cognitive Benefits

1. Urban space fragmentation and leftover spaces

In the process of urbanization, the city is constantly being injected with new relationships, values, and users. In the process of diversification of values and differences, there are some trimmed scraps. Such urban problems include the fragmentation of rapid transit networks, the derelict streets, irregular plots, abandoned land due to topography, and even the edges of roofs and buildings. At present, the urban traffic land generally accounts for 10% of the urban area and forms some fragmented conditions. At the same time, in the urban development renewal, the waste of space resources and the inefficient use of certain periods are inevitable. This situation exists not only in the horizontal space but also in vertical space. The exposure of urban problems and the influence and reduction of the rich cultural context of the city have brought a lot of leftover space. Generally these remaining spaces are defined by other heterogeneous spatial elements and are constantly influenced by various spatial elements. The transformation of this kind of passive space has a fundamental improvement in the quality of urban space.

At the same time, China’s urbanization construction has gone from large-scale growth to more emphasis on the revival of space quality, such as the “Implementation Measures for Shanghai Urban Renewal” in 2015, calling for planning and design personnel to adjust and design at the micro-space level. These changes have shown a tendency of “tactical urbanism.” The transformation of the leftover space, through focusing on the existing quantity rather than the increment, integrates the relations between heterogeneous elements, so as to obtain a better quality urban space. This is precisely the perspective of creative thinking and collage oriented by transparency. Tactical urbanism makes use of a bottom-up approach, including consideration of temporary actions or low-cost measures, to achieve a full range of interventions.

From a global perspective, from the urban spatial scale, Lavilet Park indicates that landscape can become the medium of post-modern urbanism, including complex urban life, and becoming a “category of social tools”. On a small scale, Mike Lydon and Anthony Garcia wrote about the relevant practice and action manual [1] by creating The Street Plans Collaborative [2]. Sue Anne Ware proposes a mobile garden in tactical urbanism, focusing on the quality and efficient use of space, and small-scale interventions by individual communities and local groups to improve an existing perspective of the city, affecting the long-term growth and image of the city. The Belgian designer Marcel Smets has also elevated the landscape to a place of great influence on contemporary urban design. He formulated a classification of contemporary urban space design concepts that respond to future developments. The network of indeterminacy (providing infrastructure),
carriers (containers, reactive organization forms), open spaces (ensure freedom of entry of new elements), and montage (great overlap of layers of different content and organization) as four design methods.

2. Integration of different functions and site activation

In city, there are bound to be spaces where forms and functions are mixed. The transformation of the remaining space mainly lies in the bottom-up collage thinking, and this approach must pay attention to the influence of the overall environment, especially the preconditions of the texture and boundary of the environment. At the same time, in the process of urban development, public space plays an important role in urban regeneration. On the platform of landscape urbanism, the role of landscape integration plays a pioneering role in urban renewal. The part of the city where the degree of openness, the higher the degree of publicity, and the intersection of the two parts of the space exist should be the space for priority transformation and the most vital space.

In the tactical measures to deal with the remaining space, related scholars have summarized different types and examples, including community-based public facilities, exhibitions and market spaces combined with plants, gardening and urban agricultural space, mobile greening devices, visual catalysis and art. Inkjets are used to stimulate public events and mixed functions of public spaces and parks [3]. The growth of urban density and the demand for space are the inevitable contradictions of contemporary cities. Due to the over-development and the emergence of meaningless negative space, people's sense of experience in urban space is degraded. The living environment of citizens can be changed from the environmental quality and even from the green space system [4]. All these have proven that the landscape has an important, efficient and irreplaceable role in the intervention and improvement of the urban leftover space.

Through the intervention of the landscape, it is possible to form an inclusive and integrated space contradiction, and the specific methods differ according to the site scale. However, in general, the remaining space itself uses the structural elements of the surrounding environment as the interface. Therefore, the creation of space must deal with the multiple relationships between the environment and the boundary and characteristics of the site. The activation and reconstruction of the remaining space is a continuous increase in the heterogeneous diversification and dynamic of the environmental space. It is not only beneficial to social public life, but also a new sense of belonging to the resident culture and ritual space from the perspective of cultural revival [5].

At present, there are many successful cases in the world. In Venezuela, communities derived from the problems of abandoned land, scrap yards, and urban villages have created five public community spaces by improving the remaining space. PICO estudio joins local and multinational organizations, volunteers, and community members to put in brightly coloured and heterogeneous environments to allow people to regain the sense of community, activity, safety, and solidarity. These include open-air basketball courts built on roofs, juxtaposing existing buildings, and transforming the roof to make the new stadium more functional and safe; turning the dump into a terrace and open-air barbecue. Piled with stones collected from nearby rivers to form enclosed stone walls;
design a multi-dimensional space with a spacious roof, etc. In order to maximize the benefits of the new space for the community, the design first considers enough flexibility to meet the needs of each detail at the moment by associating with the periphery and saving it. At the same time, it considers how to adapt to the future of the community. In design, the use of the structural capacity of the house provided the necessary support for the green steel frame structure and the glass window wall. Through the cover pattern, it added a lot of vitality to the entire street. Other cases include the overlapping of traffic settings and landscapes, enabling people to get a double reorganization of space experience and venue function [6].

In the small town of Koog aan de Zaan in Amsterdam, the highway divides urban space into two parts. The city hall and the church belong to two sides, and the administrative and church centers are physically separated. In order to connect these two important areas, the designers have reconstructed the space under the blind spot area and its extended space. This positive intervention includes the establishment of green land hills, the introduction of rivers to create a hydrophilic space, setting up retail stores, flower shops, supermarkets, fish markets, football stadiums, basketball courts, skateboard parks, fountains and water features, sculptures, and so on. The internal excavation of small wharves, combined with the new bridge pier facade enclosing, formed a juxtaposition of different structures. Using the bridge's pillar interface and the top surface, many mixed and multi-dimensional spatial structural elements are formed to better connect the river and connect the life on both sides of the bridge.

Figure 1 Venezuela problem community public space transformation (PICO estudio:2014)

In the small town of Koog aan de Zaan in Amsterdam, the highway divides urban space into two parts. The city hall and the church belong to two sides, and the administrative and church centers are physically separated. In order to connect these two important areas, the designers have reconstructed the space under the blind spot area and its extended space. This positive intervention includes the establishment of green land hills, the introduction of rivers to create a hydrophilic space, setting up retail stores, flower shops, supermarkets, fish markets, football stadiums, basketball courts, skateboard parks, fountains and water features, sculptures, and so on. The internal excavation of small wharves, combined with the new bridge pier facade enclosing, formed a juxtaposition of different structures. Using the bridge's pillar interface and the top surface, many mixed and multi-dimensional spatial structural elements are formed to better connect the river and connect the life on both sides of the bridge.

Fig 2 Space reconstruction under Koog aan de Zaan Bridge (https://www.architonic.com/en/project/nl-architects-a8erna/5100103)

Similar cases also include the wave theatre in Chile, designed to use mobile facilities to integrate the interface of the remaining space, and the construction materials are from all local waste materials. Among them, Sitio Eriazo, a transformation team, specifically practices for the abandoned negative space. This project makes direct use of the boundary characteristics of the empty field and combines structural materials with site material for the activation of structural
integration and filling. Other cases include the construction of the new Bastille Opera House after the demolition of the Promenade Plantée on the Vatican Boulevard in Paris; the maintenance of the original viaduct structure at Cheonggyecheon Park in Seoul; and the urban forestry in the Seattle Highway Park. The public green space, which links with the fragmented city parts, constructs a landscape of a stream canyon. The discarded parking space on the roadside of Rue Duperre in Paris uses rubber to lay the ground of the basketball court. The wall is painted with bright paint and patterns to make a comparison with the nearby buildings.

Fig. 3 Wave Theatre (Sitio Eriazo: 2015)

3. Conclusion

In recent years, the urban leftover space transformation has drawn constant attention and exploration by scholars. Under the impact of the international case, in view of the current domestic situation, relevant scholars have proposed a strategy for renewal of transport infrastructure that promotes urban space reshaping [8], where the landscape intervention method includes the construction of stratified integrated development green based on abandoned railways. Roads, jogging trails, bicycle lanes, parks, community public spaces. Others include the superposition of avenues, the retention and linking of natural wilderness, the introduction of natural communities, the integration of chronic systems with public spaces, the installation of art facilities and movable gardens, the introduction of children's activity facilities, and the connection of waterfront spaces. It can be argued that landscapeizing the leftover space is the most direct way of improving the urban environment, reorganizing the social order, and maximizing the public interest. At the same time, this has, to a certain degree, focused on the inheritance of urban contexts and the use of landscape environments for differences. The inclusion of traits further activates space. The pocket park in Wangfujing Street used the concept of “marks on the wall and shading under the trees”. Zhu Xiaodi, the architect, extracted the ideographic fragments of the brick walls, introduced and superimposed the footprints of the courtyard houses and the existing space, and expressed Attention to the traditional courtyard houses’ space and life culture has triggered further public activities. This is a useful attempt to renovate the remaining space in Beijing's Old City streets.

A Scenario Analysis of Establishment of Mt. Wuyishan National Park Based on Value Estimation

Zhao Zhicong, a* Ma Zhiye a

Department of Landscape Architecture, School of Architecture, Tsinghua University, Beijing, 100084, China

Abstract

The establishment of national park system is a new fundamental national-level strategy proposed by central government of China related to the ecological security of the nation, welfare of the whole people and the achievement of the national rejuvenation. The national park strategy aim to solve the key problems of the protected areas which are separated protection forces, overlapped spatial scopes, lack of scientific guidance in management. The natural resources are abundant and the scenery is beautiful in the city area of Wuyishan. There are 8 types of protected areas covering an area of 1,800 km$^2$ with a population of 238,800. It is the epitome of the protection and management situation of natural resources of the densely populated area in southern China.

The study sets up the value analysis framework of city area of Wuyishan. The value fell into two categories, which area intrinsic value including geological and geomorphological value, ecological system value, biodiversity value, cultural diversity value and aesthetic, and utilization value including recreation and tourism, scientific research and interpretation, settlement value. The intrinsic value is the reflection of the natural resource itself, while the utilization value reflects the degree of human utilization of natural resources, and the utilization value depends on the intrinsic value.

The factors related to the planning of Mount Wuyishan National Park are complicated. Since it is made of variety of systems--natural ecology, urban economy and social culture are linked with each other, with a lot of recessive factors are not easily to be noticed, the uncertainty of the future of the city area of Wuyishan is becoming bigger and bigger. To make sure the flexibility and integrity of this research and to take various factors and different stakeholders’ benefits into consideration, so that the future planners and decision makers can take balance as the situation changes. This research use scenario analysis to compare the national park scope.

Three scenarios are designed with the differences in size, natural resources and population. To make the decision of the three scenarios, 26 key indicators are selected for intrinsic and utilization value benefit estimation and direct and indirect protection costs evaluation. The intrinsic value index includes the area and quality of the value carriers, and the
ecosystem function. The utilization value index can be fallen into 6 categories: the number of
visitors, satisfaction, the integrity of interpretation, the perfection of the system, the industrial
benefit and social benefit. The direct cost of the scenarios include land use compensation,
infrastructure construction for protection, the cost of redemption of existing concession, while
indirect cost consist of the input of the research and interpretation, the cost of management
reform, a fund to encourage community development, etc. Based on the quantitative
calculation of each index, the advantages and disadvantages of the three scenarios are
examined. The scenario B is the recommendation plan by the planner.

Keywords: National Park, Protected area, Scenario Analysis, Value estimation

1. Introduction

The establishment of national park system is a new fundamental national-level strategy
proposed by central government of China related to the ecological security of the
nation, welfare of the whole people and the achievement of the national rejuvenation.
The national park strategy aim to solve the key problems of the protected areas which
are separated protection forces, overlapped spatial scopes, lack of scientific guidance in
management.

Wuyishan area is in Fujian Province of China, in which the natural resources are
abundant and the scenery is beautiful. It is the epitome of the protection and
management situation of natural resources of the densely populated area in southern
China.

There are 8 types of protected areas. The detail information of all the protected areas
are listed below (see Table 1 and Figure 1). The two national nature reserves are
adjacent to each other, namely Fujian Wuyishan National Nature Reserve and
in the Jiangxi Province, which is not in the City of Wuyishan. It is included in this
study, because it is very similar to the nature reserve in Fujian Province in terms of its
importance and characteristics. The protected areas in Wuyishan area is covering
an area of 1,800 km2.

Wuyishan City now has jurisdiction over 3 towns, 4 villages, 3 blocks, 4 farmlands or
tea plantations, 115 administrative villages. Its total household population is 238,800 .
The industrial structure of Wuyi City is mainly tertiary industry. Tourism economy
has been developing at a stable speed, and transportation industry continues to develop.

2. Value framework

The study sets up the value analysis framework of city area of Wuyishan. The
value is fell into two categories, which area intrinsic value including geological and
geomorphological value, ecological system value, biodiversity value, cultural diversity
value and aesthetic, and utilization value including tourism and interpretation,
scientific research and interpretation, settlement value.

The intrinsic value is the reflection of the natural resource itself, while the utilization
value reflects the degree of human utilization of natural resources, and the
utilization value depends on the intrinsic value.

a. Geological and Geomorphological Value

Wuyishan has complex geological structure and typical geomorphological
features. It is an essential part of southeastern distribution where largely
exists Danxia Landform. With the altitude of 2,158 meters, Huanggang Mountain, also
known as “Southeastern China Ridge”, is located at the top of Southeastern Mainland of China and is the highest mountain in southeastern China (apart from Taiwan). It belongs to Wuyishan, a watershed between Min(Fujian), Gan(Jiangxi) and Minjiang River and Yangzte River, and also one of the cradle of Minjiang River in Fujian and Xinjiang River in Jiangxi. With rich fossils of animals and plants, Wuyishan is a typical profile in the research of strata and chronological division of Jurassic and Cretaceous in eastern part of China.

b. Ecological System Value
Mid-tropical forest ecological system in Fujian Wuyishan National Nature Reserve is the largest and the most well-preserved compared with those in China’s same latitude. It is typical, diverse and systematic, which are also features of vegetation in mid-tropical area. (Which contains 11 types of vegetation in total).

c. Biodiversity Value
With favorable natural conditions and abundant vegetation species, Fujian Wuyishan National Nature Reserve provides an ideal habitat for rare wild animals, and it is also a place where lives the most species of insects in mid-tropical ecological system in China. It is rewarded as “Kingdom of snakes”, “World of insects”, “Paradise of birds”, “The key to analyzing Asian amphibians and reptiles”.

d. Zhu Xi’s Neo-confucianism Value
Zhu Xi is the greatest thinker, philosopher and educator after Confucius in Chinese history. Wuyishan, as a cradle of Zhu Xi’s Neo-confucianism, is inseparable from it.

e. Tea Culture Value
With a long history of tea culture, Mount Wuyi is the birthplace of the producing method of Chinese black tea and Fujian oolong tea. The historical sites such as ancient tea gardens, ancient tea factories and ancient tea roads witness the development history of Mount Wuyi's tea industry. Mount Wuyi is the start of ten thousand-li Tea Road. As the collecting and distributing centre of tea, Xingcun Town, Xiamei Village, Red Stone Village and so on witness the development history of foreign trade of Chinese tea and the communication history of tea culture.

f. Aesthetic Value
With the colorful view of the combination of unique and beautiful mountains, luxuriant forests, devious serpentine streams, fresh and quiet tea gardens and a long profound cultural landscape, Mount Wuyi shows a fantastic beauty of harmony between man and nature.

3. Scenarios of the national park area

3.1. Method
This study divides area in National park into 4 levels of different utilization: A, B, C, and D. The basic requirements for the resource utilization for each level are listed in Table 2. It means in each level there are basic regulations on the intensity of the utilization. Three scenarios of national park area and initialization zoning are proposed using the same utilization density level control. Then it will be easy to compare the cost and the benefit of each scenario. Then it will be easier to compare the cost and benefit of each scenario.

Through the comparative study of the cost-benefit of each scenario, the suggestion will
be make for proposed national park area and the utilization intensity zoning.

3.2. Scenarios of Wuyishan National Park boundary and zoning of utilization Intensity

3.2.1 Scenario I

Scenario I covers an area of 1809.8 km², includes 4 utilization intensity levels. Utilization Intensity Level A: 402.16 km², includes core zones of Fujian Wuyishan National Nature Reserve and Jiangxi Wuyishan National Nature Reserve, special protection zones of Wuyishan National Scenic Area, core zoned of Huang Long Yan Provincial Nature Reserve. Utilization Intensity Level B: 348.67 km², includes buffer zones of Fujian Wuyishan National Nature Reserve and Jiangxi Wuyishan National Nature Reserve, class 1 protection zones of Wuyishan National Scenic Area, Nine-belt Stream National Aquatic Germplasm Protected Area, buffer zones of Huang Long Yan Provincial Nature Reserve, Wuyishan National Forest Park. Utilization Intensity Level C: 1015.99 km², includes experimental zones of Fujian Wuyishan National Nature Reserve and Jiangxi Wuyishan National Nature Reserve, class 2 and class 3 protection zones of Wuyishan National Scenic Area, experimental zones of Huang Long Yan Provincial Nature Reserve, and part of "Important Water Conservation Area, Special Species Protection Area, Important Water and Soil Conservation Area". Utilization Intensity Level D: 42.98 km², includes part of areas in Mount Wuyi World Heritage Site and part of alongside areas of Hengnan Railway. See Figure 2.

3.2.2 Scenario II

Scenario II covers an area of 979.31 km², includes 4 utilization intensity levels. Utilization Intensity Level A: 335.95 km², includes core zones of Mount-Wuyi National Nature Reserves in Fujian Province, special protection areas of Mount-Wuyi National Scenic Area; Utilization Intensity Level B: 175.06 km², includes buffer zones of Mount-Wuyi National Nature Reserves in Fujian Province, Grade 1 protection areas of Mount-Wuyi National Scenic Area; Utilization Intensity Level C: 447.60 km², includes experimental zones of Mount-Wuyi National Nature Reserves in Fujian, Grade 2 and Grade 3 protection areas of Mount-Wuyi National Scenic Area, and upstream protection areas of Jiuqu River (except for 8 administrative village areas, which are: Chengdun, Hongxing, Zhoutou, Caodun, Chaoyang, Huangcun, Tongmu and Xingmu,); Utilization Intensity Level D: 20.70 km², includes the villages' construction area in the upstream protection areas of Jiuqu River. See Figure 3.

3.2.3 Scenario III

Scenario II covers an area of 706.60 km², includes 4 utilization intensity levels. Utilization Intensity Level A: 335.95 km², includes core zones of Fujian Wuyishan National Nature Reserve, special protection zones of Wuyishan National Scenic Area. Utilization Intensity Level B: 175.06 km², includes buffer zones of Fujian Wuyishan National Nature Reserve, class 1 protection zones of Wuyishan National Scenic Area. Utilization Intensity Level C: 195.05 km², includes experimental zones of Wuyishan National Scenic Area. Utilization Intensity Level D: 42.98 km², includes part of areas in Mount Wuyi World Heritage Site and part of alongside areas of Hengnan Railway.
Fujian Wuyishan National Nature Reserve, class 2 and class 3 protection zones of Wuyishan National Scenic Area, and areas along Nine-belt Stream. There are no utilization intensity level D in Scenario III. See Figure 4.

In Scenario III, the protected area is comparatively small, and species resources protection zones are easily to be eroded. However, the change to current protected areas is relatively small and the difficulty of reforming management system is correspondingly low.

3.3. Cost-benefit Analysis of the Scenarios

3.3.1 Benefit Analysis

Cost-benefit analysis is a method of assessing the value of a project by comparing the full costs and benefits of the project. Values can be converted into corresponding key indicators through actual market price assessments, simulated market assessments, and alternative market assessment methods.

16 key indicators are selected for intrinsic and utilization value benefit estimation. They are listed in Table 4.

3.3.2 Cost Analysis

10 key indicators are chosen to calculate the cost of the three scenarios. The cost are fell into two categories, which are direct costs of value protection, and the indirect costs of value protection. The detailed information of each indicator and the result of the calculation are listed in Table 5.

3.3.3 Conclusion

Based on the comparison of the benefits and costs of the above three scenarios, the summary is shown in Table 6. The values “1”, “2”, and “3” in the table indicate “optimal,” “moderate,” and “poor.”.

It is known from the comprehensive comparison that the intrinsic and utilization value of the scenario I is the highest, but the cost is the highest. In the second scenario, the value protection is good and the cost is moderate; Scenario III has the lowest value and lowest cost. In combination with the current situation of protection and the implementation of management policy, Scenario II is chosen as national park.

4. Discussion

This study provides a feasible technical method for delineating the boundaries of national parks. Through determining the value framework, conducting value analysis, designing national park plans of different sizes, and determining their basic utilization zones, the cost of multi-projects can be calculated quantitatively. In comparison with the benefits and the cost of each scenario, the most suitable national park plan was compared.

However, there are still many issues that need to be discussed, such as specific algorithms for cost and benefit. Each indicator has to be considered. Limited by the availability of data, many indicators can only be measured in terms of size.

It should be noted that the determination of the boundaries of a national park is a complex decision-making process and the factors involved are very diverse. This study
only provides a method for aiding decisions, which helps to improve the scientific decision-making.

Reconnecting green: Towards a multi-dimensional biophilic city

Eva Willemsen*; Nico Tillie

Abstract

Densification and greening of cities seem to exclude one another. How to deal with this? This research shows a first exploration of how city green can be optimized by integrating the facade-and rooftop green into the neighbourhood landscape. To do this, biophilic design principles were applied from a landscape architectural perspective. Due to the many green roof interventions as well as the existing big surface area of flat roofs, the city of Rotterdam in the Netherlands, was the main focus. Seven steps which can turn an unhealthy city into a biophilic one are described. Ecosystem services are related to these steps and serve as an indication for valuing ideas and design implementations for a city wide greening vision as a first step towards a multidimensional biophilic city.

Keywords: Biophilia; ecosystem services; facade green; rooftop green; landscape architecture, Rotterdam

1. Introduction

Many large cities in the world have an unhealthy stressful urban climate: air pollution, lack of water retention, lack of biodiversity, urban heat island effects, etc. There is also a lack of space in the urban environment and predictions are that urbanization and densification will increase (DESA, 2008). This is a huge problem for cities and very difficult to plan and design for. Urban green is regarded as big part of the solution for the environmental challenges that cities are facing. Ecosystem services, the benefits human populations derive from ecosystems (Bolund & Hunhammar, 1999), in cities should be planned for. Physical needs, security of existence, social and psychological needs can all benefit from
Biophilic Cities

green interventions (Hop & Hiemstra, 2013). Therefore, it is very important that local governments have ambitious green policies. “Nature seems to bring out the best in us” (Beatley, 2011). As it turns out, even small nature places can help just do that (Kaplan & Kaplan, 2005)

A densified city lacks an abundance of open space. There is a competition for space, between different functions such as new dwellings and green developments. Since the 1980s rooftop green has been introduced on a large scale in urban areas. The motive was to bring the maximum vegetation possible into the urban setting (Kohler, 2008). Projects were developed which resulted in beautiful green roofscape. There are some critical remarks though: First, they primarily occur in the private sector. Second, public green roofs are often unknown by citizens, as they are hardly seen from ground level and often have bad accessibility. Since mid-2000s, green façades began to emerge and green architecture became a fact. The advantages of green façades, in contrast with green roofs, is that they are visible from the street level. However, one cannot walk through a green façade. The third problem of vertical green and rooftop interventions is that they are implemented on a small scale scattered all over the city, with little to no interaction with the ground level. The effects of those green interventions are still very local, many potential synergies are unused.

Green roofs and façades are mainly architectural projects and connected in isolation of the building. There is not enough attention for this type of green interventions yet from a landscape architectural point of view. This research shows an exploration of how city green can be optimized by integrating the facade-and rooftop green into the neighbourhood landscape. Rotterdam, the Netherlands, will be the main focus due to the many green roof interventions and number of flat roofs. The results of this research is a stepwise approach how an existing city can transform into a biophilic one.

2. Methodology

The approach consists of seven steps starting from analysing the city and its potentials. From this analysis, a vision can be made that results in a concrete plan for the development of a biophilic city. The link with existing biophilic projects is made to show what a biophilic city can look like. The analysed layers are: existing green, water and public space, existing green rooftops and potential rooftops, and the urban challenges (such as densification), and opportunities. The next step is to create a vision for the city based on the previous analysis. Spatial requirements for the development for reconnecting green are partly extracted from this vision as well as from local context. The last step is an action plan and will be illustrated with example projects.

1. Look for available spaces and analyse existing green areas
2. Map existing green roofs
3. Analyse buildings for potential green development
4. Analyse urban challenges and opportunities
5. Create a city wide greening vision
6. Reconnect green
7. Action plan
3. Towards a biophilic city

“Nature in our lives is not optional, it is essential. It is not a thing or place that we periodically visit but a surrounding condition, an ideally ubiquitous context that delights, relaxes, soothes, replenishes, inspires, and uplifts us in our daily urban lives. A biophilic city is a city that looks for opportunities to repair and restore and creatively insert nature wherever it can” (Beatley, 2011).

3.1. Look for available spaces and analyse existing green areas

To design for a biophilic city it is important to take advantage of the existing green-and public spaces, infrastructure, water ways, and other connections in a city. These green infrastructures form the backbone of the city. They can and do support a diversity of human uses as well as environmental functions, and their vitality influences quality of life as much as it does the integrity of land, air, water and forest resources (Girling & Kellett, 2005). We can look at available spaces in different scales from regional to street level. Existing green areas and available areas for green development on a regional scale are regional parks, large conservation areas, greenways and rivers. The regional parks create space, landscape and a peaceful environment and show the identity of the city and typology of soil, history and landscape type (Tillie, 2016, Municipality of Rotterdam, 2005). Rivers are the core areas for the landscape, ecology, history and recreation and create connections on different scales; city, regional, national and international scale. City-or community parks, cemeteries, play fields, greenways and city gardens are the existing community green areas in a city and are an important connection with regional parks. On a neighbourhood scale, green sites are school yards, neighbourhood parks, playgrounds, and drainage ways (Girling & Kellett, 2005). It is of great value that the available green spaces and spaces for green are easily accessible and coherent. These are ecological and recreational routes through a city where there is a direct experience and accessibility of green. Other available spaces are (abandoned) alleys, streets, tram tracks and parking lots. Places that you don’t need or want to visit but have great potential for green or biophilic development. Quays and riverside trails are perfect locations for green connections as well dike trails and road sides. On a street level scale, medians, street trees and planting strips create green corridors through a city. In Rotterdam, the river Maas is an icon of the city and the multiple canals play an import role for cultural history, usage and living quality. Three regional parks surround Rotterdam and form an important part of the urban structure: Rottemeren, Midden-Delflanden and IJsselmonde. Due to these big ecological areas and the number of smaller waterways like canals, ponds, and other greens, Rotterdam is very suitable to become a biophilic city.
3.2. Map existing green rooftops

The first step to create a multi-dimensional green space is to map all the existing green roofs. Answering questions such as: Where are they located, what is the level of the intensity of green, are they accessible, do they relate, are they connected with the ground level, etc. Analysing these rooftops gives direction for planning new green rooftops. Rotterdam has the highest amount of green rooftop development in the Netherlands, with over 235,000 m² of green roofs (Municipality of Rotterdam, 2017) and the most potential to create a multi-dimensional landscape, as it has a big amount of post WWII real-estate. Only a small percentage of the existing green rooftops are always accessible.

3.3. Analyse buildings for potential green development

There are several important aspects of potential recreational green rooftops. Rooftops have to be flat for recreational green development. Due to accessibility and visibility it is wise to focus on rooftops that have a maximum of 12 meters. It is a bonus if a rooftop has the possibilities for an intensive green rooftop. Especially dense neighbourhoods with little green and little potential for ground level green development, can have enormous benefits from green rooftops. For the development of green facades another approach is made. Green facades have great visibility and work really well in dense areas. Especially small streets where there is no space for trees and other green can have great benefit from green facades and hanging green.
3.4. Analyse urban challenges and opportunities

Every city has to cope with specific challenges. Global warming and densification are key subjects of tomorrow's city planning for almost every city. Water restoration, urban heat island effects, air pollution, as well as social problems such as stress, and disconnection with nature, are huge problems. The difficulty is the lack of space in cities for creating solutions. Healthy ecosystems are the foundation for sustainable cities (TEEB, 2011). For example, trees and green rooftops serve to address the urban heat island effect and moderate and reduce urban heat and reduce air pollutants (Getter & Rowe, 2006). To connect urban challenges to green opportunities we can look at ecosystem services. Urban green and healthy ecosystems can solve many city challenges. The effects of climate change are also visible in the city of Rotterdam; sea level rise, intense rain, dynamic water levels in the rivers, and longer periods of drought and warmth (Rotterdam Climate Initiative, 2018).

The city’s effort is to create and maintain a balanced green infrastructure of parks, gardens, and other green areas with a high quality providing different ecosystem services ranging from recreation, ecological qualities to water storage and so on (Tillie, 2016). It is necessary that Rotterdam will adapt itself to climate change and its goal is to be climate-proof by 2025. If we look at the case of Rotterdam, another challenge is the experience of green in the city. Rotterdam has more green per dwelling than the other 3 big cities, Amsterdam, The Hague, and Utrecht. However, the citizens don’t experience this as such. The reason for this is the quality of green, monotonous (or not) and its usability (Tillie, 2016). Therefore, it’s not only important to create more green, it is also valuable to increase the quality of existing green in the city. The implementation of green is a step in the right direction. Which kind of problem does the service contribute to or solve? What ecosystem elements are involved in the generation of the service and where are the opportunities in the city to create this?

3.5. Create a city wide greening vision

Key is to set goals for the city. What are the most important challenges of this city? Is it the air quality, water retention or is it the mental wellbeing of its citizen, etc.? From this challenge, (or these challenges) we can create a vision for the city. The places in the city that need the most green because of its lack in green, dwelling density or other problems. For the Netherlands the green standard per dwelling is 75m$^2$ and the accessibility of green is 500m$^2$ (Bezemer et
al., 2002). Map the surface of green in the city and determine the minimum amount of green that is needed. Start at the ground level, what is already there? What is the function, and how is the quality of the green? A connection of neighbourhood green with regional green should be made in order to address weekly green and stimulate citizen to visit the nature areas outside of the city. Look for available places for green development and link this with existing green. How do they relate and, more important, how can they strengthen each other? Use the extra dimensions in the city, facades and rooftops and link these with the ground level green. Create artistic and aesthetic roof accessibilities that will attract people to the rooftops.

3.6. Reconnect green

“Reconnecting may be appropriate not only with respect to our relationship with nature, but in terms of many other reasonableness-supporting aspects of life (Kaplan & Kaplan, 2005)”

‘Daily contact with urban nature places can foster greater self-esteem, trust, and hope. It stimulates the reconnection with nature of the urbanites’ (Beatley, 2011). To create a well-connected green infrastructure which adds to daily green, it is valuable to have at least street green; trees, sidewalk gardens, courtyards, within 100m (Beatley, 2012), and larger green areas; neighbourhood parks, pocket parks, gardens, within 500m (Bezemer et al, 2002). For connecting green it is helpful to look for more solutions than only from a ground level perspective. Other dimensions are green facades and green roofs. They are the higher reaches of a city and harbour nature. Potential benefits of green facades- and roofs include green-space amenity, habitat for wildlife, air-quality improvement, and reduction of the urban heat-island effect (Oberndorfer & et al., 2007). It is important to approach them as two different interventions as they have in common the covering of building surfaces with vegetation, but there are key differences in the application and structure of these technologies and the resulting impacts on urban ecosystems (Köhler, 2008). To make rooftops more valuable it is of great significance that they are part of a bigger green infrastructure. The difficulty of integrating green rooftops is its accessibility and the place to create accessibility. The green rooftop of the Nanyang School of Art in Singapore and the green roof of the Delft University of Technology Library in the Netherlands managed to make a whole of the rooftop and ground level to increase its accessibility. These curved and sloping roofs were part of the architecture and make a good inspiration for creating accessible rooftops on existing buildings.

Fig. 4. Nanyang School of Art.

Fig. 5 Delft University of technology.
We can distinguish three types of accessibility for rooftops. The first one is based on the green slopes of architectural buildings and can be implemented at places where there is enough space. The advantages of this kind of ascent is that it is part of the green rooftop in its appearance and vegetation and functions as an extension of the roof garden. The second type is a stair which can be implemented where there is no room for a slope. This stair, depending on the size, can harbour extra commercial functions, like small shops. The last type of ascent is a tower with stairs or elevator in it. Its compact size makes it possible to reach roof gardens where there is a lack of space on the ground level. Both can be vegetated to link it with the green roof and infrastructure.

4.7. Action plan

The goal of Rotterdam is that it will be climate-proof by 2025 (Municipality of Rotterdam, 2017). The city should function as a sponge, green should have more value and it should be social and flexible. A multi-dimensional green connection can be made which is of great value. This principle can easily be applied in the inner city of Rotterdam. For instance the Lijnbaan, which has a great amount of low (under 10m) flat rooftop buildings where a second pedestrian layer can be added to. Every 10-25 year a building has to be renovated which is a perfect timing to transform this building into a sustainable green one. When there is place for new urban development, make sure that it will be a biophilic space with enough green areas and green buildings.

Creating urban landscapes using native plants restore the ecological function and value. Native vegetation is low in maintenance and supports local ecology and evolved to live with the local climate, soil type and animals. There must be areas where
residents can see and experience native wild or semi-wild nature and native vegetation (Beatley, 2011) which links with the surrounding landscape of the city. Our urban streetscapes, city parks, regional greenways and vegetative storm water facilities are ideal spaces for incorporating native plant communities. Native plants help to capture and infiltrate storm water thus improving water quality while providing habitat and biodiversity. The biggest benefit: they complete the picture by enhancing the aesthetic values of urban neighbourhoods. A good example of a project that used mainly native species is Corktown Common in Toronto. It opened with over 700 trees and thousands of shrubs and grasses that are native to Southern Ontario’s Carolinian forest ecosystem.

4. Conclusion

An attractive green city is not only beneficial for its citizens as a contribution to strengthen the economy. Green attracts firms and offices because of the pleasing setting, room for strolling and view (Tillie, 2016). Therefore it is of great value that we start now with designing our cities differently. Start by analysing the ground level for existing green and potential green. Add the second dimension analysis of (potential) green facades and rooftops. This is the base for a biophilic development. Subsequently
determine what the challenges and opportunities of the city are and link those with ecosystem services, the type of ecosystem that can treat the problems in the city. Set goals and create a vision based on the needs of a city, and the available spaces to design for. Reconnect those places with existing green and create physical, aesthetical and biological networks between the ground level and rooftop for a multi-dimensional biophilic design. At last set guidelines for architectural development. Biophilic design should at least add to air filtering, biodiversity, aesthetics and a better physical and psychological health. A biophilic city is a city where its citizens and itself can be healthy and happy. As nature in our cities and lives is not optional, it is essential.

Rural parcel pattern as condition for future landscape urbanism in Xiongan New Town

Peiran Yu*

Delft University of Technology, The Netherlands

Abstract

This paper aims to present the study about landscape urbanism within new town context in China. Theory review will describe the historical evolution of landscape urbanism with the concepts of Wall (1999), Palmboom (1987, 2010), who emphasised the relation between landscape and urban form. Special attention will be paid to the perspective that landscape provide framework for infrastructure and urban fabric, which indicates possibility for continuity and diversity of urban form. This would be reflected with the indication of existing rural village in Xiongan new town with the help of typo-morphology analysis and mapping. Parcel pattern indicates the relation of landscape and urban form that topographic condition as priority during historical construction. The research conclusion is that flooding risk and topographic condition are critical factors to achieving landscape urbanism in Xiongan new town.

Keywords: landscape urbanism, new town, parcellation pattern, topographic condition, continuity
1. Introduction

This paper addresses study on historical construction logic and expansion phases of existing villages in Xiongan new town. Analysis based on typo-morphology and layer approach indicates that expansion phases in existing rural villages accord with concept of landscape urbanism. Therefore, this paper helps to set some conditions for future adapting of landscape urbanism in this new town. Section two will discuss the important historic and current ideas of landscape urbanism, with the urbanists Wall (1999), Palmboom (1987, 2010). Section two will indicate methodology applied in this paper, method of typo-morphology and layer approach. Section three will focus on analysis of existing rural villages in Xiongan. Section four will present conclusions. Sections five will put forward discussions in relation to future adaption of landscape urbanism in this new town.

2. Concepts on landscape urbanism

2.1. City as urban landscape

Landscape urbanism is a theory of urban planning and urban design which stated that landscape is the fundamental layer for urban development. It emphasis “the idea of city as urban landscape” (Meyer 2015). A similar view is hold by Palmboom (2010). Palmboom (2010) describes city as “a phenomenon of landscape”. He holds the view that city can “no longer be conceived as an architeconic entity which stands apart from the landscape”, it is an “urbanised landscape: extensive and fluid, layered, marked by time, unpolished, arising out of a discordant interplay of natural and cultural forces, driven forward by the pragmatism of survival, with occasional flashes of aesthetic aspirations”. Palm stressed the importance of design of landscape in urban planning and urban design that urban area could be organised through design of landscape. As stated by Meyer (2015) that landscape act as “one and only element to influence by planning and design”. It addresses the perspective that landscape act as the basic framework for large-scale urban infrastructure and building programmes. Therefore, landscape provides condition for a diversification and enrichment of urban fabric. This is supported by Girot (2006). Girot (2006) argued that landscape "become a staging ground for the unfolding of future events", he emphasises that "what has systematically been called the impoverishment of landscape could now be understood as a form of diversification and enrichment." Wall (1999) agrees with this view. He describes landscape as "active urban surface, structuring the conditions for new relationships and interactions among the things it supports.” Wall’s idea reveals the interaction among landscape and the other urban layers supported by landscape. Thus, in order to achieve landscape urbanism, the first step is to understand the relationship between those layers and landscape. This is in line with the view of Wall (1999). He believes that “If we accept the premise that landscape has undergone such diverse and complex alterations, we need then to decipher the implicit "genetics” of its evolution in order to explicate a vision for the future”. Process of understanding relation between landscape and other urban...
layers is deciphering “the implicit genetics”. Study on “implicit generics” discusses relationship based on the dutch layer approach and method of typo-morphology.

2.2. layer approach

Layer approach is a typical dutch urban analysis method. This approach oriented from the idea of “time-oriented thinking in spatial planning and design” (Schaick and Klaasen 2011). It refers to “stratified model that distinguished spatial planning” and design tasks “on the basis of the differing spatial dynamics of substratum, networks and occupation patterns” (Schaick and Klaasen 2011). Landscape is a more "longstanding moving continuum" (Boeri and Lavarra, 2002; Girot, 2006) comparing with network and occupation layers. This approach provides handles and levers for designers to study “the implicit generics”. It helps to simplify the complex urban system into separate layers, then study on the relationship between different layers systematically. Layer approach has been extended by Plamboom (2010). Plamboom (2010) stated that “every intervention has to take its complex layering into consideration, to deal with its conflicts and use its potential of unexpected combinations and contrasts”.

2.3. Method of typo-morphology

As Moudon (1994) stated, typo-morphology view “urban form as a dynamic and continuously changing entity”, describe “urban form (morphology) based on detailed classification of building and open space by type (typology)”, which “combines the volumetric characteristics of built structures with their related open spaces to define a built landscape type”. Typo-morphology combined urban morphology (study of urban form) and typology (study of types of urban form), creates condition for study on the relation between urban fabric and landscape. It offers an intellectually challenging framework for thinking about the built landscape within the historical context of the city. This method “stipulates that city form can only be understood as it is produced over time” (Moudon 1994). Historical perspective of typo-morphology corresponds to the idea of landscape as "longstanding moving continuum”. Thus typo-morphology combines with layer approach, providing handles and levers to understand urban fabric in relation to the specific local landscape composition layers. This helps to reveal underlying relationship, the “implicit generics”, meanwhile, contributes to “study the nature of building design, its relationship to the city, and to the society in which it takes place”.

Fig1. Dazhuangzhuang is one of the existing villages in Xiongan new town. It located beside Baiyangdian shallow lake. (Photo reference: Google.map)
3. Rural villages as landscape area

This section addresses analysis on existing rural village in Xiongan new town to draw conclusions and disciplines for future adapting of landscape urbanism. Study will be divided into the following questions to reveal local specific relationship between landscape and urban fabric: how existing fabric has changed over the course of time and what has caused these changes? The analysis process is divided to three parts: morphology analysis to understand existing village tissue; typology analysis to understand different housing types; the last but not least, discuss the relation between village tissue and topographic condition, with the rural village “dazhangzhuang” as an example.

3.1. Housing typology analysis

As Moudon (1994) stated that from the perspective of typo-morphology, buildings can be treated as “timeless, unchangeable memories of a past”. Housing types provide clue for understanding historical expansion. Three housing types will be defined in chronological order: historical small units, courtyards with thick foundation, industrial multi-layer plants. Historical small units could be recognized by extreme “small size”. These units located in historical village center on top of marsh land. Courtyards with thick foundation are larger units comparing to the first type. The courtyard is completely private that is accessible only through the gated entrance, which act as legible spatial elements for strangers. Both historical small units and courtyards with thick foundation are constructed by private owners, this resulted these two types were both built on top of thick foundation in case of flooding risk. Differentiation among those units reflect identification of the owners, meanwhile provides visually diversity and vitality when pedestrian walking along the street. Industry plants were built in form of multi-layer related buildings.

These types indicate historical expansion process and ways that local residents react to flooding risk. Village first appeared on top of marsh land and was composed of small units. Later thicken its fringe in all directions. Areas expanded during this phase took place by larger units with courtyards and thick foundation. Then Dazhangzhuang expand itself towards Anxin. Agricultural land was replaced by multi-layer housing and industry plant.

3.2. Morphology of villages in Xiongan

Analysis process of morphology is divided to two steps. Firstly, describe the mapping result to indicate different types of urban form in those villages. This step works as reduction process to filter mass of information.

![Fig2. Three existing rural villages](Image)

(Drawing reference: Draw by author based on map from Google.map)
Secondly compare those mapping results and relate them to local topographic condition. This step works as a back and forward process to draw conclusion. These villages are in different form of parcellation pattern. Parcel in village 1&2 is much more regular than village 3. Parcel pattern in Village 3 is similar to the pattern on top of marsh land, both in form of irregular pattern. By contrast, village 1 and village 2 are more a result of artificially “planed”. We could conclu that village 3 is the first constructed village even before the dike was built. Later, since dike was built, construction logic changed from water management as priority to accessibility as priority. village 1 and village 2 appeared near the main road. Thus, we could draw the conclusion that parcellation pattern were formed due to corresponding construction logic. Construction logic changed in different historical period. The logic reflects relationship between village fabric and specific topography condition.

Then we compare parcel pattern in relation to topography map, it clearly indicates that irregular pattern concentrate itself on top of the area of high altitude zones. There are two types of parcellation pattern: regular and irregular. Irregular patterns resulted from original wetland topography. These villages were built on higher altitude and on thicker foundation to avoid risk of flooding. That’s why the parcellation pattern is irregular and follows the form of topographic condition precisely. By contrast, regular patterns relate to agriculture land. Villages on top of agriculture land are more a result of artificially “planed”. This is because agriculture land was formed under the precondition that dike prevents flooding. Thus, we could conclud that irregular pattern appeared early before the dike was built. Therefore, this specific irregular pattern reveals historical construction logic even before the dike was built.

In summary, parcel pattern changes corresponding to different ways of water management. Two types of parcel patterns will be defined according to water management: marsh pattern, refers to the irregular parcel pattern which is similar to reed pattern, and agriculture pattern, refers to the regular parcel pattern which is more an artificial result. The specific irregular pattern indicates that flooding risk and topographic condition are the most two important factors when we considering built area as a phenomenon of landscape in Xiongan new town.

4. Concepts on landscape urbanism
According to former analysis in section three, construction logic in existing rural villages accord with the concept of landscape urbanism. Parcel pattern and housing typology both relates to method of water management. Topography condition and flooding risk resulted historical pattern and housing typology. Thus, these rural villages could be viewed as reflection of landscaped urbanism. Besides, water and topography are the most critical layers according to historical analysis when achieving landscape urbanism in this specific location.

As stated by Burg (2015) “understanding the history of an area may enable the designer to make reasonable speculations about future developments”. Thus, analysis of existing rural villages indicates the hierarchy of landscape elements which influenced village fabric in this specific area. Landscape changes slowly Plamboom (1987), comparing to infrastructure layer and programme layer. Thus this hierarchy concluded from existing rural villages is still applicative to future urban design, as long as we aims to achieve a “landscape urbanism” new town. Therefore, this hierarchy that flooding risk and topographic condition as priority helps designer to make design as a reaction to these landscape layers logically.

5. Concepts on landscape urbanism

Flooding risk and topographic condition have potential to impact future large-scale infrastructure and small-scale spatial design in this new town. Low lying altitude topographic character brings risk of flooding. Thus, large-scale infrastructure needs to be protected from risk of flooding. Small-scale urban design programmes have potential to be designed as public space, providing place for social interaction and a liveable green living environment. These small spatial design programmes contribute to a more ecological and adaptive urban structure when reacting to water. As stated by Czerniak (2006), "conceiving of site suggests that landscape design projects can not only draw from an expanded field of information, they can impact areas larger than their own physical extent, making ecological sense”.

Green roof technology: from singular technical solution to a key element in biophilic architecture

Manfred Koehler\textsuperscript{a}, David Vernon Brasfield\textsuperscript{b}

\textsuperscript{a}University of Applied Sciences, Brodaer Str. 2, Neubrandenburg, 17033, Germany
\textsuperscript{b}Sunnaas sykehus HF, Nesoddtangen, 1450, Norway

Abstract

From the presentation to the IFLA Congress 2001 (Koehler et al. 2001) on the topic “Extensive green roof technology” and up today, the diverse aspects of green infrastructure (GI) technology have spread around the globe. Awareness of green roofs and their environmental functions was fostered throughout various disciplines. National green roof associations now exist in more than 30 countries. From two basic types of green roofs, “extensive” and “intensive”, the intended functionality has metamorphosed into much more detailed solutions. Local names, e.g. skygardens, living roofs, eco roofs, roof farms, etc. demonstrate the maturation of urban green roof technologies toward an increasingly multi-layered functionality. These are now central elements of the GI agenda in Cities.

Green roof professionals founded in 2007 the World Green Infrastructure Network to share knowledge and experiences and advocate the greening of buildings. More than 1000 peer reviewed articles describe the detailed research on green roof functions. Over time, focus on living walls, indoor greening, and rain gardens have supplemented the body of knowledge on GI.

At the Green Roofs for Healthy Cities Congress in 2004 in Portland, Oregon, Steven R. Kellert presented the term “Biophilia” earlier elaborated by Wilson [1]. The concept of Biophilia has since become prominent within the field, connecting human affiliation for nature with ecological functions. Cities around the globe established strategies to promote GI: incentives, guidelines, regulations, building codes, centers and demonstrations to convince stakeholders and the citizens about the multiple benefits of GI technologies.

Within a period of about two decades, the greening of buildings went from obscure to well known. Clearly exemplifying this shift is the design of the Washington DC headquarters of the American Society of Landscape Architects. In Germany the GI “white book” targets fulfillment of several of UNESCO’s SDGs.

The presentation highlights lessons learned and states the critical role of landscape architects as guides with the deepest understanding of GI’s ecological benefits and value delivery. This multi-dimensional approach includes:

- Local situations (climate, architectural history, building codes, genius loci),
- Social aspects (the wide range between elaborate private domains – and/or socially inclusive garden projects, such as urban gardens on top of buildings),
Biophilic Cities

- Ecological values (multiplicity of benefits, such as: urban climate mitigation, noise reduction, water management, biodiversity etc.),
- Design questions (building as landmark or masked by vegetation).

The State of Singapore, which has realized numerous and iconic examples of GI since it last hosted the IFLA Congress, is a perfect place to discuss all of this in depth.

*Keywords: Green roofs; Sky gardens; Place making; Biodiversity; Green infrastructure.*

1. Introduction

Green roof technology is as old as mankind. Vegetated shelters and hanging gardens are combined technical and landscaping solutions dating back to prehistoric times [2]. Given all of the inherent benefits [3], it is difficult to understand why this technology has, until recently, been so under-utilized in urban development. Extensive green roofs and lusher roof gardens are found around the globe. See Osmundson [4] for an overview of unique garden projects dating back to antiquity. While most visitors see only designed “Garden projects” on the surface, only a minority understand the engineered environmental functional details beneath this green cover. These more technical aspects are the rich environmental secrets behind, developed during the last decades. The early stage of modern green roof technology was connected with passionate architects with a favor for green flat roofs, e.g. Le Corbusier. Green roofs in Oscar Niemeyer’s projects were developed by design team member and landscape architect Roberto Burle Marx. Similar connections can be identified throughout all regions and periods. Further examples are found in the work of the German landscape architect Konrad Ben Köthner, with many hospital, city hall and head-quarter green roof projects in Europe and abroad. Köthner was additionally one of the initial practitioners facilitating connections between the roofing industry, technical and scientific disciplines and the German professional associations FLL and FBB. With the aid of ecologists, the multiple benefits of green roofs were comprehensively presented to convince politicians and urban planners of the need for integrated environmental projects. Further ideas were supplemented via ecological research and innovation, such as light weight growth media and variations in plant selection.

This story was presented at the IFLA Congress in 2001 [5]. Questions arose concerning, among other things, the prevalent focus on extensive green roofs; why not build lusher roof gardens instead? The prevalence of extensive roof types was the response to ecologists’ initiative to green all urban surfaces, also those with limited load bearing capacity.

Since then, the German green roof industry developed intensive roof garden solutions. At present about 15% of German green roofs are intensive designs. When engineering solutions support the necessary extra load bearing capacity, new roof gardens can integrate a much wider variety ecological functions, from urban food production to constructed wetlands, thus enabling a decentralization of urban green infrastructure that includes the roof (and wall) surfaces of cities.
The wide scope of opportunities for situationally responsive value creation within green infrastructure is a toolbox enabling tailored solutions for each development’s unique opportunities.

In recent years the green roof industry has awoken to the values of green infrastructure. The uptake of GI solutions is growing exponentially around the globe, accompanied by a multitude of academic inquiries concerning environmental effects. Singapore is a cradle of innovation for front runner case studies. WGIN currently has affiliated national associations active in about 30 countries.

Guidelines, norms and dissemination of best practice examples makes visionary ideas tangible. Green roofs and vertical greening have become the visible symbol of sustainable architecture, of which many aspects are not apparent to the untrained eye. The discipline of landscape architecture has been significantly elevated in this exploration of increased and multifunctional greenery. The practice of integrated design is growing accordingly, where landscape architects are included from the very beginning of projects.

2. The biophilic paradigm and urban planning

Biophilia has in recent years become a key concept within holistic design and landscape architecture. The surfaces of buildings are increasingly recognized a valuable resource and opportunity for accommodating our intrinsic biophilic needs and preferences.

In present days where more and more time is spent behind computer screens, and where more than half of the global population resides in cities where natural elements are by and large removed from the immediate local habitat, the afflictions of stress and “nature deficit disorder” [7]. have become prevalent in epidemic proportions. The deprivation of biophilic satisfaction in urban areas is a compelling reason to innovate on “grey and dead” building surfaces with green infrastructure and designs incorporating both water and vegetation.

Fig. 1. Gradient of challenge figure, adapted after [8] A caption is positioned left-justified below the figure or scheme.
As with in all architectural and landscape design, solutions should respond to the variety of needs of those who will use the project. One simple and helpful tool used in design of healthcare landscapes, based on the Maslow hierarchy of needs, was developed by Bengtsson and Grahn [8] 2014. Figure 1, adapted from [8] suggests differentiating the response of GI when prioritizing biophilic design according to the state of well-being of users, or patients in the cited example. There are obvious parallels here with the stated biophilic functions in the example from Terrapin, below.
Focus on biophilic design has permeated several standards for the sustainable design of buildings and neighborhoods, for example the BREEAM standards for buildings and communities and the relatively newer WELL standard lanced in 2013 and administered by IWBI where biophilic quality is measured both quantitatively and qualitatively. In best case situations elevated greening can establish open space qualities and a level of biophilic satisfaction comparable with landscapes at ground level. The major difference is that elevated and building integrated solutions place much higher demands on engineering, detail planning and material choices, in addition to considerations regarding species selection.

Figure 2 shows the relation between seven main functions that can be achieved by green roofs. Since not all functions can be achieved at the place and time, projects’ prioritized functions must be defined, preferably at an early planning stage of the project. In the example in figure 2 biodiversity is a main target. Certain other functions cannot be achieved on this roof at the same time.

3. Biodiversity solutions in green roof technology

Quantifiable ecological functionality is a research topic which has gained increased focus over the last 10 years [9]. Urban level biodiversity can be supported by the number, size and pattern of green roofs within a city. On the other hand, at a micro per-rooftop level, a heterogeneity of details of the green roof’s biological support systems such as variation in growth medium, moisture content, sun/shade conditions and nutrient supply will result in increased local biodiversity. Not each big sized green roof must be number one in biodiversity [10].

4. The next level of urbanism, biophilic design meets biodiversity for increased liveability.

Biophilic structures are favored by most citizens around the globe, but few are familiar with the term biophilia [11]. In addition to the esthetic qualities, biophilic design has a huge potential for yielding a rich array of ecosystem services, or ecological function. In the body of work termed “Nature based solutions” which has rapidly gained attention recently in Europe, both biophilic design and ecology are merged resulting in the delivery of multiple co-benefits. Significant amounts of research funding are currently allocated for the study and quantification of these effects [12]. The next level of these technologies is to gain traction at the political
and planning levels. This is an area where the world can learn from the pioneering work and development of Singapore, especially the accomplishments of the present era of “City in a Garden” politics or the ABC programs dedicated to enhancement of urban water features.

In Germany the so called “Weißbuch” – Process, 2017 (“White book procedure”, see link) for greenery was recently established by the National Ministry of Construction. The preliminary phase lays out the identification of targets whereby greenery can contribute e.g. to the SDGs of the UN and contribute solutions addressing the challenge of biodiversity. The second level is the “Green book procedure” where quantification of ecological benefits will be undertaken.

Under the present policy framework all cities in Germany have defined biodiversity goals in detail, but the particular details and emphasis varies between individual cities [13].

As a further example of state level policy in Berlin: there are regulations requiring all new building developments to integrate greenery as much as feasible. In cases where integrated greenery is lacking, a justification for not integrating greenery is required.

Investigating usability and constraints of urban green network in Klang Valley, Malaysia: Preliminary findings from a qualitative study

Theebaa Paneerchelvam, Sreetheran Maruthaveeran

*Faculty of Design and Architecture, Department of Landscape Architecture, Universiti Putra Malaysia, 43400 UPM Serdang, Selangor Darul Ehsan, Malaysia

Abstract

Majority Malaysian cities and towns lack of well-functioning green network such like poor accessibility considered to be an issue. Thus, this is problematic, as accessibility and connectivity are important preconditions for green space functionality. This research study determines the usability and associated constraints of urban green network in Klang Valley. Findings are based on qualitative studies undertaken in South West Bicycle Corridor, Kuala Lumpur among the user and non-user of green network (N=5) by means of semi structured in-depth interviews. The interview consists of informants from various age, gender and race. The outcomes showed all-inclusive likenesses to different societies on use of green networks. This study highlighted four major themes: Urban green network usage, constraints associated with urban green network use, attributes that influence usability and associated constraints and urban green network management and planning implication which suggested by the participants. Tough the dimension of usage and associated constraints varies based on personal preferences thus this study illustrates important strategies related to urban green network planning and management to ensure better connectivity, accessibility, safety, and maintenance for promote sustainable and well being community.

Keywords: Greenways; linear trails; green infrastructrure; user patterns; percived experience.

1. Introduction

The world’s cities are becoming increasingly congested and polluted (Blanco et al., 2009). Along with urbanization and urban green space loss, decreased quality of life and poorer health for city inhabitants have been reported (The World Bank, 2011; Maller et al., 2009; Byomkesh et al., 2012). Developing countries, such as Malaysia, have been facing similar challenges of human health and well-being as their Western counterparts and most deaths in Malaysia now are from noncommunicable diseases like obesity, hypertension (Philips Index: Malaysia’s Health and Well-being Report, 2010, Malaysia health system review, 2013) Additionally most Malaysian
cities and towns lack a well-functioning green infrastructure while, for example, poor accessibility can be an issue (National Urbanization Policy, 2006). Besides Kuala Lumpur does not have a proper green network that links all the existing open spaces (Sreetheran and Adnan, 2009). This is problematic, as accessibility and connectivity are important preconditions for green space functionality (Natural England, 2011). Urban green networks are important quality of life indicators in cities. However, urban green networks research mostly carried out in developed countries, which limits the knowledge about urban green network use, perceptions and preferences in urbanized metropolitan cities in developing countries.

Green networks or greenways are defined as “a linear open space established along either a natural corridor, such as a riverfront, stream, valley, or ridgeline, or overland along a railroad right-of-way converted to recreational use, a canal, scenic road, or other route” (Little, 1990). Urban green networks which are often designed with multi-use trails that provide opportunities for physical activity, recreation and transportation (Lindsey et al., 2008) are defined as places for nature in the city where people can fulfill recreational needs and achieve solitude and retreat without leaving the public realm (Luymes and Tamminga, 1995). In cities, urban green network mostly serve as recreational greenways which are featured with paths and different kinds of trails based on natural corridors as well as public rights of way, abandoned railbeds, and canals (Little, 1990). Urban green networks are considered more than just parks or amenities (Searns, 1995). They provide a number of significant benefits and serve a number of important functions that improve the quality of life through the use of land for multiple purposes in cities (Akpinar, 2014).

Numerous studies have illustrated the ecological, environmental, social, recreational, esthetic, educational, and economic benefits and importance of urban green networks.

2. Methods

The present study investigates the experiences related usability and constraints of urban green network. The authors interested in both the information the participants can give about the research topic and how participants talk about their experiences and attitudes. In other words, the authors interested in both of the content of the interview conversation and the way informants express them—the words they use (Matthews and Ross, 2010).

A qualitative method was used to gain understanding of this issue (Boston et al, 1995). A qualitative approach was adopted because it allows a flexible exploration of attitudes and experiences of informants and produces a richness of data that allows the researcher to gain a deeper understanding of social phenomena (Creswell et al, 2012). A semi-structured face-to-face interview was conducted at the study sites. The interview guide was used in this study, but not rigidly, allowing freedom to explore topics in more depth particularly for those urban green network users. The interview guide was a modified version of the interview guide.
form used by Somajita and Harini in Dehli. The respondents were selected based on their availability when approached by the interviewee. Each interview lasted between 30 and 60 min and was recorded using digital audio recording devices. During the interview sessions, the interviewees briefed about aim of the study and the structure of the interview process. The interview was conducted in either English or Malay (National Language) based on the interviewee’s preference. The interview was asked whether they accepted the interview to be recorded (which all did) and that he/she could just ask the interviewer to switch off at any time if not comfortable. The interview session was recorded with permission from the interviewee. The researcher also carried along a note book during the interview sessions in case if voice recording was refused by the interviewees, for example due to cultural objections to having their voice recorded something which did not occur.

1.1. Study sites

This study was conducted in South West Bicycle Corridor, Kuala Lumpur. This green network stretches 5.5 km from Dataran Merdeka runs along the Klang River for most of its length and ends near the Mid Valley Megamall. For most of its length it is a dedicated multifunctional lane; some sections (a major stretch in Brickfields) are shared with other traffic while some others shared with pedestrians. For the purpose of this study four sections which contain green elements such as trees, shrubs, hedges, and grass were identified. Among the spots are: Lebuh Pasar to Dayabumi, Dayabumi to Jalan Sultan Sulaiman to Tun Sambanthan Station and Tun Sambanthan Station to Mid Valley.

1.2. Data Analysis

The researcher analysed all the transcripts manually for relevant contents and themes (Burnard, 1991). Open coding was performed, and the necessary headings were generated to describe all aspects of the content excluding “dross” the headings were then grouped together under higher order headings. The new list of headings and subheadings was worked through, and repetitive or very similar headings were removed to produce a final list.

2. Results and Discussion

3.1 Characteristics of participants

This is piloted findings from five informants aged from 18 to 43 years. Recognizing that variables such as gender, age and different group of races in Malaysia to explore changes in usability of urban green network. The respondents consist of three males and two females whereby four of them are Malay and remaining one is Chinese. All the respondents were either married or single. Three of them had B.Sc. degrees, and remaining two had diploma and secondary school education. Lindsey et al. (2006) suggested people with a higher social status are more likely to be users of urban trails; they also assert that trails passing through neighborhoods with high-income, more educated residents are preferred. Purposive-sampling method was used in order to obtain a diverse sample of
respondents based on criteria drawn from the literature review, namely age, gender and race. Given the overall difficulty in accessing potential interviewees, snowball-sampling was used to supplement the purposive sampling. Demographic characteristics of the participants are shown in Table 1.

### 3.1 Themes

Thematic content analysis of the interviews identified 4 major themes: Urban green network usage, constraints associated with urban green network use, attributes that influence usability and associated constraints and urban green network management and planning implication.

**Theme 1: Urban green network usage**

The users were interviewed to obtain information about the reasons for using South West Bicycle Corridor. The greater part of the respondents related urban green network with diversion, wellness and being as one with family, primarily because of the relationship of green network as a place to enhance their wellbeing and prosperity. On top of that findings determine this green network functioning as linkage from one place to another place. Cyclist accounted as the highest proportion of users, followed by joggers, and then walkers. A man described (40, Malay, married, user) “I use this green network for cycling and I prefer to go with my friends for leisure activities. Sometimes I use this corridor to go to Midvalley shopping mall”. Interestingly a lady reported “I use this network mainly to travel from my house to my office and sometimes using this to go buy groceries. I cycle everyday but sometimes I just walk to my house from office using this route (green network). However, she added “sometimes this track is a meet up point for me with other friends”. Another male informant (37, Malay, married, user) mentioned “I use this network mainly for recreation purpose and one day I want to bring my kids to explore this lane, to enjoy the green sceneries”. One young participant (Female, 18, Malay, Single) said “even though this corridor is not located nearby to my house I use to visit this corridor with my family and friends, we love to cycle and sometimes we involve in physical activities such as jogging and walking since this corridor has good scenic view and we feel relax”
Theme 2: Constraints associated with urban green network use

Apart from the green network users, the non-green network user reported several constraints from visiting the green network in Kuala Lumpur. For example, a man (43, Malay, single, non-user) reported “I prefer to use main road compare to this green network since lack of safety like unavailability of street lights, it’s very quiet and there is a lot stranger. Once I heard from my friend who got attacked by theft”. Research over the years has aimed to understand how to have safe yet appealing green network. For example, as explained by Reynolds et al (2007), green network usage was associated positively with various determinants including proper trail condition, streetlights, cafeteria availability, and other trailside facilities. Apart from non-users there were some of the constraints reported by other users. For example (Female, Chinese) said “I have experienced crime scene whereby my gold chain was snatched by one man who came with motorbike. It was such a terrific moment, and no one came to help me even though I saw there were few people around that area. I feel it is totally unsafe. Additionally, some part of the green network not able to access since it was closed for construction of river of life project. Condition wise, drainage along the network need an attention since can cause flood during rainy seasons”. Another young female informant reported “as a cyclist my main concern is a parking space, it’s difficult for me when I don’t see any place to park my bicycle”. Apart from the above constraints distance was noted by a respondent as a factor which discourage him from visiting this green network frequently. For example, one man (37, Malay, Married, user) “I need to drive over there and it’s difficult to find parking lot near the green network, most of the time me and my friends park our cars at Midvalley shopping Mall parking basement and we start cycle from there”. In a research by Gordon et al (2010) stated that new exercisers indicated their primary reasons for using particular trail as short travel distance and convenience.

Theme 3: Attributes that influence usability and associated constraints.

Alone/ with others

The interviews additionally uncovered that the nearness of individuals can support safe utilize. In any case, this additionally relies upon assortment of individuals exhibit, as the nearness of other individuals may either increment or abatement the use. Almost all the respondents, when they are using South West Bicycle Corridor they accompanied by their friends or sometimes family members except one lady (Chinese, Single, user) prefer to use the green network alone since she is commuting from her house to office and its very rare she go to network in a group unless she got appointment with her friends. Another similar finding by Maslow et al. (2012) discovered that more people used the trail in groups as opposed to alone.
Safety

Safety is an important dimension in the perception of urban environments and one that is sometimes perceived to be at odds with enhancing the naturalness and aesthetics of urban green network. In Kuala Lumpur people’s concerns focused on two different aspects of safety: physical safety such as falling, health concerns about direct physical contact with polluted environment and personal safety whereby the green network as a hangout for gangs engaged in criminal activity, a place for drinking and drug use, and as habitat for the homeless. For instance, one informant (Male, 40, Malay, Married, user) reported “I slipped once at green network corridor since it was wet surface after the rain”. Another non-user (Male, 43, Malay, Single) mentioned “I used to cycle at night for my physical therapy but I’m not really prefer to cycle along South West Bicycle Corridor since its very quiet and its very dangerous since dark and no street light along the corridor” Apart from that some of the participants did also highlight the presence of disorder people around green network, i.e those violating social norms or official laws or acting in an unpredictable and threatening manner (Ross and Mirowsky, 1999). One young girl (18, Malay, Married, user) said “I always notice a lot of trashes, dried leaves, sharp objects such as broken tree branches that could puncture bicycle tires” Moreover another Chinese lady reported the drainage along the South West Bicycle Corridor polluted with trashes and it cause flood during rainy seasons”.

Accessibility

Accessibility have been highlighted by most of the informants. Most of the respondents have difficulty to access along the green network since one lady (Chinese, Single, user) have reported “some part of the network not able to access since it has been closed for ‘River of Live” project. So, it’s very difficult for me to find alternate route and without choice I need to use main road which is not safety enough to use”. Another respondent (Male, 40, Malay, Married, user) said “I need to drive to get to this green network and it’s not very near of my house. This result supported by few other studies whereby walking is largely influenced by the accessibility of the destinations (Chudyk et al., 2015; Van Cauwenberg et al., 2012).

Cleanliness

The cleanliness of the green network and its surrounding environment was by far the other top concern of informants. For example (Male, 40, Malay, married, user) said “I always notice a lot of trashes, dried leaves, sharp objects such as broken tree branches that could puncture bicycle tires” Moreover another Chinese lady reported the drainage along the South West Bicycle Corridor polluted with trashes and it cause flood during rainy seasons”. Similarly, another study indicated that high-quality
trail design can attract more visitors compared to a poorly maintained trail environment (Reichhart & Arnberger, 2010). Apart from that, another study revealed that littering should be prohibited, and litter-free environment attracts more users to the trail (Akpinar, 2016).

Naturalness

Naturalness is a key dimension that people relate to in any ecosystem, no matter how urban it is. In the most sections of the green network corridor, people saw wild nature as a shade and mentioned nearby natural areas should be protected and well maintained. One young respondent (Female, 18, Malay, single, user) said “I like to go with my family since few sections of the corridor is dedicated with green sceneries, which provide important restorative opportunities, relaxation, and stress reduction”. Few other literatures have determined the balance between nature and the built environment was fundamental for green networks (Siu, 2001; 2007a). A research in Shenzhen demonstrated that the neighborhood green network did not manage to promote physical activities. This may be due to the absence of adequate green environment, despite it being the most accessible greenway theoretically.

Time of the day

Overall results indicated time of the day is an important dimension in the urban environments. Almost all respondents reported morning, afternoon or evening as they their preferred time to visit or use South West Bicycle Corridor excepting on Chinese lady tend to use this green network even at night. She said, “I totally depending on this green corridor since my primary transportation is a bicycle and apart from traveling to office from home, I use this route to visit other places doesn’t matter at night even though it’s very dark”. Interestingly another informant (Male, 37, Malay, married, user) reported “I prefer to go there on weekend compare to weekdays since its very quiet with less people on weekdays”. Another study has similar finding for instance, Lindsey and Nguyen (2004) found substantial intertrail and intratrail variations over various seasons, days of the week, and times of the day at five greenway trails in Indiana.

Weather

Almost most of the informants felt weather is not a disturbance. For example (Male, 37, Malay, married, user) explained “hot weather is don’t bother me unless if raining, so we need to find alternate solution like wearing rain coat”. Similarly, research in western country by Duncan et al. (2008) indicated that both adults and children showed increased step counts in summer months and decreased step counts in winter months.

Theme 4: Urban green network management and planning implication

Most of the participants suggested several strategies for Kuala Lumpur City Hall to improve the usage of South West Bicycle Corridor. Numerous informants highlighted connection is an increasingly important topic. For example, one Chinese lady said, “some of my friend told me, we rather use
main road since some sections of green network has poor connection so its demotivate us to use because somehow, we still have to get back to main road when there is no connectivity, so my opinion DBKL should consider on proper planning with proper connectivity”. Another male informant suggested safety and cleanliness as part of maintenance strategies in increasing the usage of South West Bicycle Corridor. Other suggestion included the one by young women (….): “In term of management I would like to advise the City Hall to maintain the areas...keep the corridor clean and repair the condition of pavements since some sections its not really stable with lot of cracks”. This finding confirmed the results of Gobster, (1995) explained that pathway condition may also encourage the senior citizens to walk in a green trail. Other similar studies showed that green network may promote negative perceptions among the users if they are crowded, neglected, unsafe, or poorly maintained, all of which results a decline in use or complete avoidance (Boone et al. 2009). This interviewee also suggested “apart from safety its good idea to conduct campaign to promote usage and benefits of South West Bicycle Corridor since I believe there is lack of awareness among public … maybe” (Male, 43, Malay, Single, non-user).

3. Conclusion

This research provides one of the comprehensive assessments of how Klang valley green network users are perceived and used and what factors affect their use. The results of this study showed that contrary to Kuala Lumpur City Council and public officials’ views, urban green networks are more than a “luxury” and could provide important health, recreational, and leisure activities for Klang Valley people. Therefore, attributes like social and physical safety, accessibility, connectivity, naturalness, cleanliness and maintenance seem to be important dimensions that effect use of urban green network in Klang Valley. Therefore, such deep interest and concern can provide a major opportunity for green network planners, designers, and managers as they strive to create clean, natural, aesthetically pleasing, safe, accessible, and appropriate spaces that improve the quality of life of urban dwellers.

References

Parking lots are probably the most anomalous kind of space in the public realm. They are daily used by all drivers; their visual impact is enormous and yet very little is invested in them. All cities have been modified to improve the massive use of the car [1]; then, why have the parking lots always looked the same? Do they just serve as mere horizontal car storage with no other possible use? If they are just unavoidable places to leave the car in our cities, unappreciated by citizens as a space with no other possible use beyond parking [2], why is so little effort invested in trying to mitigate their impact and make them compatible with other uses that could help to improve the urban environment?

After an exhaustive analysis of several case studies, this paper proposes to transform the car parks into urban forests; forests that provide these "lost" spaces [3] with the capacity to neutralize the pollution created by the vehicles parked there, while improving the condition of this anonymous and uncharacterized lots, their negative perception by citizens and their participation on territorial green infrastructural systems passing through our cities.

If an average car travels 10,000 km a year, it means that produces 1.2 tons of CO2. At the same time, an oak, Quercus ilex, neutralizes 5 tons of CO2 a year (the average value produced by 4 cars) transforming it into oxygen [4]. It seems then that the number of cars and the number of trees in our cities should be more related, using the car parks as air purification drains. But not only: these urban forests also have a key role in improving habitats and contributing to biodiversity [5]. Tree canopies can reduce the peak of heavy rainfalls [6], while the proper use of its materials can help reduce impervious surfaces, fight heat islands, contribute to the control of water runoff and effective groundwater recharge [7] and help rebalancing the air moisture.

Sometimes the simplest actions have the greatest impact on the design of new environments. We propose to move forward new possibilities of understanding urban space and creating networks of small indigenous urban forests; permeable and dynamic spaces where you can toggle different uses depending on the occupation thereof; spaces that can neutralize, through woodland and a forest section, the CO2 produced by a huge number of cars, plus favor and shelter biodiversity enabling a different relationship with nature, not that of confrontation but of complementarity.

The lack of literature regarding parking lots makes this research very innovative and a necessary contribution to contemporary landscape and urban studies. Through very simple
designing actions they become hybrid spaces, active areas and relievers within an urban and ecological framework.

Parking lots; Urban forests; New natures; Anomalous spaces; Urban landscape

1. Statement of intent: “let’s be realistic and ask the impossible.”

This is just one more of the unusual conditions of cities: giving preference to private traffic rather than the public one, private spaces such as parking lots against public space needs. Squares, parks and gardens, sports fields, schools and universities, would already be covered by the traditional norms, but other areas that might be also considered public, have never been considered.

![Graffiti from May 68’s protests](image)

If we could look our cities from the air, we would realize that the space devoted to roads, highways and parking lots clearly stand out in our modern civilization. Since the standardization of the automobile in the early twentieth century, its use has fundamentally changed the architecture of the contemporary city, becoming one of the most important and underrated components of urban life. They have also colonized the different urban scales, from large shopping center parking lots to small interstices. Even knowing that an average car remains parked for almost 90% of its life, no one seems to pay attention to the contradiction of making places occupying a useful space in urban centers, to leave cars there almost all the time. All this means not having a clear objective about the city we want or the environment we need.

It seems difficult to give up cars to lead an urban life. We use them to move in the city and beyond it; we see them from the window of our house in any street we walk on, in any educational or cultural centers and in the shopping malls. Any kind of intervention we can imagine for a parking lot try to pose solutions to the problem with large doses of imagination but do not directly face the problem of constantly increasing cars in our cities. The time has come in which design is not able to solve the problem: How do we eliminate the excess of traffic of private cars in our cities? Applying taxes to those circulating, which would extend inequality in use or mobility as London has done for a long time or making the possibility of using public space to park on the streets more expensive? Freeing public space to collapse all urban mobility?

As urban centers have begun a process of turning their streets to favor pedestrians, restoring the importance the pedestrian over the car, we may have to start by restoring the space occupied by urban forests and the continuity of the ecological networks; a domesticated nature only in its dimensions, but intense and dense in its realization. We have to think that part of the solution is to prevent private parking in urban centers and to convert the surplus parking spaces into places that serve to relearn how to interact with the forest, with the biodiversity that it attracts and with silence and oxygenation of urban environment that are generated by green spaces.

We propose to make a small forest in each parking lot, something that would have to do with the recovery of a memory that cities have never given priority to. Actually the
Biophilic Cities

The foundation of cities has been made into a sustained confrontation to turn away from nature. This fight makes no sense at all today and is a hindrance as much as could be the reptilian brain that we maintain as a legacy of our evolution.

The largest human construction and where the vast majority of people is going to live or are living now, is the city. Its growth is unstoppable and the concentration of economic power and absorption of any raw or processed material is and will be enormous. Now consider how we transport ourselves... Shall we continue driving a one-person private car loaded with refined oil and producing an enormous amount of CO2? Shall we continue to occupy central or peripheral locations in our cities that will be turned into barren and useless spaces for any other use other than storage cars? Is the current idea of partnership between privacy, automobile and mobility the future of the city? The mobility concept still in use in our cities is almost the same as the one that followed the mass production of Ford Ts or back away in Pompeii!

The future is not the past and we urgently need to imagine it. Parking lots and other anomalous areas interests us because they occupy huge and central spaces in cities. The future of urban transportation, which is partly known, could be the use of driverless transportation that is constantly in use and whose ownership would be largely shared. From these possibilities which are already in practice in our cities, the need for parking lots is very debatable because it represents the private use of a system that apparently soon cease to exist.

The city has evolved to impose a different nature to the environment. Therefore we need to recognize that the need for trees and not private cars would look like an inevitable recovery of our pre-urban origin, but also the loss of references that has been brought upon by a sustained confrontation with Nature. Forests instead of paved areas, permeable pavements against the spread of impervious surfaces, trees of different sizes and compatible species, shrub and therefore birds, insects and other animals better than noise and CO2 [8].

The city of the future will have to resolve its expansion and reduce the time it takes to move through it; besides that, there have been since a while ago virtual communication systems much more efficient for air and gas emissions that physical transportation.

2. Ostiense Case Studio

The area of Ostiense-Valco San Paolo is located southwest of the city, bordering with walls in its access by Porta San Paolo. Strategically located in the expansion of the city to the port of Ostia, it has always been the subject of numerous plans and projects where the main focus was to connect the city with the sea. It is the first industrial district of the city of Rome due to rich railway system but also to the navigability of the Tevere. But it is not a typical industrial area because Rome never had an industrial vocation and has never pursued a future as such.

The infrastructures and the voids related to them, the abandoned industrial mono-functional compounds, the strong naturalistic character due to the profuse vegetation in the environs of the river that crosses the whole area from North to South and the disintegrated urban tissue colonized
by numerous parking lots, together with the project of the Roma Tre University to move most of its faculties and schools to this area (a cultural infrastructure) and the project promoted by Prof. Ghio to establish a Diffused Botanical Garden in these faculties, makes of this area a perfect case to understand how a developing sector faces the voids created in their planning stage together with the existing anomalous spaces. The project of the Diffused Botanical Garden is already a very attractive attempt of intermediate scale that gives continuity and attempts to connect the different public areas, enhances the ability of this area to propose this change of the reconstruction of urban forests.

If we focus on the data of the VIII Municipality of Rome, which includes the area of Ostiense and Valco San Paolo, this is an extension of 47.29 km², of which 125.810 m² are devoted to parking, while the green space sums up to 794.045 m², plus more than 2060 m² of archaeological green space and 615.330 m² of large urban parks [9].

3. Urban forests

A forest is a radical solution in the city if we keep thinking in the lines of Thoreau, considering city and forest as opposites; however we want them to begin to understand each other and become complementary, to join the experience of being a citizen and experience the pleasure of our relationship with nature, the ancestral, the virgin (or untouched). We take as inspiration the urban forests created by Afforests and its creator Shubhendu Sharma, that managed to create in just 10 years, small but dense urban indigenous forests with 50-100 kinds of species, stable and maintenance free (after the first three years of care using automatic irrigation) that reduce noise and dust and remove 30 times more CO2 than a monoculture planting like the ones associated with urban parks. Our proposal with this paper is to create a city network of small forests to promote local biodiversity.

The city is an ecosystem with different environments imposed on the natural territory that can shelter new natural ecosystems. In these ecosystems, the use of species adaptable to their bioclimatic conditions can lead to the creation of a broad diffuse botanical garden that colonizes the different urban voids with a clear didactic character.

Thus, parking lots, roundabouts, plots out of regulation or abandoned, become part of an intermediate scale of landscape where to interact with species which are not chosen by belonging to the ecosystem of the city but for its environmental optimization and its pedagogical condition, contributing in an efficient way to a new urban ecology that, starting from interstices, manages to create a new system of a certain size. This new layer within the urban fabric, the system of these derelict spaces, is an opportunity to establish a new and unexpected relation between the city and its voids and between humans and nature: touring through this new system we can understand the relation that the city establishes with his limits and can colonize spaces otherwise abandoned and forgotten, giving them a new function as air purifiers and carbon sinks. This way, unused parking spots, or the combination of few of them, can be turned into microforests becoming a
new element in the imaginary of our streetscapes.

We do not want to offer anything halfway. From the analysis of projects that have worked on this issue on the design side, you can easily deduct that to involve parking spaces in public space is a necessary and vital economic investment, but also an act of voluntarism. Our plan is more drastic. As with depaving we talked about the importance of reducing the impervious surface of our cities in public spaces such as car parks and other uselessly paved surfaces, what we propose here is to return to urban forest the parking lots that are easily relocatable (buried under built surfaces or into specific buildings), bringing nature to the people, continuing the large-scale green networks and neutralizing the pollution that undermines our health and costs of public health services, supplying a pause (this time very meaningful) within the urban tissue. This is about creating a new kind of urban space where the main investment is in its correct implementation and operation, not in its formal spatial design; changing a monofunctional space dedicated to the car for another, different multifunctional one for citizens. These are forests, recreational areas different from the existing urban green spaces; large air purifiers that drain water, which can function as a new spatial category with a significant contribution to public space and urban ecology.

As an enclave it is very favorable: in Ostienese, right next to two large disused industrial areas undergoing conversion and starting from a railway line, which in its linear setbacks it is always accompanied by vegetation. We can then create a natural network based on these corridors linked to the rail tracks to reach almost the Tevere, crossing and continuing to the Rome-Pisa railway line. In Valco San Paolo, where the various offices of the University Roma Tre will be establishing parking areas, we can create a network that goes in the opposite direction, from the river (which in this area has a larger area of influence with several sports fields) to the Via Marconi and the railway line.

Doing a quick calculation, we are proposing to convert the official 125.810m² of asphalt devoted to parking (between public and private car parks) into urban forests; transforming surfaces that disaggregate the urban tissue and impair the urban landscape, into social spaces that redefine the boundaries between built space and the environment, creating a rich and multifunctional ecotone that brings recreation to its inhabitants, a new concept of urban ecology and green continuity.

We understand the difficulty of parking in a city like Rome, where the scarcity of public funds makes it difficult to take a new action plan on these divisive spaces. But we also understand that it is in this enclave where it becomes necessary to reduce the metal invasion that is suffered by its streets. In Rome there are 2.8 million vehicles (700,000 are scooters and motorcycles) that "parked" next to each other, would occupy just over 26km². This amounts to almost twice the size of the historic center of Rome itself (15km², ranging from the Aurelian walls) or 32 times the area of the Villa Borghese. The average vehicle per thousand inhabitants (736) is outstanding in comparison with those of other European cities such as Amsterdam (324), Barcelona (386), Lisbon (400) or Milan (513); Italy
maintains one of the highest rates of motorization in Europe with 61 cars per 100 inhabitants, surpassed only by Luxembourg with 65, it falls far short of the 41 of the Danish [10]. This data translates into a totally invaded city, where any void or road widening results in the birth of new spontaneous parking. A poor transportation system, a late system of regulation for parking (until the late 80s there was no official regulation, while in cities like London, the problem was faced in the early 70s) and difficulties for the construction of underground car parks or buildings designated for storing cars, makes the case for almost all the parking to be done on the surface, with a consequential high land use (just in the center of Rome alone 2.011.255 m² are dedicated to parking). The lack of protection by the administration makes, as in the case of Ostiense, some areas designated for parking, of questionable quality, allocating the residual areas from other actions by simply drawing stalls on the asphalt, with no trees, no green space, and no shade. The consequences of a wild, free parking on the protection of the streetscape and traffic flow are immediate [11].

But more important than these numbers is the function of cleaning the air that these spaces could provide. If an average car travels 10,000 km a year, it means that produces 1.2 tons of CO₂. At the same time, an oak, *Quercus ilex*, neutralizes 5 tons of CO₂ a year (the average value produced by 4 cars) transforming it into oxygen [13]. It seems that the number of cars and the number of trees should be more closely related in our cities, using the reconverted parking spaces into forests as centers for air purification, in order to alleviate the high levels of pollution caused by the high motorization of our cities. But not only this: these urban forests also play a key role in improving habitats and contributing to biodiversity. Tree vegetation also helps control torrential rains during its peaks, while the use of permeable materials would help control water runoff, favor percolation of rainwater in aquifers, combat heat islands and help rebalance air moisture [14].

4. Conclusions

Sometimes the simplest actions have the greatest impact on the design of new environments. We propose to move forward new possibilities of understanding urban space and creating networks of small native or foreign urban forests; permeable and dynamic spaces where you can toggle different uses depending on the occupation thereof; spaces that can neutralize, through woodland and a forest section (large trees, medium trees, shrubs, underbrush, etc.), the CO₂ produced by a huge number of cars, plus favor and shelter biodiversity enabling a different relationship with nature, not that of confrontation but of complementarity.

We know we are bordering on a paradox, a utopia. We are launching into the immediate future a proposal that does not accept that the solution is to whitewash forgotten spaces of the city through huge investments needed for other social issues. We think that we have to undo some things before superimposing new actions and constructions. To undo few of those things that were done wrong is the goal, to discover new possibilities in the use of cities, to bring a memory lost to the urban context, to improve the quality of life in the city.

Investigating the Usability Pattern of Pocket Parks in Kuala Lumpur

Praveena, B. a,b & Sreetheran, M. a*

*aFaculty of Design and Architecture, Universiti Putra Malaysia (UPM), Serdang, Malaysia
bForest Research Institute Malaysia (FRIM), Kepong, Malaysia

Abstract

Research has proven that urban green spaces are beneficial to support healthy lifestyle. However densification among larger cities including Kuala Lumpur has resulted in the conversion of open spaces to pave way for development; limiting the access to green spaces for human activity, restoration and recreation. Small public urban green spaces or pocket parks have been introduced in dense city areas to contribute to the need for outdoor activities, yet research on these parks is limited. Therefore, there is a need to investigate the usability pattern of pocket parks to facilitate the park usage in Kuala Lumpur. The purpose of this study is to understand the usability pattern (how) of pocket parks (what) to improve the park usage among urbanites in Kuala Lumpur (who). Although the nature of this research is predominantly qualitative, it is conducted through intense contact in the real urban parks in Kuala Lumpur. Observation and interview will be used to document the park visitors. Then, it uses literature review on urban green spaces in Kuala Lumpur as well as observation to provide an overview of the pocket parks and describe how the parks are used by the urbanites. Finally, it uses survey data supported by semi-structured interview to identify the usability pattern and features of pocket parks that facilitate usage among the urbanites. Results of the study would include theory of pocket park users in Kuala Lumpur and theory on the characteristics of pocket parks in Kuala Lumpur and its usage. The results are expected to lead towards recommendations of parks features that promote usage in Kuala Lumpur. This study contributes in identifying the pocket parks usability pattern and recommendation of park features that promote usage in Kuala Lumpur. It will support the requirement of more small urban green spaces in the city of Kuala Lumpur and to the inclusion of pocket parks in the urban planning and management in Malaysia.

Keywords: urban environment; small public urban green spaces; park usage; Malaysia
1. Introduction

The acceleration of developments in Kuala Lumpur has reduced the amount of total green spaces in the city (Malaysian Economic Transformation Programme—ETP Annual Report, 2014). According to the report, Kuala Lumpur recorded 8.5m² green spaces per capita in 2014 in comparison with 13m² of green space per capita in 2010.

In a study to address the importance of urban nature for citizen’s well-being and for the sustainability of the city they inhabit, Cheisura, A., (2004) concluded that the experience of nature in urban environment is a source of positive feelings and beneficial services which fulfill important immaterial and non-consumptive human needs.

Small urban green spaces or pocket parks were introduced to provide facilities for recreation, reset and relaxation to all citizens in every walk of life (Seymour Jr, W. N., 1969). Recent studies have documented the benefit of pocket parks for restoration (Nordh et al., 2009; Nordh, 2011; Nordh and Ostby, 2013, Peschardt & Stigsdotter, 2013 and Peschardt K.K., 2016), physical activities (Cohen, 2014) and socialising as well as rest and restitution (Peschardt et al., 2012 and Peschardt et al., 2016). Jasmani, Ravn & van den Bosch (2016) also concluded that small urban parks characteristics have influence on bird diversity. This study highlighted the characteristics of small urban parks and their potential to support urban biodiversity and ecological function. They concluded that human activities and park surroundings have a marginal effect on the presence of bird species in small parks. However, Zube, E.H. and Moore, G.T. (1987), concluded that over the past decade, open spaces such as public and neighborhood parks, playgrounds malls and plazas have attracted considerable research attention; with public parks as the most frequently studied open spaces with less focus on pocket parks. This is supported by Peschardt K.K., Schipperjin, J. & Stigsdotter, U.K. (2012) that research on small public urban green spaces or pocket parks are still limited.

According to Hoyle, H. et al., (2017), if public green infrastructure is to be designed and managed optimally, the complex relationship between aesthetic experience, restorative effect and well-being, and perceived and actual biodiversity in relation to varying ‘natural’ environments need to be understood. Ibrahim, Md Dali & Che Haron (2016) also stated the issues and problem in managing open spaces in Peninsular Malaysia. The study highlighted the problems faced by local authorities in the management of open spaces in their area of administration. It further suggests that extra attention needs to be given to the aspect of management to ensure the sustainability of open spaces. As leisure research have only been concerned with why and how people make choices regarding the free time and recreation, more research were required on the barriers to recreational participation to give insight into life and leisure satisfaction (Henderson et al, 1988). Their study to document the relationship between barriers to recreation and gender-role personality traits for women identified 10 recreational barrier factors for women which include;
time, money, facilities, family concern, unawareness, lack of interest, decision-masking, body image, skills and social appropriateness. The time people need to reach a public park also influences the accessibility of the park (Breuste and Rahimi, 2015).

In the study on the components of small urban parks that can predict the possibility for restoration, Nordh et al (2009) documented percentage of ground surface cover by grass, the amount of trees and bushes visible from the given view point and park size as most preferred features of the pocket parks. Whereas, more green cover and enclosed green niches are important for rest and restitution according to Peschardt et al (2014). Her study also concluded that the presence of green features are not crucial for socialising while playground and view outside the park were identified as disturbing features. Nordh et al (2009) and Peschardt et al (2012) have outlined the following description of pocket parks which include; small green space between 3000-5000m² in size, well defined area, have its own entrance and distinguishable boundaries which separate the parks from surrounding public space, have at least some vegetation, places to sit, included public spaces but exclude all private, enclosed residential parks, playgrounds and parks that belong to café or restaurants. Pocket parks are usually only a few house lots in size or smaller and can be found scattered throughout the city to contribute effectively to city life (Blake A., 2017). She described these pocket parks as easier to create than maintained without functional design, community support, use and maintenance.

Grahn and Stigsdotter, 2010, identified the following eight park characteristics to classify nature characteristics of urban environment, including; ‘serene’ (e.g. silent and calm), ‘space’ (e.g. spacious and free), ‘nature’ (e.g. wild and untouched), ‘rich in species’ (e.g. several animals and plants), ‘refuge’ (e.g. safe, benches and play equipment), ‘culture’ (e.g. decorated with fountains and ornamental plants), ‘prospect’ (e.g. flat and well-cut grass surfaces and vistas) and ‘social’ (e.g. entertainment and restaurants). Whereas in their study to address the associations between park characteristics and perceived restorativeness of small public urban green spaces, Peschardt and Stigsdotter (2013) characterised their sample pocket parks into the following subgroups; ‘Geometric design’ characterised by a geometrical landscaped design; ‘South European Square’, characterised by a hardscape surface and a few trees; ‘Multi-characteristic’, an area with several functions (e.g. seating, playground, café); ‘Café/history’, characterised by a café area and a historical context and finally; ‘Traffic’, closely connected to a road with heavy traffic.

Kuala Lumpur is the major administrative centre of Malaysia. As a major urban centre in Southeast Asia, it is a perfect place to live, to conduct business and as a major tourist destination (Kozlowski M. et al., 2015). Their study on the performance of public spaces in Kuala Lumpur in terms of tropical climate concluded that a majority of public spaces in the region are not pedestrian friendly and do not reflect the tropical climate, being devoid of trees and
vegetation. According to Cheisura, A (2004), less attention is being paid to the type of nature close to where people live and work, to small-scale green areas in cities and to their benefits to the people. Her study addressed the importance of urban nature for citizens’ well-being and for the sustainability of the city they inhabit through a survey conducted among visitors of an urban park in Amsterdam. While, a different research has indicated that lunchtime park walks and relaxation exercises contributes to higher levels of well-being among employees at the end of a working day (de Bloom, 2017).

The need for adequate landscape spaces for recreation and social interaction among the multi-cultural society in Malaysia has been identified as part of the focus of the National Landscape Policy in Malaysia (2011). Under the National Key Economic Areas (NKEAs), the establishment of iconic places and attractions was listed as part of the goal for Greater Kuala Lumpur/Klang Valley. This includes the preservation and redevelopment of the existing heritage sites in Kuala Lumpur and connecting the sites through heritage trails master plan. Small urban green spaces and iconic monuments in Kuala Lumpur are included as part of this trail and has been redeveloped in line with the aspiration for Kuala Lumpur as a ‘Liveable City’ (ETP Annual Report, 2014).

This paper explored the usability pattern of three (3) selected pocket parks in Kuala Lumpur by studying the characteristic of these pocket parks and the motivations to visit these parks. It will determine the use and user patterns in the selected pocket parks and the factors affecting the use of these parks to enhance the use by the residents of Kuala Lumpur (e.g. Owen et al., 2004), as well as in studies on the use of urban green space (Schipperijn, 2010). This theoretical approach will be applied as a framework for analysing and understanding the behavioural use of pocket parks. Behaviour in this study is broadly defined as any sort of visit to pocket parks, mode of transport, length of stay, frequency of use and timing of visits. This study also intends to identify the constraints faced by the community in using the pocket parks.

2. Methodology

2.1. Site selection

This study was conducted at three (3) pocket parks in Kuala Lumpur selected based on the following characteristics; no more than ¼ of an acre; located in an urban area surrounded by commercial buildings or houses on small lots; few places for people to gather, relax, or to enjoy the outdoors (National Recreation and Park Association, 2017). The parks are selected from the lists of pocket parks provided by the City Hall of Kuala Lumpur (Fig. 1). The selected pocket parks are as following and presented in Table 1;

i. 2020 Countdown Clock;
ii. Old Market Square (Medan Pasar); and
iii. Laman Sultan Ismail.
Table 1: Details of the selected pocket parks and observed features. Park categories are adapted from Peschardt and Stigsdotter (2013)

The 2020 Countdown Clock is the latest modern landmark in Kuala Lumpur that was officially opened to the public on 15 April 2017 (mStar Online, 2017). This landmark is located at Merdeka Square and it encompasses of a sheltered plaza area, water feature, the digital clock and well-maintained landscape.

The Old Market Square or Medan Pasar is one of the oldest and historically memorable locations in Kuala Lumpur. Medan Pasar is now one of the most important public transportation hubs in Kuala Lumpur (Star Online, 2007).
2.2. Population and sampling

The subject of the study were the park users, both male and female composed of residents, visitors or working community and non-users in the radius of <600m of the selected pocket parks (Schipperjin, J. et al., 2010). Random sampling method were used to select the survey respondents and they are not limited to the three main ethnic groups in Malaysia (Sreetheran, M., 2017). The inclusion of local and international park users will reflect the true preferences and preferred activities in the pocket parks in Kuala Lumpur. The respondents are selected between the ages of 18 to 60 (SD>30). The survey was conducted at the study sites inside and outside the selected pocket parks in Kuala Lumpur. Attempt was made to reach as many park and non-park users randomly within the designated radius.

2.3 Study method

A mixed-mode of research techniques which include observation, survey analysis or questionnaires and semi-structured face-to-face interview were conducted simultaneously to gather qualitative and quantitative responses. According to Creswell (2007), qualitative research has become more accepted as a legitimate mode of inquiry in the social behavioural and health sciences than it was in the 1990s.

1. Observation

According to Yin (2011), observation is a form of primary data to be highly cherished. It is an invaluable way of collection data because it gathers data that the researcher sees with own eyes and perceive with own sense. During observations of the park users, most often through participant observation, the park characteristics, user behaviour, park usage and the preferred activities were observed and described. Pictures were also taken to document the observation. The description of the physical setting including the ground surface cover by grass, the amount of trees and bushes visible from the given view point, walkway, benches and park size were also be recorded. The components of the selected parks and the observations were recorded from January to March 2018 on random days during the weekdays and during the weekends (Sreetheran, M., 2017); including information such as the time, place and date of the field setting where the observation took place (Creswell, 2008).

2. Questionnaire

According to Zikmund (2003), a good questionnaire should satisfy two criteria—relevance and accuracy. Therefore, to meet the relevance and accuracy criteria, this questionnaire is divided into 4 sections; Section A: Personal Information; Section B: Behavioural use of pocket parks; Section C: The relationship between aesthetic experience, restorative effect and well-being; and Section D: Park use constraint and recommendation. The questions were modified from Nordh et al (2009), Grahn and Stigsdotter (2010) and Peschardt and Stigsdotter (2013) and developed in both English and Malay (national language). The questionnaires were distributed on-site by the researcher to obtain the first-hand experience with the park users. The
respondents were requested to complete on-site survey during the visit (Peschardt, K.K., Schipperijn, J. & Stigsdotter, U.K., 2012) or interviewer-completed survey (Sreetheran, M., 2017) at the selected site. The respondents were also required to describe how they use the park (Nordh, H. & Ostby, K., 2013) and their perception of park components that facilitate the park use. The quantitative data were analysed using SPSS Statistics Version 20. As for the questions, a pilot study was conducted to ascertain the reliability.

3. Semi-structured interview

To cater to the qualitative data, semi-structured face-to-face interviews that last between 20 and 30 min were conducted. The interviews were recorded in a note book for further references. Prior to the survey and interview sessions, the respondents will be briefed about the aim of the study and the structure of the survey or interview process. The interviews will be conducted in either English or Malay based on the interviewee’s preference.

3. Results and Discussion

1. Respondents profile

A large number of the respondents are in the age group of 18-30 (48.5%) followed by the 31-45 age group (42.4%); with only 3 respondents between 46-60 years old. 60.6% of the respondents are male while 39.4% are female respondents who were mostly government and private sector employees each comprising of 27.3%, followed by students, self-employed and retirees. The sample has a balance of Malaysian and Non-Malaysian respondents (Table 2), (57.6% to 42.4%); mostly residents in the Klang Valley and tourists visiting Kuala Lumpur for a short period. The majority of the respondents (60.6%) are single while 36.3% are married and one widower.

2. Behavioural use of Pocket Parks

As seen in Table 3, ‘to relax and reduce stress’ (29%) and ‘to meet others’ are the majority of response received for the pocket parks usage in Kuala Lumpur among the other components. This finding supports the claim on the two health promoting uses of pocket parks by Peschardt et al (2014); i.e. ‘rest and restitution’ and ‘socialising’. The other responses were for ‘to escape from the city’, ‘to get artistic inspiration’ and ‘to take a shortcut’. Other than the given component, seven responses (11.3%) were received for the preferences on ‘parks suitable for outing with family, especially children during weekend’. Three response was received each for ‘easiest access to nature’, to listen an observe nature’ and ‘for lunch break walks’ while only two response was submitted for ‘to contemplate and meditate’.

In response to the question on ‘How often do you visit the pocket parks?’, 42.4% of the respondents mentioned that they visit the parks sometimes, and 18.2% often. 39.4% of the respondents never visit the pockets parks and this may support the park usage preferences where the requirement for green space that may cater for family activities especially parks suitable for children are more prominent. A large number of respondents (42.4%) get to these parks and the surrounding area by foot; 21.2% by car; 15.2% by bus and 12.1% by bike. Only two respondents mentioned getting there by train. The respondents prefer to visit during weekends in the evening (72.8%) while 12.1% of response was received for visiting the parks in the morning and afternoon. Only one respondent preferred weekdays. 39.4% to 30.3% of the respondents answered spending ‘about an hour’ and half an hour’ in the parks. 12.1% and 9.1% of response were received for spending ‘about 15 minutes’ and ‘less than 5 minutes’ at the park. Only two respondents selected ‘more than a couple of hours’ at the parks.

3. The relationship between aesthetic experience, restorative effect and well-being

According to Fig. 3, for most respondents, visiting the pockets parks generally elicited calm and happiness. Eight other claimed freedom, six respondents felt safe and four respondents agreed with ‘unity with nature’. There was one response for ‘adventure’ and two for ‘unity with myself’ and others. When asked why, among the statements that were received for the relationship between aesthetic experience and well-being, respondents claimed that ‘relaxation is very important to release tension and stress’, ‘mental health is the foundation of a happy life’ and ‘the environment makes me relax and reduce stress’ among others.
A large number of respondents (n=13) reported selecting ‘culture’ which is characterised by the presence of fountains and ornamental plants as their preferred park characteristics. ‘Serene’ characterised by silent and calm environment was the second most frequently mentioned. ‘Nature’ and ‘Refuge’ received a balanced proportion in terms of preferred park characteristics. ‘Rich in species’, ‘Social’ and ‘Space’ (10.6%, 7.6% and 4.5%) were the other selected components. ‘Prospect’ that represents flat and well-cut grass surfaces and vistas were the least preferred park characteristics (Fig. 4). ‘Nature’ represents a wild and untouched environment; ‘Refuge’ for safer parks with benches and play area; ‘Social’ for parks with entertainment and restaurants; and ‘Space’ for a spacious and free environment.

Table 4. Do you feel safe at this park?

</tbody>
</table>

57.6% respondents claimed to visit the parks once a month or less while the remaining 42.4% visits several times a month or more. ‘Time’ or being too busy, ‘Lack of accessibility’, ‘Heat’ and Poor hygiene of other park users’ were the most mentioned constraints in using pocket parks, while ‘No companion’, ‘Feel afraid in forest or other natural setting’ and ‘Poor park management’ were the least mentioned constraints. It is interesting to note that two respondents claimed to not know about the availability or the existence of the selected parks (Fig. 5). This finding could relate with the claim by Saw et al (2015) that the relationship between natural park usage and happiness does not hold in a tropical city-state compared to temperate countries.
The sample has balance between response submitted on the availability of pocket parks in Kuala Lumpur. 54.5% to 45.5% agreed to not having enough pocket parks in Kuala Lumpur. However, there was an overwhelming preference (75.8%) for more improvement to the available parks; especially in the aspect of cleanliness; facilities such as benches, restrooms, play area and more greeneries. Several respondents suggested the need to improve the safety aspect of the park by installing surveillance camera.

The study suggests that accessibility, cleanliness and park maintenance, safety, activities in the park, and the surrounding environment influence user and non-users decisions to visit the park. There also seems to be a difference in the perception and use of pocket parks in Kuala Lumpur compared to temperate regions in terms of ‘heat’ and ‘cleanliness’.

This study also points out that respondents preferred park activities that include passive socializing activities such as relaxing as well as socialising or meeting other. It has generated knowledge on how we can design the pocket parks in Kuala Lumpur. Parks characterised by the presence of fountains and ornamental plants as well as a silent and calm environment were the most preferred settings.

The study supports the requirement of more small urban green spaces or pocket parks in the city of Kuala Lumpur and to the inclusion of pocket parks in the urban planning and management in Malaysia. However the effectiveness of these parks is mostly dependent upon prioritised activities and the commitment to maintain the parks.

Abstract

The global rapid urbanization has had significant impacts on the environmental quality. As with many other countries, Malaysia has not been spared from this issue. The unprecedented urban growth has occurred at the expense of many green spaces and vegetation which promote ecosystem and human health. Urban riparian is one of the greenery commonly unaffected by the urban expansion. It has vital ecosystem functions, including maintaining the river water quality, conserving the biodiversity, and stabilizing the river banks. As such, creating a conducive urban riparian zone becomes an important strategy to promote the development of biophilic cities. This study, therefore, aimed to determine the potential functions of the urban riparian to the adjacent occupants by adopting the biophilic design approaches. To achieve the objective, two forms of river reserves were investigated by comparing a vacant riparian area in its natural condition with a riparian area that has been upgraded into a fully-utilized green space. The study observed a lack of spatial integration between the green space and the built-up area in the neglected and unmanaged riparian. On the contrary, the upgraded riparian area was more popular among the public, demonstrating a positive sense of connection between the people and the site. Moreover, the upgraded area was shown to have a lower thermal condition and a better ventilation, hence having the potential to improve the living conditions of the developed area. In conclusion, the study established that there are multiple functions of the urban riparian, especially after implementing the biophilic design approaches within the area.

Keywords: urban riparian; green infrastructure; biophilic design pattern

1. Introduction

The global rapid urbanization has had significant impacts on the environmental quality. As with many other developing countries, Malaysia has not been spared from this issue. The unprecedented urban growth has occurred at the expense of many green spaces and vegetation [1] which promote ecosystem and human health. Urban riparian is one of the greenery that could survive in the urban areas [2]. Despite being an informal urban green space [3], the urban riparian area is an important component of the green infrastructure which maintains the ecosystem services from which humans gain benefits [4]. As such, creating a conducive urban riparian zone is important in promoting the
concept of biophilia and developing a biophilic city.

Biophilia theory has been demonstrated by previous studies whereby people remain strongly attached to the surrounding regardless of whether the environment is in its natural condition [5] or surrounded by the fabricated and urbanized area [6]. The theory also supports the notion that humans require healthy spaces to maintain their physical and mental well-being [7, 8]. A separated or disaggregated environment would cause an ineffective human functioning [9]. Therefore, it is vital to integrate the urban settings with its natural surroundings.

Application of the biophilic design offers a sustainable design strategy that seeks to reconnect people with the natural environment [10]. It has been proven by a case study in the Asian city [11] that a biophilic-inspired landscaping is feasible even in a tropical climate. Furthermore, a successful biophilic design does not only introduce vegetation to the built environment [8] but also regenerate the natural systems in the city as a whole [11]. Increasing the urban greenery coverage is, thus, an important initial step to implement the idea of biophilia in the urban development.

The urban riparian in Malaysia has been discovered to play vital roles in the ecosystem, including maintaining the river water quality, conserving the biodiversity, and stabilizing the river banks [12, 13]. Nevertheless, studies have shown that throughout the land use transformation, urban riparian has been used as the buffer strip with its restricted conditions [14] and available guidelines have been used in isolation [15, 16], both resulting in the mismanagement of this reserved greenery.

In essence, it is crucial to create and acknowledge the urban riparian as a green space [17] to achieve and maximize their potential functions [18]. It is also fundamental to explore and understand the natural ecosystem services [19] provided by the urban riparian which benefit humans and other living organisms. Instead of focusing on the in-situ and the directional relationship [20]; where the benefits are either realized in the same area or in a specific location due to the directional flow (Appendix A), it is possible to generate an omnidirectional relationship [20] which would provide advanced benefits [4] to the surrounding and the people. With this insight, this study intends to explore the potential functions of urban riparian to the adjacent occupants by adopting the biophilic design approaches.

2. Site Description

A poor planning by the government and the other authorities could result in a failure to preserve the urban riparian areas [21, 22]. To conduct the study, an overview of the
urban riparian condition was first acquired. Among the many rivers in Malaysia, Sungai Melana located in the Johor Bahru district was selected for this study due to its unique conditions.

Bound by the same river, the selected site has two different urban riparian settings. As illustrated in Figure 1 and Figure 2, the north-east river bank has an undeveloped river reserve with wild vegetation, while the south-west river bank has been developed into a neighborhood green area which is accessible to the locals. In this study, the urban riparian area which has been transformed into a park is labeled as Site A, whereas the undeveloped vacant urban riparian is labeled as Site B. In addition, the housing area located adjacent to the river has been properly developed without any illegal squatter. The riparian area is easily accessible, indicating its potential advanced functions for the adjacent occupants.

3. Methods

In investigating the urban riparian and its surrounding condition, direct observations and field measurements were employed on-site. An overview of the greenery coverage was first observed via the satellite imagery and then further evaluated on-site.

Fig. 2. A view of the River Melana showing the varied types of urban riparian.
varied formations of urban riparian [28], and; (iv) identification of the 14-biophilic design patterns [29, 30] for each site (Appendix B).

The potential functions of the urban riparian for the adjacent residents vary with its physical and spatial condition. Therefore, the 14 indicators of the biophilic design patterns were used to guide the development of the urban riparian space to increase the living conditions of the nearby residential area. Furthermore, the thermal environment and accessibility were evaluated in this study due to their important role in the use of a green space [31]. All the observations and measurements were completed during good weather with the study being conducted from 8 am to 6 pm. The outcome of each technique was recorded and further analyzed accordingly.

4. Results and Discussion

Based on the overall view, the urban riparian is designated as a vegetative boundary which divides the rivers and its adjacent development. Furthermore, the green infrastructure classification for all zones is limited to only tree canopy and green open spaces. None of the buildings in the zones can be categorized as the ‘greenery on structure’. In addition, the aquatic system typologies are missing due to the excessive modification of the urban channel despite it being a river area. Such phenomenon could be due to the old housing development scheme and the properties of the channel itself, such as soil condition, water flow, and water level. To expand the green infrastructure classification, it is possible to introduce the non-invasive aquatic plants which could increase the biodiversity and improve the water quality and the thermal condition. Additionally, promoting the use of vertical greenery among the residents could potentially improve the aesthetic appeal of their living environment.

Figure 3 shows that Site A has a better connection as compared to Site B. The residents in Site A could use the upgraded urban riparian because it is easily accessible and proper pedestrian ways have been designed to facilitate the connection between Zone A1 and A2. As for Site B, despite Zone B1 being a preserved environment protecting the river and the vegetation itself, the obstructing formation of the greenery has impeded any possible engagement with the adjacent occupants. In fact, the restricted public access to this reserved area has been intentional to ensure public safety and prevent any unlawful act to the river. Nevertheless, with minimal maintenance and reconstruction, the surrounding area of Site B can be improved to benefit the adjacent residents.

Table 2. Inventory of biophilic design pattern based on site
Appendix C portrays the results of the thermal investigation. The diagram illustrates the proportions of greenery of both sites in the form of tree canopy and vegetated surfaces. Site B, which is mostly covered with wild vegetation shows a higher thermal condition as compared to Site A with several designated rows of canopy trees. The location of the canopy trees allows more area to be shaded which could explain the lower temperature noted in Site A. Meanwhile, the unmaintained vegetated surfaces and tree canopy have caused less wind movement in Site B, whereas a higher wind velocity is noted in Site A.

The findings associated with the biophilic design pattern have been categorized into the nature in the space, natural analogues, and nature of the space. The results have been summarized into an inventory as shown in Table 2. Based on the inventory, the upgraded riparian (Zone A1) of Melana River has satisfied all the characteristics of the biophilic design pattern.

Firstly, in terms of the ‘visual connection with nature’, Zone A1 has fulfilled the indicators, implying that it provides views of nature which reduce stress and cultivate positive emotion. On the other hand, the vacant riparian (Zone B1) has not been well-maintained, causing the unpleasant feelings among the visitors.

Moreover, Zone A1 has satisfied the characteristics of the ‘non-visual connection with nature’ and the ‘non-rhythmic sensory stimuli’. These sensory stimuli could generate a positive effect on the physical and mental well-being of the residents. With regards to the ‘thermal and airflow variability’, the results from Appendix C show that the upgraded riparian provides a more comfortable thermal condition (30.44–31.88°C) in comparison to the vacant
riparian with a higher temperature (33.47–33.53°C).

In addition, the upgraded riparian (Zone A1) dominates in terms of the natural analogues and the nature of the space in comparison to the other zoning areas. This finding is due to the physical environment of the park, such as the playground, gazebo, and the pedestrian ways which have been designed to facilitate the recreational activities that can be done in the natural environment by the residents. Moreover, the proper management of the upgraded riparian allows the users of the park to experience freedom (prospect) and feel safe (refuge) while exploring the space within Zone A1.

In summary, each design within the upgraded riparian zone has caused a positive cognitive and psychological impact on the residents who live around the Melana River. On the other hand, the greenery area of the vacant riparian has shown less impact towards a good livability of the residence, especially in promoting the residents’ health. The findings of this study have provided a new insight into the importance of proper design, planning, and management of the urban riparian in increasing the wellness of the urban residents.

5. Conclusions

Based on the findings, it can be established that the issues of isolation and mismanagement of the urban riparian can be gradually overcome by adopting the biophilic approaches. As there is an instinctive bond between human beings and other living systems, the potential functions of an urban riparian can be maximized especially after implementing the biophilic design approaches. A locally appropriate and well-managed urban riparian along with a responsive strategy would create a better integration which benefits both the terrestrial and the aquatic living environments. Furthermore, the application of biophilic design would improve the living conditions of the residential areas surrounding the river development. It is, therefore, crucial, to comprehensively explore the relationship between urban riparian and its surrounding landscape without any directional bias.

Landscape Design As A Tool to Revitalize Biophilic Features Of A Degraded City Environment, Case Study: Old Dhaka, Bangladesh

Rehnuma M a, Quaium M F A b

a Manifa Rehnuma, Military Institute of Science and Technology (MIST), Mirpur Cantonment, Dhaka-1216, Bangladesh, People's Republic of Bangladesh
b Md. Fuad Abdul Quaium, Bangladesh University, Mohammadpur, Dhaka-1207, Bangladesh, People's Republic of Bangladesh

Abstract

Dhaka once a ‘Garden City’ to the British planners is now going through an irreversible transformation of landscape and mindscape. The uncontrolled urban sprawl is encroaching the greeneries in the city faster than any other time before. On the verge of this catastrophic future, Dhaka South City Corporation (DSCC) initiated to revitalize 31 parks and playgrounds to reclaim the lost public green spaces of South Dhaka, which is the older part of the city. Among these parks and playgrounds, this paper aims to represent two case studies- “Shahid Smritinagar Mini Stadium Field” and “Bakshibazar Park”. Each case study has its own unique set of challenges. Careful landscape analysis was done to get a perception of inherent contextual forces: both positives and negatives. Shahid Smritinagar Field is situated in a dense shanty residential area of Old Dhaka; part of which are occupied with informal plastic factories. The plastic fumes imposes health hazard to the surrounding neighborhoods. On the other hand the undulating play field becomes a wetland during heavy downpour; as a result intended daily activities come to an abrupt halt. Proposed landscape design took an attempt to deal with these two major issues through ecosystem based solutions while providing regular civic, recreational facilities for different user groups. Heavy native plantation like bamboo (Bambusa balcooa) is proposed for high degree of carbon sequestration. Nageshwarchapa, Ashoka, Kadamba, Shimul and myriads other native plants has been recommended to enhance nectarivore and fructivore biodiversity like- bees, butterflies, birds and bats. The stagnant water is partially directed to recharge ground water through new soakable drainage network. The second case study “Bakshi Bazar Park” is a left over space behind Nagar Shastho Kendra in the institutional zone of Bakshibazar. An abuse of spatial use occurred due to Illegal rickshaw and van parking activities. To bring positive changes, the left over space is proposed as an arboretum with lily ponds. Daily jogging trail and redesigned health complex are part of the future design. The place can become a pocket park for neighborhood recreation and relaxation. Landscape design scheme is attempted as an effective tool for humanizing urban ecology embedded in locality. In this paper it is thoroughly discussed how and what steps have been instigated to give nature back to the deserving residents of Old Dhaka.

Keywords: Ecosystem Based Design; Revitalization; Biodiversity; Urban Green Space; Biophilic
1. Introduction

The British town planners once identified the potential of Dhaka, the capital of Bangladesh as Garden City (Islam, Ahmed 2010). By the onset of new millennia, the city has lost much of its environmental legacy and has chosen the congested concrete structures over nature preservation. Nilufar (1999) in her study on open spaces of Dhaka city, shows that, the total amount of open space is about 17 - 18% of city area, which includes - roads, footpaths, parks, playgrounds, tracts, lakes, ponds etc. She also depicted that the open space to population ratio of Dhaka City Corporation, is only 0.12 acres per every thousands of inhabitants. ‘Draft Dhaka Structure Plan Report 2016-2035’, states current ratio of recreational area in Dhaka is 0.07 acre/1000 people.

The Local Government (City Corporation) Amendment Act (2011) divided DCC as Dhaka South City Corporation (DSCC) and Dhaka North City Corporation (DNCC) on 4 December 2011. (Ahmed, Hasan, & Maniruzzaman, 2014, c. f. Ahmed B, 2012). Upon realizing the current and future city-wide environmental crises, the current Government has taken multiple initiatives to improve the spatial quality of city life. The pro-active Mayors of Dhaka North and Dhaka South City Corporation have played pivotal roles in materializing such visions albeit struggling against different vested groups. Revitalizing the parks of Dhaka South City Corporation (DSCC) is one of such initiatives to put a stop to the encroachment and illegal activities in the parks and reclaim the public right by bring back nature to the city.

DSCC invited different consultants for the proposal. The consortium comprised of Shatotto and JPZ JV, headed by Ar. Rafiq Azam, was finally chosen as the project consultant among six short listed firms. Ar. Rafiq Azam invited two other finalists and interested young architects and landscape architects to join in this grand design process for reviving 19 parks and 12 playgrounds (Fig 1) within Dhaka South City Corporation. A thorough study was carried out to understand the associated socio-political and environmental issues at respective project sites. The city dwellers aspired the improvisation which will reform social activities in the locality along with bringing positive shifts in the three dimensional spaces.

Fig. 1

This paper aims to review the design initiatives taken by GHORAMI.JON and And ORDEN under Shatotto & JPZ JV consortium with a focus on design measures adopted to enhance the environmental qualities rather than social reformations in two of the local playgrounds and parks - 'Shahid Smritinagar Mini Stadium Field' and 'Bakshibazar Park'.

Footnote 1: Shatotto Architects, The awardee of the projects

2. Shahid Smritinagar Mini Stadium Field

Dhaka South City Corporation consists of 57 wards. Shahid Sritinagar Mini stadium Field is situated in ward 25, zone 3 (Fig 1), with an area of 0.99 acre. This playground is sitting in a 5 minute walking distance from the Lalbagh Fort (dated back to Mughal era) apparently connected through the labyrinth of alleys.

Fig. 2.
2.1 Existing Condition:

Situated in a characteristic dense mixed-use area of Old Dhaka, the Shahid Smriti Nagar play field was once Islambagh Eidgah (An open-air enclosure reserved for Eid Salah or prayer offered in the morning of Eid al-Fitr and Eid al-Adha). In the existing condition there’s a community hall with abandoned shops underneath at north of the field. On the southern side of the community hall there’s a gallery of uneven height to facilitate the viewer during tournaments. The structure obscures the open field from the eyes of the passerby. Fig 3 (site location)

Fig. 3.

Footnote 2: Website of Center for Urban Studies and Dhaka
Footnote 3: GHORAMI.JON and AND ORDEN consortium
GJAO

2.1.1 Land Use:

A large residential area predominantly resided by lower income group dwellers. The plots around the field are uneven in their profiles owing to the organic growth pattern and demonstrate mostly unauthorized proliferated multi-storied built forms. The western edge of the field is flanked by low-height makeshift structures that are illegally used as plastic factories which release detrimental fumes and odor.

2.1.2 Vegetation and Hydrology:

Though being a playfield, there is hardly any tree or plantation or even grass patch in the field (Fig 4).

Fig. 4

There are elevation changes up to as much as 1.5m (Fig 5) in the form of depressions which turn the ground into a wetland during the rainy season. It accommodates the runoffs from the surroundings and streets. The playfield lacks any decent facility for storm water drainage.

2.1.3 Geology:

The site is situated close to Buriganga River. The soil is the old natural levee deposit by Buriganga (geologically older deposits) on the old Madhupur Terrace. It is light brown and gray sand and clay silt, which slows down the infiltration of storm water runoff. The soil is 6 MSL.

2.1.4 Activities:

Despite all the stressing issues the playfield serves as a breathing place for the local users. Different user groups come and play in the field throughout the day (Fig 6). They play according to age groups and as there’s no delineation they divide the field accordingly. The elders walk along the edges to keep up with physical exercise.

The community center provide place for the nuptial ceremonies within their affordability. The catering services for the events occupy the entrance of the playground.

Fig. 6

A plethora of vendors comes around the evening and during any football matches to sell goods and foods.

Annually the field also hosts the two Eid prayer congregations. In recent years a devastating temporary cow-market takes place in the field during Eid-ul-Adha as there’s scarcity of open places in the vicinity. The aftermath of the bazaar is that the field becomes lifeless.

The obscured view may have encouraged anti-social activity like drug abuse at night.
2.1.5 Accessibility:

The field is visually blocked from the main alley on the North. The gateway is very overcrowded. On the Eastern side there’s a very narrow walk way which gives way to the local users. But it’s inaccessible from the narrow walkway physically and visually due to 4.5 m high walls around the field.

Fig. 7.

2.2 Analysis:

After thorough survey of Shahid Smritinagar Stadium playground a SWOT analysis was done to understand the key issues and opportunities of the land.

2.2.1 Key Issues:

- The Shahid Smriti Mini Stadium playfield is primarily unseen due to its high surrounding walls and out dated community center at the front.
- Impaired visual and physical accessibility may help thrive anti-social activities.
- The place offers no green refuge and water clogging hinder the turf growths.
- The hazardous fumes emitted by the plastic factories around the playground are contributing to the air pollution.
- Though there’s a community center it hardly provides any amenities like toilets, kitchen (for food preparation of events), potable water or designated children’s play area.

2.2.2 Key Opportunities:

- By removing the boundaries the field may become a special interlude in the cramped locality of old Dhaka.
- The removed boundary may aid to create a safer place for public recreational activities.
- It playground may become a green reserve in the locality by planting native trees. It will also help the fauna to flourish.
- The green reserve may help mitigate the detrimental plastic fumes and reduce the carbon footprint.
- By redesigning and relocating the community center may offer basic public amenities and scope for vendors to expand commerce.

2.2.3 Design Interventions:

In Dhaka city the concept of an ideal play field and a park is hardly applicable and out of practice. The dense urban fabric comprises these open spaces for multifunctional usages. Thus the need and application of such an open space is a hybrid of playfield and park both, necessarily an urban green space in its essences. Due to limitation of budget and time, PRA (participatory rapid appraisal) was not carried out. But informal interviews with the local people, users and Ward Counselors were taken to understand their aspirations and desires.

Fig. 8

The proposed design of the Shahidsmriti Mini Stadium playground is no exception. It’s an endeavor to bring back nature to the under-developed areas of old Dhaka - a
biophilic design approach to enhance the user experience at the midst of a dense urban scenario.

In Proposed Design Futsal instead of Football, children’s play area. The walking track is segregated by wire meshed screen to protect the joggers from accident. Nods for sitting, open gym, New Mimber for Eid Gah, vendor corner have been infused to fulfill the needs of the locality.

The entrance has been designed to be more inviting and open. The community center has been placed at the southern end of the field. (Figure 9)

Fig. 9.

Minimal intervention is posed to make the project durable, sustainable and buildable.

Disaster Management has been one of the major design concerns of the design initiative. It has driven the design decision of removing the boundaries and being replaced with poles/bollard to give way for people in time of emergency, so that people can access from all directions to take refuge.

The newly established connections with the place has been conceived to aid in enhanced user interaction with nature which is one of the patterns of a biophilic design. The proposed plantations covers native plants like bamboo (Bambusa balcooa), which sequestrate high degree of carbon. Nageshwarchapa (Mesua Ferrea), Ashoka (Saraca indica), Kadamba (Neolamarckia cadamba), Shimul (Bombax ceiba) and myriads other native plants has been recommended to enhance nectarivore and fructivore biodiversity like bees, butterflies, birds and bats.

Extended plinths of the mer in the old town were once very common. The entrance has been designed as an extended elevated plinth to welcome day to day users to sit and relax in front of the field. Dedicated corners for adda (Bangla casual word for informal chatting) are punctuated in the green belts around the park. Benches along the periphery of the field ensure uninterrupted views of the playful atmosphere inside. The walking track has been laid behind the benches for clear demarcation between activities.

Shahid Smriti Nagar Mini Stadium is a prototype design of an urban green space, with an intention of curving a niche in the over-built context of Old Dhaka. It is expected to nurture the future generations through design and build a healthier and smarter generation.

3. Bakshi Bazar Park:

Established in 1984, the Bakshibazar Park is of 0.28 acres in size beside Girda Urdu Road. It is situated in zone 3, ward 27 of Dhaka South City Corporation. The linear chunk of land has a primary health clinic on the east, and high boundary walls surround the park in three other cardinal directions.

Fig. 10.

3.1 Existing Condition:

Bakshibazar Park faced the first wave of encroachment in 2001-2002 after the Dhaka city corporation allowed a portion of its land for a three-storied clinic under the urban healthcare project. Thus the normal functionality of the park dedicated primarily to children was gradually compromised for being hidden behind a obscurring built form.
The children play area has been out of order for last 13 years. Moreover it has somewhat turned into a parking lot of rickshaws and rickshaw vans in present day scenario. A much dilapidated yet functioning one storied gymnasium stands at the back of the park.

The children play equipment are vandalized and not currently in use. (Fig 11)

3.1.1 Land Use:

Surrounded by institutional and residential areas, the park once used to function as a proper playground for children. There is a Foreign Language training center on the north and residential area on the south side. The West side end is defined by an existing outdoor cooking facility for a nearby community center. There’s Bakshi Bazar playground just in the eastern corner of the plot. But due to political issues that playfield is also restricted in nature.

3.1.2 Vegetation and Hydrology:

The Bakshi Bazar Park is a barren field with only two trees in it. Due to rickshaw parking facilities, the park has mere grasses at the edges. (Fig 13) But there are mature trees in the surrounding plots of the park, especially at the northern side. These trees provide shade over the linear park and create cooler microclimate.

3.1.3 Geology:

The soil of Bakshibazar Park is Pleistocene Madhupur clay (geologically older deposits). Madhupur clay occurring in Dhaka Metropolitan area is also known as Dhaka clay. It is above the normal flood level of the city. It is brown to brick red and massive in nature, containing ferruginous and calcareous nodules.

3.1.4 Activities:

Unlike the Shahid Smritinagar Mini Stadium the Bakshibazar Park is in disuse to the local dwellers. The parkland is completely out of bounds of the general people due to the locally influential people. With time the identity of the park is lost and even its existence is of mere dispute.

The place partially hosts Urban Primary Health Care Services Delivery Project (UPHCSDP), an initiative of Government of Bangladesh under Local Government Division.

Other than the healthcare service, the park has currently become a parking lot of rickshaw and vans.

The gymnasium is also unfit for utilization.

3.1.5 Accessibility:

The park is visually blocked from the Girda Urdu road, the only access road to the park. To access the park, one must use the walkway beside the healthcare center.

The park is located in a rather high land and hence there are no issues of stagnant water.
3.2 Analysis:

SWOT analysis of the current state of Bakshi bazar helped to identify the key issues and opportunities of the site. They are as follows-

3.2.1 Key Issues:

- The Bakshibazar Park has become unknown to the local users in due course of time.
- The dual identity of the park is confusing as healthcare clinic and also as a park.
- Impaired visual and physical accessibility may help thriving anti-social activities.
- The place offers no vegetation.
- There are no public amenities like toilet or potable water facilities.
- The children playing installations are ergonomically unfit and in state of safe usage.

3.2.2 Key Opportunities:

- By redesigning the healthcare center and boundary wall the park can be revived.
- Heavy plantation of native trees and shrubs will increase the vegetative coverage of the area.
- If need be, the high boundary wall on the north, along the institute should be replaced with more perforated delineator. It will extend the visual field of the users. It may also restrain anti-social activities in the park.
- The visitors of the healthcare center can come over to the place and make the place vibrant.

3.2.3 Design Interventions:

To fit into the user’s requirements and ease of construction of the parks and playgrounds have been designed in prototypical way. But Bakshibazar Park is proposed as an arboretum to supply plants to other parks and playground of DSCC.

Fig. 14.

In the proposed design the tree bed has been bifurcated by the lily pond (Fig 15). The healthcare center will remain in the same place but a new design is suggested with higher ceiling height. It will help the park to connect with the surrounding.

Fig. 15

To educate the young generation about flora and fauna, the arboretum may offer workshops.

The northern boundary wall is replaced with stainless steel cylindrical poles. It will elaborate the site visually and ensure the safety of the users at the same time.

4. Conclusion:

The deign interventions for both the Shahid Smriti Nagar Playground and Bakshi Bazar Park have their interest set in timeless yet most demanding contemporary issue: the socio-environmental revival of local city community. The present century presented us the enormous environmental challenges while great achievements have been made in the field of democratic freedom. The design decisions had their foundations laid on these issues, while set a course for a meaningful future evolution. The attempt to resolve the challenging issues by employing natural elements is demonstrative of a biophilic approach. It
also gives future direction for community to take responsibility of restoring and preserving nature and their collective hopes as well.

Acknowledgments

Heartiest thanks to Ar. Rafiq Azam, heading Shatotto & JPZ JV, for giving opportunity to work in this platform and also for his consent to participate in IFLA Congress 2018 representing the Jol-Shabuje Dhaka Project.

Well-being and the principles of Chinese classical gardens and contemporary landscape design

Dan Li\textsuperscript{a}, Qing Lu\textsuperscript{b}, Koen Steemers\textsuperscript{a*}

\textsuperscript{a} University of Cambridge, Department of Architecture, 1-5 Scroope Terrace, Cambridge, CB2 1PX, UK
\textsuperscript{b} Urban Space Planning and Architectural Design CO., LTD, 21/F, Xiaoyuan Center B, Chaoyang District, Beijing, China

Abstract

Background: The well-being of the urban population is becoming an ever-growing challenge for cities. The links between access to green open space and well-being activities are explicit (e.g. Ward Thompson, 2011). However, the detailed design characteristics of open green space are not well defined. This paper examines the design features of Chinese classical gardens and contemporary landscape designs that support well-being.

Methodology: The first step of the study is a theoretical analysis of the paradigms of the Chinese classical garden (CCG) and the contemporary landscape architecture (CLA) as two distinct traditions. The second part of the study uses a detailed understanding of well-being to look specifically at the design details in a case study. This study compares the well-being values of the two design traditions based on an adjusted version of Seligman’s (2011) widely cited and accepted model of measuring well-being, called PERMA*:

- P (physical activity),
- E (engagement and positive emotion),
- R (positive relationship),
- M (meaning), and
- A (accomplishment).

Then we investigate how people use, experience and perceive green open space in urban case study locations. The data of the participants’ behaviour is derived by combining GPS device tracking and monitoring data to identify indicators of well-being, complimented by user surveys. The detailed garden and landscape design characteristics of the sites that may impinge on well-being of the users, are recorded directly using a checklist developed by the researcher. The
behaviour patterns and the design characteristics are then analyzed using ANOVA and partial correlation.

Results: The analysis shows that the Chinese classical gardens and the contemporary landscape design have quite different well-being values. Chinese classical gardens have more spatial characteristics intended for contemplation. These correlate with Seligman’s positive emotion and engagement (scoring 24 occurrences compared to 23 in contemporary design) and related to cultural meanings (scoring 11 occurrences compared to 1 in contemporary design). Furthermore, Chinese classical gardens accommodate approximately more the opportunities for achievement activities (scoring 3 versus 2), correlating to Seligman’s accomplishment (A), compared to the contemporary designs. However, the contemporary landscape designs emphasize more on ecology (correlated mainly to environmental meaning) than the Chinese classical gardens, as well as opportunities physical activities (P) (scoring 13 versus 9) and positive relationships with others (R) (scoring 12 versus 6). These studies confirm the strengths of Chinese classical gardens in facilitating cultural related positive emotion (E), cultural meaning (M) and accomplishment (A). In contemporary landscape spaces opportunities for physical activities (P) and positive relationships (R) are more reinforced.

Conclusions: Based on the findings of the theoretical and case studies, we propose a design paradigm – or an assessment method – for future urban green space that combines the well-being characteristics of Chinese classical gardens and contemporary landscape architecture. In this way, new landscape design principles can explicitly contribute to supporting the well-being of an increasingly stressed and urban population.

Key words: Well-being, Design principles, Chinese Classical Garden, Landscape Design, GPS tracking.

1. Introduction

Cities have been home to an increasing number of people and this trend will continue. It is predicted that 66% of the world population will live in cities by 2050 (United Nations, 2014). The appeals for good quality of open space is thus reasonable, since it is expected to facilitate “social inclusion and community cohesion”, and “health and well-being” (Peters et al., 2010; CABE, 2008). However, the relevant design professions have not meet the growing needs: the popular urban design trend of ‘urban village’ in Europe and ‘new urbanism’ in the US only ends in underused spaces, though highlighting mixed-use (Shaftoe, 2012). The landscape architecture profession has been no better, seeing that in the recent thirty years it is experiencing ‘an ecological modernity, an ecology free of romanticism and aesthetics’ (Richardson, 2011, p. 123). Designers began to realize there are more demands for user participation in creating culturally diverse and individualized space (Aslan & Robel, 2016, p. 4). Provincially in China, another design tradition of green space, Chinese classical gardening, highlights human experiences and can provide different relevancies to contemporary design mindsets. Therefore, to achieve a design paradigm for future urban green space, this study compares and synthesizes the theories and user experiences between the contemporary landscape design and Chinese classical gardens.
1.1. Well-being

In terms of the two alternatively used word, well-being and health, well-being is more relevant to everyday context of built environment than ‘health’. Health defined by (WHO, 1948) is a non-disease status physically, mentally, and socially, while Dodge et al. (2012)’s definition of well-being is more dynamic. Well-being is the balance point of between one’s power and challenge faced, or rather, to have enough physical, psychological, and social power to overcome the physical, psychological, and social challenges. The three aspects - physical, mental, and social, is to be used in this study as dimensions of well-being.

A well accepted and cited measurement of well-being is Seligman’s PERMA model (positive emotion, engagement, positive relationship, and accomplishment) in his 2011 book *Flourish* (Seligman, 2011). However, for the environment-people conversation, the model needs to be slightly adapted. Firstly, physical activity is added to Seligman’s original model for the proved significant contribution to well-being. Secondly, positive emotion and engagement are incorporated as one measure. The reason is that in terms of the environment, positive emotion empirically comes from being exposed to nature and mindfulness, which overlaps with the second measure – engagement (losing the sense of time while concentrate on doing something). Thirdly, meaning (achieved by serving something “bigger than self”). In the green space sphere, there can be cultural meaning (MC) of being connected to history and culture, and environmental meaning (ME) endowed by ecological design.

Therefore, our PERMA* model is as follows:

- **P**: Physical activity is additional measure to Seligman’s original model due to the proved significant contribution to well-being.
- **E**: Positive emotion and engagement. In the environment, positive emotion empirically comes from being exposed to nature and mindfulness, which overlaps with the second measure – engagement (losing the sense of time while concentrate on doing something).
- **R**: Positive relationship.
- **M**: Meaning. The sense of meaning can be achieved by serving something “bigger than self”. In the green space sphere, there can be cultural meaning (MC) of being connected to history and culture, and environmental meaning (ME) endowed by ecological design.
- **A**: Accomplishment. In the green space, people can pursue for a skill for its own sake through studying, playing music, or climbing to the top of a pagoda.

1.2. Theoretical comparison of the two design traditions

The two design traditions have quite different main features and methodologies. To illustrate, the Chinese classical garden (CCG) is the “enchanting and tranquil gardens designed to reflect both the charm of nature and the ancient Chinese view of life” (Lou, 2011, p. abstract). The main feature is “though manmade, they (the elements of the garden) will look like something naturally created” (Ji, 1988, p. 41), which can also be put as “from nature but superior than nature” (Zhou, 2008, p. 26). The derivative four backbones are:
Biophilic Cities

rockery, water, planting, and architecture (Peng, 1986, p. 41; Zhang & Xu, 2011). Plus, a fifth category called “Plaues and couplets” is also an important feature (Valder, 2002). On the other hand, the contemporary landscape architecture (CLA) is defined as “any intentional change of landscape pattern for the purpose of sustainably providing ecosystem services while recognizably meeting societal needs and respecting societal values” (Nassauer & Opdam, 2008, p. 633). There are two main principles: ecological design and design for societal needs and values. Ecological design should integrate ecological processes like “watersheds, material life cycles, habitats” (Nassauer, 2012, p. 223). Yet the “Design for societal needs and values” principle does not have synthesized structure, but still share four common resources: land and landform, water, plants, and outdoor fittings and furniture (Motloch, 2000; Simonds & Starke, 2006; Weddle, 1979).

The comparison of the design paradigm of the two traditions is based on the functions of the elements of each principle and their theoretical implications on the indicators of PERMA (Fig. 1). The analysis shows that the Chinese classical gardens and the contemporary landscape design have quite different well-being values. Chinese classical gardens have more spatial characteristics intended for contemplation. These correlate with Seligman’s positive emotion and engagement (scoring 24 occurrences compared to 23 in contemporary design) and related to cultural meanings (scoring 11 occurrences compared to 1 in contemporary design). Furthermore, Chinese classical gardens accommodate approximately more the opportunities for achievement activities (scoring 3 versus 2), correlating to Seligman’s accomplishment (A), compared to the contemporary designs. However, the contemporary landscape designs emphasize more on ecology (correlated mainly to environmental meaning) than the Chinese classical gardens, as well as opportunities physical activities (P) (scoring 13 versus 9) and positive relationships with others (R) (scoring 12 versus 6). These studies confirm the strengths of Chinese classical gardens in facilitating cultural related positive emotion (E), cultural meaning (M) and accomplishment (A). In contemporary landscape spaces opportunities for physical activities (P) and positive relationships (R) are more reinforced.

2. Methodology

2.1. Study area

Beijing has a rich resource of green space of all kinds design features. According to the survey of (Chen et al., 2017), green spaces within the 3rd ring road and the 4th ring road in the northeastern district were high. From green spaces in these areas, we chose two parks to that had similar accessibility and representative of the two design traditions to study (Fig. 2). The two parks are both large community park. The representative of Chinese ‘Classical Garden, Lontang West Lake Park is within the second ring road in south eastern Beijing. Built in 1986, it is a 10-ha park mainly serving residents within 1000 meters’ distance. People come by walking, mostly without a need to cross the road and public transportations are all 500 meters away from the entrance of the park.
The representative of the contemporary landscape architecture is the Wanghe North Park near the 4th ring road in the north eastern Beijing. It is built in 2014 and mainly serves residents in nearby 1.5 km by walk. Nearly one thirds of the coming users need to cross a 30 m wide urban main road through the platform bridge.

2.2. Questionnaire survey

The questionnaire was a shortened version from the original PERMA questionnaire by Butler & Kern (2016). The questionnaire includes only 7 quick questions on self-reported health, PERMA indicators (Table 1) on a 11-point scale from 0 to 10. Four conductors including the author did the questionnaire on the gateway of each park on a Saturday (20th, and 28th January). The participants were invited to answer the questionnaire both before and after the using the park. This is to examine the well-being enhancement effect. After using the green space, the participants were also asked to recall their experiences in doing PERMA indicator related activities:
Did you come for physical activity? How many times did you watch an objective, talk with people, recognize cultural meanings, and feel the sense of achievement? Where these activities take place?

<td>0 = never, 10 = always</td>
</tr>
</tbody>
</table>

E1: Positive emotion; E2: Engagement
Overall Well-being PERMA= mean (P, E1, E2, R, M, A)

The answers were analyzed in IBM SPSS 22.0. The scoring of the overall is averaging all the items. The well-being before, after using the park, and the difference between them were calculated. The demographic backgrounds (gender, age, occupation, and frequency of using the park) were descriptively analyzed and run a Pearson correlation with overall well-being before and after using the park. To examine the relative impotence of the factors, a confirmatory factor analysis was conducted using IBM AMOS 21.0. Finally, Pearson correlation and partial correlation analysis was done to explore the correlation between the experiences and overall well-being scores and eliminate the impact of the type of the park.

2.3. GPS behaviour tracking

10 participants were invited to wear the 10 participants the Q-Starz BT-Q1000XT GPS travel logger for ten days 10 days from Jan 22th to Feb 1st. 2018. They were all over 50 years old. The participants were asked to keep the device on through the 10 days and charge the device daily.

The GPS data was downloaded from the official website of Q-starz and imported into GIS 10.2. Trips with a speed between less than 1km/h were categorized as stay, trips with a speed between 1km/h and 9km/h were categorized as walking, and trips with a speed over 9km/h were classified as bicycle or automobile trips (Carlson et al., 2015). Kernal analysis was conducted to investigate the relative probability of the waking trip in the parks.

3. Results

3.1. Site observation

Upon observation, the Chinese classical park theoretically has more occurrence of positive emotion and engagement (scoring 11 compared to 6 in the contemporary style park), meaning related to culture (scoring 5 compared to 0 in the contemporary style park), and social interaction (scoring 6 compared to 4 in the contemporary style park). The contemporary style park has more opportunities for physical activity (scoring 5 versus 3 in the Chinese classical park) and achievement (scoring 3 versus 1 in the Chinese classical park) (Table 2).
3.2. Questionnaire survey

(1) Participant characteristics
64 participants completed the after-use questionnaire. Among the 64 valid answers, 31 were from male (48.4%) and 33 were from female (51.6%). Slightly more participants were elderly people over 55 years old (54.7%), unemployed (53.1%), and did not receive high education (51.6%). 73.4% of the participants came for doing physical activity, the other purposes were play (9.4%), play with children (4.7%), take a rest (3.1%) and work (3.1%). 75.0% of the participants came to the park at least once a week, which meant they are mostly frequent users of the park. While 13 participants did not come regularly, and 3 out of 64 first came to the park. There were more female participants in the CLA than in CCG, $t(62) = 2.03, p=0.047$. Age, occupation, education, purpose of coming and frequency of coming did not differ between the participants in the two parks ($p>0.05$).

(2) Comparison of well-being before and after using the park
Generally, the well-being scores after using the park were higher than that before using the park (Fig. 3). The enhancement of the well-being score of all the participants is 0.31 (SD=0.876). The participants in the contemporary style park had higher well-being scores. Before using the park, the mean well-being score was 8.00 (SD=1.282) in CLA compared to 7.82 (SD=1.377) in CCG. After using the park, the mean well-being score was 8.32 (SD=1.317) in CLA versus 8.11 (SD=1.387) in CCG. The mean enhancement of well-being was also higher, scoring 0.32 (SD=0.800) in CLA compared to 0.29 (SD=0.964) in CCG. However, all these three differences were not statistically significant ($p>0.05$). In terms of each PERMA indicator, meaning was the most enhanced indicator, and in CCG the enhancement was higher (1.52 compared to 1.09 in the CLA).
Fig. 3. Mean well-being score differences in the two parks.

The well-being enhancement was higher in the contemporary style park than in the Chinese classical park, perhaps due to the maintenance differences. The score difference is inverse to the hypothesis that the more PERMA indicator scores in a space imply more well-being enhancement. From site observation the CCG scored higher, especially on supportiveness of positive emotion and engagement. But the results showed engagement score decreased and in CCG engagement was the least important factor to overall well-being. It is perhaps because of the quality of the facilities related to engagement. The architecture, seating area, and plantings and the whole park was not as well maintained as the CLA. The CLA, in contrast, was a newly built park with brand-new facilities. This accords with previous studies that the maintenance is an important determinant of the use of the park (Dunnett et al., 2002). A telephone survey of 515 non-park users by the British Market Research Bureau revealed that more than half respondents mentioned “less dog mess, improved safety, better maintenance, and better facilities, etc.” would encourage them to use the park a lot.

(3) Confirmatory factor analysis

Confirmatory factor analysis showed that the most important factor for well-being score in CLA was engagement (standardized regression weight = 0.98), and in CCG the biggest factor was social relationship (standardized regression weight = 0.90) (Fig. 2). Good model fits of all the models were derived (Table 3).

![Fig. 4_a Standardized regression weights of the confirmatory factor analysis of the CLA](image)

![Fig. 4_b Standardized regression weights of the confirmatory factor analysis of the CCG](image)

Table 3 Model fits of confirmatory factor analysis

<table>

</tbody>
</table>

According to (Hu & Bentler, 1999), RMSEA (root-mean-square error of approximation) >0.06 and CFI (comparative fit index) >0.95 indicates a good model fit. A Chi-square/Degree of freedom ratio between 1~3 is recommended (Kremelberg, 2010) and p value should be larger than 0.05 (Hooper et al., 2008).

(4) The experience of related activities and well-being score
Pearson correlation showed that activities associated with well-being scores were physical activity, sense of meaning and sense of achievement (Table 4). Aiming at physical activities (1=physical activity, 2=other purposes) was positively correlated with enhancement of well-being scores. Doing other activities (play, play with children, take a rest, stroll) pertained to higher well-being scores after using the park, \( r(63) = 0.29 \). The more the users sensed cultural meanings, the higher well-being scores they got after using the park, \( r(63) = 0.34 \). Also, the more achievement-evoking activities, the higher the well-being scores after using the park, \( r(63) = 0.29 \).  

From the partial analysis, the type of the garden differentiated the relationship between sense of meaning, sense of achievement and well-being score: The partial correlation is moderately strong and positive for the relationship between meaning and well-being after using the park, controlling for the type of park, \( r(62) = 0.357, p = 0.001 \). The result of the zero-order correlation showed that there was a moderate correlation between meaning (\( M=0.51, \text{SD}=0.504 \)) and well-being after using the park (\( M=8.21, \text{SD}=1.344 \)), \( r(63) = 0.335, p = 0.020 \). It indicates that type of garden moderately influences the relationship between meaning and well-being. **The Chinese classical garden is stronger in providing cultural meaning that’s helpful to well-being.**  

The partial correlation is moderate and negative, controlling for the type of park, the relationship between sense of achievement (\( M=0.59, \text{SD}=0.495 \)) and well-being after using the park (\( M=8.21, \text{SD}=1.344 \)), \( r(62) = 0.283, p = 0.025 \). The results of the zero-order correlation show that there was also moderate correlation between sense of achievement and mean of well-being, \( r(63) = 0.291, p = 0.020 \). It indicates that type of garden slightly influences the relationship between sense of achievement and mean of well-being. **The contemporary garden is stronger in providing achievement that’s contributable to well-being.**  

The most important factors of the PERMA indicators in the two parks are engagement and achievement in CLA, and social interaction and meaning in CCG. For the CLA, the answers of the highest rate for engagement was watching the skiing activity (22.22%), for achievement was dancing (23.3%). In the CCG, the social interaction was the biggest factor because users there were longer-term residents and had more acquaintances than those near the CLA. The meaning mostly referred to the pavilion (the answer rate was 33.3%).  

### 3.3. GPS tracking  

1. Speed and length of walking in the parks  

Trips in the park were of from 2 out of 5 volunteers in the CLA and 4 out of 5 volunteers in the CCG. The volunteers in the CLA walked longer time and also slower in the CLA. The average walking time in the
CLA were respectively 46.54 min per day with an average speed of 2.63 (1.060) km/h. Volunteers in the CCG walked shorter time, averaging 27.96 min per day with a faster speed of 4.06 (1.167) km/h. Even controlling the size of the park, the walking time in the CLA was longer compared to that in the CCG (Table 5).

(2) Distribution of walking in the parks

From Kernal Density analysis, the walking in the CLA is more areal while the walking in the CCG is more lineal (Fig. 5). The CLA had more open spaces for people to do activities, thus in these areas the walking can be slower (2.63km/h). The redder area in Fig. 5_a were the area walking was more probable, including the central square, the children play area, the entrance square, and the quiet relaxing area. Apart from these areas, the walking distributed along the main walking lane. The CCG had a 1 km fitness runway around the lake. Thus, the walking, mostly on the fitness runway, was faster (4.06km/h).
bigger activity area, more activities to watch.

4. Conclusion

This study explored the differences of design principles of Chinese classical gardens and Contemporary landscape architecture, and their applications on well-being based on PERMA* metrics.

(1) Both the classical garden and the contemporary garden can enhance overall well-being. The contemporary landscape architecture is slightly stronger in supporting well-being. Parks should take more care of maintenance to better play the role of supporting well-being.

(2) Future design should combine the advantages of Chinese classical garden in supporting cultural meaning through historical relevant objects, and the strengths of contemporary landscape architecture in the variety of activities to better support well-being.

(3) Future research should be more careful in choosing comparative cases. The cases should not differ significantly on confounding variables like the maintenance conditions as for comparing design paradigms.

Acknowledgments

This study received help from the Beijing Municipal of Landscape and Forestry, especially from Hong Ma and Anqi Zhao. Also, thanks for the supports from the park administration office of Longtan West Lake Park and Wanghe North Park. Plus, the three volunteers, Huixiang Li, Zhaojing Li, and Ziyi Li, were very helpful in conducting the questionnaire survey.

Abstract

Urban heat island (UHI) is a phenomenon resulting from climate change and rapid urbanization. Negative impact of UHI has been linked to heart stroke rate, mortality, human comfort, energy consumption and air pollution. Fortunately, urban green spaces, besides their various ecosystem services, have been considered as an effective element to mitigate UHI through the function which is known as cooling effect. From another hand, in the recent decades, in many cities of the word, urbanization and rapid growth have put pressure on urban greeneries and caused fragmentation of green patches or replacing them with impervious surfaces which contribute to UHI. City Beijing, capital of China, is an example of such cities with an increasing trend of UHI. This study has focused on spatial-temporal changes of green space patterns in Beijing, capital of China. Also it has been tried to understand the relation between green spaces change and land surface temperature. In order to achieve the aims of research, spatial-temporal land cover map of study area was generated using Google Earth and ArcMap software packages. Changes in land cover type and portion of green spaces area in entire case study n were evaluated. Connectivity as an important landscape metric was computed with FRAGSTATS. In the same time LST estimated from LANDSAT remotely sensed data. The result, in general, indicated a tight correlation between LST and land cover type. Urban waterbodies and greeneries showed the lowest LST, while Impervious surfaces such residential areas and roads showed the highest level. Furthermore it was showed that surface temperature was affected by the cooling function of greeneries and by land cover type. Further analysis showed that although recently some parks and green spaces has been constructed in some sections of study area and it has contributed to provide more cooling surface, but in general, the connectivity index of green patches has been dramatically decreased from 3.11 to 1.69 from 2000 to 2015, showing fragmentation in urban green landscape. It is suggested that green spaces and waterbodies are playing a vital role in cooling down cities and mitigating high temperature events. Urban green pace planners and designer may take the advantage of this study for their further plans to increase green areas and enhance their connectivity in the cities which can provide various ecosystem services.

Keyword: Urban greenery, Ecosystem Services, Urban Heat Islands, Cooling Effect, Remote Sensing, Landscape configuration;
1. Introduction

One of the major environmental challenges humankind is facing in the 21st century is climate change [1]. In this scenario, cities and citizens are suffering from different problems such as increasing urban heat islands (UHI) [2] and increasing runoff and flood event [3]. Also, air pollution and low water quality decrease people's wellbeing in the cities [4], [5].

Fortunately, trees and vegetation in an urban environment can greatly improve the microclimates, as well as mitigate UHI development by reducing summer air temperatures [6]. Urban vegetation cools climates through two major processes: shading and evapotranspiration [7]. The direct effect of shading refers to the interception of solar radiation by leaves and branches of trees; this reduces the sunlight reaching the ground below the canopy of a tree or plant. An investigation in Australia demonstrated that tree shade could reduce wall surface temperatures by up to 9 °C and external air temperatures by up to 1 °C. The indirect effect of evapotranspiration is the sum of evaporation and plant transpiration, which reduces air temperatures because of the use of energy required for transpiration. A systematic study in Chania of Greece showed that urban green areas could reduce air temperature 3.1 °C, mainly through evapotranspiration [8].

In order to protect the landscape in cities at international and continental level, and in order to preserve their biological diversity, many stakeholders have a strong interest in getting a broad view of their state, be it in terms of vegetation health, species composition or environmental conditions such as surface temperature. In particular, it has been considered worth investigating the potential of Remote Sensing (RS) and Geographical Information System (GIS) techniques for characterizing and monitoring landscape and their stability as habitats [9].

This study has focused on spatial-temporal changes of green space patterns in Beijing, capital of China. Also, it has been tried to understand the relation between green spaces change and land surface temperature.

2. Methods

2.1. Study area

The research focuses on urban green landscape of city Beijing ((39°28'-41°05'N, 115°25'-117°30'E)). Beijing is capital of China and the world’s third most populated city [10]. The city has a monsoon-influenced humid continental climate with an average temperature of 12.6 °C (27°C in July and -4°C in January). The city has been observed the urban heat islands (UHI) phenomena since fifty years ago, and the current summertime UHI reach 4.5°C in average [2]. In this study Olympic Forest Park of Beijing was chosen as case study. The Olympic Forest Park, with the area of 10 km² has been built for 2008 World Olympic Games in the northern part of Beijing's built-up area and has become a hotspot for recreation and tourism. It is covered with deciduous and evergreen trees, grasses, shrubs and a man-made dragon-shape lake. The buffer zone of the park mainly includes green and grey spaces, and grey spaces refer to buildings, roads, etc.
2.2. Land Surface Temperature

Surface temperatures represent heat energy given off by the land, buildings, and other surfaces. Instruments mounted on satellites and airplanes can measure temperatures of surfaces and reveal temperature differences at very fine scales (i.e. roofs, pavements and grassy areas). However, satellite data have a number of limitations, so we combined satellite data for surface temperatures and data from monitoring stations for air temperatures to offer the most complete picture of the study area's heat island. The land surface temperature data of the study area from 2000 to 2014 were derived from the thermal infrared bands (TIR) of Landsat 7(ETM+) and Landsat 8 TM with spatial resolution of 30m (resampled from 120m). Landsat 7(ETM+) images were acquired on August 2000, and August 2005. Landsat 8 TM images acquired on August 2010, and August 2014 (row32/path123).

2.3. Land Cover Pattern

The land cover of the study area was classified based on the supervised classification of remote sensing data, natural attribute of land cover and the classification system of the green space investigation data in the study area. Remote sensing data include the high-resolution images of the study area in 2000 (SPOT4, panchromatic 10m), 2005, 2010 and 2015 (SPOT5, fusion 2.5m). Six land cover categories were identified, namely green space, water-body, farmland, bare land, building and road. Urban green space, water-body, farmland were assumed as landscape components of green space, while bare land, building, and road assumed as grey space.

2.4. Calculation methods

GIS spatial analysis module was applied to understand the spatial change of green parches. Firstly, land cover vector data of different years were converted to 30m*30m (the same as the resampled pixel size of the Landsat TM and ETM thermal bands) raster data, and then overlay command of arc toolbox in ArcGIS10.0 was applied to overlay the landscape type distribution maps from 2000 to 2015, and analyze the changes in green patches over the time.

Numerous landscape metrics can be can indicate and reflect the structure and special characteristics of landscape pattern [11]. Here, we chose Connectivity as an important landscape metrics to measure connectivity (CONNECT) of green patches. It was calculated in Fragstats 4.0.

3. Result and Discussion

Among the green space types, cropland and waterbody within the study area have reduced by 1.2 km² and 5 km² from 2000 to 2005, while grass and forest (includes urban tree parks, green belts) have increased by 5.7 km² and 2 km² correspondingly. From 2005 to 2010, cropland dramatically reduced by 22.3 km² and disappeared while grass, forest, and waterbody have increased 6.7 km², 8.9 km² and 0.5 km² accordingly. From 2010 to 2015 there was no important change in the components of green spaces within the study area. Generally grass and forest have increased from 2000 to 2015 due to large-scale urban projects in this period specially construction of Olympic Forest
Park for the 2008 World Olympic Games within the study area. Meantime croplands and waterbody have been invaded by road, business and residential area, road.

Generally, the coverage area of greenery and waterbody was significantly negatively correlated with LST across each zone.

LST was negatively correlated with connectivity, (Figure 2). Also connectivity showed a decreasing trend in the time span, which shows the lowering connectivity of green patches because of urbanization and scarcity of green spaces.

Our result showed that both green space’s composition and configuration significantly affect the magnitude and extension of LST. This research expands our scientific understanding of cooling effect of urban greenspace. These results have important plan, design and management implication. Greenspace planners, designers and managers attempting to mitigate the negative impact of urbanization and urban heat islands can gain insights into optimizing the cooling effect in cities.

The negative correlation between LST and green patches connectivity obviously reveals the impact of rapid urbanization in the study area which caused fragmentation and isolation of green space patches and contributing to landscape heterogeneity. Based on these findings, it’s urgent to promote green space protecting policies by the stakeholders which benefit citizens well being through various ecosystem services they provide. According to previous researchers, the ecological functions of urban greeneries were closely linked to the green space coverage, community structure and landscape patterns. So, construction and designing urban green space should not be confined to aesthetic values but must highlight ecological function of greeneries network in the cites. In this regard, paying attention to vertical greening (green walls/etc) and green roofs and also optimizing the layout and pattern of greeneries is necessary to ecological and sustainable development of cities.

![Figure 2 relations between LST and Connectivity in different zones of the study area.](image)

Abstract

We are witnessing the increasing strategic promotion of landscape corridors in various regions. In decades, a variety of landscape corridors have been developed by regional landscape policymakers, especially under the promotion of Pan-European ecological network and Green Infrastructure strategy. However, one problem is, in the ongoing promotion of landscape corridors, public attitude facing with the corridor planning movement are largely ignored. The public may present a resistant or supportive attitude towards the corridor proposal and various stakeholders with different demands (cultural heritage, tourism, agricultural development etc.) involved in landscape corridor planning process may have conflicting interests. Ignoring those opinions may lead to social conflicts during the promoting process. For the perspective of landscape corridor planning, it is valuable to explore the common language for negotiation with various stakeholders.

Detecting Cultural ecosystem service (CES) could be used as an instrument to predict public attitude and provide a common language between various stakeholders. As a category of ecosystem services, cultural ecosystem service (CES) are defined as all the nonmaterial benefits for people provided by the local environment on spiritual enrichment. Thus, cultural ecosystem service contains complete emotional responses to local environment (eg. attitude, feeling, memories), which could be proposed as an efficient approach to present public attitude relating to local landscape in social-ecological systems. The purpose of this study is exploring an efficient method to predict public attitude relating to local landscape features. The study performs spatially participatory mapping exercises and structured assessments of local cultural ecosystem services and public attitude based on tracking an ongoing cultural landscape corridor case along silk route. Our research is aiming at the following questions: (1) What is the spatial pattern of cultural ecosystem service (CES)? (2) What is the public attitude for the influences that corridor planning bring to the CES-providing region and what’s the spatial pattern of local public attitude? (3) How are local public attitude and cultural ecosystem services relating to local landscape features? Through three workshops and an APP that we created for spatial public participation on smart phones, we
conduct open interview, semi-structured assessment and public participatory mapping with local responders living in the corridor planning region. The outcome reveals the spatial pattern of cultural ecosystem services, public attitude, and potential conflict area, which are related to landscape features. The cultivated land provides highest immaterial cultural ecosystem service for residents and performs high level of resist attitude to corridor planning proposal, which predicting the potential conflict area. To sum up, we conclude that cultural ecosystem service assessment provides a bridge for public attitude visualization which incorporates the potential conflict area provides a rich basis for landscape corridor decision making.

Cultural Ecosystem Service, Mapping , PPGIS, Landscape Corridor, Conflict,

1. Introduction

We are witnessing the increasing strategic promotion of landscape corridors in various regions. In decades, a variety of landscape corridors have been developed by regional landscape policy-makers, especially under the promotion of Pan-European ecological network and Green Infrastructure strategy. However, one problem is, in the ongoing promotion of landscape corridors, public residents’ idea and attitude facing the corridor planning movement are largely ignored. The public may present a resistant or supportive attitude and different interests towards the corridor proposal and various stakeholders with various demands (cultural heritage, tourism, agricultural development etc.) involved in landscape corridor planning process may have conflicting interests. Ignoring those opinions may lead to social conflicts during the promoting process. For the perspective of landscape corridor planning, it is valuable to explore the common language for negotiation with various stakeholders.

Cultural ecosystem service (CES) could be used as an instrument to predict public attitude and provide a common language between various stakeholders since ecosystem services framework have been used as a common language for people describe the value, demands and experiences for instance in landscape management [1]Thus, as a category of ecosystem services, cultural ecosystem service (CES) are defined as all the nonmaterial benefits for people provided by the local environment on spiritual enrichment including cognitive development, recreation, and aesthetic feeling” [2]. Based on the main messages in the Millennium Ecosystem Assessment (MA) [2], people have always influenced the landscape to enhance the availability of cultural ecosystem services values. And the same time, the cultural ecosystem service including human cultures, knowledge, religions, feeling, aesthetic values always have been shaped by the landscape conditions in which culture is based and people lived. Thus, cultural ecosystem service contains complete emotional responses to local environment (e.g. attitude, feeling, memories). Assessment of cultural ecosystem service could be proposed as an efficient approach to present public attitude relating to local landscape in social-ecological systems. To implementing this approach, a deeper spatial understanding of the cultural ecosystem service and conflicts with people is required [3].Several studies including qualitative and quantitative methods have been developed to explore such CES values and conflicts at various level, for instance, the study on CES of wind framing [4] or CES mapping and assessment in a community [5]. Mapping of cultural ecosystem service provides spatial pattern understanding of subjective knowledge and attitude of residents on the cultural landscape, which benefits for understanding the social
suitability of project and predict the potential conflict between different stakeholders for further planning and decision-making process. Public Participation Geographic Information Systems (PPGIS) have been particularly widely used as they allow putting the cultural ecosystem service values on a map [6].

The term PPGIS “public participation geographic information systems” was conceived in 1996 at the meeting of the National Center for Geographic Information and Analysis [7]. The concept describes the process of using GIS technologies to produce local knowledge with the goal of including and empowering marginalized populations. Based on transactionalism influence theory of human, landscape and cultural ecosystem service, mapping and assessment of cultural ecosystem service of local landscape express the subjective knowledge and attitude of residents and spatial pattern on the cultural landscape. Using PPGIS to its analytical category will greatly enhance its interpretation of complex social phenomena. Therefore, it is important to explore a GIS-based community subjective activity representation and analysis method to promote community participation and regional harmonious development.

In this study, we link participatory mapping with cultural ecosystem service assessment through PPGIS as an efficient method to predict public attitude and knowledge on a spatial pattern for landscape corridor planning. This study provides a bridge for public attitude prediction and negotiation with the conflicts between public stakeholders and decision makers for further landscape corridor planning. During the planning process of landscape corridor, conflict and negotiation happened between various stakeholders, for example, the migration and land use of residents living in the region. Due to the weakness and difficulties of expressing residents’ knowledge and attitude, the establishing of working platform is required to express residents’ knowledge and record their daily life behavior technologically.

2. Objective

Our study performs spatially participatory mapping exercises and structured assessments of local cultural ecosystem services, public attitude and potential conflicts between development preferences based on tracking this ongoing corridor case. The specific research questions are (1) What is the spatial pattern of cultural ecosystem service (CES) of public residents in the corridor planning area. (2) What is the public attitude for the influences that corridor planning bring to the CES-providing region and what’s the spatial pattern of local public attitude? (3) How are local public attitude and cultural ecosystem services relating to local landscape features? (4) What’s the potential conflict between the public residents and decision makers? We discuss how our main outcome could provide a bridge for public attitude prediction and negotiation with different stakeholders for further cultural landscape corridor decision making and management.
3. Method

3.1. Study area

The case study area is performed in central towns in Dunhuang-Zhangye part of Heixi Corridor in Western China. As important historical site, this region is located in the Ancient Silk Road which connecting the western and eastern civilization world in the past 2000 years as an important cultural route. The cultural route region obtains numerous temples, trading heritage, cave sculptures and other heritages left by the historical cultural exchange. Grassland and traditional farmland transformed from wetland as oasis area along river in Gobi desert and Danxia landform area represent the most characteristic ecosystems of the area, with livestock breeding and framing having an almost 2000 year tradition. Based on the current linear heritage and landscape situation, the regional government want to connect existing greenway patches by a heritage corridor planning project for preservation of destroyed and degraded wetlands along river and the integration of local cultural and historical features. The “Silkroute Cultural Landscape Corridor” project aim to develop a regional landscape corridor with recreational and enriching historical/cultural resource, preserving the local natural and cultural values, providing opportunities for economic development and improving existing greenery spaces, establishing new connection between them. Due to different preferences between decision makers and the public, there would be potential conflict on the developing direction between public preference and the current cultural landscape corridor proposal from the municipality. Thus it is important to analyze public attitude spatial pattern by mapping cultural ecosystem service practice and predict the potential conflicts area under the background of ongoing promoting for the Silk Road Heritage Corridor, which providing guideline for supporting further decision making. The cultural landscape corridor proposal coverage is 65.5 km². (Figure1).

3.2. Categories of cultural ecosystem service

Due to the contribution of The MA, 2005, ecosystem services could greatly consider as a key goal and effectively incorporated into policy-making in EU level and even the global. As the identification, cultural ecosystem service is non-material benefits provided by ecosystem and environment for people through spiritual developing, for instance, the enriching of aesthetic benefit, recreation benefit, and cognition of place. “(MA, 2003, Chapter 2,p.58). Thus, among ecosystem services, cultural ecosystem
services illustrate the close relationship with human individual feelings, attitude, preference, and cognition. In our exercise, cultural ecosystem services are selected as the carrier to express local residents’ attitude and reveal their daily life and knowledge of the area.

In our study, the categorization of the cultural ecosystem services is mainly based on the Millennium Ecosystem Assessment. But we dropped items like ‘knowledge system,’ ‘inspiration’, and ‘education value’ which are difficult to explain to residents and less relating to their daily life. Additionally, we integrated potential services relating to the landscape feature of the study area. Finally, we selected 8 types of cultural ecosystem services as following to express local residents’ options and attitude as follows: 1) spiritual service, 2) educational value, 3) aesthetic value, 4) social relation, 5) sense of belonging, 6) recreation, 7) economic value, 8) cultural heritage.

3.3. Data collection

Our approach applied cultural ecosystem service as the carrier for expressing public attitude and knowledge through participatory mapping and semi-structured interviews into PPGIS system (public participatory GIS). We performed a participatory mapping survey through an online app on a smartphone with the help of a local community. The survey included 9 categories of cultural ecosystem service assessment on cultural ecosystem services that people appreciate and influence to each cultural ecosystem services by the corridor planning proposal. Respondents were asked about the spatial location of each cultural ecosystem service, development preferences and the influence of the corridor planning by face to face interviews. We chose to study local residents as responders including framers, technology staff, administrations, students, and rural tourism homestays as they are key active public stakeholders infected by in the corridor planning projects. Our survey covered full- or part-time local residents who were recruited through snowball sampling. The mapping app obtains the graphic map of the area at 1:20,000 scale, in which pre-identified current land cover, residents settlement, and heritages for local residents building the sense of space. For the mapping of cultural ecosystem service, we formulated the questions such as “Which place do you think is the most beautiful and attractive scenery in your town (e.g. river view with ancient fire tower) ?” (for Aesthetic benefit). The responders were asked to point out one or more places as the description above. For development preferences, we used these typical indicator questions like “Please mark areas/places where you believe that vineyard and wine cultural resort could occur”. In addition, we asked the reason for choosing each place and they most enjoy the local landscapes. In the assessment part, the responders are also requested to express their main attitude and visions and concerns about the influence of the corridor planning project. A semi-structured assessment was performed to present public concerns about the corridor planning influence to landscapes with each cultural ecosystem service(CES) they mapped through the questions like “What is the influence of the corridor project do you think will affect the place for your recreational activities(for Recreation...
benefit)?”. The Likert scale was used to assign the negative or positive influence they thought as table 1.

</tbody>
</table>

Table 1. The Likert scale of public attitude to corridor planning influence to local landscape with CES.

3.4. Spatial analyses

We analyzed the frequency and distribution of each type of cultural ecosystem service and development preferences through descriptive statistics and T-tests for significant associations. We also used significant associations in T-test finding to explore the cultural ecosystem service that people appreciate relating to their different background. The attitude and daily life places of residents recorded by the eight types of cultural ecosystem service with 8 layers for spatial analyses in ArcGIS. The spatial analysis process includes analysis steps as following:

1). Kernel Density: to analysis spatial pattern of cultural ecosystem service and development preferences. We used the places with cultural ecosystem service and development preferences mapped by the residents as the input for ArcGIS. The active variables on hotspots revealed the area attracted most attention by the Kernel Density heatmaps. Additionally, we used the result of the semi-structured assessment as the score to examine the public attitude relating to the places with different cultural ecosystem service for the corridor planning. We assigned the scores different cultural ecosystem service layers. Finally, Kernel Density was used to generate the score regions which performed the resist and support attitude for the further corridor planning.

2). Compatibility analysis: We built the compatibility index CI system to reveal the compatibility between public attitude and current corridor proposal from the decision maker, which provide the way to analyses the pattern of public attitude and their development preference to find out the potential conflict areas between decision makers and public resident, and among residents themselves.

3) Correspondence analysis: to analysis how local public attitude and cultural ecosystem services are relating to local landscape features. It will provide the outcome of which kind of landscape features would easily have public resist/support attitude for corridor planning due to their negative/positive influence concerned by the local public resident, and what kind of cultural ecosystem service provided by the landscape features.

4. Result

4.1 Characteristics of respondents

Our survey covered full- or part-time local residents. In total, 200 respondents participated in the survey. The responders consist of 53% male and 47% female. The majority of responders as local residents are...
farmers (69%). Of the responders, most of them in our survey are landowners (36%). While there are 24% participants have no registered land ownership even though they are local residents.

4.2 Ecosystem services that people appreciate

Responses to the open question on benefits provided by local landscape were classified as ecosystem services, including freshwater and natural conservations. We asked the ecosystem services that local people appreciate. The most often mentioned concerns about appreciating cultural ecosystem service is the economic benefit (n=133). For other cultural ecosystem service selected from our study categories, recreation benefit (n=98, followed by the sense of belonging (n=97) and social benefit (n =80) are also frequently appreciated by local residents (Figure.2). In addition, we explored how appreciated ecosystems services relating to people from different background. T-test performed that residents with different landownership will have significant difference preference on the ecosystems services that they appreciate. While there was no difference in their appreciation of people with different age, gender and education level. As shown by Figure3, landowners expressed their appreciation on freshwater (82%), economic benefit (73%), natural conservation (53%).While landowners and people without land had significant differences in sense of belonging (diff =-0.290*) and spiritual benefit (diff =0.340*) among the ecosystem service them appreciate. More than half landowner appreciates the sense of belonging while 40% people without land appreciates it. Spiritual benefits were also more concerned by the landowner (38%) than people without land (22%). To sum up, the people with landownership registered have a stronger sense of belonging and spiritual benefit feeling with people without landownership. (Figure. 2).

4.3 Spatial patterns of cultural services

4.3.1. Mapping of cultural service

In our spatial analysis, economic benefits points were by far the most frequently mapped landscape values (68%), followed by recreation benefit (57%); sense of belonging (52%), social benefit(50%), cultural heritage (46%), spiritual benefit (38%) ,aesthetic benefit(24%)and education(16%). These cultural ecosystem services were not assigned equally across regions of the image.
4.3.2. Kernel density heatmaps of cultural services

The outcome of Kernel density heatmaps performs the spatial pattern of local cultural services to specific sites (Figure 4). The highest intensity of cultural services was observed close to the wetland, fishing pools, settlements, woodland and the cultivated land. Richness and diversity of cultural services were also highest around the riverside and cultivated land.

4.4. Public attitude patterns of corridor planning area

4.4.1. Public attitude of corridor planning influence to cultural ecosystem services

A semi-structured assessment was performed to present public concerns about the corridor planning influence to landscapes with each cultural ecosystem service (CES) they mapped through the questions like “What is the influence of the corridor project do you think will affect the place for your recreational activities (for Recreation benefit)?”. As the result, the local public residents presented their resist attitude for the corridor planning in the sites with economic benefit, spiritual benefit and social relation benefits as they thought the cultural landscape corridor may have negative influences to these sites because of the requisition of cultivated land and the land use change probably in the planning process. The trails and reception facilities for tourists across their land also have the negative influence on their sense of belonging.

On the other hand, the local public residents presented their support attitude for the corridor planning in the sites with recreation benefit, cultural heritage, aesthetic and education benefits. They believed that the government will invest more to improve the sites by building up more public facilities. The result of influence score to each cultural ecosystem service under the corridor planning was showed as table 3. We assigned the influence score to different cultural service layers to explore the public attitude pattern.
Table 3. Influence of corridor planning to sites with each cultural ecosystem services

4.4.2. Public attitude patterns of corridor planning area

We assigned the above influence score to cultural ecosystem service layers and collected the scores in 1000*1000m mesh cell and sum the scores in each fishnet. The outcome is the generate score region by Kernel Density performing the public attitude pattern. The spatial pattern of public attitude are depicted in Figure 5. The green region with negative scores presented the resist attitude of local public residents as they thought the corridor project cause negative influence. Whereas the public residents will support attitude for the corridor planning in the red region with positive scores because of the positive influence of local sites with cultural ecosystem services. The result performed potential conflicts between public and decision makers for corridor planning.

4.5. Relationship to landscape features

The land cover types of the area (forest, cropland, grassland, water body, settlement, and quarry) are used for different purposes and exhibited, therefore, disparate relationships to ecosystem services perceptions. Thus, we made the correspondence analysis to explore how they relating to each other (Figure 6).

The most frequently used sites, or those with the highest immaterial value for community members, were related to cultivated land. Bare land, artificial surfaces with spiritual benefit and economic benefit frequently shows the resist attitude for the corridor planning project. Grassland, shrub land, waterbody, wetland and forest: with recreational benefit, aesthetic benefit and cultural heritages shows the support attitude to the corridor planning.
5. Conclusion

The planning of landscape corridor is a complex process referring with the different stakeholders including the public and the decision makers. However, current spatial planning, integrated cultural landscape corridors management have been limited by a weak consideration of public attitude and demanded public attitude prediction and negotiation between different stakeholders to avoid potential conflicts. In this study, we suggested cultural ecosystem service mapping as the bridge to present public attitude for two reasons: First, Cultural ecological services are directly experienced and intuitively appreciated by people [8,9]. Second, cultural ecosystem service could provide a common language to describe different supply and demands [10,11].which benefits for negotiation of various stakeholder with their own demands. As these reasons, our study used participatory Cultural Ecosystem Service mapping to explore the spatial pattern of cultural ecosystem service and public attitude for the influences that corridor planning region for better understanding potential conflicts between public residents and the decision makers. Such understanding, combining place-based narratives of local public residents and social-ecological knowledge, could provide further advanced improvement for current corridor planning proposal. Thus, we argue that participatory cultural ecosystem service mapping for cultural landscape corridor planning provides a bridge for predicting public attitude on spatial pattern and negotiating with public residents. The consideration of cultural ecosystem service and public attitude can help avoiding social conflict, improve current planning proposal and contribute to further cultural landscape corridor spatial strategy making.

Abstract

The Redemption City is an emerging iconic religious tourist destination in Ogun State, Nigeria. Ten percent of its land area is made up of high bio-diverse fresh water wetlands. Recent environmental crisis facing the Holy City include flooding, deforestation, unauthorised fishing activities, high rate of sedimentation, water ways obstructions and wetlands encroachments. This paper explores biophilic restoration of Owuru River flood plain as much needed added value to the spiritual atmosphere of the Redemption City. The study is underpinned by biophilism and landscape reinterpretation. Biotope mapping of the framing four kilometres Owuru River and its four main tributaries were undertaken to comprehend inherent ecological goods and services. Further social analysis enumerates the goods and services derive from the wetlands. The biodiversity of the swamp forest is dominated by three tree associations namely Raphia species, Elaeis guineensis, or Symphonia globulifera. The core ecological goods include fresh water fishing, peasant farming, ethno-botanic resources; fuel wood sourcing; and palm wine making. Services include wetland water filtration, fluvial flood soft engineering natural control and religious interactions. The goal of biophillic design principles is drawing man towards a positive relationship with nature. Site programming towards Owuru River wetland biophillic restoration is conscious of pragmatic development with site’s hydrological system. While allotment gardens and fish farming are introduced to meet the livelihood needs of peasant farmers, praying groves were introduced in clusters. Non-motorized transportation mode including elevated deck board, nature trails and off road bike routes drive low carbon movement within the wetlands. The spiritual landscape sacredness ambience is enhanced in each of the four alcoves, trails, rest stops by numinous, cosmic, and aesthetic principles using native plant species and park furniture. The Redemption City and its biophysically restored wetlands will help illuminate why river landscapes have inbuilt capacity to attract man.

Keywords: Biophilia; Biotope Mapping; Landscape Reinterpretation; Restoration.

1.0 Introduction

The perception of landscapes as the spatial representation of an ecosystem or overlapping ecosystems place emphasis on agglomeration of ecological goods and services. Landscape then connotes a bank of natural assets on which the livelihood of local people depends. Livelihood is composed of assets, capabilities and activities towards a satisfying means of living. A study of
landscape to isolate ecological goods and services is an important strategy for meeting food security and redefining inherent functions. Landscapes on this platform are considered as socio-ecological systems- a manifestation of community and local ecosystems symbiotic relationship (Adejumo, 2012). It is about making available services for the wellbeing of man and reciprocal management to keep the ecosystem in good health. Provided ecological services display carbon sequestration, tourism, recreation, flood control, bioengineering, water filtration, sense of place and spiritual values.

The latter drives the religious belief system that influence the wellbeing of man as a spirit being. Typical examples are many belief systems where mountains are seen to connect the physical world to spiritual plane of existence. Cultural groups attach the significance of mountains to the sky world (Garrett and Garrett, 1996; Vastokas, 1990). So also are rivers and other water bodies. Gadon, (1991) noted that rivers are primary natural landscape features deemed as sacred and most often associated with female divinity. The confluence of two rivers is seen as very sacred place within the landscape. For Hindus in India bathing in a river and visiting a sacred place liberates one’s soul from karma in this lifetime. Rivers as Tirtha, in Hindu worldview are believed to be portals crossing from the profane space to sacred space (Gadon, 1991). Many cultural groups from diverse religions background believe in the healing powers of hot springs, mineral springs and sacred wetlands for various ailments (Rossman, 1936; Fishwick, 1978; Cohen, 1981; Kearns and Gesler, 1998; and Lane, 2002). The human wellbeing is rooted in religious obligations that form the rudiments for spiritual tourism.

Ecological services, including biophillic spiritual values, as link between human and natural systems resonate the fact that the two systems are in a feedback loop in which human culture changes landscapes and landscapes influence culture (Nassauer, 1995). Sustainable derivation of these values then demand ecological restoration of degraded processes to make available inherent resources. That is the scenario in Owuru River wetlands that framed the Redemption City in Obafemi-Owode Local Government Area of Ogun State. The paper explores biophillic approach to landscape restoration of Owuru River wetlands towards the improvement of ecological health of degraded riparian landscape and enhancement of spiritual value. This will certainly boost spiritual tourism perspective of the Redemption City.

2.0 Study Area
The Redemption City is an iconic Christian faith based settlement that monthly attracts hundreds of thousand faithful’s in search of spiritual succour. The 4.4 kilometres long and 880 hectares Owuru River wetlands and its four main tributaries freshwater wetland should ordinarily enhance the biophillic and spiritual values of the City but recent developmental activities including illegal logging, unauthorised fishing, land reclamation and peasant farming continue to strip the landscape of its vegetative cover. This is aggravated by fluvial flooding driven by erratic rainfall pattern in intensity and duration. Habitat loss and ecological
fragmentation are major threats to ecological health of the wetlands and the City. Hence the urgency for restoration that will benefit the residents and hundreds of thousands of spiritual tourists that monthly or occasionally patronize the Redemption City.

3.0 Biophilic Spiritual Landscapes

Spirituality is a way of life, an aspect of personality, an experience or simply a way of relating to a higher being in intangible realm. Religion include these spiritual aspects in an organized manner with defined hierarchy, history, and rules. The spiritual aspects of a person, a place, or an object cannot be seen, touched, or heard in many instances but exist as a realm, primarily outside scientific knowledge. Spirituality is then impacted by how humans interact and perceive natural landscapes as well as how the biophysical environment affects human lives. Kong, (2001) example of rain worship for groups living in arid climatic belts is fascinating. The physical and drier environment contributes to the worship of rain as a phenomenon.

This same perception of awe and inspiring natural landscapes with enchanting rivers and geomorphology trigger innate relationship which science classify as ecological goods and services. As noted by Mills, (1992) early men desire to travel down to rivers and wooded pathways to experience invisible realms. Humans delight in nature’s sense of beauty, felt the unseen powers and cultivated a sense of holiness. From that distant past until now, humans have found themselves existing not only in the bio-physical and social worlds, but also in the worlds of spiritual imagination. Therefore, spirituality is more about how humans as individuals and within groups see themselves fitting into duality of realms.

The numinous, cosmic and aesthetic dimensions of spirituality are important in understanding spiritual experiences man has in biophysical world especially at certain natural places. That is probably why Mills, (1992) submitted that the numinous, cosmic, and aesthetic dimensions of spiritual experiences define a spiritual landscape. Mills, (1992) definition of a spiritual landscape is undercurrent that drives Lane, (2002) triple axioms of sacred landscapes. The first axiom is a chosen place to be revealed (numinous). The second is an ordinary place made “sacred” through ritual and efficacy of prayers (cosmic). Thirdly it is a centre that is local and yet universal (aesthetics).

The definition of spiritual landscape for this paper follows the basic ideas of a “sacred place” but focuses only on natural landscapes in combination with the human element of perceptions, experiences and feelings. Since sacred places are often connected to some historical or religious documentation by a cultural group, this paper will free itself from such entanglement bearing in mind the Christian doctrine of the Redeemed Christian Church of God (RCCG), the proponent of the Redemption City. Therefore, the paper opts for the term ‘spiritual landscape’. The use of the term spiritual landscape allows for a more encompassing association of different natural landscapes that promotes intended Christian faith. Biophilic spiritual landscapes are more personal and relate to people’s personal spiritual experiences at such ‘places’.
Planning biophilic landscapes benefit landscape ecology conceptual framework. Landscape ecology is geared towards the identification of the various ecosystems, habitats, flora associations and species relative to the geomorphologic formations. It is also interested in how the local communities relate to the landscape as an ecological pool of goods and services. Since the objective of sustainable living is a continuous derivation of social, economic and cultural benefits from the environment, a biophilic planning that respects the biogeography must be conceived as the final restoration thinking framework for degraded ecosystem like the Owuru River.

This demands landscape re-interpretation. Landscape re-interpretation provides much needed window to understand historic antecedent especially people-nature relationship. Re-interpreting degraded local landscapes is the first step towards appropriate remediation, reclamation, rehabilitation, mitigation and restoration measures. While it is acknowledged that remediation, reclamation, rehabilitation and mitigation differ; this paper will use all-encompassing restoration as the act of bringing degraded ecosystem to its healthy and original state. Restoration of ecosystem actually referred to the restoration of fundamental processes by which ecosystems work. Ecosystem or habitat restoration is therefore restoration of its basic functions and processes that support biotic community.

Three issues should be considered in the process of restoration including remodelling of the physical aspects of the habitat; remodelling of the chemical aspects especially nutrients and toxicity; and replacing missing species or removing undesirable exotics (Bradshaw, 1996). It is apparent that successful intervention demands clear understanding of prevailing ecosystem problems.

It is a fact that services as link between human and ecological systems are opened to both internal and external influences. Hartel et al, (2014) observation of dynamism in social, tribal, cultural, institutional and economic spheres of any community is informative on what constitute agents of landscape changes. On urban scale, change in land use intensity triggered by population upsurge; informal settlements on fragile ecosystem enhanced by rural–urban migration; dumping of untreated sewage in precious wetlands; and insensitive urbanization have high capacities to redefine landscapes.

Mention should be made of unsustainable surface mining activities, poorly managed ‘slash and burn’ farming process and creation of dams with minimal consideration for socio-cultural perception of downstream rural inhabitants. So also are natural phenomena including tsunami, volcanic activities and climatic anomalies – major force behind devastating flooding and erosion in Nigeria coastline. Since any system can be dismembered physically, mentally and graphically it is necessary to fully comprehend which unit of the ecosystem needs urgent attention. That is, which ecological functions or processes are malfunctioning? What unit or units of the functions or processes are diagnosed and needs treatment?
4.0 Study Protocol

Four stages were involved in this study. The first stage focused on delineating existing drainage network and natural vegetation areas in the Redemption City. Secondary data from topographical maps, 2017 satellite images, previous soil and hydrological studies and field work were used to document existing vegetation and drainage network of the City. The second stage involved biotope mapping to comprehend inherent ecological goods and services.

Three interrelated steps including field surveys through four transect cutting of the wetlands, categorization of plant associations and structured interview of nearby communities to document fauna and fish inventory in the wetlands. Secondary data relied on information from topographical maps, 2017 satellite images and previous ecological studies.

The third stage include synthesis of structured interviews of community opinion leaders to document Owuru River restoration expectations; and questionnaires distributed to monthly tourists focused on understanding desired conservation perspectives especially how their needs can be accommodated in the final restoration scheme. The fourth stage is the biophillic design proposal based on the synthesis of the first three stages.

4.1 Biophysical Setting

Two broad ecological zones including fresh water and degraded low land rainforest are identified. The later supports the various urban layers drained by Owuru River tributaries eastward. It was pristine vegetation with characteristic 3 level physiognomy some 50 years ago. Intensive human activities especially urbanization and traditional shifting cultivation farming system fragmented the once luxuriant rainforest ecological zone. Patches of secondary bamboo association still remains at upper elevation along the Owuru River. Such patches may sometimes be difficult to distinguish from Owuru fresh swamp.

Degradation of the ecosystem translates to loss of habitat and extinction of typical faunas that roamed the zone some 50 years ago. Owuru swamp forest occupy the poorly drained soil areas of the flood plain. The organic matter contents of supporting soil are very high. The swamp forest is characterized by an even 6 meters’ trees height on the average.

Plate 1: Map of the Redemption City Showing the 4.4Km and 880 Hectares Owuru River Wetlands (Edited from Google Earth Satellite Imagery, 2017)
At its prime state the zone is structurally composed of tall trees, open canopy and an impenetrable understory with tangles of shrubs and vines. But most of the commercial tree species within the zone have been unsustainably harvested in the last 50 years leaving thick understory and scattered tall trees with boles less than 600 millimetres at breast height. The biodiversity of the fresh water swamp forest is dominated by less than 3 species at the prominent tree layer.

The conspicuous tree associations are *Raphia hokerii*, *Elaeis guineensis* and *Symphonia globulifera*. All but the later belong to the palm family. The dominance of each of the 3 species is influenced by prevailing edaphic variation, drainage pattern and level of water table. This subdivides fresh water swamp forest into three units namely Raphia Swamp Forest, Elaeis Swamp Forest and Symphonia Swamp Forest (Plate 2).

Owuru River landscape restoration will focus on these three native species in the re-afforestation program. This will be supplemented by bamboo species at the transition zone between the wetlands and the degraded secondary rain forest.

Mammals observed include *Tragelephasspekei* (Sitatunga), *Crossarchusobscurus* (Mongoose), *Cercopithecusnicitans* (white nose monkeys), *Cercopithecus mona*, *Naja melanolenca*, *Pangolin*, *Giant forest squirrel*, *Veranusnilotius* (Monitor lizard) and *Thryonomy swinderianus*. *Python sebae* are prominent reptiles.

The avifauna community is basically lower forest strata birds including; *Egrets*, *Storks*, *Ducks*, *King Fishers*, *Lily trotters*, *Pin-tailed whydah*, *Babblers*, *Bulbuls*, *Warblers*, *Sunbirds*, *Eagles* and *Forest robins*. A diverse range of the butterflies inhabited the fresh water swamp forest. Depending on the season, swarms of different butterfly species are noticed within the floodplain. Fish resources in Owuru River and the four major tributaries include *Tilapia nilotica*, *Tilapia galilaea*, *Tilapia sillii*, *Claria slazera*, *Heterabrancheus bidorsali*, *Heterotis niloticus*, *Gymnarchus niloticus*, *Cittrari nuscitharus* and *Lates niloticus*.

The core ecological goods include fresh water artisan fishing, peasant farming, ethno-botanic resources; fuel wood sourcing; and
palm wine making. Services include wetlands water filtration, fluvial flood soft engineering control and religious interactions. The importance of the Owuru River wetlands soft engineering and water purification services cannot be compromised with the reality of incessant flooding in recent years and uncontrollable reclamation responsible for the degradations and high turbidity (Plate 4). The success of the Owuru River restoration will be influenced by the provision of alternative livelihood for the local people.

Plate 4: Owuru River Showing the Level of Degradation and Turbidity

4.2 Socio-Religious Inputs
Restoring the biological diversity of the Owuru wetland demands inclusive planning that respects the inputs of the Redemption City residents and the monthly spiritual tourists. Analysis of questionnaire returned by the tourists show preference for highly vegetated natural parks that accommodate praying alcoves, meditation points and group picnic grooves. These participatory submissions and the biophysical findings constitute the undercurrent for biophillic planning programming of the Owuru River restoration. Considerations are given to the following in the wetlands restoration programming; reintroduction of four native plant species in the degraded areas and setbacks of the four main tributaries; use of shade trees on the streets; alternative livelihood for local people especially small scale; nature trail, off road bike lanes, rest stops and picnic shelters; meditation gardens and picnic groves.

5.0 Owuru Wetland Biophillic Restoration Framework
Site inventory, analysis and synthesis shows the prime position of the Owuru River and its four major tributaries in the hydrological process, edaphic variation and the vegetation associations in the study area (Figures1 & 2). Restoration framework focus on meeting the primary purpose of the settlement relative to site ecological goods, services and human needs. The primary goal of the Redemption City is spiritual upliftment of both residents and the monthly tourists. This brings into focus the numinous, cosmic, and aesthetic principles of spiritual landscape (Mills, 1992).

Conceptualizing the wetlands as Christian spiritual landscape looks into localizing biblical scenario that appreciates the hydrological description in the Garden of Eden. The Kings James Version (Tecarta Inc., 2017) account of the Bible identified four rivers that define the hydrological patterns of Eden namely; Pishon, Gihon, Tigris and Euphrates. The root meaning of these rivers relative to the names are Pishon which means ‘increase’; Gihon connotes ‘bursting forth’; Tigris is ‘rapid’; and Euphrates means ‘fruitfulness’. The four
Owuru tributaries are metaphorically viewed as the four rivers (*Pishon*, *Gihon*, *Tigris* and *Euphrates*) and the four confluences conceptualized as praying and meditation groves to characterize ‘Increase’, ‘Bursting Forth’, ‘Rapid’ and ‘Fruitfulness’.

5.1 Biophilic Proposal
The goal of biophilic design principles is drawing man towards a positive relationship with nature. The starting point is nature conscious site planning process. As noted by LaGro Jr. (2008) “sustainable approach to site planning pays close attention to the development intensity, location and considers the initial benefits and impacts of developments”. Ecosystem conscious site planning respects contextual environmental process, highlights protection of fragile natural and cultural resources.

The bottom line is to minimize developmental impacts by fitting human design into ecological patterns and processes. Site programming towards the Owuru River wetlands biophilic restoration is conscious of pragmatic development with site’s hydrological system since the improperly introduced land use and land use changes may negatively impact water quality and quantity.

While allotment garden and fish farming are introduced to meet the livelihood needs of peasant farmers, four praying and meditation groves were introduced in clusters according to the interpreted biblical Garden of Eden rivers cape. Non-motorized transportation mode including elevated deck board, nature’s trails and off road bike routes drive low carbon movement within the wetlands (Figure 3). The spiritual landscape sacredness ambience is enhanced in each of the four alcoves, trails, rest stops by numinous, cosmic, and aesthetic principles using native plant species and park furniture.

Figure 1&2: Analysis Showing the Elevation and Vegetation Plan

Figure 3: Proposed Site Plan
6.0 Conclusion

Bio-centric approach to landscape restoration is at the centre of sustainable solutions to the current environmental crisis plaguing humanity. More than other nature conscious design philosophies, biophilia will go a long way in restoring symbiotic relationship between man and nature. This has been the focal point of this paper to engage biophillic perspective as a restorative approach that invokes religious values of the Owuru River freshwater landscapes. Site programming was conscious of the social use of the wetlands by the permanent residents of the Redemption City and attributes that should
enhance the place attachment for the religious tourists. Introduced clusters of small scale aquaculture centre and small scale vegetable allotment gardens provided alternative livelihood for the artisan and peasant farmers.

Raphia hokerii, Elaeis guineensis, Symphonia globulifera and bamboo species native to the wetlands were suggested as the species for reforestation of degraded patches. They will not only attract the fauna and avifauna resident to the wetlands but also increase the naturalness on which the biophillic essences depend. Then suggested nature’s trails, rest stops, prayer and meditation alcoves will manifest desired numinous and cosmic ambience to create place based sacred Christian wetlands landscape.

Impact of Elements of Rock and Water Combination on Landscape Perception; a Visual Landscape Quality Assessment on Kaludiya Pokuna, Sri Lanka

Dissanayake.C, a Hettiarachchi.A.A, b

a University of Moratuwa, Moratuwa, 10400, Sri Lanka
b University of Moratuwa, Moratuwa, 10400, Sri Lanka

Abstract

Landscape architecture needs to encompass a place making process, carefully composing and manipulating landscape elements to address perceptual needs of humans, especially aesthetical, psychological and spiritual. The objective of this qualitative investigation is to enquire the impact of elements of rock and water combination on landscape perception and related feelings, emotions and behavior.

Past empirical studies have assessed the impact of landscape elements in isolation on user preference, yet the combined effect of elements have been less considered. This research was conducted with reference to the combination of qualities of water and rock through a visual landscape quality assessment focusing on landscape qualities derived from five visual concepts (coherence, historicity imageability, naturalness, and ephemera). “Kaludiya Pokuna” archeological site in Anuradhapura was investigated with a sample of university students (n=19, male 14, female 5, age 20-25) using a five point Likert scale via a perception based questionnaire and a visitor employed photographic survey (VEP). Two hypothetical questions were taken in to investigation concerning biophilic (naturalness) and topophilic (historicity) aspects of humans to prefer a landscape with rock and water.

The findings revealed that this combination encourages both biophilic and topophilic aspects, but in varying degrees. The identified hierarchy of visual concepts based on visitor’s preference signify coherence (93%), historicity (89%), imageability (79%), naturalness (75%) and ephemera (70%) respectively. It was further revealed that this combination creates a scenery more coherent dominating information processing aspect of humans to perceive a landscape over the biophilic and topophilic aspects. Different characteristics and secondary landscape effects created by rock and water combination have impacted in transforming a space in to place, fulfilling the aesthetic and spiritual aspects. These findings enhance a means of making places for people, resource management and historical landscape conservation. Equalization of gender based participation, taking diverse cases and increasing the sample size with more analytical photographic analysis are recommended to enhance the quality of further research.
Key words; Biophilic, Landscape perception, Visitors’s preference, rock and water combination, visual concepts.

1. Introduction

Landscape architecture is one of the most important disciplines focused on the space designing process for the human, considering not only the fundamental needs but also other aspects like psychological, spiritual and aesthetic needs. Space designing is done composing landscape elements. It can be a combinations or arrangements of hard and soft elements in an artificial or a natural setup. “Human functioning depends on information, much of this information is provided by the immediate environment. There are combinations and arrangements of elements that constantly require deciphering” [1]. It is essential to investigate the most preferred landscape elements and human perception associated with that particular elements, determining the corresponding effect on change in human behaviour, feelings, emotions and expressions.

Water is one of the most important aesthetic and functional elements of the landscape. It is essential to know the visual qualities of water when planning and designing the landscape. “Water in the landscape tends to be dominant because of its visibility, movement, reflections, colour and consequent contrast to adjacent earth surfaces.”[2]. Reflection of water as a continuously changing source of beauty in the landscape and reflected light from surfaces link the visual environment with human feelings [3]. But, water cannot generate such qualities being in isolation and should be fused with other elements, preferably hard elements. Human beings prefer isolated hard elements less. The ‘yin yang’ philosophy explains the nature of combining opposite elements together to complement the sense of satisfaction. It further describes how apparently opposite or opposing forces may actually be complementary, interconnected, and interdependent in the natural world, and how they may give rise to each other as they correlate to one another [4]. Accordingly, it is evident that, Sri Lankan as well as other eastern landscape traditions, have repeatedly used rock as a hard material combining with water and it has been continuing for a long time in history [5].

The user preference on landscape elements, element combinations and the corresponding impacts on people’s perceptions have been less considered in current landscape interventions where the quality of space has been sacrificed enormously due to the impact of economic factors, time factors and political decisions on the landscape design process.

This research focuses on user preference on combination of rock and water elements in landscape and how it impacts landscape perception. The study intends to enquire as to why water and rock material combination has been used repetitively in landscape design, with the use of supportive literature. The influence of above combination on human perception with reference to an array of qualities of water combining with rocks will be looked at focusing on human feelings, emotions, expressions, behaviours and preference to spaces.

It was limited to assess five visual concepts which are related to this combination. The architectural landscape selected included sufficient sceneries with rock and water combination and having
significant religious and historical background.

This research was conducted to fill the gap in empirical knowledge of the landscape perception paradigm. There are a number of research conducted on the landscape style, preference of landscape elements, landscape perception and the relationships of preference of water, vegetation and rock. None of them have examined the relationship of water and rock material combination and how it affects the human perception of a space.

2. Literature review

2.1 Human perception

Perception is the process of recognizing and interpreting sensory stimuli in which information is consequent through senses and a complex sensation of the inner mind, stimulated by outside encouragements. It is an active process which takes place between the organism and its environment [6]. Perception can stem from abstract notions such as memory and preference. This means that it will be affected by that person’s experience and empirical knowledgebase as well as the culture in which they were brought up in.

2.2 Landscape perception

Landscape perception is considered as a function of the interaction of humans and the landscape [7]. The human component encompasses past experience, knowledge, expectations and the socio-cultural context of individuals and groups. The landscape component includes individual elements, combination of elements and landscapes as objects. The outcomes of the interaction results are affected by both the human and landscape components. Humans are biological and social beings, therefore several theories have been combined with landscape experience which differ remarkably in the way they treat biological against social determinants of landscape experience. Further it has been discussed on two notions; moods of landscape perception, namely space and place.

2.3 Space to place transformation

It is explicated that humans perceive the landscape in as space primarily in relation to their biological needs in which they focus on the subsidiary use of the landscape. It will be transformed into a place when people perceive the landscape in terms of self-reflection such as experiences, achievements and social integration like values, norms, symbols, and meanings. [8]. Thus, when individuals or groups become familiar with a particular space and link it with their cultural values, social meanings and personal experiences, it becomes a place for them [9]. In other words, personal, social and cultural processes of appropriation
superimposes a layer of meaning on space and thus transforms it into place.

2.4 Topophilic aspects of sensing a space

The word Topophilia, which literally means “love of place” is a strong sense towards place mostly mixed with the sense of sociocultural identity among certain people and a love for certain aspects of such a place. The love of or emotional connections with a place or physical environment is mainly based on visual perception. However, people perceive the environment through more than five senses (seeing, hearing, touching, tasting and smelling) [9]. Topophilia takes many frames and varies greatly in emotional range and intensity; visual pleasure, sensual delight, fondness to place etc.

2.5 Biophilic aspects of sensation

Biophilia is the innate love towards the natural world, supposed to be felt universally by mankind. It is believed to have developed through evolutionary history as a consequence of its functional significance. This hypothesis describes the human needs of intellectual, cognitive and even spiritual meaning of satisfaction, rather than the fundamental needs of physical matters. Biophilia can be further defined as the innate tendency to connect with nature and other forms of life with the aesthetic and spiritual satisfaction [10].

2.6 Information processing theory

Information is the ultimate concept of their approach. Information has been dominant to human experience and survival throughout the evolution of the human being [11]. People need to gain information to make sense out of the environment, but an individual also values environments with capable information for exploration [12]. Further, people gain information from the immediate environment through their senses, mostly through the visual sense. This theory suggests that information is derived through the contents and the organization of the environment. Organization of an environment is an important variable in perception since it affects the degree of making sense.

2.7 Landscape preference

The content and spatial arrangement of landscape attributes could be used to predict landscape preference as suggested in theories of landscape aesthetics [1]; [13]. Further, the impact of these attributes on preference can be objectively measured through preference scores by altering the biophysical attributes in the images [14]. As per the established framework by Ode et al (2006), there are nine key concepts describing visual landscape character namely, stewardship, disturbance, coherence, historicity, imageability, scale, complexity, naturalness and ephemera [15]. Furthermore, reviewing landscape preference research may provide a better understanding on the notion of place.
attachment. In the field of environmental psychology, research on visual preference has been developed in such a way to identify and understand the values that people place on different landscapes [16].

Out of the nine parameters which explain concepts describing landscape character [15] the current investigation will look into the five aspects namely coherence, imageability, naturalness, historicity and ephemera. The justification behind this selection is that each of these concepts focus on different aspects that contribute to the visual quality of the landscape, where visual quality is a holistic experience of them all. The visual concepts presented are used to describe different characteristics of visual landscapes, rather than presenting a normative value for visual quality.

Figure 9 summarizes the relationship between the five selected landscape qualities and corresponding visual concepts described under the landscape perception theories.

2.8 Human perception on rock and water

Meanings and values related to water and rock in the landscape, varies diversely in the sources of literature on human perception, ranging from ancient religious, spiritual and even mythical references to modern technical and scientific studies. Viewing water in the landscape has been found to have beneficial psychophysiological effects, potentially serving important restorative health needs [17]. Reflection of water as a continuously changing source of beauty in the landscape and reflected light from surfaces links the visual environment with the human feelings [3]. Thus, water plays a vital role directly affecting the overall landscape perception resulting in corresponding feelings and expressions. On the other hand people are found to have a tendency of being closer, attached or being in love with rocks/stones present in landscapes. Accordingly rocks/stones are found to play a main role in appreciation of a landscape connected with an array of meanings, feelings, emotional and behavioral connotations. For instance the deep and intense love or passion of
Chinese culture for rock or stones identified as “Lithophilia”, has encouraged people even to venerate rocks [18].

3. Research Methodology

The method of study was based on a public perception based approach. A visual landscape quality assessment was conducted to understand the landscape attributes, their spatial patterns and their importance to people with reference to thirteen identified landscape qualities that contribute in creating the five visual concepts; coherence, imageability, naturalness, historicity and ephemera. It was attempted to identify the most influential factors on landscape preference associated with rock and water combination present in a landscape.

Two hypotheses were tested via a combination of qualitative and quantitative data collection, namely photo projective method (PPM) [17] and questionnaire survey. The assessment context and the instructions were provided to the observers who were asked to rate landscape quality to express preferences among landscape scenes in a selected location. A sample of University students (n: 19, age: 20 – 25, female: 5 and Male: 14) of the same ethnic group and same region were engaged as respondents for the final data collection. Visitor employed photograph (VEP) method was adopted in capturing the sceneries with a moderation to ensure the quality of the photographs. Two hypothetical questions were derived by reviewing the theories on the landscape perception as applicable to the subjects of Sri Lankan context. (For the summery of research design see appendix A)

Hypothetical question 1,
Do people prefer spaces with rock and water because of the inherent tendency of humans to connect with nature? This refers to the influence of the notion of biophilia (naturalness) on landscape preference.

Hypothetical question 2,
Are there any influences for the people to prefer a landscape because of the historical influence and cultural identity of rock and water? This refers to the influence of the notion of topophilia (historicity) on landscape preference.

3.1 Case study

Among an array of Sri Lankan historical landscapes where different rock and water combinations can be found, Kaludiya Pokuna was selected as the case to investigate the biophilic and topophilic aspects. It has both natural and historical value without any domination and reputed for its qualities emerged by the said

Fig. 4 – Contextual map - Kaludiya pokuna monastery landscape, Source: Google earth
Further, the study focuses on a religious landscape because this combination has played a significant role in religious landscapes in the eastern world. It is also one of the monastic landscapes with adequate sceneries with rock and water which is proven to be a designed landscape [5].

4. Findings and analysis

As the first step, diverse landscape qualities perceived by participants based on their overall perception of Kaludiya Pokuna was brought in to focus. Secondly the contribution of the elements rock and water to generate such qualities and its impact on the overall landscape perception was considered. Data has been presented and analysed to identify the relationship between the five visual concepts and thirteen landscape qualities. How each visual concept has been impacted by the characteristics which are created by elements of rock and water is being discussed. Furthermore, special behaviours, feelings, emotions and expressions regarding their most perceived sceneries have been recorded via sketches and photographs.
4.1 Landscape qualities in the overall Kaludiya Pokuna landscape

Participants were asked to walk around the landscape and find the location where they perceive the best scenery of Kaludiya Pokuna. Figure 6 presents the most preferred locations to capture the best scenery by each participant (n=19). They were requested to make sketches based on the elements/qualities present in the most perceived sceneries. It was found that the subjects have mostly selected sceneries with elements of rock, water, trees and monuments.

Figure 7 represents the landscape qualities perceived by subjects presented in relation to the five visual concepts.

Figure 8 reflects the fluctuations of five visual concepts with reference to the overall landscape perception. This can be considered as a manifestation of all the elements, attributes of the Kaludiya pokuna landscape. According to the results 93% participants voted for coherence, 89% for historicity, 79% for imageability, 75% for naturalness and 70% for ephemera. The most voted visual concept is coherence while the least is ephemera. To get the mean value, it has been considered that all qualities give equal contribution to create a visual concept.

4.2 Contribution of rock and water to feel spatial qualities

The elements rock and water were recognised as influential factors for feeling specific qualities in a landscape. Figure 10 represents the rating for rock, water and overall landscape elements to create visual concepts with reference to the most perceived sceneries of participants.

According to the result, water and rock have highly influenced in creating coherence. But water has dominated in making people feel naturalness while rocks are highly dominating in making them feel historicity. However the results reflect that both water and rock are influential elements in creating visual concepts. According to the findings, the hierarchy of visual concepts derived are as below.
As revealed by the interviews, it was the first time for most of the participants to visit “Kaludiya Poking”. They selected sceneries around the pond focusing on the water surface, rock boulders and trees as most preferred, except one participant. Viewing natural sceneries while being in designed spaces of the “Kaludiya Pokuna” were preferred by 74% of the participants. That includes spaces where they have retaining walls and arrangements to sit and witness a natural scenery combined with the surface of water, boulders, trees and the mountain. 26% of the participants preferred to see sceneries which included more designed elements. Thus, a majority of the people preferred to see more natural sceneries with water surfaces, rock and trees while being in a physically comfortable and designed space. According to the comments of participants it was found that,

- Satisfaction of fundamental needs - 21% of participants
- Satisfaction of spiritual and aesthetic needs - 79% of participants

As identified in the photographic analysis, though it was a novel space for the participants, they became familiar with the environment linking it with their cultural values and personal experiences. Rock and water were dominant in 95% of the participants’ photographs and 89% of the participants preferred to see a reflective water surface. It was found that people preferred to be in different levels to see the water surface with different viewing angles for a better degree of reflective surface. Further, the distance from the edge of the water surface also differed from person to person. 47% of the participants preferred to observe the scenery keeping a 1-2 meters level difference from the water surface. Significantly, female participants selected...
locations which were very closer to the water surface and preferred to see more details in the scenery while males preferred much broader sceneries. Accordingly, findings of the photographic analysis have further strengthened the results of the questionnaire survey.

5. Conclusion

This investigation focused on seeking the impacts of elements rock and water on landscape perception and their influence in generating perceived qualities of a landscape characterised by corresponding human feelings, emotions, expressions, behaviour and consequently preference of a space. The study tested thirteen landscape qualities established to have an influence in generating five visual concepts namely coherence, imageability, naturalness, historicity and ephemera via a perception based approach. The objective was to find the most influential factor/factors on landscape preference and the contribution of rock and water combination in this regard. Two hypothetical questions were taken into investigation. It was found that biophilic association of humans have been influenced by rock and water combination in a considerable level in landscape preference. Further this combination was found to associate with aesthetic, mental and spiritual satisfaction of humans. The biophilia hypothesis was partially proven and it was placed as the fourth parameter (75%) in the hierarchy of visual concepts based on responses. Parallel with the philosophy of yin yang, being a combination of opposite/complementary; hard and soft elements, perception of rock and water combination has contributed in providing aesthetic and mental satisfaction for the participants beyond satisfying their fundamental needs. In addition, it was demonstrated that historical influence and cultural identity of rocks have influenced the familiarity and attachment to a space consequently transforming it in to a place. Thus, people become tied with the material environment due to love of place as mentioned in theory of Topophilia. The characteristics and secondary landscape effects created by rock and water combination have affected in creating a strong sense which trigger the human senses to convert even a newly perceived space into a place for people. Therefore topophilic hypothesis has been partially proven and found as the second parameter of hierarchy of visual concepts based on preference (89%).

Thus this combination was identified to satisfy both Biophilic and Topophilic aspects of landscape preference. Accordingly hypothesis one and two are partially correct. However, these are not the only aspects having an impact on landscape preference regarding rock and water element combination. Beyond the expectations of the study, the results revealed that the most influential factor to prefer a landscape is coherence (93%). As per literature, coherence refers to the manner as to how different elements of a composition have been combined together in correct proportions to generate a pleasing visual effect in the environment. Accordingly, harmonisation of rock and water in correct
proportions was identified to create a pleasing effect in a landscape scenery.

This combination was found to assist concentration and relaxation of the mind, releasing fatigue and making spaces more memorable and unique. Imageability (79%) was identified as the third in the hierarchy of factors influencing landscape preference. All the visual concepts were found to contribute in varying degrees with reference to the said combination as presented in figure 11.

It was found that information processing was dominant in perceiving a landscape over the biophilic and topophilic aspects of humans, in preferring a space with rock and water combination.

This study was delimited to the impacts of rock and water combination in the perception/preference of a religious landscape with reference to landscape qualities and corresponding visual concepts. Accordingly, the findings can be applied in future religious landscape solutions as well as for conservation of historical landscapes.

It is recommended to execute the study with a diverse array of landscapes and samples representing the differences of age, education level, cultural background and ethnicity to generalize the impact of said combination to a wider context. Incorporating both male and female participation to equalize the impact of gender based perception and increasing the sample size can be suggested for a more valid result.

Further, a more analytical photograph analysis can be suggested; conducting a comparative volumetric analysis on proportions of the elements visible in photographs and locations of the participants.

Acknowledgement

This is the opportunity to appreciate the persons who were behind me to make this dissertation a success. It was only because of the immense support, assistance, criticism and encouragement offered by many persons that I was able to complete the endeavor. I must mention the supervision and guidance of Dr. Anishka Hettiarachchi. Her commitment is appreciated through and through. And Prof. Shirani Balasooriya for her patient advice. And also thank department head Dr. Gamini Weerasinghe for his support, Prof. Samitha Manawadu for giving the directions. Archt. D. P. Chandrasekara and Archt. Janaka Dharmasena for guiding the whole way. I thank my parents for their support in every way. None of this would have been possible if not for them. And friends who helped me without even a little bit of hesitance must be mentioned Binushka Jayasanka, Aruna
Welagedara, Yeshmanthi Ekanayake. This acknowledgement does not cover all the people that helped me get this far—most of their names I do not even know. However I would like to leave a last word, saying how greatly in debt I am to everyone for their kind assistance and coordination. Therefore with great pleasure I take this chance to dedicate this humble work to them all.

Abstract

Current situation of Sri Lanka face critical conditions on therapeutic landscape installments. Juvenile delinquents in probation centers has unique refracted behaviors according to what they perceive. This study discusses if these landscape spaces truly fulfill their need or are these spaces functioning just because they doesn’t have a better choice to satisfy their requirements. Methodology of this study flows through a Literature survey and case study survey. Case study survey has done by using research tools like questionnaire, Behavioural mapping, observations and Social development scaling method through Linkert Scale. Moreover, this study explores six factors of therapeutic landscape architecture. Namely these factors represents as variety, extent, scale, enclosure, fascination and interaction. Contribution of the landscapes in Thaldena and Weraluwatte child probation centers in Sri Lanka were critically evaluated. Finding shows the effect of these factors on rehabilitation of juvenile delinquents. This study discusses on the issues related to less implementation and appreciation of therapeutic spaces. Furthermore it analyses how above therapeutic factors support to rehabilitate juvenile delinquents. The study will support to create guidelines for future landscape architects to overcome issues of designing therapeutic landscapes.

Key words- Therapeutic landscape architecture, rehabilitation, Juvenile delinquents

1. Introduction

Therapeutic landscape architecture has the ability on healing human critical psychological conditions. This landscape architectural method has being used as a media to rehabilitate scattered psychological conditions for Juvenile delinquents, Prisoners, drug addicts, cancer patients, elderly people and many distinctive conditions. [1](Darbouze, 2007), (Rebecca, 2007). Both natural and built environment helps to buildup such landscapes. Therapeutic landscapes lays its main foundation on an investigation on user behavioral, government regulations and restrictions, visual impacts on users, and interactions. A landscape architect has the ability to give solution for dispersed psychological conditions. Among all the people who dealing with this situation juvenile delinquents are getting attention of a special
requirement of rehabilitation in the future. One of a restorative method that can heal wounded situation of a juvenile delinquent is therapeutic landscapes within outdoor space.

1.1. Research need

There are many juveniles that has not being able to rehabilitate properly through the appointed process. Current research shows that the environmental aspect plays a main role of the psychological restoration. Landscape architects has the ability to contribute a restorative media for human mind. When designing restorative spaces designers intend the space will benefit to people to stress restoration [2](Kaplan, 1992). Unfortunately, there are lacking areas in Sri Lankan restorative landscape designs. This situation affects negatively for people because landscape design is the main bridge between human and nature since it fills the gap in-between natural and built environments [3](Xiangqiao Chen & Jianguo Wu, 2009). As the matter of fact therapeutic landscape spaces is the key to ease human mind. When the connection between human and landscape loosened, human mind become more unstable and it is hard to heal human mind without the influence of landscapes. The contribution to the rehabilitation is becoming low due to the less implementation and appreciation of healing architecture. This additionally effects on “spatial profitability” which can be defined as the profit we can gain from a landscape design project. If people uses the designed spaces for their wellbeing effectively, that landscape design is low in spatial profitability. Delinquents’ ultimate rehabilitation outcome is becoming low due to this less implementation of space. Which discourage safer future to the society.

To minimize this issue this therapeutic landscape designs must give much creative and satisficing solutions which are contributive to juvenile needs. For that, the factors which should be in this designs have to be found and the designers have to consider that factors to give much profitable, much responsive, much restorative and relaxing therapeutic spaces.

This study is an effort to study about the architectural attributes to create much effective rehabilitation media through landscape designs.

1.2. Research problem

Are there any factors in an effective therapeutic landscape designs which affect for juvenile delinquent’s successful rehabilitation? If so, what are they and how they affect?

1.3. Objectives

Objectives are to identify the factors which affects for rehabilitate juvenile delinquents within designed therapeutic landscapes, and to find how these factors support to create comfortable and effective rehabilitation through the process of juvenile rehabilitation.

1.4. Methodology

(See Appendix 1 for a flow chart showing the methodology) above diagram describes the flow of methodology. This methodology conducts a mixed method which involve qualitative and quantitative study.
1.5. **Case study criteria**

Weraluwatte and Thaldena rehabilitation centers in Sri Lanka will be selected to study the effect of therapeutic landscape effect. Above rehabilitation centers are popular among people as the best juvenile rehabilitation centers in the county. Both centers have their unique landscape qualities. These two probation centers has highly concern about the surrounding environment on rehabilitation. Furthermore these centers has applied therapeutic landscape measures on immediate landscape. Nevertheless these centers have comparative levels of therapeutic landscape implementations. These places are ideal for a comparative study to analyze the study criteria.

1.6. **Outcome**

This research will explore and present the factors which influence effectiveness of restorative therapeutic landscape design aspects with special reference on rehabilitation of juvenile delinquents. It will give guidelines for landscape architects to overcome issues of designing therapeutic spaces. Through that the utilization of therapeutic landscape designs will increase and also it will contribute to maximize the profit we gain from that space.

1.7. **Scope and limitations**

This study will be limited only to consider on rehabilitating juveniles through therapeutic landscape architecture. Juveniles are open to outdoor till morning to evening. These spaces are mostly functioning at day time, in cause of the government regulation the study will be limited only to day time observations. There are many aspects to measure the effectiveness of designed landscape spaces, but this study will only be done by observing main user behavior. Also there are many factors which contributes to increase effectiveness of designed landscapes according to scholars’ opinions, but in this study only six parameters will be measured out of them. Also there are number of methodologies to move on with this research area and only questionnaires, behavioral maps and cognitive scaling methods will be used to do this study. Only three case studies will be selected and this whole study will be done within a time lime limitation of five months.

2. **Therapeutic landscape and rehabilitation of juvenile delinquents.**

2.1. **Therapeutic landscape architecture**

Designed therapeutic landscapes are environments which can restore stressful mind conditions. These design interventions are popular for creating a rehabilitative surrounding for special need users. [4] (Sanoff H., 1990) Restorative environments makes human restorative experience enhanced to reduce mental fatigue. [2] (Kaplan S., 1992) These designs contribute users to be more tolerant, more effective and healthier lifestyles. People always tends to navigate themselves by following surrounding environment. [5] (S. Kaplan & R. Kaplan, 1982) few restorative landscape architectural properties can build up a therapeutic landscape space. These spaces navigate human behavioural patterns by effecting on human cognitions.
Surrounding landscape helps to rehabilitate juveniles’ psychological conditions. In designed therapeutic outdoors juveniles acts calm and tamed with each other. In addition to psychological and emotional benefits that the landscape can bring some studies suggest it could actually gain some positive social interactions as well. Such as these landscape open a chance for self-appreciate, helps to gain mind restoration and also to makes a room for interact with each other’s. These value of benefits makes a child to uplift their positive behaviours toward the society.

2.2. Rehabilitation of Juvenile delinquent’s psychology

Juveniles are separated from their existed social background, relatives, friend and family on their probation period. They begins a new life with a foreign society. Replacement of day today life is foreign to an adolescents, which may lead to stressful situations.

Studies shows juvenile delinquents behave very aggressively and untamed inside build surrounding. [7] (Glaser, 1992) although it is, the inner child behavior of a juvenile always outtakes on their play times. Outdoor spaces helps the children to integrate with themselves and also with the surrounding population.

Several rehabilitation centers around the world has respond to landscape architectural factors in terms of spatial qualities. Rehabilitation by designed spaces helps to achieve a successful outcome of a child.

2.3. Theoretical background based on therapeutic landscape architectural solutions on rehabilitation of juvenile delinquents

When considering medical-geographical rehabilitation, therapeutic landscape plays a major role of emphasize human psychological recovery. Researches has found to heal broken philological conditions of human cognitions through medical geography. [8] (Smith, 2005)

Restorative experience can introduce through a form of therapeutic landscape architecture. An allusion to Kaplan, human mental fatigue can be reduces through restorative environment. [2] (Kaplan S., 1992)

Sensory experience of the surrounding environment can appreciate physical and psychological wellbeing. Osei has found, special care needers gets a positive benefit through sensory design in therapeutic architecture. The human five senses stimulated by different sources provided by the environment.[9] (Osei, 2014)

3. Theoretical Framework and Methodology.

3.1. Theoretical framework of the study

When considering the studies of different articles there are many landscape architectural factors effect on juvenile delinquent’s psychology. This factors are categorized as Physical landscape, social landscape and emotional landscape spaces. This study elaborates six factors which influence human behaviors.

1. Variety (Physical attributes)
2. Extent (Physical attributes)
3. Scale (Physical landscape)
4. Degree of enclosure (Emotional landscape)
5. Fascination (Emotional attributes)
6. Interacting areas (Emotional landscape)

(See Appendix 2 for a figure showing factors influencing juvenile's psychology)

3.1.1. Physical attributes of therapeutic landscape architecture

According to therapeutic landscape architecture many factors helps to elaborate human psychological rehabilitation. Physical attributes are the factors which created physically through built environment. These factors helps juvenile to accelerate their positive thinking and mind rehabilitation. Some of the factors can be identify as variety, extent and scale.

3.1.2. Emotional attributes of therapeutic landscape architecture

Above various factors of therapeutic architecture medicinal and most mind restorative attribute are emotional landscape attributes. Therapeutic landscape architecture has the ability to influence positive attitudes of human through mind restoration. Some unique factors of therapeutic landscapes can heal scattered human minds. These factors can be identify as Degree of enclosure, fascination and social interacting areas

3.2. Physical attributes

3.2.1. Variety.

Variety gives choices for people. Human mind always seek for various opportunities in environment. [10] (Eco, 1980) May be too much choices also can be uncontrollable, but in every space there should be variety to some extent. Both functions and spaces should have variety to suite human needs and improve the opportunities to feel and enjoy that whole space. Variety of spaces can be created by giving various facilities, uses, forms, elements, etc. Variety can helps to accelerate mind enthusiasm without being board. Variety can enrich the therapeutic quality through a balanced involvement of it.

3.2.2. Extent.

Extent is highly effective factor of therapeutic landscape. [2] (Kaplan S. , 1992) one can encounter his or her spiritual contemplation through enjoying distance vicinities. Current researches shows that two different characters in distinct places which is visually connected, helps to rehabilitate scattered psychological conditions.

3.2.3. Scale

Scale effects for human mind and comfortability. Glaser has shown scale as an important factor of a therapeutic measure. Human scale is important to scale the elements around the therapeutic design. As delinquents psychological measures they get scared and nervous through huge elements on existence.

3.3. Emotional attributes.

3.3.1. Degree of enclosure

Degree of enclosure is very sensitive architectural factor that can effect a delinquent psychology. [11] (Thiel, 1986) On a perspective of a landscape architect, juvenile delinquents can be encourage to feel safe by controlling of the degree of enclosure of landscape spaces. Degree of enclosure of the space can offer in from different forms,
angles and special characteristics within the space.

3.3.2. Fascination

According to Professor Kaplan’s findings, fascination is one of the most unique characteristics of a therapeutic landscape. [5] (S. Kaplan & R. Kaplan, 1982) A designed landscape can cater for human’s emotional fascination in order to generate restorative experience. Restorative experiences depend upon interest or fascination. Fascination allows juveniles to function without using direct attention.

3.3.3. Social interaction

As above statement, social interactions help to enrich restorative experience for mind rehabilitation. [8] (Smith, 2005) Juvenile delinquents are judicially appointed to being apart from the society. Although this is a judicial requirement for delinquent, in order to rehabilitate juveniles need to be expose to the society. Landscape spaces can enhance considerable amount of social interactions among outside people of the center and also within the center. This human relationship consolidation can help to heal bad influence, rage and fear of juvenile delinquents towards people.

3.4. Methodology

Most of similar studies have done by using mixed methods. Photographic surveys are usually used to prove and analyze observations. In some studies there are number of case studies and in some studies few cases were selected in within one case study. This method also seems to be effective. Also using cognitive mapping will be effective because this studies are dealing with adolescence behaviors.

So it will be better if this study also can move on with mixed method. Both Qualitative and quantitative. Also photographic survey will be important to prove and analyze observations. Selecting one or two case studies and within that case studies, selecting few cases to study will be effective. Use of tools like behavioral maps and cognitive maps will support to select this cases and to further study on human behavior within that spaces.

4. Case studies and data presentation

4.1. Case study 01: Weraluwatte child probation center

4.1.1. Physical landscape attributes.

4.1.1.1. Variety

See appendix 3, appendix 4 and appendix 5 for bar charts showing data relatively on variety of space, variety of facilities and variety of visual experience in Weraluwatte child probation center.

4.1.1.2. Extent

See appendix 6 for a bar chart showing extent in Weraluwatte child probation center.

4.1.1.3. Scale

See appendix 7 for a bar chart showing scale in Weraluwatte child probation center.

4.1.2. Emotional landscape attributes

4.1.2.1. Degree of enclosure

See appendix 8 for a bar chart showing degree of enclosure in Weraluwatte child probation center.
4.1.2.2. Fascination
See appendix 9 for a bar chart showing fascination in Weraluwatte child probation center.

4.1.2.3. Social interaction
See appendix 10 for a bar chart showing social interaction in Weraluwatte child probation center.

4.1.3. Juvenile Behavior
See appendix 11 for a map showing juvenile behavior in Weraluwatte child probation center.

4.2. Case study 02: Thaldena Rehabilitation center

4.2.1. Physical landscape attributes

4.2.1.1. Variety
See appendix 12, appendix 13 and appendix 14 for bar charts showing relatively on variety of space, variety of facilities and variety of visual experience in Thaldena rehabilitation center.

4.2.1.2. Extent
See appendix 15 for a bar chart showing extent in Thaldena rehabilitation center.

4.2.1.3. Scale
See appendix 16 for a bar chart showing scale in Thaldena rehabilitation center.

4.2.2. Emotional landscape attributes

4.2.2.1. Degree of enclosure
See appendix 17 for a bar chart showing degree of enclosure in Thaldena rehabilitation center.

4.2.2.2. Fascination
See appendix 18 for a bar chart showing fascination in Thaldena rehabilitation center.

4.2.2.3. Social interaction
See appendix 19 for a bar chart showing social interaction in Thaldena rehabilitation center.

4.2.3. Juvenile behavior
See appendix 20 for a map showing juvenile behavior in Thaldena rehabilitation center.

5. Data Analysis.

5.1. Delinquent’s behavior in designed landscapes

5.1.1. Design following behaviors
Design following behaviours are human behaviours which follows the expectations of designer which were tried to gain by measures, materials and other therapeutic elements used in that particular therapeutic landscape. These behaviours occur due to mind rehabilitation needs of delinquents through landscape. If the landscape has facilitate these needs it is comfortable to the user.

5.1.2. Design against behaviors.
Design against behaviours are human behaviours which doesn’t follow the expectations of designer. These expectations were tried to gain by using standard architectural measures, aesthetical measures, materials and other landscape elements without considering therapeutic measures. As a matter of fact many unexpected user behaviours may occur. Ultimately designer’s main target will be failed. These are design
against behaviours. These behaviours occurs due to specific therapeutic need of delinquents. Lack of therapeutic consideration leads to this kind of behaviours.

5.2. Weraluwatte rehabilitation center

5.2.1. Design following behaviors

Many of the designed spaces are represent positively on juvenile’s behavior. As examples:
1. Playing and creating social bonds with other people through interaction in the play area as designer expected.
2. Pathways are designed to walk in a disciplined manner. Anthropometrical dimensions are used to gain this situation.

5.2.2. Design against behaviors

Some of the design spaces are not functioning according to designer’s expectation. As examples:
1. Looking through throne wrenches on to borrowed landscapes.
2. Exceeding expected users on seating designed to accommodate only one person.

See appendix 21 for a line graph showing Linkert social development analysis in Weraluwatte child probation center.

5.2.3. Linkert social development analysis

This chart indicates the average marks delinquents which has been given by their psychologist. These mark has being given on two months observation on their behaviour. Darker line indicates the scaling done after two months of first scaling. According to this chart it shows that the juveniles’ social skills has considerably upgraded.

Above analysis indicates delinquents are positively responds to the therapeutic factors of the landscape and successfully rehabilitate within the landscape.

5.3. Thaldena rehabilitation center

5.3.1. Design following behaviors

Many of the designed spaces are represent positively on juvenile’s behavior. As examples:
1. Views towards the lake
2. Integrating peers while gardening
3. Contemplating through spiritual landscapes, designed using scale and colour factors.

5.3.2. Design against behaviors

There aren’t many design against behaviors in this center. Although it is some of the spaces occur minor behavioral conflicts. For example unauthorized seating on the river bunt as unsafe behavioral pattern.

See appendix 22 for a line graph showing Linkert social development analysis in Thaldena rehabilitation center.

5.3.3. Linkert social development analysis

According to this chart delinquents has develop their social skills through the landscape. Scaling done on July is higher than the scaling done on August. Therefore above ranking visualize juveniles needed therapeutic outdoor surrounding.
6. Conclusion

Weraluwatte child probation center and Thaldena rehabilitation center has provided therapeutic measures through landscape architecture. The administration in both facilities understand that outdoor space is essential to the wellbeing of delinquents and recognize the need bough from the government law. Since there are no regulations or represents for the outdoor spaces in probation centers, there can be installs mind soothing spaces in order to help rehabilitation process.

This study was started with the objective of finding the factors which influence effectiveness of juvenile behaviours in therapeutic landscapes. Through the study six factors which can be name as variety, extent, scale, Degree of enclosure, fascination and social interaction was identified as they can influence on juvenile’s rehabilitation thoroughly.

A good therapeutic landscape should create a sense of place and make the expectations of complete rehabilitation on juvenile delinquents. For that, above six factors should be introduced to the designs to the certain extent they are required. This factors effect on healing scattered mind conditions and rehabilitate user perception.

To reach this absolute landscape architecture landscape architects, architects, designers, urban planners and many others in the field have to understand the human needs and human psychology. They should understand that following the standards is not designing. By solitary following the anthropometrical measures we can’t achieve what we need. Designer or landscape architect have to understand human dynamisms and locomotives. He should understand changing human needs and feelings. Also landscape architect should smoothly identify the opportunities given by the site and convert these opportunities to fulfill the needs of the user. Landscape architecture can be a killer or healer both. Landscape architects has the responsibility and the ability to heal people through their design.

7. Bibliography

Gibson, J. (1966). The senses considered as perceptual systems.

Acknowledgments

I thank Dr. Gamini Weerasingha, the Department Head for being an inspiration for us and supported in many ways for this research. His encouragement and support is very much appreciated. Then, research coordinator Archt. Janaka Darmasiri for his commitment and supervision he gave us to succeed in this research. This research would not be a reality if I didn’t received the guidance of my research supervisor L. Archt. Kuwshika Gunasekara, Archt. D. P Chandrasekara, L Archt. Shiranee Balasooriya in each and every step I took throughout this research.

Applied Biophilia to the AusZen Garden in Determining Visual Preference

Olga Blacha

University of Newcastle, University Dr, Callaghan NSW 2308 Australia

Abstract

There are visual factors that can determine possibilities of testing aspects of biophilia within a visual context. The biophilia concept utilizes a foundation for an environmental land ethic that E.O. Wilson characterizes as a genetic disposition that links human survival to valuing living systems. Considering biophilia or ‘the love of life’ (Kellert and Wilson 1993) as an interconnecting feature of biotic systems is a description rather than evolutionary as explained by J. Baird Callicott. Using biophilia principles as a primary reference of human relations to gardens; in this case a Japanese style links with its natural historical underpinning using current research, and to examine if this translation into Australia, using native plants effects the preference of the AusZen garden. Browning pronounced evidence-based biophilic design principles that results in positive outcomes including being ‘smarter at work.’(Browning 2012). Other factors including stress recovery and enhanced high order cognitive functioning identified previously by Ulrich (1993) where over 40 years of research conducted on aesthetic preferences for varying landscapes. This research provides empirical support for the biophilia hypothesis (Gullone 2000). Identified patterns of biophilic design summarised as ‘direct experiences of nature’, ‘representations of nature’, and ‘spatial experiences found in natural settings’ (Browning 2012) to results linked improvements in concentration, reduced stress, comfort, interest levels, heart rates and blood pressure, emotional responses, well-being and cognitive performance. Specific biophilia pattern aids production of creative, therapeutic, productive spaces. Evidence suggests effective biophilic spaces may display several of these patterns in tandem, either multiple possibilities or singular patterns. In testing the ‘AusZen’ design, the set of select and modified patterns replaced with an indicative visual plant focus. Examining Nature in the Space correlates with a visual connection to nature, from an observed view preference. Disseminated the Japanese garden style, ‘AusZen’ into quantifiable visual data patterns, derived from tangible principles collated from historical underpinnings. Applying Browning’s 14 patterns and ‘visual landscape assessment statistical methodologies’ conducted from online databases including Science Direct, JSTOR, Taylor and Francis and EBSCOHOST and researchers including (Goto, 2012; Litwin et al., 2017; López-Martínez, 2017; Qi, Zhang, Wang, Liu, & Li, 2017; Roth, 2006; Seiko, Kamal, Puzio, Fujii, & Herrup, 2013; Sowińska-Świerkosz & Chmielewski, 2016; Sowińska-Świerkosz, 2016) and other key biophilic sources. Factors tested via Pearson’s correlation coefficient. The analysis may
replicate a strong linear association of plant type measures and visual quality to be ascertained, (Ozkan, 2014) Examining native over exotic vegetation preference reliably by isolating processes and factors gleamed from visual assessments. Altering variables to native Australian vegetation and exotic (not naturally occurring in Australia) vegetation. Constraints used to ascertain ecological responses are restricted to preferences of five garden types, with the AusZen garden represented in the Melbourne International Flower and Garden Show (MIFGS) from March 21-25, 2018 at Carlton Gardens, compared with other exotic/native gardens, all of which are the same size 5m x 5m. The sample consists of two native gardens, one tropical exotic and two exotic gardens. Validity determined by the online survey conducted on site to allow visitors to authenticate preferences.

Datasets include age, gender, garden preference, location and education. The garden visitors complete a survey/questionnaire. Results that determine preferences for certain plants are homogenous regards to their landscape style. (Litwin, Bacior, & Piech, 2017) In this case, the Japanese design garden provided a cultural contradiction, which substantiated the hypothesis that the design style visually overrides the plant selection.

Survey and questionnaire results conducted from MIFGS, suggests there is a correlation of Visitors attending the show to a preference for Native plants and the AusZen Garden. The AusZen garden, which used Biophilic patterns and principles, reinforces the hypothesis as to why this particular garden is preferred over others.

Keywords: Biophilia, Satoyama, Senzai Bori, AusZen, Green Aesthetic

1. Introduction

Biophilia was segmented into 5 main factors that shaped the first prototype AusZen garden design after assimilating the initial research, including plant selection and design principles such as meigakure (Biophilic Pattern 7 (BP)), fuzei (BP 6), and mono no aware (BP 13,14) that has included the 14 Patterns of Biophilic Design (Browning, Ryan, Clancy, 2014).

2. Ecological Restoration and Ethical Considerations

A balance of human values that respects nature’s intrinsic values is an implicit foundation in the formation of the AusZen Garden. The process of Ecological restoration (Flannery, 2002; Griffiths &
Robin, 1997) should be initiated from factors impacting on ecological, economic, cultural, aesthetic and spiritual values, and in the case of the development of the Japanese Garden authenticity; from applying a cultural tradition that Satoyama embodies, a human–ecological systems based on rectifying historical decline with future management. (Indrawan, Yabe, Nomura, & Harrison, 2014; Takeuchi, Ichikawa, & Elmqvist, 2016). Such values simultaneously manages and repairs ecosystems for their underlying value, rather than for the benefit of humans alone. In practising ecological restoration, identifying a path for both ethical and satisfying relationship between humans and the rest of nature is crucial to the ongoing development of the AusZen Garden concept developed in 2015. Selecting *Doryanthes excelsa* stems (BP 9) as a replacement for imported bamboo in screens, provides a deliberate visual component of Satoyama, using local abundant material that was similar and lightweight, other examples is in the selection of stepping stones, crushed sourced locally and recycled timber treads.

3. **Plant Preferences**

There has been studies on landscaping preferences and socio-economic status of residents (Peterson et al., 2012). One study has addressed the value associated with the native plant labels, and suggests willingness to pay for landscaping plants increases when labelled plants are native and decreases when plants are labelled as invasive (Yue, Hurley, & Anderson, 2010). Martin, Warren, and Kinzig (2004) identified a positive correlation between vegetation richness and socio-economic status.

4. **Psychological and Cultural**

Research has demonstrated that Cultural patterns of categorization of colours exist as individuals actually perceive hues independently and categorise them differently (Bornstein, 1975) This suggests that plant hues should automatically attract specific racial groups. This investigation will form as part of the post survey questions.

5. **Human health threats, allergies and seasonality.**

Considerations such as external sources including LED lighting can impact on health (Geddes, 2018). In relation to Pollen Allergy specific plant selections were refined following evidence that; ‘Improved pasture grasses are more allergenic than Australian native grasses along with pollen from exotic trees, which are planted for their autumn colours, is more allergenic than pollen from Australian trees’ (ASCIA, 2017). Connecting low allergenic selections to the metabolic plant feedback hypothesis (Gertsch, 2016) would benefit humans in close proximity to plant materials. The World Health Organisation notes Green spaces are important to mental health. Ascertaining exact spatial requirements considered by limiting the initial garden project scale to a small courtyard or public space. Having access to green spaces, which is increasingly denser and reduced can reduce health inequalities, improve well-being, and aid in treatment of mental illness. Some analysis suggests that physical activity in a natural environment can help remedy mild depression and reduce physiological stress indicators. (World Health
Organisation, 2016) Aromatic and edible plants including *Goodenia macmillanii* produce stimulating or calming reactions identified in therapeutic research (Seiko, Kamal, Puzio, Fujii, & Herrup, 2013). Seasonal preference (Buhyoff & Wellman, 1979) and bias is one of the key factors in consideration for any garden show. It is possible that the seasonality effect may not be that prominent in Australia, but flowering times are important indicators (Entwisle, 2014). Research suggests winters that include significant snowfall are stimulated by spring, and conversely, autumn and colour associations strongly differentiates a summer landscape (Schloss, Nelson, Parker, Heck, & Palmer, 2017). This preference has to be tested in Australia which has contingent seasons, ‘Sprinter and Sprummer’ (Entwisle, 2014) and climate itself is to be an important factor in accepting personal preferences.(Schloss et al., 2017) along with duration of exposure to the landscape. (*BP 1, 2, 3, 4, 5, 6, 7*)

6. **The Green Aesthetic (Ryan, 2012), and Stratacell Technology**

The Green Aesthetic encompasses the Corporeal Aesthetics of Plants, where the ‘esthetic attraction is not a superficial concern—it’s an environmental imperative. Beauty could save the planet.’(Hosey, 2012).

Attractive design discourages abandoning or demolishing it: if one appraises the garden, it will be a valued amenity.

Long-term value is impossible without sensory appeal, because if design does not inspire, it is destined to be discarded. ‘In the end,’ writes a Senegalese poet, ‘we conserve only what we love.’ (Baba Dioum, 1968.)

Hidden technology repurposed and reapplied via the Citygreen Stratacell; initially developed for street tree planting in urban areas extrapolated. The 500mm x 500mm x 250mm recycled plastic interlocking cells now used for producing levels for aboveground; in this case as the formwork of the AusZen garden, with plants placements into, around and onto the cells, building height profiles from ground level to two metres. The pieces are interchangeable, stackable, easily installed and removed. There is no mess or waste which followed biophilic principle - Pattern as Precedent (*BP 8*) (Browning, Ryan, Clancy, 2014).

7. **Terra nullius**

Where land belongs to nobody that initiates a reaction to recreate place, where absence invokes a new ecological consciousness, predicated on what is in and around that place. Ascertaining connection to the land from one’s location and dwelling. (*BP 14*)

The location of the site in Carlton. The Royal Exhibition Building and its surrounding Carlton Gardens designed for the great international exhibitions of 1880 and 1888 in Melbourne. Joseph Reed designed the building and grounds. The site, (*Error! Reference source not found.*) managed by a World Heritage Committee, with the Melbourne local Council conducts maintenance of the site for the public. This place in the growing hub of Melbourne can offer the visitor the opportunity to view the landscape within its boundaries.
8. Governmental Inputs and Legislation

State plans include Environmental Planning and Assessment Act 1979, and State Environmental Planning Policies. The NSW State Department’s ‘Better Placed’ policy incorporates residential, mixed-use and commercial, affordable housing, education, health, Green Grid (Metropolitan Greenspace Program administered by the Greater Sydney Commission), public art and master planning. This policy, launched in 2017 to tackle issues including enormous powers of developers; where they will give more to communities, NSW Government Architect Mr Poulet notes. ‘It’s a complete change from when Meriton developer Harry Triguboff said 10 years ago that if people wanted to see trees, ‘they can go to Katoomba, there are plenty of trees there’. (Williams, August 18, 2017). The Green Grid established to be the ultimate green infrastructure, design-led strategy network of interlinked open spaces, parks, bushland and waterways for people moving in and around the city to access green space. (BP 10)

9. Heritage and Historic Urban Landscape (HUL)

Carlton Gardens (S37 48 22 E144 58 13), was World Heritage Place listed in 2004 (Ref: 1131bis), and has as part of the regulations for site protection imposed by Melbourne Council. Tree and root protection zones (Error! Reference source not found.), impaction on the ground and garden structure should be considerate of the location, based on negative feedback directly related to MIFGS noted in ‘Alienation of the World Heritage Carlton Gardens’ by residents and the Carlton Gardens Group in 2008. From reviewing this literature, the garden structure developed carefully to resolve issues of weight, material use, and respect for avenue plantings.

Japan enacted the ‘Landscape Law’ in 2004 to highlight the importance of preserving landscapes in improving the quality and viability of community life. HUL and its links with authenticity (Rey Pérez & González Martínez, 2018) provides the impetus approach of developing an authentic Japanese Landscape Garden emerged in conjunction with ICOMOS heritage guidelines. The focus on integrating goals of urban heritage conservation with social and economic development currently in local Government Plans of Management, and providing a garden style that works within these particular requirements is a useful tool for the landscape architect. Noting 36C, ‘cultural heritage, emphasis needs to be put on the integration of historic urban area conservation, management and planning strategies into local development processes and urban planning, such as, contemporary architecture and infrastructure development, for which the application of a landscape approach would help maintain urban identity.’ When all towns and cities considered historic, and the ICOMOS guidelines applied, the incorporation of a garden developed from either a local, state or national heritage significant list provides support to adopt such developed landscape formats.

The HUL approach is a paradigm shift that puts heritage management as part of a
centralized effort for the sustainable development of urban areas. Such non-traditional, multi-disciplinary efforts are key in creating new knowledge pathways in solving urban challenges of the future. Looking Back to the Future.

10. Values

An analysis of the heritage values (social, scientific, historic and aesthetic/symbolic) assists in allocating the threshold that varies between UNESCO world (Outstanding universal level), commonwealth National Heritage (Outstanding heritage value to the nation), state and territory (Importance in the state or territory) to local heritage (importance to the local community). The heritage values inherent in the AusZen Garden identified with the goal of achieving outstanding universal value. The Garden biophilic considerations is directed at that same specific criteria of World Heritage Listing – ‘to exhibit an important interchange of human values, over a span of time or within a cultural area of the world, on developments in architecture or technology, monumental arts, town-planning or landscape design’

11. Methods

Pearson correlation analysis conducted using SPSS 16.0 (SPSS Inc., Chicago, USA) (Pallant, 2003) The online survey for garden preference focused on general questions Regarding the boutique gardens, including types of plants and style. The survey contained questions about education levels, gardening experience and practices, and demographic information. Specific questions about plant choices from plant preference to garden style preference from the online survey was concentrated in the impromptu questionnaire immediately recorded against the online survey. Rationale behind this
method was to ensure there was no bias directed to the AusZen garden. The purpose of these questions was to gauge and validate the preference for flowering plants in the AusZen Garden.

Questions include:

- Were you attracted to any plant(s)?
- Do you know the name of any plants in the AusZen garden?
- What was your first impressions of the AusZen garden as compared to the other gardens?
- Did you know that the AusZen garden consists entirely of Australian native plants?
- Did prize panels affect garden preference?

Analysed data from interviews and survey was combined using JMP Pro 11 statistical software (SAS Institute, Cary, NC). For interview data, we compiled basic descriptive statistics from visitors' responses to all questions. Post surveys questions produced onsite probed preferences regarding experience in gardening (Chart 1) with the data providing this randomly selected demonstrated a particular interest in the garden and flower show focus should correlate with, having interest in gardening, and flowers and not in the Formula One Grand Prix, which was on that weekend approximately 3kms away.

Motivations and knowledge by examining relationships between key categories of information. To determine if the sampled groups’ preference for a particular garden style, (Chart 1) survey included a Likert scale range for the five show gardens, where participants had time to review each garden to aid recall.

Analysis of the age group dataset highlights Diversity and variability regarding the sample population with average age of 56 with standard deviation of 15 reflects the current demographic age distribution weightings for this event, from the median age of people in Australia was 38 years (ABS, 2016)

The position of gardens along one of the main avenues of the show (Error! Reference source not found. & 2) was the site for completing the online survey and questions about garden style preference. The boutique garden competition ranged from traditionally used European styles, one with plant beds and sunken fire pits with native plants, to exotic plant selections including a secret garden with rigid rectangular stone raised beds and hidden water feature. One garden presented a corporate style garden with large, exaggerated pillar funnels and hard, industrial materials with exotic, tropical plant selections. One garden used unnaturally shaped circular blue rings, with cut foliage hanging from the top that separates nature from construction. The Japanese Style garden using only Australian natives was located off centre. The education level (potential plant knowledge) and household location (less or greater access to a garden or park/ natural location).

We coded gardeners' responses to open-ended questions about plant preference (exotic or native or both) and garden style setting to characterize their knowledge and practices. To evaluate if ‘gardeners’ attending the show were generalists or specific in relation to plant and garden preference (Chart 4 – Categories of Visitors to MIFGS)
12. Survey

The Gardens at MIFGS was identified due to the exact size limitations of 5m x 5m which is listed with title, position number and plant selection is RAW - A86 (native) (Fig.5), L’orbt Du Plantes - A85 (exotic) (Fig.6), Secretum Hortus - A84 (exotic) (Fig.7), AusZen - A83 (native) (Fig.8), and Patina Garden - A82 (tropical/exotic) (Fig.9), see (Table 2).

The case study at MIFGAS provided the venue to present the following queries:

- Do the socio-demographic and location correlates with landscaping preferences?
- Is there a bias towards native plants currently in the gardening community that attending MIFGS?
- Does that bias continue in the type of garden style choice?
- Are the visitors at the show capable of identifying native from exotic plants?
- Can visitors distinguish the Japanese garden (AusZen) style as a native or exotic garden?
- Did prize label (1st, 2nd, 3rd) displayed on signage next to the garden impact on preference? (Fig. 1, Chart 3)

Datasets include age, gender, garden preference, location and education (Chart 4). The garden visitors complete a survey/questionnaire. Results determine preference for certain plants that are homogenous in regards to their landscape style (Litwin, Bacior, & Piech, 2017).

The survey had to include the competition aspect of the Boutique Gardens at the show due to the display board presenting the results of the competition to the front side of the garden in a prominent position (Fig. 1).

13. Statistical analyses

58.67% of survey sample comprised of females, which is a higher percentage than females in the Australian general population with a standard deviation of 0.49, which is reflected in the current population (ABS, 2016). 89% noted they lived in a house, situated in a rural or urban setting, which is higher than current census data of 72.9% (ABS, 2016). There is a greater representation of TAFE/University educated in the survey sample of 77% than is the current norm, of 22% (ABS, 2016) (Chart 4). During the show, the Australian Landscape Conference 2018 ‘Design with Nature’ was being conducted at the Melbourne Conference Centre where attendants visited the garden on Saturday after 5pm. None of this group was surveyed.
Biophilic Cities

Chart 1 - Plant Preferences

Chart 3 - Plant Exposure

Fig. 2 - Wollemia or Wollemi Pine Main Focal Element

Chart 2 - Post Survey Questions
14. Results

Over 90,000 visitors was recorded Melbourne International Flower and Garden Show in 2018 (MIFGS) from March 21-25. From the 75 surveys completed at the site, and follow up questions highlights a 44% preference for the flowering Grevillea ‘Cooroora Cascade’, a gold coloured large flowered ground cover, whilst the standard Casuarina ‘Cousin It’ drew attention due to its novelty (not widely seen in nurseries) could not be determined in terms of preference. The plant in the garden that drew instant attention was the Wollemia or Wollemi Pine (Fig. 2), possible due to its size (being the first release of the plant, with most visitors acknowledging its size and health).

The Wollemi pine captured the sampled visitors’ attention whom all but 14 ignored the place result recorded on the panel next to the garden. When queried regarding if the 75 visitors’ responses regarding plant preference impacted by the prize; 80% of the sample stated that they did not notice (Chart 3). Observations was recorded that the press and a large number of visitors who did not want to complete the survey, or whom did not spend enough time viewing the gardens, which was recorded (over 335) were attracted to the winner of the Boutique Garden, which also attracted the bulk of the media attention. The AusZen garden did attract plant enthusiasts compared to the other boutique gardens whom had a strong plant vocabulary and knowledge. A group whom conducted the survey did affect the findings. It was difficult to attract a greater range of visitors; however, there was a number of overseas visitors.

The predominant preference for the Boutique garden was the AusZen (Fig. 6), when questioned to those who completed the survey online at the Show, 80% noted that it was due to the ‘tranquillity’ produced by the garden (BP 11, 12). The results initially indicate that the Japanese Style Garden type preferences among residents along with visitors were consistent with those found by Seiko Goto (Goto, 2012), type predominantly with a Japanese ‘Zen’ design aesthetic.

15. Discussion

The best way to integrate biophilic civic-led interventions into landscape planning can
stimulate improvements for those, in particular workers who do not have the opportunity or access to parks or green spaces remains to be determined (Chart 3). The more colourful plants with stronger tones, especially found in with the *Grevillea 'Coorora Cascade'* (Proteaceae) (Fig. 10) reinforces the findings on hue bias (Bornstein, 1975)

Results from this study indicate that visitors with high levels of home ownership may prove most receptive to designs and native plant selection that reinforces an increase in the use of more sustainable landscaping biophilic principles.

A City of G20: the Path towards Eco-urbanism of Hangzhou

Youcao Ren*
Department of Landscape, The University of Sheffield
Arts Tower, Sheffield S10 2TN, UK

Abstract

The G20 summit which was held in 2016 presented Hangzhou to the world as a garden city. In this paper, we explore how the concept of nature and the natural environment were developed and embraced in Hangzhou’s urbanism. Since early 1980’s Hangzhou was re-decided a cultural and tourism city. It is argued that in the following four decades the city has made effort in preserving existing natural features as well as creating new ones, making the city one of the greenest in China. By reviewing historical background of Hangzhou and its development strategies in corresponding to national policies, it is revealed that the city’s eco-urbanism is long supported by both the general public and the government. Behind the case of Hangzhou is current Chinese government’s attempt of encouraging urban transition, while the G20 summit was simply the opportunity of indicating it.

Keywords: Garden city, G20, Chinese urbanism, environmental governance, national policy
1. Introduction

Today China among all countries is expected to endure the largest urban growth in the coming decades. By the end of 2016, 57.4 percent of the total Chinese population lived in urban area [1], meaning Chinese urban population will reach 790 million in total. Megacities (exceed 10m) and big cities (5m-10m) in particular suffer from various urban issues: housing shortage, air pollution, breaking down of the natural ecosystem, decreasing of green space and beyond. Although the central government has started to downplay the importance of GDP growth in assessing the performance of local officials in recent year, local governments are still much interested in developing economy rather than to put their focus on how to make cities better places to live.

Hangzhou is the capital city of Zhejiang province, one of the most developed provinces located in southeast China. By the end of 2017 the area of Hangzhou city reached to 16,847 km², its population reached to 9.468 million. September 2016, Hangzhou embraced the opportunity of hosting G20 summit. As a growing big city the successes of Hangzhou in presenting itself as a green city seems to indicate Chinese government’s attempt of developing eco-urbanism. However, this success was also criticised as a ‘product’ made by the government’s temporary policies during the summit. In this paper we aim to explore below research questions to challenge this criticism: What are the strategies of Hangzhou’s path to building a garden city and how they are established? Our main focus of below discussion will be put on the city centre area.

2. A Review of Hangzhou’s urban history

2.1. Introduction to Hangzhou’s Cityscape

How to involved city landscapes in the process of urbanization? In centre Singapore the Central Catchment Nature Reserve is proposed, occupies a considerable amount of green space. By doing this Singapore has provided its people an untouched nature in its highly urbanised environment. People in Hangzhou enjoy the similar privilege, only it is granted by the city’s natural cityscape.

Hangzhou is much known for its unique cityscape throughout history, and the well-known impression of ‘Paradise in Heaven; Hangzhou on earth’ remains of importance in its current development. The world heritage site West Lake, or the Xihu Lake in literal Chinese (650ha, listed in 2011), locates in the west of the city centre. In Figure 1 we can see the lake is surrounded by mountains on the north, the south and the west, its east connect to the city’s most centre area. The lake and its surrounding mountainous areas have long functioned as the city’s cultural and tourism centre. The Grand Canal, which was listed as a UNESCO heritage site in 2014, connects the north and south ends of the city. The historical centre of Hangzhou was built around the West Lake and along the Grand Canal, while the city’s east edge is defined
by the Qiantang River (Figure 2). Now following the expending of Hangzhou’s urban area, the river has been included in the city and functions as another important natural feature. Hangzhou’s urbanism has an undeniable close relationship with its natural/semi-natural features. These features have provided the foundation for its ambitious to becoming biophilic in the past two decades. This recognition however, remains general. In below we shall further explore how these features are treated by local urban policies in order to achieve an ecological city environment in details.

Figure 1. The West Lake and its Relationship to surroundings

Figure 2. Major Natural Features in Hangzhou

2.2. Hangzhou’s urban history

As above-mentioned Hangzhou’s urban development long relied on its city landscapes. In the Sui dynasty (581-619) the Beijing-Hangzhou Grand Canal was constructed, making the city one of the most important economic centre national wide. In the Tang dynasty (618-907) local governors of Hangzhou introduce the water to the city for irrigation and mitigating the drought problem. The lake was treated, expanded and designed. In this process, this natural lake has become of great aesthetics and cultural value. Since then urban living in Hangzhou is more or less associated with the lake. The city was the capital of the Southern Song (1127-1279) dynasty for one and a half century. It grew as the biggest city in China – even among the biggest in the world – during the time period. [2] Yet the political importance of Hangzhou did not last much longer after the collapse of the dynasty, instead it remained an important cultural centre in south-east China as well as a famous tourism city.

Also similar to Singapore, today Hangzhou’s image as a city with abundant lush greenery and a clean environment is not easily created. Despite its natural advantages Hangzhou has had suffered from the consequence of inappropriate urban planning which ignored the value of the urban environment. The first city plan of Hangzhou since the founding of the People’s Republic of China was established in 1953. In the plan, Hangzhou was decided an ‘artsy scenic-tourist city. Its main development focus is its tourism and culture’, whilst ‘certain consideration on light industry’ was
also proposed. Yet in the former half of Cultural Revolution Hangzhou was decided ‘a heavy industrial city’ in order to keep up with the Great Leap Forward (1958-1962), an economic and social campaign by the Communist Party of China from 1958 to 1962. Multiple heavy industries were launched in the north of the city, while the lake and the canal were greatly neglected in the development. Urban environment was reported greatly decreased during this time period, which has had left many difficulties to the city’s future development. During 1966-1976 the situation was not much improved, although heavy industries were not as highlighted as they were a few years before. After the Opening Up and Reforming in 1978 local government seek to re-plan the city as a ‘historic cultural and tourism city’. [3] This proposal was approved by the central government in 1983. However, urban issues appeared in the decades of 1950’s to 1970’s were still considered a great distraction to modern urbanism during the 1980’s. By reviewing these historical plans it is for us to realise that the actual history of Hangzhou’s modern planning which highlights its cityscape and natural features has only been four decades (Figure 3-5).

Figure 3-5. An overview of Hangzhou’s city plan from 1981-2020. (Source: http://www.hzplanning.gov.cn/hzzg/lngh5.html)
3. Building Garden City: Local Strategies

3.1. The Perseveration of Existing Natural Features

As Hangzhou’s city characteristic has been re-defined back to cultural and tourism, preserving existing natural features has become one the main focus in its recent urbanism.

Figure 6 and 7 presented the approved city plans during 1978-2000 and 1996-2010 respectively. Comparing the two plans we can notice the west lake and its surrounding urban area remain almost unchanged, despite the obvious expending of the city itself. This suggested that the West Lake and its areas are being carefully protected during the city’s development. It is worth to note that both of these two plans were published before the West Lake was listed a UNESCO site, suggesting the city’s spontaneous awareness of preserving this important natural feature. The specific West Lake Cultural Landscape Protection Regulation (西湖文化景观保护条例) which required building heights control around the lake was published in 2011 in responding to its successful application of World Heritage site.

As the city has grown rapidly since the founding of PRC, the urge of preserving city centre arise particularly when we considering the area’s significant historic and cultural values. If we take a further look at Figure 4 and 5, it could be noticed that new urban areas have been planned along the Qiantang River. This indicates one of the most important urban transition of Hangzhou in the past two decades, which is to enter ‘the Era of Qiantang River’ from ‘the Era of West Lake’. Qiantang River, which locates at the south-east of the city, has officially being highlighted in Hangzhou’s development. The notion was first suggested by the local government and approved by the central government in 1983. Further developing the plan, Hangzhou government has decided that ‘the city shall expend to the east (of the city), tourism should be led to the west (of the city). Future development of Hangzhou shall be proposed across the Qiantang River’ in 2001. [4] Known as Qianjiang New District, the area developed along the river is now announced as the new economic centre of the city (Figure 8). This decision has released a lot of pressure in dealing with urban issues in the city centre area. Successful preservation of city centre has therefore become more likely.

To avoid possible challenges brought by the city’s rapid development, urban development around all these natural features, the lake, the canal and the Qiantang River, are now under careful consideration. This is particularly emphasised in the most recent city plan which was published by the Zhejiang provincial government and approved by the central government in late 2016. The response to this plan from the central government was even more explicit: it was addressed that ‘architectural heights surrounding landscape style areas such as the West Lake, the Qiantang River, the Grand Canal, and the Xixi Wetland, should be strictly controlled’. [5] It was also required that the city’s characteristics, particularly the cultural landscapes and the
natural landscapes, should be highlighted in future urban design.

3.2 Building New Green Spaces

By reviewing city plans in above Figure 6 and 7 we can notice an obvious increase of public green space in the city centre area. In cooperation of the preservation of existing features, local planning strategies of Hangzhou has also addressed the importance of increasing green space no later than the 1990’s. In 1994 Hangzhou was already listed one of the earliest ‘National Garden Cities’ by the Ministry of Housing and Urban-Rural Development of the People’s Republic of China, meaning its effort of building green infrastructure was recognised.

In the urban scale, newly planned green spaces – city parks, ecological landscape corridors and are designed to either connect or respond to aforementioned major natural features in the city. It is expected that the city’s green spaces will be eventually constructed into a web-liked green space system. Multiple acts regarding urban green space were published since 2000, including the Hangzhou Park Management Regulations (杭州市公园管理条例,
published in 2001, revised in 2014), the Hangzhou City Green Management Regulations (杭州市城市绿化管理条例, published in 2011) and the (杭州市城市绿化管理条例实施细则, published in 2012). In below Figure 9, which is the 2016 version of the city plan, we can see how green spaces are designed on the urban level for the time period from 2001 to 2020.

The city’s enthusiasm for building green infrastructures is now greatly supported by local residents. In a smaller scale, the building of green spaces, particularly green walls and roofs, is actively participated by the public during the past two decades. These activities are often community-led (although financially supported by the government), giving the general public much more power in deciding the location and type of green space. At the same time, supervision and maintenance of green space has become more efficient, as communities and residents often take over the responsibility spontaneously. The rising influence of public participation in making the city greener is particularly observed in the city’s historic areas and old communities, where their green coverage is often lower than new districts. The government and local communities provided free cane seedlings to community residents through volunteers every year, encouraging citizens to plant vertical greening on conditional walls and roofs (Figure 10).

Since 2010, 420,000 square meters of green roofs has been increased in the city centre, meaning a total of 58.56 million square meters of green space has been increased. [6] By the end of 2016, the average green area and urban parks were 14.3 square meters per capita. The urban green space rate in the central urban area was 37.2%. The green coverage of built-up areas was 40.5%. [7] These numbers are expected to reach to 15.1 square meters per capita, 38% and 41% respectively by 2020.

Along with the increasing green rate, the emerging of diverse urban green spaces further proved that Hangzhou has fully recovered from afore-mentioned damages and once again started focusing on its relationship with the city’s natural environment. Since this stage we can expect the increasing significance of urban design and landscape architecture in Hangzhou’s city development.

Figure 9. Hangzhou’s urban green spaces at the city level
3.3 Garden City for the Public or Garden City of Particularity?

In the past decade Hangzhou further developed above strategies in dealing with its urban environment. The G20 summit held in 2016, as an international event which received great attention, greatly reflected Hangzhou’s ambition of becoming a garden city. Using preparing the summit as an opportunity the government of Hangzhou investigated 50 billion yuan (8.2 billion U.S. dollars) in improving city environment. 605 projects which aim at improving local environment were initiated and completed during the preparation period which lasted over 400 days. When hosting the summit Hangzhou surely was expected to be presented as a positive example of Chinese urbanism.

One might question Hangzhou’s achievement during G20 is of particularity: during the whole week when the G20 was held, traffic in city centre was restricted; a week-long vacation during the summit was granted to local residents, as they were encouraged to travel out of town; Factories in the surrounding areas and cities were shut weeks before the summit. In the Report on the Development of China’s Eco-cities 2017 (中国生态城市建设报告) which was published by the Chinese Academy of Social Science, Hangzhou’s response to the G20 summit was included as one of the ten most noticeable events in regard to promoting eco-urbanism. It was considered a positive example by the report as the success of the city’s achievement during the summit is almost undeniable. However, it is also noticed that such achievement was, and is still, supported by considerable effort both politically and financially. It would not be too difficult for us to imagine that other cities might not have similar resources.

When admitting Hangzhou’s urban environment presented during G20’s has certain particularity we shall still ask the question: was the city’s achievement as a garden city a temporary result as criticised? We have already reviewed Hangzhou’s local development strategies and plans during the past few decades, now it is worth to explore how the city’s strategies interact with national policies.

If we look back to the time period during 2002-2007 when president Xi Jinping was the party chief of Zhejiang province, evidences of Hangzhou being highlighted as a garden city on the national level long before the G20 could be revealed. Hangzhou government initialed its plan of ‘ecological city development’ in 2002 – back when Xi
was just appointed to Zhejiang province. In 2003 the Zhejiang government announced the central government’s determination of building the province into a ‘green province’ by publishing the Hangzhou Ecological City Construction Plan (杭州生态市建设规划), notions in this plan has been promoted since after. Two years after, in 2005, Xi proposed his famous quote ‘lucid water and lush mountain are invaluable assets’ during his visit to Anji, a county locates in the north-western Zhejiang province. This notion was only greatly highlighted national-wide since the 18th National Congress of the Communist Party of China which was held in 2015. In comparison, Zhejiang province has already been developed under its guidance for over a decade. What has been promoted in Zhejiang province was a pilot of Xi’s notion, and now it reflects the central government’s consideration of China’s new urbanisation. [8] In this sense, both Hangzhou being selected for hosting the G20 and being introduced as the ‘paradise’ by President Xi in the summit closing ceremony can be considered a signal.

In June 2017, which was a year after the G20 Summit, Hangzhou was nominated ‘National Ecological Garden City’ from over 300 ‘National Garden City’ by the Ministry of Housing and Urban-Rural Development of the People's Republic of China. In comparison to the concept of National Garden City which emphasises green rate solely, the National Ecological Garden City has introduced the broad concept of ‘urban ecology’ into its assessment. How urban residents react to the urban environment has also been included as an important aspect. In detail, indicators such as urban heat island effects, comprehensive species indices, local plant indices, and public satisfaction with urban eco-environment have been added (table 1-2). Hangzhou’s version of building itself as a garden city has been further accelerated.

**4. Conclusion**

This paper has reviewed Hangzhou’s urban history, local development strategies and related national policies in relation to its concept of the garden city. Despite its long history, Hangzhou’s urban planning history which emphasised on its city characteristics has only been less than four decades, but its accomplishment is quite noticeable. In current stage the conservation of existing natural features and creating new green spaces are considered of significance in Hangzhou’s urban planning. Today the city enjoys an obvious improvement of urban environment from multiple aspects.

Hangzhou was chosen and designed as a representative of the garden city on the national level. Its historical background and natural cityscape provided foundations to this decision. Meanwhile, the city’s path to becoming a garden city is long supported by both local and central governments, as well as its prosper economy. It is revealed that the central government’s current eco-development policy represented by the ‘lucid water and lush mountain are invaluable assets’ in fact has its long history in Zhejiang. Local cities’ urban policies have had been greatly influenced by this notion during President Xi’s tenure in the province. The G20 summit certainly accelerated the central government’s determination of promoting Hangzhou’s city image, but it was hardly the deciding factor in the city’s garden city notion.

Table.2* Selected assessments for National Ecological Garden City

*Note that above-expected numbers are only cut-off numbers for the assessment rather than the city’s actual indicators.
By exploring the case of Hangzhou it is indicated that the relationship between China’s rapid urbanism and carefully crafted strategies for achieving eco-urban living is now gradually being highlighted. How urban designers and landscape architects should respond and contribute to this new notion has become of importance.

Abstract

In this study, we present a new perspective on Japanese gardens by analyzing the manner in which the gardens in Kyoto take advantage of the naturally occurring differences in elevation due to faults and by searching for the relation using the area’s topographic classification. This analysis is intended to highlight the manner in which human design can be made more harmonious with nature. 15 gardens that belong to the temples that are built near the faults running through Kyoto are analyzed. The results show that a high percentage of gardens that were located near the fault lines utilizes the difference in heights that were produced by the faults either as a part of the landscaping of the gardens or as the main feature of the garden. Further, the utilization of terraces that were produced by faults could be divided into two groups: those that include stone arrangements in the main feature and those that use the terrace as a base for presenting the greenery that is observed in front of a beholder as the main feature. Furthermore, the gardens can be divided into those that form a landscape using the difference between elevations as a pedestal for presenting the shrubs and stones and those that form landscapes by maintaining individual outlines while helping the formation of the main features of the landscaping.

Keywords: Japanese garden, terrain, land form, temple, view

1. Background and Purpose of the Study

Since ancient times, gardens in Kyoto have been designed with an objective to create an environment that provides visual and acoustic pleasure to people when the gardens are observed from a particular perspective. These beautiful landscaping features hide a secret that can be traced back to the time during which the topography of Kyoto was formed. The Kyoto Basin contains many active faults that constitute a fault zone. Most of these faults run through mountains. Additionally, several temples are located at the foot of or between the mountains, and these temples have become indispensable because they are built near the faults of Kyoto.

Previous studies about the gardens and topography of Kyoto include investigation of the environmental features by performing quantitative analysis of the inclinations and elevations of landscaping [1], investigation of the topographic classification of the Kyoto Basin [2], and investigation of the relation...
between Shinto shrines and faults \[3\]. No study has been published yet that elaborates on the formation of topographic features by faults, which are considered to be the landscaping features for the gardens in Kyoto.

In this study, we present a new perspective on Japanese gardens by analyzing the manner in which the gardens in Kyoto take advantage of the naturally occurring differences in elevation due to faults and by searching for the relation using the area’s topographic classification. This analysis is intended to highlight the manner in which human design can be made more harmonious with nature.

2. Study Method

2.1. Research Method

This study analyzes 15 gardens that belong to the temples that are built near the faults running through Kyoto. All of these gardens are included in "Nihon Teienshi Taikei" \[4\]. The gardens are listed in Table 1, and their locations are mapped in Figure 1.

We captured photographs from some parts of gardens that were designed to be the highlights of the viewing experience such as the center of the abbot's quarters or the stepping stone. From these centerpiece positions, we conducted a photo shoot of the surroundings to capture the major features of the garden landscape such as waterfall stones. We additionally measured the inclinations and elevations (Table 2), prepared cross-section plans and sketches of the gardens, and catalogued the flora. For gardens with water features, such as ponds or streams, the sources of water were verified with the temple staff.

The height of the point of view was set in the following manner: the ground level (hereinafter, GL) was 0 m; the garden wherein the abbot's quarters was accessible
to the public was set to be GL + the height of the abbot’s quarter + 0.8 m; and the gardens wherein the abbot’s quarters was not accessible to the public was set to be GL + 1.55 m.

3. Results

3.1. Whether Terraces Produced by Faults Could Be Used as the Main Features of a Garden

A location at which fault-based terraces are successfully used as the main feature is the garden of Tenryu-ji temple. The garden of Tenryu-ji is located to the western side of the Kyoto Basin in the Saga Arashiyama area (Fig 1). This neighborhood is also a famous tourist destination, and the garden is designated as a Class 1 Special Place of Scenic Beauty for the Nation. The garden features natural scenery due to the mountains of Arashiyama, Kameyama, and Ogorayama; all of the aforementioned mountains have faults running through them. The three terraces that are produced by the faults are located in the garden itself. As depicted in the photographs that are provided in Figure 2, maple trees are planted and stones are arranged on the fault-based terraces that are located in front of the garden to create the main feature of the garden.

A location at which terraces were not used as a main feature is the Abbot’s Garden of Nanzen-ji temple. As depicted in Figure 3,
this garden is located parallel to the fault line, and its design is self-contained without any elevation changes. The terraces that are produced by the faults cannot be used as the main feature of this garden.

The gardens in which the terrace is used as the main feature are 12 examples in total; 1, 3, 4, 5, 6, 7, 8, 9, 12, 13, 14, 15.

3.2. Stone Arrangements on Terraces Produced by Faults that were used as the Main Feature

An example of stone arrangements on fault-based terraces is the Tenryu-ji garden. At the center of a terrace that runs across the front side of the garden landscape, stone arrangements that utilize the differences in elevation level were observed (Figure 2).

The gardens in which the terrace is not used as the main feature are 3 examples in total; 2, 10, 11.

An example without the presence of stone arrangements is the Ginkaku-ji garden. As depicted in Figure 1, several faults exist in the eastern side of the Kyoto Basin. Ginkaku-ji, which is located in the area where several faults are concentrated, is extremely famous along with the Kinkaku-ji temple on the
western side and is busy because of several tourists and students, who visit this location during school trips, throughout the year. Terraces produced by the faults continue into the mountainous surroundings of this temple. As depicted in Figure 4, although stone arrangements are placed on these terraces, they are obscured from the chosen points of view by garden plants. Therefore, these stone arrangements are not a part of the main feature of the garden.

The gardens in which stone arrangements on terraces produced by faults that were used as the main feature are 7 examples in total; 1, 3, 4, 6, 12, 13, 14. The gardens in which stone arrangements on terraces produced by faults that were not used as the main feature are 5 examples in total; 5, 7, 8, 9, 15.

3.3. Linear or Planar Topography

As depicted in the tracing in Figure 2, the garden of the Tenryu-ji temple is an example of the topography that appears as lines. In this garden, the edge of the terrace is visible through the trees that include maples. An example in which a particular topography appears as a plane is the garden of Ryosoku-in, which is illustrated in Figure 5, where rhododendrons and stones are placed on the slope for presentation to convert the entire slope into a landscaping feature.

The gardens in which topography is visible as lines are 4 examples in total; 1, 4, 6, 14. The gardens in which topography is visible as planes are 3 examples in total; 3, 12, 13.

---

Fig 4. Photograph of the main feature of the garden of Ginkaku-ji temple (above) and its plan (below).

Fig 5. Photograph of the main feature of the garden of Ryosoku-in (above) and its plan (below).
3.4. Water Systems and Topographic Classifications

When faults are present, there is a high probability that flowing water will exist. From among the investigated gardens, 10 gardens depicted the presence of the flowing water. At the gardens of Tenryu-ji and Ginkaku-ji, we even observed water flowing out of terraces that were produced by faults.

Further, according to Uemura (2004) [6], different types of topography were observed above and below the faults. As can be seen in Figure 1, the following differences were observed when the locations of the 15 gardens and the topographic classifications were superimposed.

We observed four cases of transitions (9, 10, 11, 12) from an alluvial fan or a valley plain to a sub mountain. Transitions from an alluvial fan or valley plain to low terraces were observed in two cases (1, 14), and transitions from an alluvial fan or valley plain to a hill were also observed in two cases (2, 13). Further, transitions from a hill to a sub mountain were observed in five cases (3, 4, 5, 6, 7). Only one transition from a low terrace to a sub mountain was observed (8), and a transition from a high terrace to a hill was observed in (15).

Results that were obtained from all the 15 gardens are presented together in Table 3.

a: Fan, Valley Plain, b: Backmarsh, c: Low River Terrace, d: High River Terrace
4. Conclusion

Gardens that satisfied various conditions were classified and organized into the tree diagram that is depicted in Figure 6. This diagram can be considered as an index for viewing gardens in a manner in which they exploit fault-produced topography. As could be observed from these results, it is clear that a high percentage of gardens that were located near the fault lines utilizes the difference in heights that were produced by the faults either as a part of the landscaping of the gardens or as the main feature of the garden. Further, the utilization of terraces that were produced by faults could be divided into two groups: those that include stone arrangements in the main feature and those that use the terrace as a base for presenting the greenery that is observed in front of a beholder as the main feature. Furthermore, the gardens can be divided into those that form a landscape using the difference between elevations as a pedestal for presenting the shrubs and stones and those that form landscapes by maintaining individual outlines while helping the formation of the main features of the landscaping.

These results indicate that the ideal presentation of natural topography was chosen by people who lived several hundred years ago and has been maintained in the form of a beautiful landscape until today. Faults may, at times, be harmful for humanity in the form of natural calamities, such as earthquakes, and their secondary disasters. At the same time, faults are agents that depict the beauty of humanity coexisting in harmony with various natural features.

The role and needs of animals in the definition of urban landscape architecture

Cynthia Giard Prefontaine, Federica Larcher, Marco Devecchi, Domenico Bergero

Abstract

Inter-relationships among humans, animals and landscape have always been historically very important. There is an increasing number of animals in the cities. Some of them are pet animals (dogs and cats in particular, but new species are increasing, e.g. ferrets and certain birds). Some others are simply attracted by cities, like pigeons or seagulls. For some extents, humans are more and more concerned about the possibility of providing good conditions of welfare to their pets, in terms of quality of life. But gardens and parks, for different reasons, are not always open to the dogs, and even the small areas that are provided seem not to be always suitable. Moreover, a lot of animal places are in poor conditions due to low quality design or insufficient daily maintenance. This situation will worsen with the undergoing pet animals overpopulation. The choice of dog breeds is also changing, and breeds with increasing needs in terms of habitat are rising. An approach for integrating human and animals habitats could be very interesting in terms of approaching biophily in other terms. The rising interest for animal welfare will push researchers to find solutions for this integration.

New species are also seen today as pets, in particular, in urban environment, the number of poultry animals, horses or small ruminants is increasing, and this will diversify the needs for comfortable animal environments.

Parks are other habitats that are undergoing deep changes in this particular moment that involves massive extinctions and biodiversity reduction.

From the other hand, some animals are not welcome, because they are pollutant, undesired or dangerous in terms of public health. The example of rats or pigeons, is important.

Then, there is a need for a new definition of urban landscape architecture, to build healthier places for pets, to avoid undesired health risks induced by the presence of humans and animals, and to increase the “one health” concept and the welfare of pet animals and owners. Bird gardening can be considered as a part of this concept.

In this paper, examples of landscape design coherent with animal needs, and a perspective of this issue, are given.

Keywords: landscape architecture; urban; animals; pets; welfare
1. Introduction

The XXI century fixed the birth of a new paradigm for cities planning, design and management: the multifunctional role of the green infrastructure was recognized and became a goal to be achieved for all the cities in developed and developing Countries. The urbanization and land consuming, together with the growth of people living in and around cities, enhanced the need to take care of the quality of the urban environment. Since 1990s, scientists started working on urban ecosystem, urban ecology, and urban nature. New methods and indicators were developed outlining that the quality of urban green spaces is one of the key factors for improving the quality of life in such dense urbanized environments [1].

At the same time, inter-relationships among humans, animals and landscape have changed. The consciousness about the needs of animal in urban environment is a new issue in architecture, but also at technical and political level. Due to the important rise in biophilic sensibility, there is an increasing number of animals in the cities. Some of them are pet animals (dogs and cats in particular, but new species are increasing, e.g. ferrets and certain birds). Some others are simply attracted by cities, like pigeons or seagulls. New species are also seen today as pets, in particular, in urban environment, the number of poultry animals, horses or small ruminants is increasing, and this will diversify the needs for comfortable animal environments.

Humans are more and more concerned about the possibility of providing good conditions of welfare to these pets, in terms of quality of life. But in urban environment, gardens and parks, for different reasons, are not always open to the dogs, and even the small areas that are provided seem not to be always suitable. Moreover, a lot of animal places are in poor conditions due to low quality design or insufficient daily maintenance. This situation will worsen with the increase of pet animals population.

Creating healthy and resilient cities, integrating the urban ecology principles into design and management actions, is recommended [2]. Urbanization affects ecosystem eservices in terms of habitat loss, habitat fragmentation, storm water management, water and air pollution and loss of cultural values. Multifunctional networks (greenways, ecological networks, blue-green networks, river ways, and parkways) provide the connectivity in urban ecosystems [3], enhancing the habitat size and quality for wildlife and domestic species.

In this paper, some examples of inter-relations between human and animal populations in particular in urban environments are given, together with an outlook of possible interventions to approach this problem in the next years.

2. Urban green utilization

Urban landscapes are the everyday environment for the majority of the global population: since 2015 almost the 80% of the Europeans lives in urban areas.

Urban green has many different reasons to be increased and managed. Historically, we define Parks, Equipped areas, Historical areas, fitment and special areas.
All of them are important. Sanesi et al. [4] conducted a study on the perception of green spaces by citizens, showing how they are perceived as essential elements to mitigate heat waves. The citizens have a clear perception of the poor size of the green spaces in their city, and they underlined the lack of maintenance, especially in periurban locations. In addition, women and pensioners pointed out problems related to the lack of security and surveillance, especially during the evening.

In Italy, Bologna has always been at the forefront of urban green management, especially with regard to urban agriculture and horticulture. Mapping and quantifying flat roofs suitable for gardening, Orsini et al. [5] determined that the city has a potential of 82 ha of rooftop gardening surfaces, enabling the annual production of over 12,000 t of vegetables a year, covering the 77 % of the urban vegetable requirement. Also the Turin metropolitan Authorities have been recently involved in several projects in order to improve the quantity and quality of local food production, and to promote an informed consume by citizens. With the idea that urban agriculture can also contribute to reduce the cost of managing urban green areas and to introduce alternative forms of management of public spaces, in 2013 the Turin municipality promoted the project ‘Torino città da coltivare’. The surface of urban gardens in the last five years enhanced up to more than 100 ha (5 m2/inhabitant) and in 2017, the first report for the urban food strategy was launched. European and Regional research projects are in progress in order to assess the urban strategy for the implementation of the ecosystem services provided by urban agriculture, horticulture and, more in general, green areas [1].

3. Animal welfare

The management of urban green areas took into account the presence of animals, but the new perception of animals changes the framework.

As an example, the surface required by horses (paddocks, boxes) to express their normal behavior is often conflicting with the limited surfaces available in cities.

The assumption that animals are conscious and capable of experiencing negative sensations and emotions is at the core of most people's concerns about animal welfare. Investigation of this central assumption should be one goal of animal welfare science articles [6].

Different approaches have been proposed to assess animal welfare. Welfare is multidimensional, comprising good health, comfort, expression of behaviour, and so on. Its overall assessment therefore requires a multicriteria evaluation [7]. The most common list to evaluate animal welfare is the so called list of the five freedoms [8] including:

** Freedoms **

1. Freedom from thirst, hunger and malnutrition
2. Freedom from discomfort and exposure
3. Freedom from pain, injury, and disease
4. Freedom from fear and distress
5. Freedom to express normal behavior
But this concept, dating from early ’90, is nowadays even unable to refer to the new biological knowledge, and is undergoing a revision process [9]; new tools have been developed to study animal behavior to assess their level of wellbeing [10]. Unfortunately, on the other hand, the new concepts of welfare are not taken into account widely when planning for new buildings or cities.

4. Animal populations

Animal population, in developing countries, is quickly changing. As an example, the Italian population in 2016 was 60.6 million, while a ISTAT [11] survey in 2017 listed for our country this amount of livestock:

- Bovines 5,775,000
- Buffaloes 405,000
- Swine 8,775,000
- Sheep 7,284,874
- Goats 1,026,263
- Horses 388,324
- Donkeys and mules 74,215.

In the same year, Assalco-Zoomark [12] reported, for pets, 60,459,000 animals, and in particular:

- Dogs 6,967,000
- Cats 7,482,000
- Small mammals (rabbits, ferrets, hamsters…) 1,833,000
- Reptiles, turtles, iguana, snakes 1,364,000
- Aquarium fish 29,915,000
- Small birds 12,898,000.

From these data, pets population equals human one; cats are more than dogs, and bovine are less numerous than dogs. Indeed, this is the mirror of a changing society. Pet animals, in developed countries, are largely living in urban environments. In 2017, in Great Britain, the estimated population of dogs was 11,599,824 and for cats 10,090,924 [13] and it is estimated that the density of pets varies substantially, with the lowest densities in rural areas, and the highest in the centers of large cities where each species could exceed 2,500 animals.km-2 [13].

This situation must be managed also in terms of human health. Research suggests that pet animals are deeply relevant to people’s health (negatively and positively). Pet bylaws adopted by town and city councils have largely escaped notice, yet they are meaningful to consider in relation to everyday practices, social norms, and cultural values, and thus in relation to population health [14], [15].

Moreover, the reasons to keep animals close to cities changed: in ancient times, cats were kept to deter rodents and exploited for their fur, dogs were protectors of the home and pigs were not only food, but helped to reduce the amount of rubbish where they were kept [16].

The proliferation of urban livestock, especially chickens, rabbits, bees, and goats, has also posed particular regulatory challenges to cities. Scant planning scholarship on urban livestock focuses mostly on how cities regulate animals, but few studies attempt to characterize urban livestock, ownership and management practices, e.g. in the US, in relation to these regulations [17].

5. Controlling populations and urban spaces

A limitation in the possibility of managing animal populations is the level of knowledge about their consistency. This is particularly true for pets. In Italy, there is a canine registry office, but the efficacy of this
registry is questionable: if we look at the following table [18], we can see that the ratio humans / dogs (third column) in Italian cities varies deeply. In Torino, there is 1 dog for 13 inhabitants, while in Palermo the ratio is 160. Doubts can rise.

The quantity and quality of urban spaces intended for dogs is also a major concern: in spite of the large quantity of green areas of Italian cities, the availability of areas for dogs is not wide.

We count in Torino, for example, 54 areas for dogs, with a total surface of 90,008 m². However, only 16 of these areas are equipped with separate sectors for large dogs and small dogs! This is, obviously, a great concern for owners.

6. Birdgardening

Urban environments present unique challenges for landscape designers wishing to incorporate wildlife attractants into their designs. Cities are surrounded by relatively large expanses of native vegetation and provide many opportunities for effectively enticing native wildlife into urban spaces. Patches of landscape can be designed that mimic vegetation composition found on the peripheral edges and may potentially lure wildlife by providing food and cover. These areas may also provide regenerative patches of native vegetation within the urban matrix, thereby offering connectedness to larger areas of native vegetation. Such corridors encourage wildlife movement and may aid in the retention of wildlife populations [19].

Social factors reflecting increased urbanization are on the other hand negatively correlated with bird species richness. However, noise is the factor that explained most of the variability. Anthropogenic noise can have a significant negative impact on the conservation value of urban parks for bird species [20].

7. Biodiversity

For many, urban areas are sometimes viewed as concrete jungles, with depauperate fauna and flora dominated by non natives and homogenous taxa across regions. Although such views are understandable, in truth, urban areas house a great deal of species both native and nonnative to the surrounding region [21].

Green spaces in cities, such as parks, allotments, cemeteries, and wastelands, are important components of green infrastructure and provide habitats for numerous animal and plant species. Over the last decades, many studies have shown high species richness and abundance in urban green spaces. This has particularly been the case for studies on birds and plants, but also for other taxa such as mammals, butterflies, and carabid beetles [22].

Urban areas across all of Europe seem then to contain higher levels of biodiversity than unpopulated areas. Surveys of 15 urban and suburban parks in Flanders, Belgium, revealed that the 15 parks contained about 30%, 50%, 40%, and 60% of the total number of wild plant species, breeding birds, butterflies, and amphibians still occurring in Flanders, respectively. Urban parks therefore function as an important reserve of biodiversity in Flanders [23]. Urban ecosystems can support bees with trees, shrubs, herbaceous plants, flower
beds, weeds [24] as well as selected edible plants [25]. However higher levels of spontaneous species and cultivated plant communities are present, including more exotic species than rural plant communities, that supply floral resources all year long. Moreover, urban sites are often warmer than surrounding landscapes. Extent of green areas, plant species diversity, floral density have positive effects on plant-pollinator interactions [26]. In addition, green urban areas are rarely treated with pesticides respect to agricultural areas.

In addition, it is essential to increase people awareness of biodiversity, highlighting that the richness of species in natural environments deserves to be protected for the benefit of both nature and individuals [27].

8. Risks and pest animals

From the other hand, some animals must be controlled, because they can became a problem in urban environment. The best example are pigeons (carriers of ticks), that are harmful for monuments, buildings and even for human health. Other animals can be cited as rats (carrying fleas), seagulls, crows, magpies, mouse, coypus, mosquitoes and tiger mosquitoes. Pet animals can also become a problem: in the city of Detroit, there is an emerging problem of roaming dogs presence. The primary cause this problem in the city is the poor economy and the problem is worse in the most distressed neighborhoods. Several factors serve as barriers to addressing the issue. First, the actual number of roaming dogs is a question of contention in the city. Second, weaknesses in the city governing system and scarce resources have limited the public response to the problem [28].

Conflicts between people and wild animals in cities are as old as urban living itself. In the United States it is only recently, however, that many of the species now found in cities have come to live there.

The increasing kind and number of human-wildlife conflicts in urbanizing environments makes it a priority that effective and humane means of conflict resolution be found. The urban public wants conflicts with wildlife resolved humanely, but needs to know what the alternative management approaches are, and what ethical standards should guide their use [29].

Animals can also be seen as a potential harm for the transmission of pathologies, also for the presence of parasites. The Lyme disease is a good example. Increased urbanization globally and increasing access in developed countries to open urban spaces (e.g. unbuilt areas that are vegetated or sites with exposed soil, including floodplains of waterways) provide also potential increased risk of exposure to environmentally acquired pathogens (including helminths). Cities are also prominent entry points for air travel, thereby potentially increasing inputs of pathogens [30].

9. Conclusions

From this paper, the need for more conscious management of animals (both domestic and wild) in urban environment, and urban green areas in particular, is evident.

Raising education, culture and awareness on urban horticulture and ecosystem services topics is the further aim, together with the promotion of monitoring programs in order to gain the quality of the urban ecosystem and citizens well-being. A new planning and design multidisciplinary strategy in cities requires the integration
among agronomists, ecologists, landscape architects, urban planners, biologists and veterinarians, politicians, and representatives of the civil society using an inclusive approach [1].

Biophilic Design applied to the Outskirts of Metropolis City of Jakarta

Alicia Wellsan, Nur Intan Mangunsong

Student in University of Trisakti, West Jakarta, Indonesia

Lecturer, Department of Landscape Architecture, University of Trisakti

Abstract

A metropolis city is an important city in a nation, and Jakarta as one of the metropolitan cities should show the best of what it could offer. One of the things includes a healthy environment for the citizens to live in, however, seeing the devastating environmental condition of Rawa Buaya village located in West Jakarta has proven otherwise. The Rawa Buaya village has a limited land area and a great part of the people living in the village is a low class economic society. Most of them has very little knowledge about the importance of having a healthy environment and did not have the will to make a change. Biophilic design is an innovative way of creating a healthy place where nature blends together with a modern built environment and this was the answer to recreate and renew the village of Rawa Buaya. In addition to that, the basic human needs include a green open space and a healthy environment to live in everyday, which a biophilic design can offer. The first phase of the project was to counsel the citizens about the importance of having a healthy environment and how to build a vertical green space infrastructure in their own backyards, letting them understand that what they create provides the ‘elements’ to solve urban and climatic challenges by the help of nature and creates a healthy environment. The last phase of the project involves a routine check up on the vertical garden and examine the difference after the green infrastructure has been done. However, the project itself cannot be accomplished well unless the citizens participate in taking care of what they have built. Therefore, by this project we hope that more people will realize the importance of the strong bond of the relationship between the nature and the people, and that the benefits; improves mood and relieves stress could be felt by the citizens.

Keywords: green infrastructure; healthy environment; metropolis city; vertical greenery

INTRODUCTION

Rawa Buaya is a small yet populous village located near the river bank with an area approximately 4.67 km² filled with complicated housing areas, warehouses, small pathways that are mostly not up to standards. There are 10,779 head families living in Rawa Buaya and realizing how limited their sources, it seems that this village needs a repair. A lot of universities, organizations had tried to come and create
programs, counseling sessions, activities that would help the villagers to understand better about what they should and should not do about the way they organize their lifestyle. Indonesian people likes to plant their yard with plants that could be use every day as a food, such as Solanum lycopersicum (Pohon Tomat) or herbs like Allium sativum (Garlic). Therefore, they each have their own plants on pots in front of their houses or across their house on the street, which could block the pathway of the vehicles passing by.

GOALS
This study’s aim is to examine the significance of applying biophilic design such as building green infrastructures for Rawa Buaya villagers in order to provide a healthy environment for children and adults.

METHODS
This research was conducted with a descriptive method of analyzing the behavior of the villagers on how well they are capable of taking care of their own environment. The collection of secondary data such as soil fertility, climate data and the history of Rawa Buaya itself are done by literature study.

This alluvial soil contains high fertility and is good for planting as a agricultural land. Since Indonesian people likes to plant, then this kind of soil suits their lifestyle. This soil does not have a stable profile because the age of this type of soil is still young so it does not have a solid soil structure. In the event of a severe flooding, this type of soil will be easily washed away and dissolved in water which will then undergo a deposition process mixed with mud.

Land use
Rawa Buaya used to be a swamp that cannot withstand the weight of towered buildings or heavy equipments in the warehouses. There have been enormous changes that could cause the village to tear apart in the future time.

Urban sustainability
The Rawa Buaya Village could be called sub-urban since many development has been done, creating a biophilic environment in Rawa Buaya is one way of sustaining their lifestyle.

Lack of space
The lack of space in the village in one of the problems they are having, what could be the solution to creating a biophilic environment in a crowded village, what can be applied to a limited space to create a healthy lifestyle that these villagers can live by.

It should be done by analyzing which part of Rawa Buaya need the most reconstruction because the number of people and houses are so overcrowded that renovation is unwanted.

Biophilic design in villages
Children that play around in nature has a better cognitive response, they are more
active and know how the world works, they are better at being creative and capable of creating something new or innovative. In this era, technology, TV, video games and phone limits their capability of being innovative and stopping them to do instead make these children watch more.

Since Rawa Buaya has a huge number of families in such a small village, creating design with the purpose of ‘outdoor lifestyle for children’ could be a great idea. Keller (2006) lists four basic principles (translated from German language) that says:

1. Nature, with its vast sources for play provides a lot of things for children to fantasize and help build their creativity.
2. A direct contact with nature allows the mind of children to develop a sensitive appreciation for earth.
3. The forest provides an ideal place for children to freely run and move around, that could develop trust and children gains self-confidence.
4. Children gain competence in social relationship by playing around with other childrens.

CONCLUSION

Biophilic design correlates to almost every part of Rawa Buaya Village, from its purpose to sustain the village itself.

However there are socioeconomic factors that is possible for a biophilic design cannot be applied here in Rawa Buaya. The villagers may not welcome the new infrastructure, second, the length of time needed and the urgency of creating a biophilic village in Rawa Buaya is so minimum that it will not be posed as an important work by the government.

Abstract

In 2002, Malaysia Quality of Life report, the frequency of park user in Malaysia is still low although the benefits of green outdoor environment as a restoration site is being recognise in most of modern cities. Therefore, there is a need to investigate the use and constraint of green outdoor environment at workplace in order to identify the preference of green outdoor environment among office employees. A survey was conducted involving 32 respondents as sample of the study (20 females, 12 males) aged between 20 and 59 years. Participants were office employees from various industries randomly selected in highly compacted areas with offices in Kuala Lumpur and which consists of green outdoor environment. This study aims to identify the use and constraints of using outdoor green environments by office employees and investigates their preferences for outdoor green environment. It was found that most of the employees visited green outdoor 3-2 times per week (43.8\%) over the last six months by doing various activities such as walked to and from public transportation or parking space, meeting colleagues and others. The results were leading towards positive perceptions towards green space in the work environment and increased positive workplace attitude and recommendations for integrating a green space for offices in Kuala Lumpur. It was found that green outdoor environments were health-promoting assets at workplaces, and that increased access to such environments for the employees can lead to decreased levels of stress. Furthermore, green outdoor environments at workplaces were related to a positive overall attitude toward the workplace (81.3\%). However, due to the time limit during lunch break or after working hours, 62.5\% of the employees were unable to spend much time at green outdoor area. The findings from this survey has the potential in providing information for the planning and management of green outdoor environment in Malaysia. This information is vital for the local town councils in providing the management plan for green outdoor environment in Malaysia in the future and also to the National Landscape Department to enhance the current policy on urban green spaces.

Keywords: Biophilia design; office green space; work-related stress; self-reported health
1. Introduction

Worldwide, work-related stress is considered a major challenge to workers’ health and the health of their organisations (World Health Organization, 2011a). The European Agency for Safety and Health at Work (2000) reports that work-related stress is one of the most significant European health and safety problems, and it affects nearly one in four workers. Work-related stress can impair an individual’s psychological and physical health, as well as an organisation’s effectiveness (World Health Organization, 2011), and studies suggest that between 50% and 60% of all lost working days are related to stress (European Agency for Safety and Health at Work, 2000b). This represents a major cost in terms of human distress and impaired economic performance (ibid.). Work-related stress was previously considered as being primarily a problem in the developed countries, but it is now also an issue of growing concern in developing countries due to processes of globalisation and the changing nature of work (World Health Organization, 2007). A review on qualitative research, which addressed work-related stress, found that stressors at work were reported more frequently than stressors associated with other role areas, and concluded that research on occupational stress is especially relevant to efforts aimed at reducing overall stress levels (Mazzola, Schonfeld, & Spector, 2011).

Against this background, it is hardly surprising that individuals, companies and communities are very concerned about the topic (European Agency for Safety and Health at Work, 2000) and that a lot of resources are invested in stress management programmes (Goetzel & Ozminkowski, 2008; World Health Organization, 2004). Contemporary stress management programme at workplaces typically focus on psychosocial factors, and do not address the growing body of research on the environmental psychology of workspace (for a meta-analysis see van der Klink et al., 2001). However, studies show that the physical working environment is significantly related to employees’ stress-level (Rashid & Zimring, 2008; Vischer, 2007). The effect of the workplace outdoor environment for employees’ level of stress has mainly been ignored, even though the relationship between access to green outdoor environments and human stress in other contexts is supported by a vast body of empirical evidence (Nielsen & Hansen, 2007; Stigsdotter et al., 2010; van den Berg, Maas, Verheij, & Groenewegen, 2010). Theoretical explanations for this relationship are based on cognitive or evolutionary perspectives.

Few studies have addressed the potential benefits of access to a green outdoor environment at work for employees, companies and societies. However, the few that have indicate that access, either visual or physical, to such environments during the working day is related to increased health (Kaplan, 1993), wellbeing (Hernandez, 2007; Leather, Pyrgas, Beale, & Lawrence, 1998), job satisfaction (Kaplan, Bardwell, Ford, & Kaplan, 1996; Kaplan, 1993; Leather et al., 1998; Shin, 2007) and work performance (Kaplan et al., 1996; Pati et al., 2008), and to decreased perceived levels of stress (Pati et al., 2008; Shin, 2007). Recent studies show that, despite the potential benefits, the majority of office workers do not go outdoors during the working day, mainly due to a perception of being too busy and a working culture that does not include outdoor behaviour (Hitchings, 2010; Lottrup, Stigsdotter, Meilby, & Corazon, 2012).

Therefore, this research sought to study the use and preference of green outdoor environment at workplaces by office employees in Kuala Lumpur, whilst...
investigating the effect of green outdoor environment use and self-reported mental health.

2. Methodology

2.1 Participants

The total participants for the study were 32 respondents who worked within the area of offices with access to the green outdoor environment in the city of Kuala Lumpur (Figure 1). Kuala Lumpur as the capital city of Malaysia is the main choice of local and international real estate investors (Boo, 2003) and deemed as the major provider of office space in the country. In term of occupancy rate, Kuala Lumpur peaked the highest among the major city in Malaysia. To further identify what are the existing office spaces offered in Kuala Lumpur, reference is made with Property Market Report published by National Property Information Centre (NAPIC) (Figure 2).

![Figure 2: Location of Central Business District, Golden Triangle and Within City Centre in Kuala Lumpur (Source: Kuala Lumpur City Hall)](image)

According to the survey, all participants were being employed at the time of participation and came from various sectors including finance, oil and gas industry, retail, business, education, government agency, real estate, construction and health.

2.2 On-site survey

A survey was conducted for four weeks in a month of February 2018. The questionnaire contains thirty (30) questions, both closed-ended questionnaire with multiple questions and open-ended questions. The questionnaire’s sections were inspired by several other studies on use and users of green outdoor environment (Gobster, 1995; Lindsey, 1999; Schipperijn et al., 2010). The survey was conducted in two languages, namely Malay and English to cater for the cultural diversity in Malaysia including the expats (Sreetheran, M., 2017).

The users at each green outdoor area were surveyed on-site on weekdays, in the afternoon from 12.00 until 3.00 pm; and evening from 3.00 until 7.00 p.m. (Sreetheran, M., 2017). The sample was taken during the lunch break and after work where the number of office employees being outside of their offices is high. Typical working hours in Malaysia are from 8.00 am until 5.00 pm and lunch break from 1.00 to 2.00 pm.

The first part of the questionnaire consists of respondents’ physical work environment and the distance from their office to the nearest urban green outdoor. Distances were broken into: less than 300 metre; 300-500 metre; 500 metre to 1 kilometre; and more than 1 kilometre. The respondents were also asked for the frequency of use of the green outdoor (daily, several times per week, weekly or never) and duration of use (less than 5 minutes, about 15 minutes, about 30 minutes, about 1 hour, and more than 1 hour). The respondents were also asked the reasons of using the green outdoor near their offices. Their choices included the following options: to walk, having meal, meeting colleague, exercise and other reasons. The respondents are allowed to choose more than one reason. They were also asked
characteristic of green outdoor environment according to their preferences.

Section B until Section G of the questionnaire contains about the physical work environment; the emotion while visiting green outdoor environment in term of time balance, social and community, lifestyle, nature surrounding, and perception towards green outdoor environment. They need to rank their responses on five-point scale ranging from ‘very agree to very disagree’ (Lottrup et al. 2012). The final section of the questionnaire consists of respondents’ socio-demographic status such as gender, age, race, education level, occupation and how long he/she has been employed in the company.

All data was recorded into database and analysed accordingly using Microsoft Excel.

3.0 Result and Discussion

3.1 Demographic background

The results of the study presented the information from 37.5% (12) male and 62.5% (20) female respondents. Respondents between ages 30-39 were the majority with 47% (15) participations while respondents between ages 50-59 were the minority with 6% (2) representatives in the survey. Ninety four percent (94%) of the office employees have the access to green outdoor.

Table 2: Demographic background

3.2 Visit frequency

It was found that most of the employees visited green outdoor 3-2 times per week (43.8%) over the last six months by doing various activities such as walked to and from public transportation or parking space, meeting colleagues and others. Although 59% of the respondents claimed that they only ‘visited’ green outdoor just by walked to and from certain places, they do not perform physical activities which allow them to utilise the facilities that are available or enjoying the scenery at green outdoor area.

3.3 Use patterns and constraints

The majority of respondents (62.5%, n=20) reported that they were experienced obstacles to go out and visit green outdoor during working hours because of the time limitation and indicated they were too busy. This result is connected with Lottrup et al.
Biophilic Cities

(2012) and Hitching (2010) discussed in their studies where the employees were too busy to go outdoors during their working hours. Three of respondents also stated that they only have an hour of lunch break and managed to grab a quick lunch before heading back to their offices and after working hour, they have to rushing back to pick up children from school and day care (Bonke, 2002). Therefore, these employees were unable to spending off more time visited green outdoor area outside of their offices during their working hours or after. According to 59.3% (n=19) respondents, he/she preferred to visit air-conditioned place compared to green outdoor area during lunch break due to the hot weather. This finding is similar to the study that was conducted by Sreetheran (2017) who mentioned that the user chose to visit outdoor in the morning or later in the evening in a tropical country like Malaysia. Other researches by Jim and Chen (2006) and Wong (2009) also stated in their papers that users avoided hot afternoon to visit outdoor in other highly dense Asian cities like Guangzhou and Hong Kong.

3.4 Perception towards green outdoor

The respondents were asked to rate their emotional aspect before and after visiting the green environment outside of their workplaces using a 10-point grading scale; one for ‘very unhappy/feeling stress’ and ten for ‘very happy/joyful/satisfy/free from stress’. Almost half (43.8%) of the respondents rate 5 (neutral) before visiting green outdoor area and rate more than 5 after their visits (81.3%). As reported by several studies, this finding is similar with Biophilia Hypothesis where natural settings have restorative capacities to the visitor (Ulrich, 1984; Hartig, Mang & Evans, 1991; and Besthorn & Saleebey, 2003). Using dichotomous questions, the respondents were asked to answer ‘Yes, Not Sure or No’ on their perception towards the nearest green outdoor environment at workplace. Figure 3 was obtained from respondents’ responses. In addition to the perception of green outdoor, 31.3% gave opinions on green outdoor environment near their offices.

For example, a female respondent from green outdoor C (Jalan Tun Perak) suggested that to improve the facility such as more benches, tables, and potted plants to make it more friendly-user. These characteristics were being cited by Schroeder (1982) where urban visitors preferred man-made feature contributing to high site quality such as paths and other features for passive activities (sitting and relaxing). One male respondent from green outdoor B (Jalan Raja Laut) suggested relocating the green outdoor area far from the busy road to more quiet and serene area with café or smoking zone. This finding is consistent with the study conducted by Lottrup et al. (2012), Grahn and Stigdotter (2010). In the study, the green outdoor visitors preferred to be in serene place, close to nature and having a space to perform a certain outdoor activities during the working hours, in line with perceived sensory dimensions (PSD) which has been identified by Grahn and Stigdotter (2010).

4.0 Conclusions

Green outdoor environment may comprising natural landscape or built landscape. Therefore, in this study, the focus was on the green environment at workplace which includes green space outside of their offices where people can do common activities such ‘walk-throughs’, having lunch, sitting and talking, and relaxing (Faris et al., 2008; Hernandez, 2007; Sherman et al., 2005). The good impact on the exposure to the green outdoor environment was also stated by De Vries et al. (2013) that green outdoor environments promote positive social contact among its visitors. According to Sianoja et al. (2017), current working life is
demanding. Therefore, there is a need to gain more theory-based knowledge on how to optimise the lunchtime or before leaving work for recovery from work, for example by brisk walk in the park or green outdoor area.

A comparative study of the application of the Storm Water Management Model in the construction of urban green space under the perspectives of sponge cities

Ming Shao, a Xiong Li, a

aBeijing Forestry University, Haidian Street 35, Beijing, 100083, China

Abstract

Recently, the acceleration of urbanization leads to the serious hardening of the underlying surface in cities that are located in China and the waterlogging caused by the hardening damages the development of cities. According to the <Basic Situation of Natural Disasters in China (2016)> published by Ministry of Construction, about 90% counties in 31 provinces, autonomous regions and municipalities in China were affected by different degrees of natural disasters, losses caused by flood significantly expanding compared with the damages in 2015. Rain and flood in urban cities become an issue that must be solved in China’s urbanization procedure.

Aiming at the social background, the Ministry of Construction has published <Work Plan 2014>, clearly indicated ‘speed up researching policy measures on the construction of sponge type city’. In December of 2014, <Technical Guidance of the Construction of ‘Sponge Cities’ (For Trial Implementation)> was published, which introduced the concept of ‘sponge cities’.

However, because the construction of sponge cities in China starts fairly late, China’s sponge cities are experiencing limitations and disadvantages compared with those cities in other countries. The most important is that China underestimates the bearing pressure of green space counter to rain and flood.

At the beginning of twentieth Century, the United States proposed the model of Best Management Practices; at the end of twentieth Century, the United States proposed the model of Low Impact Development; Australia proposed the model of Water Sensitive Urban Design; the British proposed Sustainable Urban Drainage; also the theory of Active, Beautiful, Clean Waters Programme in Singapore was proposed in 2006. All these has been tested by time and well accepted by people.

To conduct a more concise quantitative analysis on rain and flood in urban cities, the research found that researchers represented by American, Danish, Englishman studied and developed a series of models to manage rain and flood in urban cities. They conceive an idea that is based on and refers the calculation and stimulation conducted by computer model. Those models
aiming to different scales, environment and requirements are designedly optimized and they have different functions and range of use.

Based on the view of the designing and construction of green space in sponge city, by the stimulation of the green corridor project that was conducted at Binhu East road, Qian’an, Hebei Province, the research illustrates the application and academic achievements gained in the procedure of the location, effectiveness evaluation and effectiveness estimation of the designing of green space in sponge cities via the comparison and analysis of the modules and functions of various rain and blood management models (SWAT, SUSTAIN, SWMM etc.) which are developed by China and other countries, trying to generalize the application channel of the various modes in the designing and construction of green space in ‘sponge cities’ in China so as to find the possibilities of the localization and promotion of the above modes.

Keywords: sponge city; model for stormwater management; urban green space; green corridor

1. Introduction

In recent years, the progress of urbanization in our country caused more and more serious degradation phenomenon of hardening city underlying surface. It leads to frequent phenomenon of urban waterlogging, which has brought the serious crises and challenges to the development of the city.

According to statistics, many domestic tier-1 cities suffered serious waterlogging phenomenon only in two months of May and June of 2013, like Changsha, Chengdu, Xiamen, Fujian province, Kunming, and more than 270000 people were injured \(^1\); In May 2014, a heavy rainstorm occurred in Qingdao and Shenzhen, resulting 18 people casualty and 3 injured \(^2\). In 2015, the Ministry of Civil Affairs released the “2015 Basic Situation about National Natural Disasters” \(^3\). The total of 36 times of heavy rain occurred in China with serious waterlogging disaster in tier-1 cities like Nanjing, Wuhan, Shenzhen, Shanghai. In mid-November, rare winter flood season happened in Jiangxi, Hunan and Guangxi with more than one million people affected; In 2016 and the “2016 Basic Situation about National Natural Disasters” \(^4\), nearly 90% of nationwide county-level administrative region of 31 provinces were affected by different degree of natural disasters, which includes heavier floods and geological disaster losses than in 2015. Among which, sponge pilot cities in provinces like Hebei, Hubei, Jiangxi and Anhui still had more serious disaster. Serious waterlogging even happened in early July in Wuhan of Hubei due to heavy rainfall, which caused serious influence to people's life and property safety.

The safety of rain-flood has become a problem that must be solved in the process of urban development.

2. Present situation of sponge city construction

In the ‘2014 Key Point Work’, Ministry of National Housing and Urban Development determined “the urge to speed up the distributory transformation of rain and wasted water to improve the level of city drains, to greatly push forward the low impact development mode, to accelerate the policy measures of construction of the sponge city ”; From 2014 to 2015, the first announced batch of 16 urban construction pilot cities began to be built, with a planned investment of 30 billion yuan in three years and a construction area of over 400 square
The construction of sponge city has attracted the attention of social media and the masses. Compared with the mature urban sponge system in foreign city, China's urban construction sponge started relatively late with shortcomings and limitations. For instance, a large amount of present construction of sponge cities in China transfer urban rain flood pressure to the urban green land, which ignores the basic natures of green land and the limit of rain flood carrying capacity of green land, leading to the overload of rain flood pressure of green land. Not only did it not cut off the expected urban rain flood problem, the basic functions of green land have also been damaged to a certain degree.

How to scientifically and accurately conduct the quantitative analysis about the rain flood control index and flood control ability of sponge city in the process is an urgent problem in the urban green land design.

3. Brief introduction of water management models

Under the drive of this issue, researchers represented by the United States, Denmark, Britain have developed a series of urban water management models for the sake of the quantitative analysis with higher precision of urban rain flood indexes by using the computer model for calculation simulation to provide the analysis method of auxiliary parameter for the design. These water management models are specially designed and optimized for different scales, environments and requirements with their different application range and function.

3.1. Watershed scale simulation models

With the development of computer technology, the watershed hydrological model appeared as early as in the 60 s and 70 s of the 20th century. Its development focus on is in the large-scale basin analysis with core functions mostly made up by the measurement of a wide range of runoff, ecological stock estimation of watershed scale, designation of watershed response unit, and so on. Among which being widely used are the Sacramento model developed by the NWS and the SWAT model developed by the USDA.

3.1.1. Sacramento

Being a continuous operation model of lumped parameter, Sacramento model is improved and developed on the earliest Stanford river basin model by the Sacramento prediction centre of hydrological office of NWS. By mathematical calculation, its main function are years of simulation for runoff confluence, distribution of rainfall and snowmelt runoff based on the soil moisture content, osmotic quantity, drainage and evapotranspiration process of the river basin scale runoff.

3.1.2. SWAT

SWAT (Soil and Water Assessment Tool) model is an open source plug-in model through secondary development on ArcGIS platform by USDA and its prototype is the field scale non-point source pollution model CREAMS in the 1970s. Its main functions are the predicting simulation of land management and regional meteorological impact on supply of river basin water environment under the complex and diverse conditions of soil conditions, land usage
mode and management mode in the large scale basin. The SWAT model is a widely used watershed simulation model both in China and abroad.

3.2. Urban green land scale simulation models

Green land is one of important undertaking unit in urban rain flood control. Faced with small scale cities or urban green land space, countries continue to develop a great deal of water management models targeting the city and urban green land on the basis of watershed hydrological models, among which the widely used is basically the model developed by the EPA. Especially the SUSTAIN model plug-in based on ArcGIS platform and independent software model SWMM are most widely applied.

3.2.1. SUSTAIN

SUSTAIN (System for Urban Storm-water Treatment and Analysis Integration) is a plug-in model through secondary development on ArcGIS platform by EPA in the 1970s and 1980s. The model of combines the partial algorithm model and genetic algorithm in the early SWMM5.0 to apply the analysis models of hydrological, hydraulic and water quality. With comprehensive consideration of cost control and optimization method, it uses ArcGIS platform to couple the simulation and optimization phase, which can not only develop, evaluation, selection and settings of BMP in construction region with different scale from two aspects of cost and efficiency, it can also provide comprehensive and practical evaluation from the perspectives of economy, environment and engineering for the management measures.

3.2.2. SWMM

As a city heavy rain management developed by USEPA between 1961 and 1971, SWMM (Storm Water Management Model) can simulate the accumulation and erosion of urban rainfall runoff and various pollutants. Its transmission system can realize hydrological, hydraulic and water quality simulation and its results can be output in a variety of ways, and be modified and updated in recent years. Presently, SWMM model is also the most widely used in the construction of the development of low impact model in China.

3.3. Urban pipe network simulation models

3.3.1. MOUSE

MOUSE (Model for Urban Sewers) is a urban storm runoff Model developed by DHI in 1984 to simulate the urban runoff and pipe flow. At present, MOUSE mainly provides design basis for LID by predicting water level changes in urban pipe network while also compares the purification efficiency of pollutants targeting on different models of LID.

3.3.2. Info Works

Info Works is a hydrological water quality model for urban drainage systems developed by Wallingford in 1997. Being mainly used in the planning and design of urban water supply and drainage, sewage system, river and coastal engineering projects, this model provides technical support for many domestic practical projects, such as drainage, sewage pipe network analysis, drainage system
selection and surface source pollution control planning.

3.4. Model selection

First of all, according to the basic attributes of each model, this paper compares and analyzes the water management models from the above five aspects of the docking platform, scope of application, simulation program, simulation function and data requirements. The results are shown in table 1.

</tbody>
</table>

The result of simulation model by comparing shows that in basin scale model, data demand of Sacramento model is bigger compared with the SWAT model and the water quality simulation could not be conducted. Among the simulation model of cities and urban green land scale, SUSTAIN model and SWMM model all have emphasis on their functions. SUSTAIN is more about detailed quantitative analysis for BMP measures while SWMM focuses on quantitative calculation of runoff rain pollution. MOUSE and Info Works model are more focused on the analysis of city pipe network simulation. Based on the actual demand of Chinese sponge city green land design, SWAT, SUSTAIN and SWMM model are selected for further comparison of functional modules.
4. The application of water management models in the green land construction design process of sponge city

This study sums up the six design processes in the “Sponge Urban Construction Technology Guide” [7] to be four steps of the targets determined of the early stage, plan forming in the initial stage, effectiveness evaluation of middle stage and plan optimization in the later stage to consider the application possibility in the design process at different stages of the green land construction of sponge city based on different functional modules focuses on SWAT model, SWMM model and SUSTAIN.

4.1. Control target determination

Construction goal of sponge city green land is to have a certain degree of control on the rain runoff pollution problems of the city instead of bearing the pressure of urban rain flood completely. Thus, before sponge city green land construction, the construction position of green land in urban overall planning and construction needed to be clear to determine its runoff control rate, pollutant removal rate and related specific indicators. The simulated objects in this stage are the city scale runoff and precipitation distribution, and the runoff estimation of the specific region.

The SWAT model mainly adopts the concept of the representative basic unit to determine the corresponding simulation parameters and results by generating HRU according to the specific soil types and land use methods of each sub stream. At the same time, the modelling definition and basic simulation of the responsive units can reduce modeling simulation time cost by guaranteeing simulation precision under the condition of large deviation greatly.

Some kind of hydrological response unit were obtained by inputting the SWAT model after the terrain data, basin data and soil type data vectorization processing to carry out generalization process of underlying surface type scale of the same corresponding unit and initial calibration of sponge city renovation or generalized index. Through the secondary simulation of the SWAT model, the reasonableness of its runoff pollution control was verified to identify the corresponding land use planning and control objectives. This goal can guide the design method and scale of sponge system in the next green land design plan.

4.2. Plan forming

In the design of sponge city green land, the corresponding scale estimation and spatial distribution simulation should be carried out for the low impact development measures. The simulation object of this stage is the estimation of runoff and pollution abatement of green land scale and the distribution simulation of the low impact development measures of the facility scale.

The efficiency of this phase estimation is only a rough simulation forecast. SUSTAIN model in rain pollution effectiveness evaluation phase needed a large number of detailed data and land information data, which is difficult to get. So the choice of SWMM to estimate the size of low impact development measures is made. In the estimation, the distribution relationship between the same kind of low-impact development measures and the flow direction of each other can be ignored to be calculated in the model after the same kind of low-impact development measures in the green land design plan.
impact development measures and are combined and simplified.

Distribution simulation measures in this phase can choose SUSTAIN model which is based on ArcGIS platform of low impact development measures of spatial distribution simulation and the main uses two modules of its framework of management and BMP layout. After drawing sketches plan, it can be input into ArcGIS platform after its vectorization on CAD platform for and corresponding standards of site selection can be determined, such as a number of indicators of rainwater catchments area, slope, impervious rate, depth of groundwater and road buffering area distance. By the overlaying analysis of the module in figure 1, the possible spatial distribution of the corresponding low impact development measures was determined with results example shown in figure 2. On which basis, it is further screened according to the specific site conditions, the rain flood control target and policy measures to enable designers to make specific design by combining the functional requirements and landscape requirements to get the rain preliminary design plan of flood control.

![Fig.1 The site selection module of SUSTAIN model](image1)

![Fig.2 The sample of siting analysis result](image2)

4.3. Effectiveness evaluation

After completing the design of green land program, it is necessary to carry out an accurate assessment of the efficiency of runoff and pollution to determine of the result of the plan has reached the goal of the first step. The simulated object of this stage is the estimation of runoff and pollution abatement of green land scale.

The accuracy requirement of effectiveness evaluation of this phase is high. As a simulation model of vectorization quantization based on ArcGIS platform, the accuracy of SUSTAIN model can be guaranteed more compared with the simulation of the vector quantization of SWMM model. Mainly by four modules of
framework of management, land, BMP and transmission simulation in SUSTAIN model [9], this process inputs the corresponding land information data, soil conditions, design information onto ArcGIS platform to form the model base, and builds structure for each measure and tube drainage in low impact development measures simulation module of SUSTAIN model for to provide a basis for simulation in runoff calculation and the rain pollution reduction. In the process of the urban green land construction of sponge city, policy makers can compare the simulation results with project control objectives at this stage to further adjust the design details on the basis of the comparison results to complete the basic control requirements of the project.

4.4. Plan optimization

One of the important factors of the design of sponge city green land is the design stage of the plan extended to the later stage of construction drawing design and the balance control between the plan and the cost. The simulation object at this stage is the relationship between plan efficiency and plan cost.

This stage mainly uses integrating unique module of SUSTAIN model to make cost optimization analysis. The model integrated the two algorithms of SSM and NSGA - II for the plan optimization [10], including the improved genetic algorithm NSGA - II can generate effectiveness evaluation curve for BMP and LID facilities construction and maintenance cost to assist designer to determine the optimal design plan. It requires researchers to determine the plan of the structure of BMP facilities variables according to the required optimization goal and make decisions for each variable parameters interval and incremental settings, which uses the Sustain model to do a large number of combinatorial optimization calculation, and output the corresponding calculation results in the form of chart as shown in figure 3. In urban green land construction in the process of sponge city, cost and benefit calculation curve provided by the Sustain model can aid decision makers in making the final adjustment and choice in such aspects as overall cost control and the plan optimizing to reach the optimal effect.
5. Conclusion

In the construction of sponge city green space, the designer must adopt both qualitative and quantitative analysis methods to ensure the reasonable and effective design scheme. Water management models provided the corresponding calculation way, but from a single water management model analysis, the inevitable exist error and function of lay particular stress on, and errors. Relative on the whole, because each model has different characteristics and focusing on the function, if through the basic modules, use and expanding functions of contrast research, applying the linkage, can result in sponge to different stages of the urban construction to provide important role.

Abstract

Compared with traditional visual communication methods, virtual reality can utilize and integrate high-presentation computer software and hardware and various advanced sensors to create an immersive and interactive information exchange environment, providing landscape architecture design various possibilities in education, research and design process. Landscape design presentation is mainly a way to convey the design's work to other people. It is an important and direct way for designers to communicate design concepts and express spatial environment between clients and their counterparts. Till now, there has been various ways for presentation, such as rendering images, diagrams, solid models, and animation presentations. Compared with the traditional representation methods, virtual reality technology has its own advantages and disadvantages. Due to the higher complexity and possibility of virtual reality technology for equipment, platforms, and transmission methods, its display strategy in design presentation needs special consideration.

Four process of presentation work was summarized to compare different presentation methods, including modeling, environment rendering, displaying and public participation. Two basic types of virtual reality technology are represented: the fixed-end VR and the mobile-end VR. A comparative study between two different scales of projects - the plan of Jingzhang High-speed Railway Green Corridor and the design of the Central African Garden in the Beijing World Horticultural Exposition – were down to explore complexity and potential of the two virtual reality technologies, and try to build strategies for presentation with virtual reality.

Through the research, a strategy framework of virtual reality design is summed up. The strategy is based on four aspects mentioned above, and started from the complexity and potential of the two aspects, VR and the combination of VR and other methods. Finally, the suggestions of model building, rendering and selection of equipment are proposed.
**Keywords:** Virtual Reality; Presentation Strategy; Visual Communication Methods

1. Introduction

The presentation of landscape design is mainly a way to convey the scheme of design to other people. It is an important and direct way for designers to communicate design concepts and express spatial environment between clients and their counterparts. Till now, there are 4 traditional ways to display landscape architecture design: single-image renderings; diagrams to express design structures and design processes; solid models built from various materials; animations with continuous illustrations by editing and rendering.

Compared with traditional image propagation technology, virtual reality (VR) can utilize high-presentation computer hardware and various advanced sensors to create an immersive and interactive information exchange environment, providing landscape architecture design various possibilities in education, research and design process [1].

This paper will do research on two types of VR mode, which are based on two different types of VR playing devices, including fixed-end VR and mobile-end VR. Fixed-end VR refers to Oculus Rift, HTC Vive and Sony PS VR represented with external computers and professional sensors device. Mobile-end VR refers to devices that use Gear VR, Days VR, and Google Cardboard, kinds of low-cost recommended glasses, as the main device and mobile phones as players [2].

Virtual reality has become an important way to express the landscape design, and it has its own advantages and disadvantages compared with traditional visual communication methods. Due to the higher complexity and possibility of virtual reality technology for equipment, platforms, and transmission methods, its display strategy in design presentation needs special consideration.

2. Methods

2.1. Single Scene - Contrast in 4 Processes

The research divides the post-design presentation work into four processes: modeling, environment rendering, displaying, and public participation. Taking the presentation of one scene as an example, the workload and presentation characteristics of different ways are compared.

Among them, modeling and environment rendering are part of the workload, which reflects the input of the design team to the project, including manpower, equipment and capital. The lower the investment in the process, the higher the efficiency of the process itself. Displaying and public participation is the process for expression and feedback evaluation. It reflects the actual output effectiveness of the project. The better the results presented in this part, the more satisfying the clients and user groups will be, and the feedback evaluation of the project will be clearer and more accurate, which can reduce duplication of work and repeated trials and have a positive effect on the promotion of the project.

The factors that measure input include the human resources, the time it takes, the demand for work platforms and equipment, and additional capital investment (such as cooperation and consulting). Measured output factors include the attractiveness of the attraction to clients, the ease of platform...
construction for displaying information, the accuracy of the client’s understanding of the presented information, and the effectiveness of the client’s feedback to the designer that can be more clear to understand client’s demands, thereby reducing the possibility of repeated work and accelerate the overall process of the project.

Modeling
Modeling is the process that the designer build a 3D digital model in the computer using modeling software such as Sketch Up, Rhino, 3DMax and other tools after the designer completes the design. This process mainly prepares for the later environment rendering. It is a key step in the transformation of the design scheme into the physical space model, and it is also the most workload-concentrated step in the work flow. In this process, due to the need to present a 360-degree scene, the fixed-end VR and the mobile-end VR need a large amount of work; the scene of rendering and animation can be selected at a relatively fixed angle, so the workload is smaller than VR; the solid model (mainly the pre-cutting preparatory work) and diagrams often require different depths of modeling based on the intent of presentation, so the workload is more flexible.

Environment Rendering
The environment rendering is the process of rendering and adjusting the model to make it into a finished product that can be used for actual presentation. The rendering processing equipment and processes between different representation methods are quite different. Among them, VR, rendering images, and animation often rely on V-ray, Lumion, 3D MAX and other rendering software rendering the light environment and material on the model to obtain a realistic or artistic image. Fixed-end VR and animation often needs continuous images that cost more workload than rendering images and mobile-end VR. Larger and more detailed models need more workload cost and higher equipment requirements.

In the rendering process of rendering images and diagrams, it is often assisted with post-processing software such as Adobe Photoshop, or directly using it to create matte painting, to make the image closer to the real environment, or to highlight a stylized atmosphere. Animations are often edited by editing software like Adobe Premiere and after effects software like Adobe After Effect, including music and dubbing direction. The processing of the solid model is independent of several other presentation methods, mainly the cutting and erection of the physical model. According to the purpose of expression, the workload and requirements for the equipment are also different.

Displaying
Displaying is the process by which designers present their designs to clients. The mobile-end VR often utilizes the linkage between the cloud platform (like 720yun.com) and the mobile phone software. The hardware end only needs to provide the mobile player and VR glass like Google Cardboard. Logging in to the cloud platform allows you to view the uploaded panoramic images, which is very convenient. For 360-degree immersive experience, this method is conducive to clients for experiencing a more realistic environment. In particular, it can help clients experience a more realistic sense of scale and spatial experience.
The fixed-end VR has a deeper immersive experience than the mobile-end VR. Since the device can capture the user's activity status and feed back into the VR environment, the user can directly interact with the design program, which enables users to more accurately assess the design. The platform display of the fixed-end VR often needs to construct an independent VR experience space, which includes the construction of sensing devices, transmission devices, and calculation devices, and requires a certain amount of space. It is more complicated and requires higher equipment that is less convenient.

The display modes of rendering images, diagrams and animations are more diverse. Compared with VR, they often have lower costs, more flexibility, and greater controllability. However, there is a lack of immersion.

Public participation

Public participation mainly refers to the feedback process of clients after they have hearing designer’s solutions. Different types of expressions often leave different impressions and feelings on clients, and evaluations and feedback on design plans will also vary. This indicator mainly shows the accuracy and effectiveness of customer feedback: accurate feedback means that clients can better obtain the ideas that designers expect to convey, and their own appeals can be more accurately conveyed to designers. This will ultimately reduce repeated changes and adjustments to the project and optimize the entire design process.

VR can give the customer a more comprehensive and real experience. Therefore, direct and effective feedback can be obtained. Among them, the amount of information displayed by the fixed-end VR is more comprehensive than that of the mobile-end, so the feedback result is more effective. In addition, the presentation of VR is more interesting and attracts more public to participate in the evaluation of the project.

The display of diagrams, images, and animations is often performed on clips of project segments. Therefore, the transmission of information are not comprehensive compared with VR. The feedback results are often one-sided.

By comparing the 6 methods, the characteristics of them in the 4 processes can be summarized as the following table, where “■” represents the input generated by the workload, and “◆” represents the output of the project.

Fig. 1. Characteristics of presentation methods in 4 processes

2.2. The additive effects in the complex presentation of plural scenes

In a complete project composed of a plurality of scenes, the input process and the output process are often repeated.
The repetition of the input process is reflected in the repeated use after the construction of the 3D mold, that is, after completing modeling, it can be used to render a variety of presentation methods. Therefore, the workload of various expressions in the actual project is not linearly stacked. Once the VR or animation modeling is completed, the modeling workload of the renderings, models, and diagrams can be greatly reduced. The more presentation methods used in the design, the more reduction of workload in single way is, but the total workload is still rising.

The repetition of the process of output is also reflected in the repeated use of multiple expressions, that is, the same scene is repeatedly used in different ways. Due to the overlapping of information, the output effectiveness of each expression is weakened. The more presentation methods used in the design, the less effective the single method will be, but the overall effectiveness of the information conveyed will increase. While it is worth noting that clients are not precisely the machines that receive all the information they are given. Excessive repetitive methods may enhance the impression of a certain scene or idea, but it may also create annoying negative emotions that may affect the evaluation of the project.

The accumulative changes of different presentation methods are various. When choosing expression ways of a project, it is possible to choose inputting repetitive ways to reduce the workload, and to choose the ways that with low output repeatability to enhance presentation effectiveness. The accumulative effects of different expressions are shown in the table below. The more “-”, the more repetition of input accumulates; the more “+”, the more repetitive the accumulation of output. In general, the more “-” and the less “-” the closer the combination is to an ideal process.

2.3. Particularities of the Project - Comparison of Project Size

In practical projects, the scale and presentation are closely related. The study compares the presentation of the two basic types of projects. One is a larger-scale, conceptual plan, and the other is a garden design with small size. There is a big difference between the needs of the two sides from clients.

Large-scale planning
The scale of this kind of project is huge, and the client's appeal tends to focus on a clear and attractive target, concept and structure. A large number of possible image scenes are often used for the intuitive translation of the concept to achieve the possible effects, so presentation methods are mainly based on diagrams, expressing research and analysis of the project environment, the overall structure of the project, and planning strategies at multiple levels. In order to reduce the workload of modeling and rendering, the scene created
through VR, renderings, and animations that reflect the scenes are often clearly distinguished from the small-scale design. On the one hand, the bird's-eye view are often used, reduce the expression of details, and enhance the expression of overall structure; on the one hand, only the core section of the projects are modeling and rendering.

The Jingzhang High-speed Railway Green Corridor Project is an experimental project that the research team has participated in. It mainly transforms and upgrades the abandoned railway land in the section of the urban area of Beijing, forming a 9.6-kilometer-long green corridor connecting the city's core area with the suburbs. In this project, VR is used for the presentation of the hubs and the presentation of a partial bird's-eye view. In addition to this, many other methods except the physical model are used in the project. According to the survey of presentations and exhibition results, VR did not bring a clear understanding of the design to the experiencer, and even produced some misunderstandings, but most of the experiencers expressed that they were very interesting and had a strong interest in the project.

The output of VR in large-scale planning is often limited. Due to the tendency to express the overall atmosphere rather than the simulation of the actual space environment, VR that consume a lot of modeling and rendering workload are often not as effective as other methods. The essence of the problem lies in the fact that the amount of information that the project itself needs to convey and the amount of information that VR displays are unequal, resulting in a lot of wasted work. In the display of large-scale planning projects, a large amount of information is often required to be conveyed to clients in a centralized way, which is too complicated. Therefore, ways like animation and diagrams that is recapitulative are more able to avoid unless expressions and allows clients to receive the core content of the project. However, VR can also create some special spatial feelings, especially non-normal viewing angles such as bird's-eye view, which can be enhanced through VR to enhance the feeling of space and bring a deep impact to the clients.

Small-scale Design

Small-scale design, such as garden design, urban plaza, or detailed design of a large-scale project node, often has low requirements for goals, concepts, and structures, but it has high requirements for spatial environment and design details.
Scenes that are closely similar to the constructed projects built in the future allow designers and clients to avoid repeatedly evaluation and revise of the program. In this kind of scale, VR can exert its characteristic to a greater extent. On the one hand VR can bring the most real space feeling to the customer, this is that any other presentation methods is difficult to reach, the fixed end VR can even bring feedback that simulates people's movements such as sit-downs, and lookouts in the scene, so that people can clearly feel the changes in space. On the other hand, since the perspective viewed by the customer in the VR is free, it is beneficial for the customer to review the details of each part and make more accurate assessment of the details in the scene.

The research team used VR to display the entire garden scene in the design of the Central African Garden in the Beijing World Horticultural Exposition. In the actual experience, the customer had a deep impression on the whole trace and spatial experience of the garden, and the evaluations and suggestions from clients showed that the design are not misread and has a good guiding role in the in-depth design of the project.

Fig. 5. VR rendering of the Central African Garden

The effectiveness of different scales of expression is summarized in the following table:

Fig. 6. Effectiveness of different presentation methods in two scales

3. Conclusion

Through the comparison of various angles, this paper summarizes the following strategies for the selection of VR:

- VR has its own great potential for excavation, and it has accurate and attractive features in information transmission. However, its high demands on workload, equipment, and communication platform are undeniable problems.
- Give priority to project characteristics and client needs, and determine the necessity of using VR in the project first. In the large-scale projects with strong conceptual and focus on the overall structure as well as atmosphere of image expression, VR has a low efficiency of project output and will also increase a large amount of workload. For some small-scale designs with spatial feeling perception, VR has obvious advantages.
- After deciding to use VR, coordinate the entire project workflow based on cumulative effects of different presentation methods. The combination of different presentation methods makes the project more effective to be expressed.

Abstract

As the scale of the city continues to expand in China, the urban heat island effect has become an urgent problem to be solved. Urban green space is an important component of urban ecological system, which can effectively relieve the urban heat island effect. This article chose Beijing city for study object area where the speed of urbanization and land use situation altered obviously and quickly. Some remote sensing images from 2002 to 2017 were employed. Calculation of vegetation fraction and land surface temperature was based on the software of ENVI 5.1. The trend of summer land surface temperature alternation in study area was concluded by using the statistical data from ArcGIS 10.2 software. The coupling relationship of NDVI and land surface temperature were studied. Some suggestions in urban planning and Urban forest built were put forward in the end.

Keywords: Urban forest; remote sensing; land surface temperature retrieval; vegetation fraction

*Corresponding author: Qing Lin, E-mail: lindyla@126.com.
With the advancement of urbanization in China, a large number of construction activities have resulted in excessive carbon dioxide and heat emission; At the same time, the city underlying surface have also changed, and a large number of high-accumulation bodies such as buildings and roads have led to the "high temperature" in city\(^1\). Urban forests, as a kind of urban landscape, play an important role in improving the urban thermal environment. How to quantitatively assess the cold island effect of urban forest is the focus in this study.

As a capital city, Beijing is a high leveled urbanization city, and the heat island effect is prominent and complex. At the same time, it is also a pioneer area for urban forest construction. At present, Qiu Hailing studied the coupling relationship between vegetation coverage and land surface temperature in Beijing\(^2\); Jia Liuqiang et al studied the green space shape in Beijing and the influence of area on its cooling efficiency, and he proposed that the area, perimeter, and cooling efficiency in the park are clearly positively related.\(^3\) This paper selects the inner region Wuhuan as the research object, based on the Landsat7 ETM remote sensing image, inverts the vegetation coverage and surface temperature data at the regional scale, studies the temporal and spatial variation between the two, and quantitatively explores the correlation between them. The conclusion can provide a scientific reference for the urban forests construction that alleviate the heat island effect in large cities.

---

1. The area overview

Beijing, as the capital city, has a relatively complete urban development. With its strong urban construction and dense population, which will inevitably lead to the urban heat island problem. Therefore, this study selects a relatively complete construction and a relatively significant heat island effect within the Wuhuan area in Beijing as the study area (Figure 1).

2. Data sources and preprocessing

The remote sensing image from the United States Landsat 7 ETM satellite was selected as the basic remote sensing data. The study area was located in the strip number: 123, line number: 32. The imaging time for the four remote sensing images was August 3, 2002, September 3, 2007, August 16, 2012, and September 7, 2017. The remote sensing image from Landsat 7 ETM satellite includes 8 universal bands. In this paper, the 3rd and 4th bands are used to extract the normalized vegetation index (NDVI) in the study area, and the 6th thermal infrared wave band is

---

\(^2\)Qiu Hailing. Beijing urban heat island effect and cooling effect for green space[D]. Beijing Forestry University, 2014.

used for land surface temperature inversion. The spatial resolution of the 6th band satellite image is 60m*60m, and the rest are 30m*30m. First, ENVI5.1 calibrates the image data during the four periods to eliminate the radiation error caused by atmospheric scattering, and then uses the vector boundary layer to crop the image data in Wuhuan area, and then selects the corresponding remote sensing data to calculate the normalized vegetation index and surface temperature inversion. Finally, using ArcGIS10.2 software to process the data, compare and calculate the correlation between surface temperature and vegetation coverage.

3. Calculation method

3.1. Vegetation coverage calculation

The method extracting vegetation coverage using remote sensing data mainly includes empirical model method, vegetation index method and mixed pixel decomposition method. In this paper, vegetation index method is used to extract vegetation coverage in Wuhuan \[^4\]. Among many vegetation indices proposed by scholars, the normalized vegetation index is the most widely used. Therefore, this paper selects the normalized vegetation index for calculation, and its expression is:

\[
\text{NDVI} = \frac{(\text{NIR} - \text{R})}{(\text{NIR} + \text{R})} \quad (1)
\]

In the Landsat 7 ETM satellite remote sensing image, NIR represents the brightness value of the TM4 band, and R represents the brightness value of the TM3 band.

Based on the normalized vegetation index, the vegetation coverage is calculated. When calculating the vegetation coverage, the pixel bisection model method is used and its expression is:

\[
F_v = \left( \frac{\text{NDVI} - \text{NDVI}_{\text{soil}}}{\text{NDVI}_{\text{veg}} - \text{NDVI}_{\text{soil}}} \right) \quad (2)
\]

In the formula, NDVI represents the normalized vegetation index, NDVI\text{veg} represents the vegetation index for pure vegetation, and NDVI\text{soil} represents the vegetation index for pure soil. Where NDVI\text{v} is 0.7, NDVI\text{s} is 0. When the NDVI is greater than 0.7, the Fv value is 1; when NDVI is less than 0, the Fv value is 0.

3.2. Land surface temperature inversion

This paper selects the atmospheric correction method for land surface temperature inversion\[^5\]. Before calculating the land surface temperature, it is necessary to calculate the land surface emissivity and blackbody radiation measurement. Among them, the specific emissivity of vegetation

and architecture is calculated and the specific emissivity of water is taken as 0.995. Its expression is [6]:

\[ \varepsilon_{\text{green}} = 0.9625 + 0.0614 \text{Fv} - 0.0461 \text{Fv}^2 \] (3)

\[ \varepsilon_{\text{building}} = 0.9589 + 0.086 \text{Fv} - 0.0671 \text{Fv}^2 \] (4)

In the above formula, \( \varepsilon_{\text{green}} \) represents the specific emissivity of the vegetation, \( \varepsilon_{\text{building}} \) represents the specific emissivity of the building, and Fv is the vegetation coverage calculated above. The land surface emissivity is obtained by inversion calculation.

Based on the land surface emissivity, the black body radiance in the thermal infrared band is calculated and its expression is:

\[ B(T_s) = \frac{[L_\lambda - L_\uparrow - \tau \cdot (1 - \varepsilon) \cdot L_\downarrow]}{\tau \cdot \varepsilon} \] (5)

Where \( B(T_s) \) is the thermal radiance, \( \tau \) is the atmospheric transmittance in the thermal infrared band, and \( \varepsilon \) is the surface radiance.

After obtaining the black body radiance at the temperature \( T_s \) in the thermal infrared band, according to the inverse function of the Planck formula, the true land surface temperature \( T_s \) is obtained. The expression is:

\[ T_s = K_2 / \ln(K_1 / B(T_s) + 1) \] (6)

In the Landsat 7 ETM remote sensing image, \( K_1 \) is 666.09, \( K_2 \) is 1282.71. The calculated TS is the true land surface temperature in Kelvin (K).

### 4. Correlation between vegetation coverage and surface temperature

Table 2 Statistical results on surface temperature in Wuhuan, Beijing, 2002-2017

The vegetation coverage data for the study area was imported into the ArcGIS10.2 platform for statistics (Figure 2). Dividing the vegetation coverage in the study area from low to high according to 0.2 as the difference and classify it into five categories (Table 1). Combined with the data analysis in Table 1, the low vegetation coverage area in the Wuhuan has decreased from 143.08km² to 62.20 km²; The medium-low vegetation coverage has dropped from 206.47km² to 198.24km²; The area covered by medium vegetation has increased from...
133.38km² to 186.18 km²; The medium-high vegetation coverage increased from 82.54 km² to 111.67 km²; The high vegetation coverage increased from 101.04 km² to 108.23 km². The overall vegetation coverage showed a decreasing trend first and then increase, from 44.56% in 2002 to 39.33% in 2007, and then to 50.85% in 2017. Combining the development in recent years, the city continued to expand between 2002 and 2007. A large amount of farmland and forest land has transformed into construction land; From 2007 to 2017, a large number of international activities have been organized and carried out, and the vegetation coverage has picked up.

4.2. Surface temperature evolution characteristics

The land surface temperature inversion image was imported into ArcGIS10.2 platform for statistical calculation (Figure 3). The four images from 2002 to 2017 were reclassified according to the mean standard deviation method. The temperature was divided into low temperature, medium-low temperature, and medium-high temperature, high temperature, and ultra-high temperature. relevant statistical data were obtained (Table 2). Combined with the data in Figure 3 and Table 2, it can be concluded that the thermal environment in the study area was warming up overall and peaked in 2007, and eased after 2007. In 2002, high-temperature and ultra-high temperature plaques were mainly concentrated in the central urban area and in the western part. Near the Wuhuan area, mainly medium temperature and low temperature parts; with the acceleration of urban construction, in 2007, the temperature change was more dramatic than that in 2002. There were more reductions in medium temperature and low temperature parts, and more high-temperature and ultra-high temperature plaques. After 2007, the proportion of medium-high temperature, high-temperature, and ultra-high temperature plaques was higher in the study area.
4.3. Correlation analysis on vegetation coverage and land surface temperature

In order to more accurately reflect the correlation between land surface temperature and vegetation coverage, the grid analysis method is used to calculate the correlation between the two. First, the grid is used to divide the study area, and the length of each grid is set to be 1200m*1200m. The study area is divided into 507 grids. The grid covers the data information for all land surface temperature and vegetation coverage in the study area. The spatial resolution of the vegetation coverage image is 30m*30m, so each grid in the image contains 1600 original raster data. The spatial resolution of the land surface temperature image is 60m*60m, so each grid in the image contains 400 raw raster data. The average value for the grid data is calculated by ArcGIS 10.2 software to represent the vegetation coverage and land surface temperature values in the grid, and the grid coverage image of the vegetation coverage and land surface temperature is obtained (Figure 4). Finally, the vegetation coverage data and land surface temperature data for all the grids are imported into Excel software, and the correlation between the two is studied, and the regression analysis results on the ground temperature and vegetation coverage between 2002, 2007, 2012 and 2017 are obtained. (Figure 5).

According to the regression analysis results, there is a significant negative correlation between vegetation coverage and land surface temperature. In 2002, 2007, and 2012, regression equation determination coefficient ($R^2$) is 0.55, 0.53, 0.63, and 0.62, respectively, and at the 5% significance level, the four models pass the test, indicating there is a strong correlation between them. From the slope for the regression equation, the slope is respectively -10.445, -6.0767, -12.739, and -10.384. This indicates that for each 0.1unit increase in the vegetation coverage index within the Wuhuan in Beijing, the land surface temperature will be reduced by 0.61°C to 1.27°C.

5. Conclusion

Based on the above study, the following conclusions are obtained:

(1) During the period from 2002 to 2017, the vegetation coverage and land surface temperature in the Wuhuan have undergone major changes. The vegetation coverage generally shows a decreasing trend at first and then increase. The land surface temperature generally rises first and then maintains at a higher level.

(2) There is a negative correlation between vegetation coverage and land surface temperature in the study area. For every 10% increase in vegetation coverage within the study area, the average land surface temperature will be reduced by 0.61°C to 1.27°C; Conversely, when the vegetation coverage decreases, the average land surface temperature will increase to the same extent. This conclusion can also provide a quantitative assessment basis for urban forest construction results in Wuhuan.

The conclusions can provide reference and guidance for planning and constructing...
urban forests to improve the thermal environment in large cities similar to the study area.

The Embodiment of Cultural Connotation of the Black Bamboo Park Scenery Name in Plant Landscape and the Combination with Modern Park Design

Renjing Zhao,*Xiong Li*

*Beijing Forestry University, No. 35, Tsinghua East Road, Haidian District, Beijing, 100083, China

Abstract

Humanistic-natural landscape and garden has an inseparable relationship with the traditional Chinese culture. As the crystallization of wisdom of the Chinese nation, Chinese traditional culture has laid an important cultural foundation for the development of many traditional gardens. So the traditional Chinese Garden is honored as “poetic habitat”: many scenic spots are named from literature and landscape painting, and the planting also coordinates well with the entire aesthetics. The scenic spots names of traditional Chinese landscape garden can be said that with Chinese characteristics and cultural recreation, is the gardener's cultural wisdom. The article took the Black Bamboo Park as an example and chose the methodology of analyzing cultural connotation of the scenic spots names. It discussed the issue that how the planting landscape responses to the pursuit of “artistic conception” in their scenic names, in the aspect of characteristic space-making and creating landscape features. Also, the passage also explored whether to combine the modern landscape design with the cultural-oriented scenic spots names and its corresponding landscapes, and how to better reflect the cultural wisdom of gardeners. It aims to provide some references to planting and naming in the modern landscape designing process.

Keywords: Landscape Architecture; Scenery name; China traditional culture; Planting design; Modern park

1. Introduction

Landscape design and appreciation are often set forth from the four elements of mountain, water, plant and building, and the scenery name, the couplet, the plaque are often the crowning touch. The scenery name, as a kind of literary language of garden, is the conciseness of the cultural wisdom of gardeners. While performing the idea of gardeners, it also has the function of associating and rendering artistic conception. With the development of social economy and the improvement of people's living standards, park has become an indispensable part of people's life. But with the advent of rapid urbanization, some modern parks that lack local cultural features emerge in endlessly.
As a modern park with traditional cultural features, the scenery name of the Black Bamboo Park is not only responsive to the plant landscape, but also full of poetic meaning, which fully embodies the garden cultural wisdom. Based on the analysis of the scenery name of the Black Bamboo Park and the fit of the plant landscape, it explores how to integrate the traditional cultural wisdom into the planning of the park and the feasibility of enriching the cultural characteristics of the modern park with the help of the cultural connotation and plant landscape.

2. Overview of the Black Bamboo Park

The Black Bamboo Park is located at the southern end of Baiyi road, Hfian district. The garden covers a total area of 45.73 hectares, and the water surface is about one third of the total area. The Nanchang River and the Shuangzi Canal pass through the park, and the rivers, lakes, embankments, islands, continents, and canals spread throughout the park.

The Black Bamboo Park has a long history. Since 1953, it has proposed the characteristics of creating parks with “bamboo landscapes, bamboo victories, and bamboo fame” and gradually built scenic spots with different scenery. There are many types of bamboo, tall and straight, with great charm, enjoying the reputation of “the first bamboo garden in north China”.

Bamboo, one of China's oldest plant species, existed on Chinese land hundreds of thousands of years ago and is an important part of Chinese traditional garden culture. At the same time, bamboo culture is also an important part of Chinese culture, which contains distinctive national characteristics and interprets the rich connotations of traditional Chinese culture. The Black Bamboo Park has been holding bamboo festivals in the park since 1947 to show the meaning of bamboo culture to the public in a more intuitive way. The garden wisdom contained in bamboo culture has long been subconsciously entering people's material life and spiritual world.

From the beginning to the present day, The Black Bamboo Park has condensed the strong traditional culture atmosphere. The scenic spots are dominated by bamboo and stone landscape, and fully integrated with poetry, calligraphy and painting culture. In the process of landscape restoration and construction, the whole garden is themed with bamboo, which displays the inheritance and development of traditional cultural wisdom, and forms a unique landscape of natural.

3. General Layout of The Black Bamboo Park

Since the beginning of the planning and construction of the Black Bamboo Park in 1953, according to the location and the terrain at that time, the principle of building a park with the theme of mountain forests was proposed. In formulating the near-term planning plan in 1976, it was more clearly stated that “the park should be characterized by lush trees, natural water features and simple garden architecture.” The beauty of the landscape is even more valuable due to its natural features.
The overall landscape of the park is modeled on water and natural, showing the pattern of three lakes, two islands and one embankment. The lake is surrounded by mountains and five arch bridges connect the lake, island and shore. The pavilions and porches were scattered in the garden, and bamboo and flowers are distributed among them. The eastern lawn area is surrounded by trees. The grass spreads trees around the space to create a quiet and elegant atmosphere, fully displaying the individual beauty and group beauty of the plants. In the south of the park, there is a landscape of hills, streams, and trees. Through the change of the terrain, the combination of various trees forms a rich landscape level. Walking along the road, you will feel as if you are in the deep mountains and valleys, and get physical and mental pleasure. Lake area is a region where tourist activities are concentrated. The change of the lake and the planting of lotus have increased the contrast between the actual situation and the size of the entire scenic spot. The northeastern part of the park is flat on the ground and the plant landscape that focuses on changing seasons brings visitors a rich visual experience. The northern part of the river is a landscape unique to the Garden on the Yangtze Delta, and its own scenery echoes the overall environment of the park. The overall layout fully reflects the wisdom of traditional Chinese gardens. (Fig. 1)

4. Scenic profile of the Black Bamboo Park

In each functional area of the park, there are scenic spots with buildings as the main scene or plants as the object of display. Such as “Yuanhuazhujun” scenic spot, “Yunshiyuan” scenic spot, etc. (Tab. 1)

5. The Types of Scenery Names and Landscape Analysis of Main Scenic Spots

As the expression of ancient gardeners’ cultural wisdom, the scenery names come from allusions, fables, and poems, creates corresponding garden landscapes according to their origins. Through the changing terrain, rich plant configuration, thematic sculptural pieces and architectural collocations to create a variety of landscape effects. The cultural connotation contained in the scenery name is presented. This article selects important scenic spots related to plant landscapes in the Black Bamboo Park.
Based on the origin of the scenery names, the scenery names are divided into three categories: mythological allusions class, poetry and lyrics class, classic quintessence class. Different types of scenery names reflect different landscape styles. At the same time, the connotation of cultural wisdom contained in the name of the scenery also reflects the historical characteristics of garden culture in the process of social development.

5.1. Mythological Allusions Class

Such scenery names are often extracted from the mythological allusions to character characteristics or character stories as the prototype, taking plant landscape as the object of construction, using techniques such as comparison, symbolism, etc., abstract expression of gardeners' feelings of the character story.

5.1.1 "Yuanhuazhujun"

The scenic spot is located on the left side of the east gate of the park, and the overall environment is fresh and elegant. From the last year of the Shang Dynasty, Bo Yi and Shu Qi were rather hungry and did not eat food for the relief of the Zhou Dynasty. Therefore, they named the spot as the "Yuanhuazhujun". A scene depicting Bo Yi and Shu Qi's picking wild vegetables in Shouyang Mountain on a blue stone highlights the theme. With the upright and beautiful Phyllostachys propinqua McCl, Phyllostachys aureosulcata McCl to create the surrounding environment, lush, patchwork. At the same time, with the bamboo's integrity, tenacity, willingness to break and unwillingness to bend, and the appearance that the appearance is straight, the middle is empty to metaphorize the determination of Bo Yi and Shu Qi who would rather starve to death and lose their integrity. Fully integrate traditional allusions with bamboo forestry, embodying the cultural wisdom of gardeners.

5.1.2 "Banzhulu"

Old pine and cypress trees are planted on the top of the mountain, and the foothills are flourishing. Ehuang and Nuying's sculpture is standing beside the shore and reflecting in the lake. It is relatively weeping and full of affection. (Fig. 2) The entrance to the scenic spot is further visited by the Yanmen descendants for their legends and carved on the stone.

“Banzhulu” is where the two mountains meet each other, and the valleys are winding and quiet. ‘Tanakae’ are planted on both sides of the hill and rocks, these are the backgrounds for Ehuang and Nuying sculptures. The spots on the leaves metaphorized the tears of Ehuang and Nuying.

5.2. Poetry and Lyrics Class

This type of scenery name starts from the artistic beauty depicted in the poetry and lyrics and fully applies the plant material to the landscape. Make visitors fully feel the beauty depicted in the poetry and lyrics. Or directly plant the plant species involved in poetry and lyrics, reproduce the scenes, and more intuitively express the mood of poetry.

5.2.1. “Chengbi”mountain house
In the northwest of “Chengbi” mountain house, there is a small pavilion with a peaked roof called “Liuyin” pavilion. There is no complex engraving or painted decoration, simple painting with brown oil, simple and natural. There are three willow trees and three poplar trees planted next to the pavilion, and even if you stay in the pavilion during summer in June, you will not feel hot. Lush bamboo grows in the southwest, accompanied by a gentle breeze, the branches make sounds. The branches of the willows are old and prosperous, and the thick shade of trees is blocking the sun. Fully reflects the meaning of “Liuyinyiqing”, which means the thick willow shade makes people feel refreshed.

5.2.2. “Xiaoshengzuiyue”

“Xiaoshengzuiyue”, Which means the moon was intoxicated by the sound of a vertical bamboo flute. “Xiaoshengzuiyue” is the theme of Moon Island. The island's mountain path twists and turns, flowers and trees are beautiful, green bamboo grows luxuriantly. It presents the wonderful artistic conception of Li Bai's poem, the meaning of the poem is walking into the bamboo forest through the secluded path, the green leaves gently brush the pedestrian clothes. In the patio, there is a sculpture of “the girl blowing a vertical bamboo flute”, point to the theme of the scenic spot. The Lagerstroemia indica L blooming in the mountains are graceful and gorgeous. Under the shadow of a thick bamboo forest, the blooming flowers are particularly dazzling. Scattered terraces, followed by planting crape myrtle, combined with the terrain to form a slope.
5.2.3. “Bayi” pavilion

The scenic spot is located in “Qinglian” island scenic spot, connected to the surrounding environment by three bridges called “Mei”, “Lian” and “Hong”. The island's flowers and trees are thriving, the pine and bamboo are full of life, and the blooming lotus flowers surround the island.

The poem appreciate the bamboo is more verdant under the blow of the wind and snow, and appreciate the painting, recite the verse, and enjoy the beautiful scenery. “Bayi” pavilion fully integrates the ancient bamboo culture into the landscape construction. The interior walls are carved with poems praising bamboo, on the column of the porch is a plaque called “Bayi”. “Bamboo Rhythm Stone” is engraved with wind bamboo, rain bamboo, frost bamboo, snow bamboo pattern and poetry. It integrates the scenes of the bamboo's four seasons scene in the habitat, and the bamboo planting beside the stone. This building has Garden on the Yangtze Delta is located in the luxuriant bamboo forest, face to the lotus pond, back against bamboo forest.

5.3. Classic Quintessence Class

This type of scenery name refines the Chinese classic culture, or integrates the classics of other cultural fields into the garden landscape through plant configuration. Or refines the traditional garden culture and present it in a more refined way.

5.3.1. “Kuahaidongzheng”

The scenery name is one name of the eight famous pieces of Chinese chess. The scenic spot skillfully combines garden art, sculpture art and chess culture. In order to foil the situation of the dangerous situation in the chess board, the overall environment also coincides with it. The plants and sculptures of the high and low levels echo each other, with high bamboo planting to show the manager to hold up the chest, and the momentum of the victory. With the low shrub as the background of the soldier, show the soldiers to fight bravely, waiting for the command to start at any time. The chessboard is surrounded by mountains on three sides, with Ginkgo biloba L towering in the mountains, enclosing the scenes of the "two armies" in a small environment. Visitors can look at the whole situation and try to marshal their ancestors. They can also participate in confrontation and enjoy the "battlefield" battle.

5.3.2. “Jiangnanzhuyun”

The scenic spot is located in “Yunshiyuan” scenic spot, “Yunshiyuan” scenic spot is a garden in the Black Bamboo Park, covers an area of about 7 hectares. The main landscape is constructed of mountains, rivers, water and bamboo, and the landscape architecture is correspondingly landscaped. The scenery is elegant, delicate, quiet, chic and full of poetic charm. With bamboo as the theme, ten scenic spots have been set up to form a landscape garden with the style of Garden on the Yangtze Delta.

“Jiangnanzhuyun” is a sunken garden to make landscape with bamboo and stone, which is a masterpiece of” Yunshiyuan” scenic spot. The entrance is set with a green
marble carved Su Shi word – “Jiangnanzhuyun”. (Fig. 4)

![Image](Fig. 4. “Jiangnanzhuyun”)

With bamboo and wall as the background, more prominent the style of Garden on the Yangtze Delta. The area is planted with *Phyllostachys edulis*, *Phyllostachys propinqua*, ‘Tanakae’, *Arundinaria fargesii*, *Arundinaria graminea*, *Sinarundinaria nitida* and so on. With bamboo as the main plant configuration, it fully displays the connotation of bamboo culture, to win with fewer forces, to win by novelty, to return to simplicity, to pursue the principle of nature, and to cultivate the famous bamboo in “JiangNan” region to reflect the theme.

### 6. The combination of scenery name culture and modern park design

With the improvement of living standards, people’s demand for urban gardens has gradually shifted from the pursuit of beautiful scenery to the spiritual level. The garden culture is rooted in the traditional culture, and the culture in the garden means preserving the cultural heritage of the forefathers and creating the culture that is valuable today. \(^1\) In addition to a beautiful garden landscape, a park that is popular among the people must have its own unique garden culture. \(^2\)

As a carrier of traditional cultural wisdom, scenery name also exists as an important garden language. The so-called “scene is written by the text, culture as the point of the landscape”, the culture integrates with the landscape to show its charm, and the landscape is more elegant because of the cultural wisdom. Rich cultural wisdom of the scenery name, only need to use a few isolated words and phrases to arouse the association of visitors, to outline the mood of the landscape in the mind of visitors, it will not only guide the tourists to appreciate the landscape, appreciate the historical culture, but also expand the charm of the landscape garden, and use this unique art form to add color to the landscape garden. No matter what kind of cultural wisdom features to carry out the park planning layout, artistic conception creation, the creation of the artistic conception, the landscape treatment or the plant landscape, the scenery name is a most intuitive way of expression. Summarized the scenery names of Chinese classical imperial gardens and private gardens with plants as the main landscape, and found that there were 198 landscape names related to plants in about 65 gardens. \(^3\)In the modern park, the name of the scene also serves as a communication medium to convey the historical context of the city, showing poetry, painting, and artistic conception. When on the way of landscape in modern park to express the excellent traditional
culture, and with the aid of scenery name to highlight the theme, with moisten things silently penetration method to make people feel the wisdom of traditional culture in the process of leisure and entertainment, it’s also an important way to realize regeneration of traditional culture.

7. Conclusion

The themes of many scenic spots in Black Bamboo Park come from the artistic conception of landscape in historical allusions or poems and paintings, from the architectural style, the couplet plaque and the plant landscape, the expression method fully responds to the cultural wisdom connotation of scenery name. To create a good landscape effect while conveying historical and cultural wisdom, embodies the concern and protection of traditional cultural wisdom, inheritance and development.

The design of modern park is still inseparable from the expression of traditional cultural wisdom, and the traditional theme of culture is used to consolidate the landscape theme. Plant landscape configuration is a kind of a carrier of traditional culture. Under the premise of ensuring its functionality, it combines traditional culture to create the landscape effect of poetic painting and extracts the name from the traditional cultural wisdom. To create a natural plant community and landscape, highlight China’s natural landscape culture, and finally achieve the pursuit of “artistic conception” in the scenery names.

Abstract

There are 409 parks of different sizes and types in Beijing. The rates of people’s visit to these parks vary widely. Due to the subjectivity of people’s practices in urban planning, the actual usage of parks often differs from the designer's original intentions. Several problems emerged such as overuse, misuse and lack of use. Post occupancy evaluation (POE) is a evaluation method which takes the average trend of people's subjective feelings as the standard of evaluation after the environment is built. POE can reflect how the environment supports and meets people's needs after the construction of parks, and also can help landscape architects to understand the users' spatial distribution preference, and thus a feedback mechanism is formed to improve the quality of parks. With the rise of Internet and social medias, a vast volume of new data provides us with real-time distribution of tourists in green spaces, and along with their ratings or evaluations of parks they visited. Taking parks within the second ring road area in Beijing as the research object, this paper evaluates the use of parks from three aspects—the usage counts of users online, the satisfaction and the interest points of the visitors. Researchers pick up visitors' subjective reviews and their check-in position information as basic data from social media platforms such as "dianping" and “weibo". Through the data analysis, several charts will be drawn to reflect the users’ topic hotness of different parks and their functional areas. Meanwhile, researchers use Natural Language Processing platform to do word segmentation, POS tagging and other operations to filter tourists' comments. High frequency key words about emotional expression, Atmosphere description and interest points will be extracted and grouped. Based on the above data, we concluded the focuses of visitors in different group.

Keywords: social media, post occupancy evaluation, topic hotness of parks,

1. The Use Status of Beijing Urban Parks

Urban parks provide convenient places for residents to return to nature. According to the statistics of the official website of the Beijing City Greening Bureau, by the end of 2017, there are 409 registered parks in Beijing, which cover comprehensive parks, community parks, country parks, wetland parks, Forest Parks etc. There are spatial and temporal variations in the use of parks with different types and area. The variation may lead to some problems of visiting experience. For example, some parks are overcrowded during holidays, causing visitors to experience a crowded and noisy tour, while other parks are lacking of attraction, making people feel cheerless.
The frequency of use in different areas of the same park is also very different. Due to the subjectivity in design practice, current usage of parks are sometimes inconsistent with designers' intentions and resulting in problems such as overuse, misuse, and insufficient utilization.

2. Related Concepts

2.1. Post occupancy evaluation

The specific meaning of POE method refers to: After the construction of the evaluated project for a period of time, the evaluator collect the users' evaluation data and analyze these data scientifically to understand the users' satisfaction level and find suggestions of subjects. The post-occupancy evaluation of built parks can reflect how the park environment supports and meets people's needs, help the landscape architects find the users' spatial distribution preferences. Additionally, it form a feedback mechanism in the design, expand the traditional design process which has been transformed into a cyclical process of “design--evaluating -- re-planning”. The data collection methods of POE are mainly questionnaires, interviews and document analysis. Semantic Differential, Likert Scale are data collation method that be used usually. However, during the evaluation process, most of the questionnaires and interviews presuppose the scope of the answer. The respondents are often under pressure from the investigators, and it is difficult to find some deep-seated problems. Moreover, the errors caused by the questionnaire's recovery rate and efficiency also require a lot of energy to correct. These limitations have affected the overall accuracy and efficiency of the POE evaluation.

2.2. The advantages and applications of social media data.

With the rise of the Internet, the application of new data has begun to penetrate into various research fields. This type of data is often called "big data." New types of data are characterized by a large number, variety of types, and high processing speed. These data are generated in terminals such as mobile phones, mobile phone signaling, public traffic card records, and bank consumption records. They cover location information, digital information, text information, and trajectory information, and are collected and stored by major online operating platforms. These data require new processing models to have greater decision-making power, insights, and process optimization capabilities.

For landscape architects, information from social media and professional review websites can provide us with information about the real-time distribution of tourists in green spaces, the trajectory of visitors in parks and the satisfaction level after visitor’s’ use. Moreover, these online comments come from the initiative post of the appraisers. Because these appraisal comments are not guided and interfered by the interlocutors, they are more supportive of the research. These new data can be used as the substitute for traditional questionnaires and be basis for the evaluation of built environments.

3. The evaluation case of parks within the Second Ring road in Beijing

2.3. Data Collection

The sources of data for this study are 3 social media websites which respectively called "Weibo", "Dianping.com” and "Mafengwo.cn". “Weibo” is the name of
Chinese microblog. Similar to Twitter, Weibo is one of the most popular social networking platforms in China with the highest penetration rate and the highest number of users. "Dianping.com" is a leading living information and trading platform in China. It is the first independent third-party consumer review website established in the world, covering approximately 200 million monthly active users. "Mafengwo.cn" is a travel information website popular among young Chinese generation. The website's reviews on attractions, restaurants, hotels, etc. all come from the true sharing of hundreds of millions of users, helping hundreds of millions of travelers make free-flowing plans. Reviews on the three platforms introduced above respectively represent the subjective evaluation of objects by comprehensive community, citizens, and tourists.

This study takes parks within the Second Ring Road of Beijing as the research objects. There are 21 parks within the second ring, ranging from 1.8 hectares to 273 hectares. The main types are urban comprehensive parks, linear parks and roadside green spaces. As Second Ring Road is also the dividing line of the urban edge of Chinese ancient capital, many traditional blocks and ancient ruins are preserved in this area. A part of these comprehensive parks are built around important cultural heritage sites such as the Tiantan Park and Beihai Park, attracting a large number of tourists from all over the world. Researchers have classified these parks as comprehensive parks (class A) which is distinguished from other modern comprehensive parks (class B) with various functions and facilities. Moreover, most of linear parks are built around the ancient city walls, the ruins of the gatehouse or the moat, which are mostly distributed on the edge of the Second Ring Road or the central axis of the city. Roadside green spaces are located in densely populated blocks with good residents’ accessibility. Of course, because of the extensive traffic system coverage within the Second Ring Road, all these parks are highly accessible. By extracting key information from web page source code. The study captures the position information and sign-in text contents of the “Weibo check-in” website pages, the satisfaction rating and text contents of parks in “dianping.com”, and user's recommended ratings and subjective evaluation contents for parks in “mafengwo.cn” A total of 208,008 evaluations were collected for this data collection. The number of comments for each park and parks' related information are shown in the table below.
Table 1 The number of reviews and related information of parks on the three media platforms

2.4. Data Analysis

2.4.1. Topic Hotness of Parks
From the check-in and comment data volume of the three media platforms, it can be seen that there is a great difference in user popularity among 21 sample parks which are not far apart. The user popularity, usage, and visitor density of parks (comprehensive park class A) far exceed other types of parks. The number of comments accounted for 58 percent of the total number of comments. Among these parks, Beihai Park has the highest topic hotness, with 53,998 reviews, and the volume of data in “weibo” and “dianping.com” are all ranked first in all sample parks. But according to the statistics of “mafengwo.cn”, Tiantan Park has the highest topic hotness, which may be caused by the different among user groups of the three websites. Tiantan Park is an important tourist attraction in Beijing. It is a place where ancient emperors worshiped heaven. There are many magnificent architectures and a spectacular central axis in the park, with solemn and orderly layout. Beihai Park is built on the site of the ancient imperial garden. There are a large area of water surface, mountains and flexible park roads. Although Beihai Park is not the most popular scenic spot in Beijing, it meets the diverse needs of the general public for leisure fitness and daily visiting. The popularity of modern parks (comprehensive park B) ranked second, and the number of reviews accounted for 21% of the total comments. Most of these parks with
relatively large areas have completed functional zone, various facilities, beautiful lakes and abundant plants, which can provide citizens with a good place to relax and meet the needs of various groups of people. Although they are not very prominent on travel websites, they also have a high degree of popularity in “Dianping.com”. linear parks and roadside green spaces did not attract much attention. Due to the large number of linear parks in sample area, comments of this type of park accounted for 19%. These two types of green space are in a small number of comments on “Mafengwo” travel network. Part of the type of park such as the Nanguan Park are no user reviews recorded which can reflect that foreign tourists rarely pay attention to this type of green space.

As can be seen from the scatter gram in Figure 3, there is a clear positive correlation between the area of the park and tourists’ enthusiasm of comment posting. That is to say, larger parks can attract more tourists. However, in parks of relatively similar size, the visitors' topic hotness does not vary with a clear linear relationship, indicating that the area does not affect the enthusiasm of tourists in parks with area varying in small spans.
2.4.2. The satisfaction evaluation of park use

Social media platforms give their users the right to rate the star rating of the evaluation object. This is similar to setting a semantic gradient in the traditional questionnaire to measure the satisfaction level of visitors to the built environment of the park. But the difference is that this star rating is more direct and accurate, and the result is more comprehensive. However, it is regrettable that parks can not be evaluated according to the designer's needs in a certain content. “Weibo” has a large amount of data and a relatively comprehensive user group. The total score of the evaluation is 10 points, starting from 0 points and increasing by 2 points. According to statistical results, the comprehensive park with a high degree of concern has the highest satisfaction among tourists. It is not only A-class comprehensive parks represented by Beihai Park and Jingshan Park, but also modern parks in the group of B-class comprehensive parks represented by Taoranting Park and Longtan Parks also scored 8 points. In contrast, the score of linear parks are very low except for the Xibianmen park, which scored 8 points. Most of others scores are about 4 points.
The full score of “Mafengwo.cn” is 5 points, and there is no obvious increasing gradient. The result of Figure 6 showed that the satisfaction degree of each park varies little, but the accuracy is higher. The general trend is still that comprehensive parks got a higher degree of satisfaction. In particular, the A-type parks all scored more than 4.3 points. The ratings of linear parks and the roadside green spaces were all low as indicated above. The value distribution of park satisfaction is also different with the Weibo data. For example, Xibianmen Park, which scored highest in the Weibo evaluation, has got the lowest score that was only 2.4 in the result on Mafengwo.cn. This may be due to the contingency and error caused by the small sample size of linear parks on Mafengwo.cn to a certain extent. Many unknown small parks, such as Desheng Park, have not even received any feedback from tourists.

In the data analysis results of dianping.com, all parks are highly satisfied. The full score of the website is also five points, and the increasing gradient is 0.5. Different from the previous two platforms, 11 parks in samples scored 5 out of the full rating on the website. Most of these full-score samples are A-type comprehensive parks, but there are also other three types of parks. Low segment Park samples are still distributed in smaller strip green spaces and roadside gardens, with a minimum score of around 3.5. Summing up the data from three platforms above, the park with the highest satisfaction level within the second-ring road is the Tiantan Park. The park is built around the Temple of Heaven, where the ancient emperor worshiped the heavens. It is the site of famous world cultural heritage. Tiantan park has the largest floor area compared to other samples. There are not only has magnificent buildings, spectacular central axes and thousand-year-old trees, it also seeks to arrange larger public square to meet the needs of the surrounding residents' daily leisure activities. Several other A-class comprehensive parks, such as Beihai Park and Jingshan Park, scored immediately behind. The scores of the B-type
comprehensive parks are also high, with more than 4.2 points. These parks provide improved infrastructures and landscape view that satisfied diverse demand of different visitors. The parks with the lowest scores are Guanyuan Park and Desheng Park, both of which are located in the northwestern part of Second Ring Road. Guanyuan park is a small roadside park. It is the smallest one of 21 sample parks which covered only 1.8 ha.

2.4.3. The analysis of visitors’ interests

Through the statistics of high-frequency vocabulary in social media user reviews, it is possible to find out what content in the park has caused visitors’ interest and left a deep impression on visitors. Since the evaluation content is all completed by the evaluation subject spontaneously, these interest points cover various aspects such as the planning and design of the park, operation and management, and the experience of trips, which are of great significance to the construction of the park.

Language Technology Platform (Hereinafter referred to as LTP) is an open Chinese natural language processing system that provides users with efficient and accurate language processing cloud services. The service content includes word segmentation, part-of-speech tagging, named entity recognition, dependency syntax analysis, semantic role tagging, and so on. Through the LTP platform, text comment data of social media users will be processed by word segmentation and named entity recognition programs. This process uses words such as “park” and “garden” as keywords to filter out comments that are not related to the study object. After preliminary filtering, it was found that some users prefer to feedback their emotional state of life in the weibo check-in data, and the connection between the check-in location and micro-blog content is so weak that the use of the park is less reflected. Therefore, reviews from the dianjing.com and mafengwo.cn are used as the main data sources for the word frequency statistics. According to the statistics, high-frequency vocabularies of 21 sample parks are shown in Table 2.

Table 2 The Statistical table of High-Frequency Comment Words of Parks

![Fig. 9 The statistics bar chart of the types of keyword occurrences](image)

High-frequency vocabularies to be counted can be mainly divided into several groups: landmarks, celebrities or historical events, large-scale events, usage patterns, composition of visitors, location information, park landscape, facilities and services, park area, ticket or free and trip atmosphere.

On the website of dianping.com, landmarks are the most popular labels, including famous buildings, historical heritages, or the landmark of park. Compared to roadside parks, such vocabularies appear more frequently in the comments of comprehensive parks. Additionally, use patterns and related vocabularies of landscape have also been mentioned more frequently, indicating that citizens pay more attention to the everyday use and landscape view of parks. The high-frequency vocabulary of use is mainly for fitness, walking, dancing, playing cards, etc., and it is more frequently seen in the evaluation of street gardens. In terms of landscape vocabulary, plant landscapes are mentioned by many citizens, such as eucalyptus, tulips, and wax blooms, and the proportion of flowering plants is large. These plant landscape vocabularies often appear together with seasonal flower viewing activities, indicating that citizens have great enthusiasm for ornamental flowers.

In the user evaluation of Mafengwo.cn, the type of landmark vocabulary also occupies the largest proportion, and related vocabularies of celebrities and historical events.
events also appear frequently. Compared with the data of “dianping.com”, the tourist group has more attention to the historical value, while the visual landscape effect is not very concerned. Moreover, key words about the location are also been highly concerned, such as surrounding important urban nodes (the Russian Embassy, Tongren Hospital, etc.). Location information and the surrounding environment can easily help tourists form a new cognitive maps. Similarly, the flow of people in the surrounding urban functional areas is likely to be part of the user of the park. However, unlike the Mafnegwo.cn, such vocabulary often appears in descriptions of roadside gardens and banded green spaces, rather than comprehensive parks.

Besides the most frequently occurring types of vocabulary, other types of vocabulary are also recorded by users in two network platforms to describe parks. For example, because tourists visit many parks in a short time, they are more sensitive to the park area and more inclined to describe the atmosphere of the open space, such as quiet, clean, noise, etc. Residents is more concerned about the content and function of the park, such as festival performances and fitness venues. As for the infrastructure services provided by the park, the two groups have the same level of concern. These keywords include food, snacks, parking, amusement facilities and fitness equipment. Moreover, whether the park is free or whether the tickets are cheap are also a hot issue for all users. Except for these categories of words, there are other high-frequency vocabulary like summer, low-carbon life, water landscape, five-color soil and a famous song related to Beihai park. All these labels show that the design concept, landscaping techniques, seasonal landscape are concerned by the users too.

3. Summary and Prospect

3.1. conclusion

From the analysis above, it can be concluded that the satisfaction level of visitors has the same trend as parks’ topic hotness. Within the area of Second Ring Road, Parks that receive more evaluations also tend to have higher satisfaction level with social media evaluations. These parks are mainly comprehensive parks built to protect important cultural heritage. Other comprehensive parks with relatively large scale have received high satisfaction too due to the rich and convenient facilities and services. On the contrary, smaller parks like linear parks and roadside green space have performed slightly worse in terms of topic hotness and satisfaction.

There are similarities and differences between tourists and ordinary citizens in their concerns about the park environment. The landmarks and the location of parks are greatly concerned by both groups. For tourist, The location of parks has an important impact on accessibility and landmarks bring their journey commemorative significance and historical knowledge. For ordinary citizens, the site of landmarks provides a place to meet friends or a Object of reference. In other respects, ordinary citizens pay more attention to the use pattern and landscape, while tourists tend to feel the trip atmosphere, understand the historical events and related celebrities of parks.

3.2. Advantages and Limitations

Social media data have the following advantages. 1. It avoids the pressure of the questionnaire collector on the evaluator and ensures that all information is the true
feelings of the user, instead of checking the answer in the questionnaire designer's regulations. 2 the social media platform provides huge amount of data, avoiding errors caused by the limited questionnaire samples. 3 The computer's rapid processing capabilities allow researchers to quickly and easily obtain statistical results. 4 The data update speed of the platform is so fast that enable the long-term stable research can be conducted. All These characteristics introduced above make the POE evaluation more accurate.

But at the same time, the limitations of this method are also obvious. Due to the complete spontaneity of the user, the text content contains excessive information irrelevant to the evaluation. Filtering out this interference information and grouping these massive data according to the specific content that we want to evaluate requires strong language processing platform support. For instance, during the process of trying to analyze the composition of visitors, it is found that in these reviews, it is difficult to identify the user’s age group and occupational characteristics. In this regard, social media data is far less convenient than questionnaires. Therefore, combining the traditional questionnaire with the modern web platform is a development direction that can better improve the POE evaluation.

The Construction of Chinese Smart Campus from the Perspective of Landscape Architecture

Hu Nan, Li Xiong

*Beijing Forestry University, No.35, Qinghua East Road, Haidian District, Beijing 100083, China

Abstract

China has formally introduced the concept of Green Campus (GC) from 1996, and with gradual strengthening of education, GC construction documents have been gradually introduced. Especially in 2013 China Green Building Council developed ‘Evaluation Standard for GC’, and in 2016 China GC Design Alliance established, promoting active ways to create GC, thus creating a harmonious coexistence between human and nature. After more than 20 years’ practice, China's campus environment is constantly optimized. Based on the GC construction, we explore the way of building Smart Campus (SC) from the perspective of landscape architecture, so as to provide reference for current campus construction.

The SC construction in China can be divided into three levels, planning, designing and constructing, respectively. In planning stage, composite index system, including Greening Rate (GR), Living Vegetation Volume (LVV) and Green Looking Ratio (GLR), is gradually established. According to practice, better campus environment can be achieved when GR is up to 35%. Moreover, with focus on ecological benefits, researchers have proposed the concept of LVV, and put forward that green space structure can be basically controlled when LVV average value is in 0.3-0.5m$^3$/m$^2$. In addition, based on full consideration of campus environment and ecological benefits, green space’s landscape effect is also important. Experiments show that when GLR is in the range of 25%-50%, it will bring better feeling to users. The above three indexes constitute a composite index system to control the overall green space construction, which becomes the SC construction foundation.

In designing stage, environment function, concentrating on landscape beautifying, education-teaching and cultural commemoration, guides campus construction. Landscape beautifying is embodied in different functional partition, such as identifier landscape in entrance area, participatory landscape in living area and recreational landscape in teaching area. Education-teaching creates characteristic green space pattern, such as the integration of campus and botanical garden of Zhejiang Agriculture and Forestry University, the combination of LID facilities and green space by Tsinghua University. Cultural commemoration shows campus tradition, for example, Nanjing and Beijing Forestry University as two important green
universities, opened a memorial space, showing people's respect for the famous forest scientist, Liang Xi. The function oriented campus construction is the key content of SC construction.

In constructing stage, the applied plant materials, such as native plants combined with ancient trees and cultivated species, formed rich campus green background and created characteristic plant landscape. Taking the *Ginkgo biloba* road in Beijing Forestry University, the *Platanus acerifolia* road in Tsinghua University and the Sakura road in Wuhan University as representative, road plant landscape is closely related to campus structure and often chooses native plants. Giving full consideration to plant materials and landscape is the wonderful part of SC construction.

To sum up, the three aspects of Chinese SC construction complement each other, providing a complete framework for current campus construction and a reference for further exploration of SC construction.

**Keywords:** landscape architecture; smart campus; China; construction

### 1. Introduction

The construction of Chinese smart campus (SC) contains many aspects. The study of SC construction mainly concentrates on the information technology in colleges and universities, aiming to enhance the quality of campus information service and application, thus creating an open, innovative, collaborative, and intelligent information service platform [1]. The construction of SC is not only limited to the simple exploration of digital campus. This study focuses on the campus environment which is closely related to the users of the campus. In recent years, the concept of Green Campus (GC) has provided a good guidance for the construction of Chinese campus, and becomes an important reference for exploring the construction of SC in China from the perspective of landscape architecture.

China has formally introduced the concept of GC from 1996 [2], aiming to create a healthy, applicable and efficient teaching and living environment for students and teachers [3]. With gradual strengthening of education, GC construction documents have been gradually introduced [4-5]. Especially in 2013 China Green Building Council developed "Evaluation Standard for GC", and in 2016 China GC Design Alliance established, and in 2017, the second Chinese Green Campus Development Symposium has held, thus promoting colleges and universities to respond actively to the call for GC construction, and the positive discussion of the way to construct GC, aiming to create harmonious learning and living environment for teachers and students.

### 2. The smart campus construction frame from the perspective of landscape architecture

From the perspective of landscape architecture, Chinese SC construction concentrates on campus landscape creation which takes the green space as the carrier, aiming to search for the harmonious relationship between people and campus. This includes three aspects, namely the establishment of a composite index system in the planning stage, the multiple types of campus construction in the designing stage, and the diversified application of plant materials in the constructing stage. Base on the existing condition of Chinese campus
construction, taking the existing research on the construction of SC as the basis and combining with the actual cases, the way of construction of SC has been explored. Through concluding and analyzing, the construction framework of SC from the perspective of landscape architecture is gradually formed. (Fig. 1)

3. The composite index system in the planning stage

From the perspective of landscape architecture, the construction of SC first concerns the index control of campus green space (CGS). As there are differences in the level of CGS construction in China, it is very important to build composite index system to guide the construction of GC. Based on the experience accumulated in construction practice, in planning stage, composite index system, including Greening Rate (GR), Living Vegetation Volume (LVV) and Green Looking Ratio (GLR), is gradually established, that controls the overall construction of CGS in the planning stage and becomes the basic of SC construction.

3.1. The decisive index——Greening Rate

GR presents the proportion of green space in a certain area of construction. It is a key index that regulates and restricts the construction and development capacity of the site, and ensures the basic environmental quality of the site. It has strong operability and is widely used. At present, the CGS planning in China is basically based on the index of GR. The research shows that the GR in colleges and universities is basically controlled at 30-50%, and some of them are below 20% [6]. According to the practice of Chinese campus project planning, a good spatial environmental effect can be achieved when the GR is up to 35% [3].

Attention should be paid to the following problems in cognition of the index of GR. First of all, although the construction process of campus is based on meeting the requirement of GR, it is necessary to further balance the relationship between green space and other lands. Secondly, the builders should correctly understand the connotation of GR and strictly observe the provisions of the index, and could not confuse the two indexes of greening rate and greening coverage rate. At the same time, as the decisive index of CGS construction, GR is the basis of standardizing the campus green line, but this index cannot fully control green space construction and be regarded as the only indicator of CGS planning.

3.2. The ecological index——Living Vegetation Volume

With the concern of plant ecological benefits, it is difficult using GR to evaluate the green space function level of different plant species and different greening structures. In the early 1990s, the concept of Living Vegetation Volume (LVV) was put forward. It refers to the volume occupied by all stems and leaves of all growing plants, which can more accurately describe the rationality of the spatial structure of green space and quantitatively study the correlation between greening and environment. The LVV can be analyzed by measuring the tree factor or the remote sensing image and laser scanning point cloud data, and then measured according to formula.

Study for campus LVV in China is relatively small, for the measurement of city LVV relatively can be used as a reference: Li [7] of Jiamusi University estimates the campus 0.46m$^3$/m$^2$, Liu [8] estimates
Shenyang city 0.35m$^3$/m$^2$, Tang [9] and Li [10] estimates Beijing six districts 0.29m$^3$/m$^2$, the largest of which is Shijingshan district 0.74m3/m2, the smallest Chaoyang district 0.14m$^3$/m$^2$, Zhou [11] estimates for 0.33m$^3$/m$^2$ in Ningbo, Jiangbei district for large 0.37m$^3$/m$^2$, Haishu district for small 0.29m$^3$/m$^2$. It can be seen that the average value of LVV in the area of campus construction in 0.3-0.5m$^3$/m$^2$ can basically control the space structure of green space.

The following questions should be paid attention to the cognition of the LVV. First of all, the influence factors of LVV are relatively complex, ensuring tree size and quantity, reasonably controlling the proportion of Joe, irrigation and grass and the proportion of coniferous and broad-leaved forest helps to improve the unit area's LVV. Secondly, the CGS structure of different functional areas is different, and the corresponding values of greening are different. Strengthening the requirement of LVV of different green spaces can control the use of large area of lawn, avoiding to appear single structure and high cost of the campus landscape. At the same time, considering that the CGS is generally used as open space, according to the LVV of unit area of urban forest which is less than 0.8m$^3$/m$^2$ are forest types with smaller canopy density [12], we can see that the LVV of CGS should not be too high.

3.3. The comfort index——Green Looking Ratio

Based on the full consideration of green line and ecological value, we should also pay more attention to the green space effect. Some studies have shown that the GLR has a great influence on landscape preference and landscape perception [13]. GLR refers to the proportion of green plants that people see in the eyes. Scholars at home and abroad have carried out a number of studies since twentieth Century. At present, camera fixed-point photography is often used to obtain the image of human eye field, and then the GLR is calculated by image analysis. Experiments have shown that a linear relationship between GLR and green sensation is similar. When the GLR is in the range of 25%-50%, it will bring users a better feeling [14-15].

At present, there is less research on the GLR measurement of CGS, Li [13] estimates the GLR of three colleges of Harbin, results have shown that the main entrance is to 35-40%, the main road is to 40-70%, the sports field is to 10-20%, the main teaching building is to 25-30%, and the leisure space is to 50-80%. It can be seen that GLR of different functional areas of the campus is different, the GLR of the leisure area is high with the sports field is low, and the other areas are basically controlled within the range of 25-50%.

The following questions should be paid attention to the cognition of the GLR. First of all, according to the characteristics of the campus and regional functions, we should formulate different levels of GLR. Secondly, by adjusting the collocation of the shrub layer and the vertical planting of the wall, there will have a significant influence to the GLR. At the same time, GLR can effectively regulate the comfort degree and construction effect of CGS, which is one of the indicators that cannot be ignored in the planning stage of CGS.

4. The multiple types of campus construction in the designing stage

Landscape is the place where people and nature depict a picture of mutual reflection, overlap, separation and even opposition, and it includes material, space, individual perception and group culture psychology.
Campus landscape is the picture which reflects the symbiotic relationship between teachers and students. From the perspective of landscape architecture, the construction of SC is not only to embody the form beauty of landscape, but also to explore and pursue the deep value of landscape. In the designing stage, the function of campus environment mainly concentrates on three aspects of landscape beautifying, education-teaching and cultural commemoration. The construction of multiple types of campus environment is beneficial to the performance of the characteristics of campus and is an important aspect of the construction of the SC.

Landscape beautifying is embodied in different functional partition, such as identifier landscape in entrance area, participatory landscape in living area and recreational landscape in teaching area. The tree hole garden near the dormitory of Beijing Forestry University was originally used as sports space, which was then transformed into a bicycle parking shed, but with the shed was demolished, leaving a space covered with moss. Designers would like to depict a picture that people look at each other no matter time goes by, and aims to create a quiet rest and whisper space for teachers and students. Through the organization of space, landscape will create different possibility of looking and cause different stories [17] (Fig. 2). In order to ensure the unity of architectural language and the environment around Beijing Forestry University Teaching and Research Center building, designers translated the management philosophy of Beijing Forestry University into the core of landscape, which can be classified as ‘Xi Shan Xing Lv’ that means travelling around nature. The east, south and the north side of the building is created as the green space which gradually becomes the city interface. The spindle square is defined as the landscape growth of building language. The sunken garden further analyzes the meaning of the subject of ‘Xi Shan Xing Lv’ [16]. The PM2.5 air quality sensor glass art device is placed in the sunken garden, which can real-time monitor the PM2.5 particle concentration in the air, and convert it to digital signal, and dynamically control the color of LED light. As there are some plant patterns in the laser-micro-engraving glass, the device not only echoes the surrounding environment, but only makes the garden have multiple meaning of art and ecology [18].

The abundant plant resources make the campus to be a place of natural class. Education-teaching creates characteristic green space pattern, such as the integration of campus and botanical garden of Zhejiang Agriculture and Forestry University. The botanical garden has a rich collection of 2500 kinds of plant materials as well as the national key protected plants and other rare plants. Through the four major projects of the implementation of plant resources, plant landscape, plant culture and plant information, the botanical garden has become the domestic first-class university botanical garden with landscape appearance, scientific connotation, ecological characteristics, humanistic qualities and scientific education [19] (Fig. 3). Tsinghua University Sheng Yin garden used to be the teacher housing area, but with the change of campus environment and the limitations of the site itself, it gradually becomes a low-lying and environmental crumbling place. Site transformation has balanced historical protection, functional renewal, storm water management, revitalization and revitalization, and has explored the inherent logical mechanism of landscape design and storm water management [20].
On the aspect of cultural commemoration, the campus memorial space is the place where the characteristics and culture of the campus are directly displayed. Nanjing Forestry University and Beijing Forestry University are two important green universities in North and South China, in memory of our famous forest scientist, Mr. Liang Xi, the two universities has opened memorial spaces in the campus. In Nanjing Forestry University, the bust of Mr. Liang Xi stands in the curved square in front of the library. Around the statue, some plants, such as Ginkgo biloba, Cercis gigantea, Buxus megistophylla and Sabina chinensis hedges have been planted. In Beijing Forestry University, the bust of Mr. Liang Xi stands in the west side of the main building, in the background of Acer truncatum, on both sides of Sophora japonica, surrounded by Buxus megistophylla and Buxus sinica hedges. The regular plant landscape is lined with figure statues, forming a solemn memorial space that integrates with the overall campus environment (Fig. 4).

5. The diversified application of plant materials in the constructing stage

In constructing stage, the applied plant material is important. As one of the elements of landscape architecture design, plants play an important role in the construction of CGS. Enriching the application of native plants and balancing plant species diversity is an important way to achieve sustainable development of CGS in the construction of SC. Plant landscape is the direct embodiment of the application of plant materials, and is also one of the important ways to express the campus landscape. Giving full consideration to plant materials and landscape is the wonderful part of SC construction.

Plant species, based on native plants, old and famous trees, and combined with cultivated plants, formed a rich green background for the campus. Study on application of native plants in campus at this stage can be listed as followed. Chu [21] estimates 6 universities in Harbin, the native woody plants application accounted for 62.5% of the total, Wang [22] estimates 10 universities in Beijing, accounted for 33.7% of total, and more than 60% of the native woody pants are the commonly used species in the greening of Beijing. Mao [23] estimates 8 universities of Hangzhou, accounted for 35.64% of total, Liu [24] estimates 56 universities and 54 middle school in Chongqing, accounted for 40.3% of total, Yang [25] estimates 9 universities of Kunming statistics, accounted for more than 45% of the total, Huang [26] estimates the South China Agricultural University, accounted 57.4% of the total. To sum up, the proportion of native plants applied in the campus is only 30-50%, and the introduction and application of native plant resources should continue to develop.

Study on the statistics of campus plants application shows that the number of plant species in Chinese campus remained at around 100-200, and geographical distribution showing an increasing trend from north to south. This is consistent with the condition in urban landscape, such as 100 species in Beijing, 200 species in Hangzhou and Shanghai, 300 species in Guangzhou [27]. Secondly, according to the general life style of plants, the number of trees and shrubs in the campus is higher than that of vines and herbs. Mao [23] and Shen [28] found that the diversity index and evenness of tree and shrub layer is higher than that of vine and herb layer, and evenness has been in an imbalance state.

Plant landscape is closely related to campus structure and often chooses native
plants, taking the Ginkgo biloba road in Beijing Forestry University, the Platanus acerifolia road in Tsinghua University and the Sakura road in Wuhan University as representative. The Sakura road in Wuhan University mainly plant Japanese cherry trees, with total length of about 600 meters, passing through the old college building, the Sakura house, the History museum, the Kunpeng square, the Valentine slope, and the Song Qing stadium [29]. The Sakura road not only attracts many teachers and visitors, but also carries the historical memory during the war of resistance against Japan, which is a witness of Sino Japanese friendly relations after the establishment of diplomatic relations between China and Japan in 1972 (Fig. 5).

In order to protect and utilize rationally, the plant resources condition should be understood clearly and accurately. The teachers and students from the school of landscape architecture, forestry and biology took three years to complete the Beijing Forestry University campus plant guidebook, which records the historical changes of nearly 400 kinds of plants in the campus, and is a creative work fusing plant cognition, photography, drawing, color measurement, planting plan and other multi-disciplinary. This is the unique green wealth of the campus that creates a new way to display and popularize the university’s own plant resources. It is not only a valuable textbook for teachers and students to popularize campus plant resources, but also becomes cornerstone of the construction of campus green culture.

6. Conclusion

The construction of SC is an important aspect to speed up the reform of ecological civilization, build a beautiful China and promote green development. Landscape architecture plays an important role in the construction of GC. From the perspective of landscape architecture, the construction of campus environment with green space as the carrier is more concerned with the construction of SC. This paper puts forward the suggestion of SC construction from three levels, including composite index system in planning stage, multiple types of campus construction in designing stage, and diversified application of plant materials in constructing stage. The three aspects complement each other, providing a complete framework for current campus construction and a reference for further exploration of SC construction.

Research on the Mitigating Effect of “Greening Blanks” on the Heat Island Effect——A Case Study of Baoding City

Xiaolei Yue, a Yuchong Yang, b Qing Lin*

aXiaolei Yue, Beijing Forestry University, Beijing and 100083, China
bYuchong Yang, Beijing Forestry University, Beijing and 100083, China

Abstract

The urban heat island effect has gradually become one of the most significant problems in urban climate with the development of urbanization in China. As the important component of urban ecosystem, the urban green space can effectively alleviate urban heat island effect[1]. By adopting the method of remote sensing data inversion and comprehensive application of GIS and RS technology, this paper got the spatial and temporal evolution map of surface temperature and vegetation coverage of different periods in Baoding city center, and analyzed spatial and temporal evolution law of the last ten years. Through using the grid method to study the coupling relationship between vegetation coverage and surface temperature, this paper found that the average temperature of the surface could be reduced by 0.9 -1.3 degrees when the vegetation coverage in the study area was increased by 10%, thus made quantitative suggestions for the ‘leaving white and adding green’ in the study area.

Keywords: Vegetation fraction; land surface temperature; Urban heat island effect; “greening blanks”

*Corresponding author: Qing Lin, E-mail: lindyla@126.com.
In 2017, Beijing put forward the policy of ‘greening blanks’ and ‘building urban forest’. The policy of ‘greening blanks’ aims at the other types of land outside the planned green space, or the space of improving the living environment of the city and reserving space for the long-term construction through greening in the context of unclear use of urban planning and unidentified or unimplemented permanent plan after demolition in a short term\(^2\). This policy is not only implemented in Beijing, but also focuses on the Beijing-Tianjin-Hebei region, aiming at forming a continuous ecological security pattern in this region.

In recent years, the urbanization of Baoding has been accelerated with a large number of green space being replaced by grey infrastructure and the increasing urban built-up area, thus brought about declining vegetation coverage of Baoding year by year, the weakened landscape and ecological function and the intensified urban heat island effect. Taking the Baoding city center as the research object, this paper carried out correlation study of the vegetation coverage and the surface temperature between 2007 and 2017, aiming at quantitatively studying the alleviating effect of ‘leaving white and adding green’ on urban heat island effect and making suggestions for the relationship between urban development and ecological green space construction of Baoding.

1. Overview of study area

The study scope is the Baoding city center (Fig. 1), including the Jingxiu District and the Lianchi District. The regional geographic coordinates are 113°40′~116°20′ of the east longitude and 38°10′~40° of the north latitude. The north of the center is 140 kilometers away from Beijing. Characterized by the warm temperate zone continental monsoon climate, Baoding has four distinct seasons and an average annual temperature of 13.4°C.

2. Data sources and preprocessing

The study selected three remote sensing images of Landsat 7 ETM satellite of America as the basic remote sensing data, of which the imaging time was September 3, 2007, August 16, 2012, and September 7, 2017. And the satellite track number of them were p124/r44, including 8 universal bands, of which the third and fourth band were used to extract the NDVI and the vegetation coverage information of the study area, and the sixth band is the thermal infrared band image, which is used to study the surface temperature of the study area. The spatial resolution of satellite images is 30m*30m, except for the sixth bands of 60m*60m. The time of the satellite over Baoding is about 8:50 in the morning. The imaging time of the three periods is basically the same, and the

\[\text{[2] Haidian District Landscaping without artificial plants and flowers[N]. Beijing daily. 2017.05.05((04) Focus News-Beijing)}\]
quality of the remote sensing images are good with precision meets the calculation requirement.

In dealing with these data, the radiometric calibration and atmospheric correction processing of the three period image data are first used to eliminate the radiation error caused by the atmospheric scattering, and then the image data of the Baoding city center is cut through the vector boundary layer. Furthermore, the remote sensing images of the corresponding bands were selected for the NDVI calculation and the surface temperature inversion. Finally, the ArcGIS10.2 software was used to process the relevant data in order to compare and calculate the correlation between surface temperature and vegetation coverage.

3. Calculation method

3.1. Vegetation coverage calculation

The method extracting vegetation coverage using remote sensing data mainly includes empirical model method, vegetation index method and mixed pixel decomposition method. In this paper, vegetation index method is used to extract vegetation coverage in Wuhuan[3]. Among many vegetation indices proposed by scholars, the normalized vegetation index is the most widely used. Therefore, this paper selects the normalized vegetation index for calculation, and its expression is:

\[ \text{NDVI} = \frac{\text{NIR} - \text{R}}{\text{NIR} + \text{R}} \] (1)

In the Landsat 7 ETM satellite remote sensing image, NIR represents the brightness value of the TM4 band, and R represents the brightness value of the TM3 band.

Based on the normalized vegetation index, the vegetation coverage is calculated. When calculating the vegetation coverage, the pixel bisection model method is used and its expression is:

\[ \text{FV} = \frac{\text{NDVI} - \text{NDVI}_{\text{soil}}}{\text{NDVI}_{\text{veg}} - \text{NDVI}_{\text{soil}}} \] (2)

In the formula, NDVI represents the normalized vegetation index, NDVI_{veg} represents the vegetation index for pure vegetation, and NDVI_{soil} represents the vegetation index for pure soil. Where NDVIIV is 0.7, NDVIS is 0. When the NDVI is greater than 0.7, the FV value is 1; when NDVI is less than 0, the FV value is 0.

3.2. Surface temperature inversion

This paper selects the atmospheric correction method for land surface temperature inversion[4]. Before calculating the land surface temperature, it is necessary to calculate the land surface emissivity and blackbody radiation measurement. Among them, the specific emissivity of vegetation and architecture is calculated and the specific emissivity of water is taken as 0.995. Its expression is [5]:

\[ \varepsilon_{\text{green}} = 0.9625 \times 0.0614 \times \text{Fv} - 0.0461 \times \text{Fv}^2 \] (3)

Fig. 2 Spatial and temporal evolution of vegetation coverage in 2007~2017

\[ \varepsilon_{\text{building}} = 0.9589 + 0.086 \text{ Fv} - 0.0671 \text{ Fv}^2 \quad (4) \]

In the above formula, \( \varepsilon_{\text{green}} \) represents the specific emissivity of the vegetation, \( \varepsilon_{\text{building}} \) represents the specific emissivity of the building, and Fv is the vegetation coverage calculated above. The land surface emissivity is obtained by inversion calculation.

Based on the land surface emissivity, the black body radiance in the thermal infrared band is calculated and its expression is:

\[ B(T_s) = \frac{[\lambda L - L_\uparrow - \tau (1 - \varepsilon) L_\downarrow]}{\tau \varepsilon} \quad (5) \]

Where \( B(T_s) \) is the thermal radiance, \( \tau \) is the atmospheric transmittance in the thermal infrared band, and \( \varepsilon \) is the surface radiance.

After obtaining the black body radiance at the temperature \( T_s \) in the thermal infrared band, according to the inverse function of the Planck formula, the true land surface temperature \( T_s \) is obtained. The expression is:

\[ T_s = K_2 \ln \left( \frac{K_1}{B(T_s) + 1} \right) \quad (6) \]

In the Landsat 7 ETM remote sensing image, \( K_1 \) is 666.09, \( K_2 \) is 1282.71. The calculated TS is the true surface temperature in Kelvin (K).

4. Results and analysis

4.1. Evolution characteristics of vegetation coverage

Vegetation coverage refers to the percentage of vertical projection area of the vegetation’s growth area in the study counting area, including the trees, shrubs, grass and crops\(^6\). The image resolution of the third and fourth bands in the Landsat 7 satellite images is 30m, which means the individual pixel in the image represents the vegetation coverage within the range of 30m. The degree of vegetation coverage is indicated by the depth of color, of which the deeper the color is, the higher the vegetation coverage is, while, the shallower the lower. Calculated the vegetation coverage image of Baoding city center by ENVI5.1 software and introduced the result into ArcGIS10.2 software for statistical processing, and finally got four vegetation coverage images in 2007, 2012 and 2017 in the study area.

As can be seen from Fig.2, the vegetation coverage in the Baoding city center was declining between 2007 and 2017. In the urbanization of Baoding, its construction land has increased rapidly with its city central gradually expanded to the suburb and the city gradually occupied some farmland and woodland, thus resulting in the obvious decrease of the vegetation coverage in 2017 than in 2007 in the study area.

4.2. Surface temperature evolution characteristics

The image resolution of the thermal infrared band (sixth band) in the Landsat 7 satellite images is 60m*60m, which means the individual pixel in the image represents the vegetation coverage within the range of 60m*60m. The degree of vegetation coverage is indicated by the depth of color, of which the deeper the color is, the higher the vegetation coverage is, while, the shallower the lower. Calculated the

vegetation coverage image of Baoding city center by ENVI5.1 software and introduced the result into ArcGIS10.2 software for statistical processing, and finally got four vegetation coverage images in 2007, 2012 and 2017 in the study area. (Fig. 3)

It can be seen from Figure 3 that the surface temperature of the Baoding city center was on the rise, as the rising urban heat island effect gradually spreading from the central city between 2007 and 2017. In 2007, the heat island effect of the central region was more obvious, of which the types of land use in the suburbs were mainly farmland and a small number of villages, thus the heat island effect was not so obvious. In 2017, with the rapid development of the city, the influence range of the heat island effect has been spread rapidly from the central area to the suburb. The area of the built-up area of Baoding is gradually expanding, with a large number of land use types in the suburb been gradually transformed from farmland to construction land and the underlying surface properties of the suburban areas been changed, therefore the urban heat island effect's coverage has been changed.

4.3. Correlation analysis of surface temperature and vegetation coverage at different periods

Through processing the data of vegetation coverage images and surface temperature images in the research area and taking the average value by the grid method to make an detailed analysis of the study area, this paper extracted data information in an all-round way.

The research area is meshed first with the border length of each grid is 900m*900m and 565 grids were presented and the coverage of all the data of surface temperature and vegetation coverage in the study area. Each grid contains 900 original grid data due to the spatial resolution of the vegetation coverage image is 30m*30m, and each grid of the images contains 225 original grid data due to the spatial resolution of the surface temperature image is 60m*60m, Then, the average value of the grids are calculated by ArcGIS10.2 software to get the partition grid image of vegetation coverage and land surface temperature (Fig. 4). Finally, the vegetation coverage and surface temperature data of all grids were introduced into Excel software to study the correlation between them, bringing out regression analysis results between surface temperature and vegetation coverage in 2007, 2012 and 2017 (Fig. 5).
There is an obvious negative correlation between surface temperature and vegetation coverage in the study area as can be seen from Figure 5, of which the higher the vegetation coverage is, the lower the surface temperature in the corresponding sites is. The determinant coefficients ($R^2$) of the regression equations of 2007, 2012 and 2017 are 0.877084, 0.612018 and 0.823626 respectively as can be seen from Figure 5, indicating a strong correlation between them. While, the slope of the regression equation in 2007, 2012 and 2017 is -13.304, -8.9846 and -10.714 respectively with the absolute value ranges from 8.9846 to 13.304. What can be concluded from these data is the increase of vegetation coverage of the region can effectively change the surface temperature, indicating that when the vegetation coverage index of the Baoding city center is increased by 0.1, the surface temperature will be reduced by $0.9^\circ\text{C}-1.3^\circ\text{C}$.

5. Conclusions and suggestions

The results showed that the vegetation coverage and the surface temperature changed greatly in the Baoding city center between 2007 and 2017. It is caused by the continuous expansion of urban and rural construction land in Baoding, the decreasing area of urban vegetation coverage and the strengthening urban heat island effect. In addition, there is a significant negative correlation between surface temperature and vegetation coverage in the study area, which means that the average surface temperature of the study area can be reduced by $0.9^\circ\text{C} - 1.3^\circ\text{C}$ when the vegetation coverage in the study area increases by 10%

The relationship between urban heat island and urban development should be balanced in the development of Baoding’s future cities. In 2017, the existing vegetation coverage in the Baoding city center was 40%. If the urban expansion was uncontrolled in the future construction, the surface temperature would rise by $1^\circ\text{C}$ when the vegetation coverage in the study area increases by 10%, which means that the temperature of local area may rise above $5^\circ\text{C}$. Therefore, it is necessary of ‘leaving white and adding green’ in urban development, and contribute to the ecological environment in Baoding. In ‘adding green’, on the one hand, rational planning and utilization of land, strictly keeping the ‘red line’ of land and ecological protection, controlling the development boundary of the city, overlying the wasteland or the unplanned land after demolition at a short term, increasing the green coverage of the city is needed. On the other hand, what should be done is to use the method of vertical and roof greening to increase urban greening coverage in the built-up area of the city.

Abstract

The organic unity of structure and form has always been the goal of the construction industry. However, because designers habitually neglect the structural problems of small-scale landscape structures and lack of professional structural knowledge, design works are often not ideal. With the arrival of the digital age, more and more scholars are trying to improve this situation with new finite element analysis tools and have achieved some research results. Through case studies, this paper introduces how to quantitatively analyse a structural system by using Karamba3D, a finite element analysis tool developed based on the Rhino/Grasshopper parametric platform, and optimize the analysis results with some algorithms and plug-ins to get a relatively optimal solution to the structural morphology. Finally, four methods for structural optimization by using this tool are summarized to help designers to take full advantage of finite element analysis tools in the design of landscape structures.

Keywords: karamba3D; Finite Element Analysis; Structure optimization; Landscape Structures

Fund Items: National Natural Science Foundation of China (No. 51578173); National Natural Science Foundation of China (No. 51678180)
1. Introduction

The difference in scale causes the structure stress of landscape structure being simpler than architecture, and therefore its structural problems are often ignored by designers. In addition, with the constant refinement of the division of disciplines, structural knowledge of architectural and landscape designers is becoming increasingly scarce. The above two reasons lead to the separation and contradiction between the appearance form and structural morphology in most of the design works. There is neither a pleasing form nor a light and efficient structure, resulting in high costs but little profit.

The greater freedom of form creation in the landscape structure design enables the designers to actively explore the most reasonable structure as far as possible and pursue the expressive force of the structure itself. Famous architect Nervi thinks that “the structure should have its own expressive force, and a reasonable structure itself is beautiful”. [1] When the structure plays the modelling role and satisfies the use demand with the lowest cost and the best performance, this design work will certainly be praised. The Hannover Expo-dome, designed by Thomas Herzog, is a good example (Fig. 1). The structure not only has a response to the environmental tendency of circulation space but also correspond to the theme of World Expo technology and ecology. The design work achieves the perfect unity between structure and form by adopting various methods from the whole to the details and had excellent visual effects. [2]

The digital age gives designers some finite element analysis tools that are easy to learn and operate, such as the RhinoVault plug-in based on the Rhino platform, the finite element analysis plug-in Karamba3D and Millipede based on Rhino/Grasshopper platform and so on. Designers can use these tools to get accurate data on various mechanical properties of space structures and have a preliminary judgment on the structure rationality of the design works. Then these properties indexes can be optimized by using various algorithms or plugins. Many famous designers and architectural firms have used these new tools to create many great works. For example, the CIAB pavilion designed by Zaha Hadid in 2013. The designer extracted the primary and secondary stress lines by using Karamba3D and converted it into beautiful

Fig. 1. Hannover Expo-dome designed by Thomas Herzog

Fig. 2. CIAB pavilion designed by Zaha Hadid Architects
force-flow pattern (Fig. 2). In addition, many architectural colleges and academic groups have done in-depth research on the teaching of finite element analysis, such as the "Shanghai digital future" summer camp planned by College of Architecture and Urban Planning, Tongji University which introduced the design method and teaching mode of structure performance into teaching practice. Research on Digital Structural Performance Morphologies published by professor Yuan Feng in 2014 explored the education on structural performance-oriented design based on this event.\(^3\) In Towards an Integration of Architecture and Structure Performance Design published in 2017, he sifted through the pertinent research and practical projects on "structural performance-based aesthetics" and "structural performance-based tectonic culture", and predicted its prospective trend.\(^4\) In the same year, Meng Xianchuan, professor of architecture and urban planning college in Nanjing university, published Some Thinking on Tectonic Design with Finite Element Analysis: a Case Study on Karamba3D. He revealed and reflected the new possibility brought by the new finite element analysis software for construction design.\(^5\) In this context, this paper summarizes four structural optimization methods based on finite element analysis tool Karamba3D through some structural optimization cases study which can be used to help designers achieve the goal of organic unity between structure and form.

2. Structure optimization method

The tool used in this paper is Karamba3D, a finite element analysis plug-in developed under the Rhino/Grasshopper platform. It was jointly developed by Clemens Preisinger and Bollinger Grohmann Engineers to facilitate designers to use, which can achieve the structural performance-oriented landscape structure design combined with the Grasshopper parametric geometric model and a variety of optimization algorithms.

Karamba3D-based structural analysis and optimization process is usually divided into five steps (Fig. 3): 1) Create a parametric model 2) Define boundary conditions 3) Analysis results 4) Optimize processing 5) Visualization of results. In order to use a variety of algorithms or plug-in to iteratively optimize the structural system, firstly, a parameterized model needs to be created by

![Fig. 3. Structure analysis and optimization flow chart based on Karamba3D](image-url)
using Grasshopper, and then data association between the model data information and finite element analysis tools can be established. Secondly, defining boundary conditions including the structural elements, supports, loads, cross sections and materials, and selecting the optimization objectives from the analysis results of structural performance, such as strain energy, maximum displacement, the total mass of the structure and so on. Finally, optimizing the structure system by using the appropriate algorithm or plug-in, and visualizing the analysis results.

2.1. BESO algorithm

The Bi-directional ESO (BESO) is perfected on the basis of the Evolutionary Structural Optimization (ESO). It can not only remove low-utilization materials in the structure, but also grow in the most needed part, so that the structural system evolves into an optimal form. [6] The pedestrian bridge designed by BKK Architects from Australia and Xie Yimin research team with a net span of 72m. In order to obtain the maximum structural stiffness, the BESO algorithm is used in the conceptual design. Under the same load condition, the algorithm generates the corresponding optimal forms according to the two support conditions. The first type of support condition is that one side is a fixed support and the other side is a sliding support. The second type of support condition is that both sides are fixed supports. In the end, the former produces a typical truss form, the latter forms an arched structure. (Fig. 4). [7]

Table 1. The dendriform structure optimization results
The algorithm integrates successfully into Karamba3D, a finite element analysis tool, which sets up two components for beams and shells: BESO for Beams and BESO for Shells. In the next case study, a simple dendriform structure is optimized with the help of the former component (Table 1). The structural analysis elements are composed of the top hyperbolic single-layer lattice shell and the dendriform structure, and displacement and three-axis rotation are constrained at column base. The load consists of the gravity of the structure itself and the uniform load at the top of the shell. All beams are circular hollow section, the cross-section diameter of the top single-layer lattice shell is 11.20cm, wall thickness is 0.56cm, and the diameter of the branch beam is 22.00 cm, the wall thickness is 1.32 cm, and the trunk beam diameter is 44.00 cm, the wall thickness is 2.40 cm. The BESO algorithm is applied to the oblique beams of the top single-layer lattice shell, and the optimization target of the structural mass ratio is set to 60%. After optimization, the number of oblique beams used to reinforce the structure in the top single-layer reticulated shell is reduced by 40, and the maximum displacement of the structure under the two load conditions is not significantly increased. BESO for Shells has a similar function and can distinguish between the different utilization areas in shell structure.

2.2. Cross-section optimization

Karamba3D has an "Optimize Cross Section" component that can automatically select the optimal solution from the list of cross-sections set by the user based on the force state of the beam or shell. In the official case of the shell bridge cross-section optimization, it can be seen that under the condition of gravity load and external load on the bridge deck, the cross section of the thin shell near the supports is significantly thickened (Fig. 5).

This method was used to further optimize the cross-section of the dendriform structure described above (Table 1). In order to ensure a certain structural reserve, the target value of the element utilization is set to 70%. The cross sections diameter are in the range of 4cm to 40 cm, and wall thickness of all the beams is 0.05 times the diameter. After BESO algorithm and cross-section optimization, it is found that the structure quality is reduced from the initial 10918.99kg to 6465.25kg, and the maximum displacement is significantly reduced. These data prove that the cross-section optimization effect is obvious.
2.3. Octopus and Galapagos plug-in components

Galapagos is a single-objective optimization component in grasshopper. It contains genetic algorithm and annealing algorithm, which is suitable for some simple single-objective optimization problems. Octopus is part of a range of tools developed by Robert Vierlinger at the University of Applied Arts Vienna, and Bollinger + Grohmann Engineers, which can be used for multi-objective optimization combined with the principle of Pareto Optimum and evolutionary algorithms.

In a case on the Karamba3D official website, the Octopus plug-in is used to optimize a concrete pedestrian bridge under the gravity load (Fig. 6). Firstly, establish a parametric model of the bridge in grasshopper. Then the independent variables are set to the width of supports, the arch highness, and width and height of the cross section at the middle of the pedestrian bridge. The optimization objective are the maximum value of the bridge highness, the maximum displacement of the structural system, and the minimum value of the structure mass. Since the optimization objective tends to the minimum value by default, the bridge highness value needs to be turned into a negative number to be inputted to the Octopus plug-in. The optimization solution set is displayed in three-dimensional coordinate axes (Fig. 7), and each axis represents an optimization index. The scattered squares represent different solutions, and the lighter the colour is, the older the generation is. The solid square is the Pareto Front solution. Each square can be clicked to feed the solution back to grasshopper, or to be marked and deleted. Designers can choose the relative optimal solution in the solution set according to their needs.

In addition to using this plug-in to optimize Karamba3D's analysis results, designers can also set optimization objectives to non-structural performance indexes. For example, in the official case of inclined column position optimization (Fig. 8), it is necessary to use 10 inclined columns...
to support the surface roof, and not to collide with the two buildings below the roof. Therefore, the three optimization objectives are the minimum value of the structural mass, the maximum value of the minimum distance between the column bases, and the minimum number of the intersection between the columns and the two buildings. After inputting the model parameters of the column position as independent variables to the Octopus multi-objective optimization plug-in, ideal optimization results can be obtained.

2.4. Force Flow lines and Stress lines

The component of "Line Results on Shells" in Karamba3D can be used to extract the force flow lines or stress lines in shell structure, and then the efficient and Innovative structure can be obtained by removing the material between the force lines or transforming the stress lines into the structural skeleton. In the design work of AA Summer DLAB 2015, Elif Erdine and Alexandros Kalle-gias led the team to design a red concrete landscape wall with 2.2 meters height, 4 meters width, and a varying depth of 3 ~ 25 cm (Fig. 9). In the conceptual design stage, Karamba3D was used to analyse the structure of the surface wall, and then the force flow lines were extracted based on the analysis results. This form was obtained by removing the material in the area between the force flow lines. Then the high-strength red concrete was poured into the CNC engraving template, the design result of organic unity between form and structure were obtained after the template was removed. Patrik Schumacher, a partner of Zaha Hadid Architects, has studied how to use Kammba3D to analyse the hyperboloids, and then extract the primary and secondary stress lines in different directions from the analysis result, and finally transform them into beautifully adapted rib-patterns (Fig. 10). [8] The CIAB exhibition pavilion introduced above has also been designed and built by using the same method. In addition, continuous changes in structural properties can also be correlated with material densities to generate innovative forms. The 15th International Architecture Exhibition in Venice showed a chair created by Zaha Hadid, Patrik Schumacher and Stratasys, a 3D printing company. The designer used finite element analysis tool to obtain the structural performance data of the chair when a person was sitting and adjusted the material density distribution according to the data to optimize
the structural performance, and the result also got a beautiful form. (Fig. 11).

**Fig. 11.** 3D printed chair designed by Zaha Hadid Architects

3. **Conclusion**

Karamba3D is a powerful finite element analysis tool that can combine the advantages of grasshopper parametric model. While changing a certain model parameter, it can carry on the real-time structural analysis to a series of models that produce quickly. In addition, a relatively optimal solution can be selected from these models by using some algorithms or plug-ins based on the analysis results. This paper summarizes four structural optimization methods based on finite element analysis tool Karamba3D through some structural optimization cases study of the dendriform structure, pedestrian bridge and so on. Designers can use BESO algorithm and cross-section optimization component to gather materials in the most needed area, and also can use Octopus or Galapagos plug-in to find the optimal form of structural performance under some rule restrictions, for example, the mass of the structure is optimized under the restriction that the columns do not collide with the buildings in the case of inclined column position optimization. In addition, the force flow lines or stress lines of the structure can be extracted to create the “force form” by removing materials in the area between force flow lines or converting the stress lines into structural skeleton. The author hopes that the emergence of these new tools and methods will be an opportunity to break the barrier between the form design and the structure design of landscape structures, and to achieve the goal of cooperative development and organic unity between both sides.

4. **Acknowledgments**

First of all, I am extremely grateful to my supervisor, Lu Shiliang, for his patient guidance and trust from the selection of the thesis topic to the successful completion. At the same time, I am much obliged to the IFLA organization for giving me the opportunity to participate in the 55th International Federation of Landscape Architects World Congress 2018. In addition, I would like to express my sincere gratitude to Karamba3D official website for providing these structural optimization cases. Last but not least, I would like to express thanks to my colleagues in the studio for their support and help in the writing process of this paper.

Landscape elements and bloodsucking midge breeding sites

Kaowen Chang*

National Chiayi University, No.300 Syuefu Rd., Chiayi City 60004, Taiwan (R.O.C.)

Abstract

The purpose of this study is to analyse the relationship between landscape factors and the larval breeding sites of bloodsucking midge (Forcipomyia taiwana). The study intent is to establish the environmental management strategies that make the designed landscape *per se* the environment that is difficult for the larval breeding sites to form. Studies have indicated that unsuitable landscape designs can increase the population of the bloodsucking midge in green spaces. However, we have little further information about which kind of designed environmental factors that affect the formation of the larval breeding sites. As a result, the landscape professionals are in lack of information to establish effective strategies for midge prevention at the early stage of a site preparation. Therefore, in this study, we use spatial analyses, GIS technique, and field survey data, and statistical technique of logit regression to analyse how the surveyed landscape factors can influence the occurrence of larval breeding sites of bloodsucking midges. The results show smaller canopy width 1-3m promotes algae growth while other larger canopy widths relate with less algae growth, the medium tree height of 4-6m and half shaded presents suitability for algae growth while other heights and less than half shaded areas discourage algae generation. The results of ground materials indicate the covers that either have less ability to retain water (‘sandy soil’), is covered by other strong competitors for water and sunlight (natural grass), have shorter installation history (new high-tension brick ), or have sufficient sunlight isolation (thick leaves) present a better ability to prevent algae growth.

*Keywords: Forcipomyia taiwana; bloodsucking midge; landscape; environmental control method*
1. Introduction

Bloodsucking midge (Forcipomyia taiwana), also publicly called ‘little black mosquito’, is a substantial nuisance blood-sucking insect distributed in Taiwan and also in warm and humid areas in mainland China. Its female imagoes are human blood-feeding and bite on human skin especially the expose parts, such as hand, foot, face, and calf. The imagoes of Forcipomyia taiwana are active in the daytime and the size is approximately 1.4mm. Due to this small size, it is difficult for people to aware their stops on the skin. The reaction of the bites can be itching and swelling in various sizes for several days. Depending on the constitution of the individual, it can trigger allergies [1].

Studies have indicated that unsuitable landscape designs can increase the population of Forcipomyia taiwana (bloodsucking midge). However, we have little information about what kind of design or environmental factors that relates to this issue. As a result, the landscape professionals are in lack of information to establish effective strategies for midge prevention at the early stage of a site preparation. The purpose of this study is to analyze the relationship between landscape factors and the larval breeding sites of bloodsucking midge (Forcipomyia taiwana). The study intent is to establish the environmental management strategies that make the designed landscape per se the environment that is difficult for the larval breeding sites to form.

Because Forcipomyia taiwana is human blood-feeding, the human inhabitances and activities become an important factor to the midges’ population. Due to the warm and humid weather conditions and dense human population in Taiwan, the distribution of Forcipomyia taiwana covers a wide range including the areas of eastern, central, and southern Taiwan especially in the county of Tauchun, Chumhaw, Yinlin, and Tainan [2-3].

The various types of green spaces not only provide ecological services to sustain our environmental quality, but also offer people the opportunities for contacting with nature, participating activities, relaxing psychologically, and energizing physical strength especially in the highly populated and urbanized environment of Taiwan. However, since the blood sucking midges’ active time and people’s major outdoor setting use in the daytime are overlapped, many cases have been reported that people have been densely bitten during their stays in the outdoors causing adverse reactions pertaining allergies and skin irritation. To mitigate this situation, although the use of insecticide can temperately reduce the population of blood sucking midges [3], the insecticide application causes the public’s concerns for health and can lead to the Forcipomyia taiwana population rebound after a temporary reduction. It is apparent that a more sustainable and healthy management means needs to be studied. Therefore, this research intends to explore a mitigation method from the angle of environmental prevention.

Forcipomyia taiwana is a diurnal insect and is often active at the areas less than 2 meters height. The blood-sucking activity is cycled starting approximately from 8:00 am, reaching its most active time between 12:00-15:00, and stopping around 18:00 [4-5].
The suitable temperature for *Forcipomyia taiwana* is ranged 18-27°C. The population fluctuates generally following the seasonal change. The largest population happens in summer and smallest population happens in winter. The population outbreak often appears during the spring rainy period [6]. Studies have found the population of *Forcipomyia taiwana* positively relates to temperature, rainfall, rainfall days, and monthly temperature [7]. A similar conclusion was drawn in a study in Hawlian, Taiwan, indicating the population is dynamic based on sunlight hours, rainfall, humidity, and temperature, and the *Forcipomyia taiwana* population decreases when the temperature is higher than 35°C, lower than 10 °C, or the moisture is excessive [8].

The distribution of *Forcipomyia taiwana* is mainly in hills and low altitude mountains in Taiwan and Mainland China. An earlier Mainland China study reported the case of the female *Forcipomyia taiwana* carried Japanese encephalitis virus [9]. However, there are not enough reports to support *Forcipomyia taiwana* is a disease vector. Recent studies have found an extended trend of its population, spreading to cover almost all counties especially in the eastern areas in Taiwan [6-7]. Comparing studies along time, the distributed elevation range of *Forcipomyia taiwana* has also extended from 150m in earlier records, to 200-400m, and to the recent records of 350-400m [3,6]. Lately, the estimation is that approximately 78% of the population is in the area under 250m and 15% is distributed in between 250-500m [3]. This spread has been seen a reflection to the overall temperature raise by global warming phenomenon.

*Forcipomyia taiwana* is a completely metamorphic insect. Its life cycle experiences the four stages of egg, larva, pupa, and imago. Most eggs hatch within 3 days, then go through 16-18 days larval stage, and 3-5 days pupal stage to reach the imago stage. The time before imago stage is in the range of 21-26 days. The imago can live for another 22-26 days [10]. The male *Forcipomyia taiwana* feeds on dew or nectar while the female feeds on human blood. The needed blood time for female is 4-6 minutes a day, the female lays eggs after 3-4 days feeding on blood, and the average number of eggs laid is nearly 30-40. *Forcipomyia taiwana* often lays eggs in a scattered manner at sites that are humid and provided with algae for its consumption. The eggs are in brown-black color with the length approximately 0.3mm. The larva is terrestrial and ingests algae as the main source of food. In the latest stage of lava, it climbs on to drier location to form pupa. The imago frequently inhabits in bushes or lower trees less than 2m and wait for hosts [11].

During the stages of egg, larva, and pupa, *Forcipomyia taiwana* inhabits in the environments that provides algae for food. Since the flying ability of the imago is inefficient, most imagoes stay close to its larva site. Study found that the imago population concentrates within 100m from their larva sites, and most population stay within the range of 300m. The observed population significantly decreases as the distances further from their larva sites.

The larva mainly feed on blue-green algae, green algae, and other algae in the breeding sites. Freshwater algae include various different species. Most of the species
visually appear as green color as most of them contain chlorophyll and carry out photosynthesis. Based on the growing environments, algae can be classified as floating or fixing algae. Because Forcipomyia taiwana larva is terrestrial, its breeding site is related to the growth of fixing algae. Forcipomyia taiwana inhabits in sites that aggregate algae [2,5]. Forcipomyia taiwana larva feeding on blue-green algae can shorten nearly half of its developing days to become an imago [12]. The locations with indirect sunlight and high moisture are suitable for algae growth. Studies also found the ditches, fencing walls, or shaded places within 20 meters from residences often breed Forcipomyia taiwana larva [13]. The moisture condition of the groundcover material is a factor for breeding sites. Ground covers with sands and dry soil relates to less larvae found [14] while the soil pH value does not show effect. In addition, the shady places close to structures and people can be candidates for breeding Forcipomyia taiwana larva.

Forcipomyia taiwana are observed to haunt about two land use types. One is the agriculture land use, such as bamboo farm and betel nut farm. Another is the landscaping green spaces, such as green settings at schools and parks [2,7]. In addition, the frequency of human activity significantly affects the population density of Forcipomyia taiwana [13]. The active range of Forcipomyia taiwana has been found limited to the place near their larva breeding sites as well as relating to distances from people’s constant appearances [13]. The settings have sufficient blood sources from people’s residences and activities, such as parks, recreation areas, schools, agricultural communities, are potential locations for being rampant. Therefore, we understand environmental factors in landscaping designs, such as plant type, canopy coverage, plant height, and groundcover material that influence the population of Forcipomyia taiwana.

Forcipomyia taiwana often bites on human skin on the parts with no covers, such as dace, neck, lower neck, foot, and hand. The spot bitten usually appears wheal and extreme itchy within an hour and may lead to a delayed type hypersensitivity appearing blisters, pustules, itchy eruptions, or sometimes allergies that need medical treatment [1]. We know that the green spaces infested by Forcipomyia taiwana often associate with frequent human activities [7] and in fact causes impacts on the visits to recreation areas, shops, and on quality of life. As many of those green places have an important role for various functions that support ecological values, aesthetic quality, social capital, psychological and physical health for the public. Therefore, this study intends to understand the effects of characteristics of landscape elements on the larva breeding site of Forcipomyia taiwana.

The larva of Forcipomyia taiwana is terrestrial, ingest mainly blue-green algae, green algae, and other algae, those algae usually grows on different ground covers, such as brick, concrete, or bare soil. The growth of algae needs suitable conditions of micro-climates and sun light. In green spaces, plants and landscaping produce nature beauty provide outdoor recreation, environmental education settings, and comfortable environments supporting activities for the public and children,
however, inappropriate designs of green spaces may also become the settings that provide the algae for the larva of *Forcipomyia taiwana*. Thus, the management of green spaces is proactively seeking the strategies that can give considerations to the two sides of the creation of green spaces and prevention of *Forcipomyia taiwana*, yet the supporting studies that can provide the basis for possible solutions have been under development.

Studies indicated that an inappropriate design of green spaces may grow *Forcipomyia taiwana* [7,15] but little research has been done regarding which design, configuration, or environment factors that affect the growth of *Forcipomyia taiwana*. As a result, the landscape and planning professionals are difficult to reflect this consideration into their practices. Therefore, this current study explores the relationship between landscaping factors and algae growth as the indication of larva breeding site, investigating the characteristics of landscaping element, including tree canopy, tree height, shade density, and ground cover types, and use the method of spatial analysis, and GIS to explore the prevention strategies in landscape design and planning, so the configurations of settings per se can avoid the formation of larva breeding site.

2. Method

2.1. Study site

The study site is located at Chingshui Yan Recreational Area, Shetou Township, Changhua County, Taiwan. Based on survey reports, this region is an infested area of *Forcipomyia taiwana*. The site is at the fringe of Changhua City and the foot of Bagua Mountain. This study site is approximately 12 Ha (120,000 m²) and its elevation is 100m-125m. The slope of the site is prepared and generally smooth around 5-8%. The monthly average low and high temperatures are 19.4 ℃ and 28.0 ℃. The yearly average rainfall is approximately 1,400mm and the relative humidity is 77%.

Chingshui Yan Recreational Area was originally developed for the use of scout camp and currently used as a recreational area for the public, offering facilities including prepared camp sites with different paving material, restrooms, lodges, auditorium, pavilions, and large shelters. The site offers green areas throughout. The vegetation types include the combinations of majorly trees, natural grown ecological areas, natural grass land, and open lawn.

2.2. Data collection and analyses

This study used empirical field survey as the data collection method. The researchers first prepared and organized the site plan drawings into GIS for later data entry. In the field surveys, the surveyor recorded the pre-identified features, including algae growth spots, tree height, projected canopy area, the leaf density levels, and the groundcover or pavement material. The variables are listed in Table1 and 2. The collected raw data were entered into layers with the identified feature attributes as GIS vector data. Then, we assigned 1x1m grid on the data map to extract the types of tested variables in each grid. The total sample size is 57066. We used the statistic technique of binary logistic
regression to analyses which variables promote the algae formation.

2.3. Results

In this section, we report the results of whether the tree canopy, height, light penetration condition, and ground material affect formation of algae for larva breeding sites of *Forcipomyia taiwana*. To answer these questions, we conducted field surveys to collect the data that include tree canopy width, height, light penetration conditions, ground material, and algae growth locations, and used ArcGIS and Binary Logit Regression for examination.

Table 3, 4 shows the estimated results. First, the model fit and model coefficient Omnibus test, results of the likelihood ratio chi-square presents the model fit is significant at $\chi^2=5675.405$ and $p<0.001$. This result indicates the estimate model is better than the null model. The results shows that the coefficient canopy width, tree height, and ground material are positively significant indicating those environmental factors are influential to algae formation. Results of Omnibus test indicate the coefficients are significant in the model level.

The table 5 show the effects of the characteristics of tree canopy, tree height, light penetration, and the ground cover on the algae formation for *Forcipomyia taiwana* breeding sites. The predicted odds ratios represent the probability of the algae formation when the condition of factor changes. In comparison with the no-tree condition, the areas under 1-3m width tree canopy increase 103% in odds to grow algae (OR=2.029) while the areas under 4-6m, 7-9m, and more than 10m canopy in width would receive less odds to grow algae by 47%, 64%, and 65%. For the areas under different tree heights, the areas under tree height 1-3m have 75% less chance to grow algae while the areas under 4-6 received an increase 344% in odds to grow algae. Tree
shade levels indicate the ability for sunlight penetration. The half shade areas receive 40.1% increase in chance to grow algae while little and some shade conditions have respectively 51% and 63% decrease in odds to form algae.

The ground materials show an overall positive significant influence compared with the main road feature. Based on OR value of materials, ‘RC ditch’ presents the most positive influence on algae formation by 6443.77 times in odds to grow algae. The ‘high-tension brick’ also shows its high effects. The areas constructed by ‘high-tension brick’ have 266.98 times in odds to generate algae. The ground material ‘bare soil’ presents 107.83 times in odds to grow algae than main road, followed by the ground material of ‘clay’ (66.6 times in odds), ‘close lightly pebble’ (60.8 times), ‘gravel sand soil mix’ (34.75 times), ‘pebble gravel sand mix’ (34.29 times), ‘multi-layer leaves’ (33.18 times), ‘one-layer leaves’ (30.75 times), ‘RC’(27.84 times), ‘sand soil mix’ (11.31 times) ‘new high-tension brick’ (9.62 times), ‘natural grass’ (6.23 times), and ‘thick leaves’ (0.99 times), while the ‘lawn area’ and areas made of ‘asphalt’ are not significantly different.

2.4. Conclusion

Forcipomyia taiwana is human blood-feeding that bite on human skin to cause itching, swelling, and trigger allergies [1]. Because Forcipomyia taiwana often haunt in landscaping settings and bite people conducting outdoor activities, we intend to understand which characteristics of plants and ground conditions can compose the environments that generate algae for breeding larva of Forcipomyia taiwana so we can understand considerations in landscape planning and design to mitigate the population of Forcipomyia taiwana.

Based on the results, we learn that the tree canopy width, height, shady areas, and the types of ground material significantly affect the algae formation for breeding Forcipomyia taiwana larva. Smaller canopy width 1-3m promotes algae growth while other larger canopy widths relate with less algae growth. The medium tree height of 4-6m presents suitability for algae growth. The results show half shaded conditions under trees promotes algae growth and the less shady conditions discourage algae growth. These results indicate that sunlight condition under tree is one of the conditions for the larva breeding sites of Forcipomyia taiwana. Trees with these conditions need to adjust to their site maintenance and accompanied ground cover condition to reduce the forming of larva breeding sites. The ground materials show an overall influence on algae growth. Among the material types, the not-covered RC ditch structures provide preferred humidity and suitable sunlight for algae growth and thus become the most preferred sites for algae.

The materials of ‘high-tension brick’, ‘bare soil’, ‘clay’, and ‘close lightly pebble’ are the first five ground materials in effectiveness order that promote breeding sites of Forcipomyia taiwana larva. Those materials are characterized having higher ability to retain water in the material or trap water to stay in the soils framed in the material, such as the framed-brick. The next group of materials in their effect order- ‘gravel sand soil mix’, ‘pebble gravel sand mix’, ‘multi-layer leaves’, ‘one-layer leaves’, and ‘RC’ present that particle sizes may provide surface for growing algae (‘gravel sand soil mix’, ‘pebble gravel sand mix’, and ‘RC’) and a combination of moisture retention and sunlight of fallen leaves are needed to be either accumulated to become thicker or changed (‘multi-layer leaves’, ‘one-layer leaves’).

In comparison among the mixes of pebble, gravel, and sand, we found the mixes with more proportion of bigger objects (pebble and gravel) have larger chance to growth algae than the ground that contains smaller particles (sand). When comparing the thickness levels of fall leaves, we found the thinner leafy cover relatively promotes algae growth than the thick leafy cover does. The least influential group of ground cover contains ‘sand soil mix’, ‘new high-tension brick’, ‘natural grass’, and ‘thick leaves’. The materials in this group indicate the covers that either have less ability to retain water (‘sandy soil’), is covered by other strong competitors for water and sunlight (‘natural soil’), have shorter installation history (‘new high-tension brick’), or have sufficient sunlight isolation (‘thick leaves’).
present a better ability to prevent algae growth.

In this study, the inclusion of tested environmental factors is limited due to the composition and material installed in the study site. Future studies should include more sample sites with diverse vegetation types, such as shrub condition, and installed ground material to understand the interactions between algae generation and the landscape compositions. Moreover, future studies should consider the effects based on the combination of variables to understand specific environmental condition composed by landscape elements.

Abstract

As cities begin adopting smart technologies, one common goal is creation a digital twin of the city. A virtual three dimensional (3D) representation of the city in question from which advances in urban planning, data analytics and logistical operations can be simulated. Unfortunately the representation of vegetation in virtual cities remains mostly unexplored or oversimplified owing to the complexities involved in modelling it in 3D.

Urban trees and parks are known to be vital in making cities more liveable by providing both a psychological as well as a physical relief. Few other cities in the world exemplify this idea as much as Singapore which positions itself as a “City in a Garden”. Likewise, the digital twin of Singapore (Virtual Singapore) would also need to find ways to accurately represent the sheer diversity and volume its tropical trees in this new 3D environment.

The aim of this interdisciplinary research is to develop efficient tools and techniques to model spatially, biologically and semantically representative 3D Trees for Virtual Singapore. This paper outlines the initial developments in which the team consolidates a multitude of data sources and develops a methodology to efficiently populate large-scale city models with representative simplified 3D trees that are based off the best available data.

The team adopts the CityGML standard, the framework for Virtual Singapore, within which the vegetation theme is delineated into solitary vegetation and plant cover. The team demonstrates the extraction of existing trees from airborne light detection and ranging (LiDAR) data and classifying them into these two broad categories. This is then further cross referenced against an existing 2D database of managed trees. The classified tree locations and extracted information are then used to parametrically generate CityGML tree models based on allometric equations derived from measurements from mobile LiDAR data.

The methodology developed was tested on a 25km² site in Singapore. It demonstrates an efficient means to dealing with the representative modelling of 3D trees over large-scale city models and provides insights into dealing with both trees pre-identified within as well as outside of an existing georeferenced database. The findings also shed light onto the problems and limitations of modelling vegetation at these scales but provide a viable solution to populating large scale city models with representative 3D tree models.

Keywords: Virtual city models; CityGML; 3D Trees
1. Introduction

In the face of rapid urbanisation, smart technologies offer a possible solution to better comprehend the constant state of spatial-temporal flux in which cities undergo. One of these smart technologies involves the creation of a digital twin of the city in question [1] - an example of this is Virtual Singapore [2]. A massive virtual three dimensional (3D) representation of the city from which landscape architects, architects, planners, engineers and researchers can make advances in urban planning, data analytics and logistical operations such as the calculation of the solar-power generating potential of a city [3] or the planning of railway infrastructure projects [4].

The idea of a digital twin in order to replicate and run simulations of complex systems is not unique to the building of virtual cities [5] and the potential of having such a platform to perform a multitude of virtualised simulations is understandable. However, ambiguity around terminologies and use cases exists [6] along with differences in the process of generating these 3D city representations—all of which are interrelated dependent on the type and the needs of the model in question. Regardless of these differences, it is commonly understood that a 3D city model comprises of geometric (roads, buildings, trees, terrain) and non-geometric data (semantics, information) which are generated through 3D reconstruction and data integration through various methods such as photogrammetry, laser scanning which are then cross referenced with traditional 2D GIS databases [7]. This typically revolves around the generation of models of buildings, roads and other hard structures, but the use of 3D vegetation representations remains mostly unexplored—a common occurrence in the modelling of 3D cities [6].

Perhaps in no other city is the need to accurately represent virtual trees as pressing as it is in Singapore (Fig. 1) [8]. With over 50 years of foresight to continually green the island, Singapore now has more than an estimated 2 million trees which line our roads, shade our public spaces and provide shelter for animals in the nature reserves [9]—thus making them an essential component of our urban landscape both visually and biophysically. Urban trees and parks are known to be vital in making cities more livable by providing both a psychological as well as a physical relief from the otherwise urban landscape amongst other potential benefits [10]. Few other cities in the world have exemplified this idea as much as Singapore which positions itself as a “City in a Garden” [11,12]. Likewise, the digital twin of Singapore would also need to find ways to accurately represent the sheer number, density, variety and size of trees which differentiates us from other cities. However, this presents itself as a complex task to find efficient means to model all of them in this new 3D environment.

Fig. 1 – While building models are modeled and even textured, trees are missing from the city model.
In general, 3D tree models can be generated by either a non-procedural, interactive approach or a procedural approach. Some of the work using an interactive approach include image-based [13], light detection and ranging (LiDAR) based [14,15], graph-skeleton based [16,17] and sketch-based techniques [18–20]. An interactive approach which requires user’s input is inherently not scalable despite producing realistic tree models but a procedural approach which generates trees automatically based on a set of predefined rules makes it more suitable for the large scale modelling of trees.

The potential uses of these 3D tree models goes beyond generating realistic visualisations as more knowledge can be derived from our digitised landscapes than a mere visual understanding [21,22]. This includes the possibility to move beyond the visually perceivable environment to link with numerical models which simulate real world dynamics and create scientific visualisations and projections that act as a means to communicate and analyse complex relationships between the inhabitants and their environment [23].

Examples of such studies include microclimatic analysis can help to determine the species or layout of trees to reduce urban heat island effects [24,25]. Understanding the millennium old tradition of planting trees as a direct reaction to flooding [26] by leveraging off coupled simulations [27]. New directions in the design and planning of our parks, roadside greenery and nature areas can be derived to better understand their “Landscape Performance” - a measure of the efficiency with which landscape solutions fulfil their intended purposes and contribute towards sustainability [28]. Scientific rigor can be exercised by coupling models with simulations for more credible visualisations [29]. Documentation of existing trees to provide permanent 3D digital records can be subsequently monitored using change detection algorithms [30,31]. Animated or even virtual reality tours [32,33] of heritage roads, parks as well as conservation areas can be used as a means of communication, community outreach or as an educational tool to non-destructively understand our landscapes.

2. The Adoption of CityGML

As part of Singapore’s National 3D Standards effort to establish such a comprehensive 3D representation of the city, the CityGML 3D specification (version 2.0) was studied and used as a reference for the development. CityGML is an official OGC standard established since 2008 [34] and is seen as a cost-effective mean for a sustainable maintenance of 3D city models with well-defined themes and meaningful semantics being captured which would facilitate interoperability and offer a consistent digital representation of the city. It is made possible by its open data model and XML-based format for the storage and exchange of city model information.

The CityGML standard has defined nine city themes to classify various city features, of which vegetation is recognised as important enough of a feature in the city to be the focus of one of these themes. Within this, the theme is further classified into two types of vegetation classes - Solitary Vegetation Objects such as trees, and Plant Cover which represents vegetation areas such as forests (Fig. 2) [35].
Another interesting concept that CityGML introduced was the notion of Level-of-Details (LoD), where objects of each city theme could be expressed in up to five variations of complexity; LoD0 being the coarsest representation, and LoD4 being the most detailed and sophisticated representation (Fig. 3) [35].

At present, the Singapore CityGML standards for defining the LoD of solitary vegetation objects is still a work in progress but keeping aligned with the spirit of the existing LoD definitions, the generalised LoD solitary vegetation models follow a similar process of increasing in geometric complexity (Fig. 4). In this paper we deal only with LoD2 models which are geometrically simpler and thus more computationally acceptable to mass populate Virtual Singapore. While the model is less complex, the semantic information within the tree would still allow for rapid simulation and analysis purposes alongside the other simplified elements such as buildings and roads.

While each solitary vegetation object is modelled as a single entity, the modelling of plant cover requires a few more considerations as a result of the lack of data on the exact location and species of the multitude of trees within these natural areas. At the same time, it is important to work within computational budgets as 3D models with large polygon counts could affect the visualization performance and hence, the user experience. As such, several forms of representation are being tested using different techniques to evaluate their suitability and performance (Fig. 5). In this paper, we model plant cover as a group of

---

**Fig. 2** – Within CityGML, the vegetation theme is pre-defined into two types, solitary vegetation representing trees or palms and plant cover representing forests or grasslands.

**Fig. 3** – The levels of detail (LOD) defined by CityGML for buildings (source: IGG Uni Bonn)

**Fig. 4** – Our current delineation in the level of details for solitary vegetation stipulate that an LoD0 model is purely its 2D representation, LoD1 is an extrusion, LoD2 is represented by a trunk and its crown, while LoD3 consists of more detailed geometrical representation of the various components of a tree.

**Fig. 5** – Several methods of modelling plant cover are being explored from the use of voxels, digital surface model (DSM) meshes or individually modelled trees but semantically grouped as plant cover.
individually modelled trees derived from remote sensing and allometric relationships as described in the later sections.

3. Data Sources

The team relies on data obtained from two main governmental agencies, the National Parks Board (NParks) which provides botanical information and georeferenced tree data points as well as the Singapore Land Authority (SLA) which is the source for various spatial national level datasets listed below [36]. All data are georeferenced to the SVY21 Coordinate system with orthometric height based on SLA’s height datum. In this paper, the case study is a 25km$^2$ site centering on the Ang Mo Kio-Bishan Park in Singapore.

3.1. NParks Tree Database

The NParks tree database consists of over 500,000 georeferenced data points in 2D GIS format indicating the identity, coordinate, species, girth, height ranges and other attributes (a web interface to this database was recently made public [37]). One important point to note is that while the extensive database covers the entire Singapore, it is limited to trees which are actively managed by the board. As such in the process of the research, it became clear that just attempting to populate Virtual Singapore based on the NParks database alone would be insufficient (Fig. 6).

3.2. Flora Fauna Web

The Flora and Fauna Web [38] is another online resource made available by NParks which serves as a user-friendly portal to search for species level information on both plants and animals within Singapore. In particular, the paper extracted the “plant shape” attribute of the individual tree species where available in order to guide the eventual modelling process.

3.3. Airborne LiDAR & Imagery

Airborne LiDAR (ALS) data were collected in April 2014 using an Optech ALTM Pegasus with up to 4 range measurements, including 1$^{\text{st}}$, 2$^{\text{nd}}$, 3$^{\text{rd}}$, and last returns. The data were then processed and saved in a LAS format to a vertical and planimetric accuracy of $\pm0.15m$ or better with a minimum of 5 points/m$^2$ and pre-classified (Fig. 7). Airborne imagery was obtained using a Leica RCD30 with a 60 megapixel resolution which produced an eventual orthophoto mosaic imagery in TIFF format with a resolution of 10cm with a spatial accuracy of $\pm0.5m$ RMSE or better.
3.4. Mobile LiDAR

Mobile Airborne LiDAR (MLS) data were collected between Aug 2015 and June 2016 using a Riegl VMX-450 at approximately 40pts/m² at 70m range at a speed of 60km/hr with a measurement rate at minimum of 200,000 points/sec/head (Fig. 8).

3.5. CityGML Building Models

LoD1 building models were provided with a height error tolerance of ±0.5m and an absolute pointing accuracy of ±0.5m. While building footprints were extracted from LoD2 models and used in the data processing processes later.

4. Methodology – Data Preparation

4.1. Selecting Ten Representational Species

Out of the 1000+ species within the NParks database, ten species—representing approximately 34% of the trees in the database (Table 1)—were selected based on several factors including total population count, planting style or a representative species of a particular sub-type. For example, Archontophoenix alexandrae while not in the top ten in terms of population, was selected because it was the most widely planted solitary palm in the database.

Similarly, Syzygium myrtifolium was selected because it is usually planted as a continuous hedge and thus would allow us to explore a different planting style as opposed to the solitary planted tree.

4.2. Measurement Data Extraction from MLS

MLS data was extracted for roads whereby the selected species were planted along the center divider because they were scanned from both sides and would form a more complete data capture as compared to trees on the side of roads. Identified trees were manually extracted from the MLS scan using PointCloudScene (version 20180314) [39] and then digitally measured using CloudCompare (version 2.10.alpha) [40] (Fig. 9).

Fig. 9 – Trees were digitally measured using CloudCompare’s Cross Section tool

These measurements include, total height of tree, height of crown (from main bifurcation, if visible, to top of crown),
North-South and East-West measured trunk and crown diameters which were then averaged into a single parameter. In total 1451 trees were measured digitally (Table 2) - with the exception of *Syzygium myrtifolium* which had to be measured in the field due to the proximity in planting with adjacent trees (See Limitations). It should be noted that this process of extracting such parameters from MLS data is currently being automated by other members of the team.

### 4.3. Derivation of Allometric Equation

We derived two sets of allometric equations using the power law model \( Y = aX^b \), which \( X \) and \( Y \) are tree attributes of interest, while \( a \) and \( b \) are constants) to describe the statistical relationships between tree attributes [41,42]. One set predicts tree height, crown height, and average crown diameter using trunk girth as input for trees within the NParks database. These equations were fitted through the *nls* function of R package ‘stats’ (version 3.4.0) and were generated for each of the ten selected species (Table 3).

In addition, data from seven tree species were combined to derive a generalised allometric equation of tree attributes for Singapore’s urban trees. The three excluded species are *Acrhontophoenix alexandra, Syzygium myrtifolium* and *Samanea saman*.

Total 1451
The first two were excluded because their forms are not comparable to the rest of the urban trees. The former is a palm, and the latter is usually pruned or maintained as hedges. *Samanea saman* was excluded to improve model fit of the power law allometric equations, especially for relationships between trunk girth with tree height and crown height. Another set of generalised equation uses tree height to predict other attributes for trees extracted from ALS data (Table 4).

4.4. Extracting Trees from ALS

As previously explained, NParks tree database does not reference every single tree in Singapore. As such to locate trees outside of the board’s purview as well as those within natural areas, one possible method is the identification and extraction of vegetative material from ALS data [43]. In our paper, the pre-classified point cloud data was used to generate a canopy height model (CHM) of 0.5m resolution. However, the classification of the airborne LiDAR data exhibited errors which resulted in multiple points especially around building facades which were incorrectly classified (See Limitations) as well as vegetation points which were not classified correctly or gaps in the data resulting in pits in the data. As an intermediate solution, the LOD2 building footprints were buffered and used as a mask to remove errors along building facades, any points above 70m in height were removed (the tallest known tree in Singapore is reported to be 60m [44]) and pits were interpolated [45,46] in order to minimise errors (Fig. 10) during the detection process.

A tree detection algorithm was then applied to find individual trees of at least 5 m tall from the smoothed CHM by identifying local height maxima within a specific-sized fixed square window [47]. We used smoothing and tree-finding fixed square window size of 9 and 5 pixels respectively after a visual inspection of the output indicated a balance between not over-detecting multiple points in a single tree crown while not excluding the smaller-crowned trees. The algorithms were implemented through the *CHMsmoothing* and *FindTreesCHM* of the R package rLiDAR (version 0.1.1) [48]. It should be noted that the extraction methodology used is currently a temporary placeholder while other team members work on a better means of extraction.
4.5. Classifying Extracted Tree Points

From this initial extraction, a series of subtractions were made based by removing points which coincided with known trees within the NParks tree database as well as removing points manually which were found to be wrongly extracted (Fig. 11). This resulted in 2 sets of data, one of already referenced trees from the database, and another from unknown trees extracted purely from ALS data. These two are then further delineated into trees within the NParks database which fall within the 10 identified species and those that do not, as well as trees outside the NParks database which are then further classified as solitary vegetation and plant cover (Fig. 12).

In this case, the Point Density tool in ArcGIS (version 10.3.1) was used to generate a 5m resolution raster from which points falling within cells of >4000 trees within a 100m radius were classified as plant cover. The purpose of this classification is to enable the parametric modelling process to be based on the best available data of that particular identified tree.

5. Methodology – Modelling Process

5.1. Seven Shape Typologies

Instead of using the same 3D tree model to represent all the trees in the city, we then categorised all of the species in the database into 7 main shape typologies based on extractions from the FFW data. 6 of these shapes are then modelled using an extruded pentagon whose vertices are manipulated to give the impression of the respective shape typology while keeping the polygon count as low as possible (Fig. 13).

Fig. 11 – Extracted tree positions were cross referenced against those from the database as well as building and road outlines to produce a map of the remaining non-georeferenced trees.

Fig. 13 – 6 Shape Typologies were modelled based off an extruded pentagon. The palm in this case had to be modelled differently with fronds at the top of the extruded pentagon.

5.2. Parametric Modelling

The script to generate the parametric models was created using Rhinoceros and Grasshopper [49,50] (Fig. 14). The script takes in a comma separated file (CSV) and generates a 3D Wavefront OBJ file along with a respective material file. In instances where by the trees fall within the NParks database, information such as the identity, coordinates, girth, species and shape...
information were used as inputs and the model was parametrically generated based on the developed allometric equations. The identified ten species in particular were each allocated a unique equation which governs the form of these species based on their documented girths (Fig. 15). Other species were modelled using the generalized equation and adjusted for their respective shape typology.

Tree locations which fell outside of the known tree database were put through the same script, but in this case the generalised allometric equation was reversed and a model of a random shape was generated based on tree height as opposed to girth. These were then segregated into plant cover and solitary vegetation classes based on the density filter described above. Randomisation in the algorithms ensures that no two trees would ever look exactly identical to improve the visualisation quality.

The resultant models are visually seamless in that there is no visual distinction between the different classifications (Fig. 16) although semantically this would be identifiable once we embed the respective information into the models by converting them into the CityGML format.

Fig. 14 – The Grasshopper script extracts identity, species, coordinate and girth information and parametrically models the trees with an OBJ as the eventual output. This OBJ file is then combined with the original attributes to form a CityGML model.

Fig. 15 – The 10 identified species each have their own allometric equations which govern their form based on a given girth size. Greyed out models indicate girth sizes which are larger than the average.
CityGML is required to store semantic information which the OBJ format does not allow for. Hence, a conversion tool was developed to combine the generated OBJ models with the respective semantic information from the NParks. The conversion tool was written on Python (version 2.7), by extending libraries that had previously been developed but catered specifically for the vegetation theme. The eventual CityGML tree models will not only be geometrically representative but also be embedded with the semantic information (Fig. 17) allowing for the possibilities to include these models in city-scale analysis and simulations that require a semantically rich description.

**5.3. OBJ to CityGML Conversion**

CityGML is required to store semantic information which the OBJ format does not allow for. Hence, a conversion tool was developed to combine the generated OBJ models with the respective semantic information from the NParks. The conversion tool was written on Python (version 2.7), by extending libraries that had previously been developed but catered specifically for the vegetation theme. The eventual CityGML tree models will not only be geometrically representative but also be embedded with the semantic information (Fig. 17) allowing for the possibilities to include these models in city-scale analysis and simulations that require a semantically rich description.
rich 3D environment with models all of the essential elements of a city, including trees.

6. Limitations

6.1. Classification Errors in ALS Data

Classification errors and gaps in the scan lines from the ALS data result either in misidentified or overestimated tree positions. While some of these might be able to be corrected by reprocessing the data (Fig. 18) it is anticipated that manual corrections still need to be performed to single out anomalies within the extracted tree locations. Solutions to this issue is currently being explored by other members of the team who intend to use satellite imagery to supplement the extraction process.

![Fig. 18](image18.png)

Fig. 18 – It is possible to reclassify the data in an attempt to resolve some of the errors especially around building facades and roofs, however this does not completely eliminate the problem.

6.2. Data Alignment Issues

As expected, there are alignment issues between the different data sources. One of which is positional errors when comparing NParks tree database locations with those extracted from ALS. The likely cause of this error lies in the instrumental errors used in the geo-tagging of the trees during field operations. Again the team is working on ways to minimise these errors using MLS data to correct the roadside trees.

6.3. MLS Measurement Issues

While the initial intention of digitally measuring trees in the center divider was such that they would be scanned from both sides, problems arose when the scans were sometimes misaligned or noisy resulting in difficulties in deciding which scan line to take as reference. In addition, *Syzygium myrtifolium* had to be manually measured simply because the trees were planted too closely together making it impossible to measure them digitally (Fig. 19). This will likely be an issue moving ahead when we attempt to measure other species in similarly densely planted arrangements.

![Fig. 19](image19.png)

Fig. 19 – Scans from both sides of the road misaligned (left) while densely planted trees are impossible to differentiate between one another (right).

6.4. Only Ten Species Measured

Due to constraints of time, the project decided to focus on ten species only and models the rest using a generic allometric...
equation derived from data of these ten species. However, there are instances whereby this method fails, for example girths of *Ficus barteri* and *Ficus macrophylla* are recorded to be more than 10m. Using the generalised algorithms these result in trees with impossibly large crown (Fig. 20). While this is an exceptional case, the fact is that every species should have its own allometric equation in order to better model them. Likewise, trees within the forest are known to grow differently from their urban counterparts [51] which are particularly managed resulting in artificially governed growth rates.

6.5. Synthetic versus Actual DSM

Finally, as a test of how accurate the generated models are, we generated synthetic digital surface models (DSM) of the virtual landscape using *Point Cloud Components [52]* in an attempt to compare them to the DSM derived from ALS data (Fig. 21). From visual inspection, it can be noted that the virtual trees typically have a smaller crown size than their real life cousins resulting in a smaller overall canopy coverage. We hypothesise that this might be due to measurement of samples which were planted in the road center divider as opposed to those along the sides of the roads or in parks. Trees along the center divider tend to be more heavily pruned resulting in artificially smaller crowns. If this difference in pruning is significant enough, the parametrically generated tree models would likely exhibit a similarly reduced crown size. More work will be needed to decide how to resolve this issue.

Fig. 20 – Unusually large trees as a result of elevated girth measurements of certain species.

Fig. 21 – While generally similar, the crown sizes tend to be underestimated in the synthetic DSM (right) as opposed to the original extracted DSM from ALS data (left).
Smart Cities

7. Conclusion

The paper has demonstrated a methodology and developed tools with the potential to populate large scale city models with virtual trees. There are no doubt limitations but it is impossible to obtain accurate data on every single species let alone every single tree in any city in the world, Singapore included. As such the approach of using the best available data for the different categories of virtual trees allows for the modelling work to proceed while leaving an avenue for improvement should more species be measured or if improved data sources could be obtained from future remote data acquisition campaigns.

8. Future Work

The project team as a whole will continue to improve on methodology and tools developed from areas of data extraction all the way to eventual semantics and models. This includes improved identification of tree crowns from combining CHM and satellite imagery, correction of known tree coordinates, improving the current LoD2 models (Fig. 22), automated extraction of tree parameters, the building of a more advanced tree library and the development of LoD3 trees amongst other things in order to generate biologically, spatially and semantically representative 3D trees for Virtual Singapore at the various LoDs (Fig. 23).

Acknowledgments

The Time-oriented Impact of Sunlight Shading on Landscape Design Elements in Atrium Buildings
Chuang-Hung Lin, a* Chi-Hao Lu, a Shao-Wei Lu, a

aDepartment of Architecture, National United University, 1 Lienda, Miaoli, 36003, Taiwan

Abstract

Due to the difference in the shape of a building’s structure proportion, the layout for a common atrium building affects the scope of the sun’s shadow, sunshine duration all year round in the atrium space, and the design achievements of landscape elements from pavement and planting (trees, bushes, and grassland). Utilizing the atrium buildings at National Tsing Hua University as an example, this research discusses the effect of microclimate on landscape design element. First, simulate the position and height of the building structure. Second, numeric calculation software was applied to accumulate the scope of the sun’s shadow and sunshine duration all year round. According to the research findings, the RSH (relative sunshine hours, %) values of each measuring point, it is found that the minimal and maximal RSH values on equinoxes are respectively 0% and 75%, the minimal and maximal RSH (%) values on summer solstice are respectively 0% and 81%, and the minimal and maximal RSH (%) values on winter solstice are respectively 0% and 86%. When considering what kinds of shade plants should be chosen, the conditions for the “crown layer” to receive sunshine are considered by the EVSH (equivalent vertical sunshine hours) curve distribution profile of seasons. It is therefore suggested if apply a symmetric and geometric pattern landscape design to an atrium building and conduct an appropriate planting layout plan should after sun shadow analysis to meet the plant’s growth demand. So as to create an ecological multi-layered green environment where plants and people can achieve mutualism.

Keywords: building shadow; RSH (relative sunshine hours, %); EVSH (equivalent vertical sunshine hours) curve; planting design

1. Introduction

The lack of sufficient sun exposure slows the rate of photosynthesis and the production of chlorophyll in ground plants. Long-term deprivation of sufficient light exposure will result in unhealthy plants and unfavorable conditions for the differentiation of flower buds and the development of fruit that influence ornamental quality and the greening effect, but few studies have addressed the location and growth condition of trees subject to the shading effect from nearby buildings. The intensity and duration of sunlight varies significantly under different conditions, such as latitude, season, region, and even the geographic location. In response to the above characteristics of sunlight, plants control their internode length, leaf size, count, and the density of their chloroplasts. Plants also determine the optimum timing for flowering and other physiological processes (Levitt, 1980; Boardman, 1977) from those characteristics of sunlight.
By taking the open space enclosed by Buildings on the campus of Tsinghua University as the example (see Figure 1.), uses computer simulation technology to analyse the changes of sunshine shade of surrounding buildings in different seasons, in order to discuss the effect of microclimate on landscape design elements. This research uses RSH (%) value and profile EVSH distribution of seasons to consider the conditions of trees, shrubs, and grasslands at different heights receiving sunshine, which can help landscape designers to create abundant and various ecological environments through visual intuitive judgment.

2. Research Method

2.1. Definition of terms

1. RSH (%): RSH refers to the ratio of the sunshine hours of one measuring point being shaded by the building in the research scope and the duration of possible sunshine hours not being shaded by the building in the open space.

\[
\text{RSH} \left( \% \right) = \frac{\text{sunshine hours}}{\text{duration of possible sunshine}}
\]

The duration of possible sunshine for equinoxes, summer solstice, and winter solstice in Hsinchu, Taiwan (120°59"E, 24°47"N), which is used to respectively calculate RSH, as below:

(1) duration of possible sunshine for equinoxes = 12hr
(2) duration of possible sunshine for summer solstice = 13.6hr
(3) duration of possible sunshine for winter solstice = 10.5hr

2. The equivalent vertical sunshine hours (EVSH) curve: according to the definition of this research, EVSH refers to the curve drawn by gradually gaining the sunshine hours of the building at different heights, and then, connecting the points with the same RSH in order.

2.2. Research scope and subject

This research is conducted on the campus of Tsinghua University. The atrium in the east is defined by the Auditorium (2F) and General Building I (3F); the atrium in the west is enclosed by General Building II (8F) and General Building III (8F); the street trees are planted in rows between the 2 areas. The 5 green areas of A, B, C, D, and E are divided within the scope of the site (see Figure 2.) to calculate and compare the RSH of the plants and review the afforested areas to be used as the principle of the measuring points.

Figure 1. Site environment in the research scope
2.3. Simulation and analysis

1. Simulation shadow maps are overlapped to calculate SH (hr)
   First, software is used to make a 3D model of building volume, the time period is from sunrise to sunset, and the time interval is hours, in order to simulate the shadow maps of equinoxes, summer solstice, and winter solstice. Then, 13, 15, and 11 shadow maps for equinoxes, summer solstice, and winter solstice are generated, respectively. Finally, software is applied to overlap the shadow maps to calculate SH (hr).

2. RSH (%) is calculated and drawn in the plane graph
   Secondly, SH (hr) is simulated for each season, which is used to gain the RSH (%) and 5 numerical intervals of 0~20%, 20~40%, 40~60%, 60~80%, and 80~100%, which are used to draw the RSH distribution diagram.

3. EVSH (Equivalent Vertical Sunshine Duration Curve) curve was drawn in a profile map of the atrium
   The RSH at different heights is gained gradually, and the points with the same sunshine hours on the profile map are connected to draw EVSH for the convenience of judgment and analyzing the shading condition of plants in different seasons (spring, summer, autumn, and winter), as well as reviewing the suitability of plant (trees, shrubs, and grasslands) growth at different heights.
3. RSH (%) distribution in the whole area all year round

3.1. RSH (%) distribution of each area on the ground floor

1. Equinoxes: according to the RSH (%) distribution diagram for equinoxes in Figure 3, it can be known that building shading in Area B is the most serious, thus, the trees in this area may have the phenomenon of excessive growth, while the shrubs and grasslands may have the phenomenon of poor growth or withering; followed by Areas A, C and D; in Area E, the surrounding area is lower, thus, its RSH is relatively higher and the plants grow well.

2. Summer solstice: according to the RSH (%) distribution diagram for summer solstice in Figure 4, Area B remains the area where the RSH value is lower (0%~40%), the plants in Area A have the opportunity to gain appropriate sunshine, and some plants in Areas C and D are shaded by the building, thus, the plants planted in rows easily have the situation of uneven growth and poor growth. On the whole, the shading status in the area close to Area B is more serious than Areas A and E.

3. Winter solstice: according to the RSH (%) distribution diagram for winter solstice in Figure 5, the RSH value is seriously insufficient in Areas A and B (less than 20%), which is mainly caused by the northbound courtyard space enclosed by building 8F, thus, the plants in this area grow poorly. On the whole, more than 50% of the area throughout the whole area in winter has insufficient RSH (RSH is less than 40%).

As shown in the 3 RSH distribution diagrams, the RSH values in many blocks on the site do not experience progressive increases or decreases with the change of seasons due to the effect of the shade of high-rise buildings, meaning the RSH values in some areas are insufficient all year round. Thus, in terms of the growth status of plants in this area, the trees have the phenomenon of excessive growth, while the shrubs and grasslands have the phenomenon of poor growth or withering.
Figure 3. RSH (%) distribution diagram for equinoxes

Figure 4. RSH (%) distribution diagram for summer solstice
3.2. RSH (%) distribution of each measuring point on the ground floor

1. Area A: as shown in Table 1; the RSH (%) values of all the measuring points in the area during winter solstice are 0, and there is almost no direct sunshine reaching the ground floor. On equinoxes, in addition to measuring point A1 having the maximal RSH (42%), the RSH of other measuring points is 20~40%. On summer solstice, the RSH values of all the measuring points have average distribution in the interval of 40~60%.

2. Area B: as shown in Table 2; the RSH (%) values of all the measuring points on winter solstice is 0, and there is almost no direct sunshine. On equinoxes, the RSH (%) value of all measuring points is also 0. On summer solstice, in addition to measuring point B6, the RSH (%) values of other measuring points are 0~22%. On the whole, the shading of high-rise building causes a serious shortage of sunshine in the whole area, thus, the growth status of plants in this area is not ideal.

3. Area C: as shown in Table 3; the RSH (%) value on winter solstice is 38%~47%. On equinoxes, the RSH (%) values have significant change in luminous environment, ranging from the minimal RSH (25%) of measuring point C5 to the maximal RSH (75%) of measuring point C7. On summer solstice, there is also a significant change in RSH (%), ranging from minimal RSH (22%) of measuring point C6 to maximal RSH (85%) of measuring point C1. On the whole, there is a great gap in the luminous ...
environment of *Melaleuca leucadendra* “planted in rows” in the area. While the effect of luminous environment on winter solstice is even, there is a great difference in luminous environments on equinoxes and summer solstice in the whole area.

4. **Area D:** as shown in Table 4; the RSH (%) on winter solstice is 38%~86%, which shows significant difference in RSH. On equinoxes, the RSH (%) value has a significant change in luminous environment, ranging from the minimal RSH (25%) of measuring point D5 to the maximal RSH (75%) of measuring point D7. The RSH (%) on summer solstice is 37%~66%. On the whole, there is a great gap in the luminous environment of *Melaleuca leucadendra* “planted in rows” in the area; however, as its luminous environment is similar on summer solstice due to the layout, there is great difference in luminous environments on equinoxes and winter solstice.

5. **Area E:** as shown in Table 5; the RSH (%) values on winter solstice, equinoxes, and summer solstice are 47%, 50%, and 44%~59%, respectively. On the whole, as the surrounding buildings in this area are lower, its sunshine duration is even.

4. East-west profile EVSH distribution of the seasons

After the sunshine hours and RSH of each measuring point in each area are calculated, the transverse courtyard space between General Building I and General Building III in the research scope is used to draw the profile map to discuss the difference in RSH at different heights all year round, in order to gain the effect of the distance of the adjacent buildings on sunshine for plants; the sunshine distribution diagrams on equinoxes, summer solstice, and winter solstice are used to review the differences in the luminous environments of each measuring point, as well as the suitability of plant (trees, shrubs, and grasslands) growth at different heights. They are further analyzed, as below:

1. Equinoxes: as shown in Figure 6; the RSH values of the areas with a height of below 15m in Area A is 20~40%, and the RSH of some areas with a height of below 5m is 0~20%. As seen, the growth conditions for shrubs and grasslands is not ideal.

2. Summer solstice: as shown in Figure 7; the RSH value of some areas in Area A is 80~100%; however, the RSH of some areas with a height of below 20m remains at 0~40%.

3. Winter solstice: as shown in Figure 8; it can be seen from the profile map that the RSH value in Area A is relatively low, as it is affected by the shade of 8F buildings: the RSH value of the areas with a height of below 10m is 0~20%, and the RSH value of the areas with a height of below 20m is 20~40%, thus, it is detrimental to the growth of trees.

![Figure 6. RSH (%) distribution diagram of east-west profile on equinoxes](image)

![Figure 7. RSH (%) distribution diagram of east-west profile on summer solstice](image)
5. Conclusion and Suggestions

This research has reached the following conclusions:

5.1. There is great difference in RSH (%) values for the same tree variety in different measuring points all year round.

According to the RSH (%) value of each measuring point, it is found that the minimal and maximal RSH (%) values on equinoxes are respectively 0% and 75%, the minimal and maximal RSH (%) values on summer solstice are respectively 0% and 81%, and the minimal and maximal RSH (%) values on winter solstice are respectively 0% and 86%. Therefore, the luminous environments for the same tree variety are significantly different in this site.

5.2. People should consider suitable planting distances near adjacent building in the atrium.

There is a great difference in RSH (%) values in the measuring points of Terminaliamantalyi for Area A and Area B. Thus, the plants in these areas have the phenomena of the poor growth and “excessive growth”. When considering what kinds of shade plants should be chosen, the conditions for the “crown layer” to receive sunshine are considered by the EVSH distribution profile of seasons (equinoxes is less than 40%), meaning the RSH (%) values of trees that have a height of 15m and are within 15m from the adjacent 8F building.

5.3. People should consider plants suitable for luminous environments at different heights to realize the layout of multi-layer plants (trees, shrubs, and grasslands).

According to the greening index of a green building, the main aim is to realize multi-layer planting. The profile EVSH distribution of seasons is used to consider the conditions of trees, shrubs and grasslands, and their ability to receive sunshine at different heights, which can help landscape designers to create abundant and various ecological

Figure 8. RSH (%) distribution diagram of east-west profile on winter solstice
environments through visual intuitive judgment.

5.4. People should consider the differences in luminous environments in the atrium from different directions to lay out landscape design elements.

The shade distributions of atrium buildings from different directions are quite different. The symmetric or geometric design is obviously not suitable for living plants, thus, it is suggested to refer to sunshine conditions to design soft and hard pavement areas, in order to reduce maintenance and management costs. Moreover, the visual intuitive judgment of the EVSH distribution of seasons can briefly present which areas have the phenomena of being too hot in summer (RSH80% or above) or shading time is too long in winter (RSH 20% or below). This method can address plants in atrium buildings with insufficient sunshine, meaning their poor growth can be improved. In addition, the seating layout and people’s degree of comfort can be further reviewed, in order to provide a more comfortable environment for activities in the courtyard space and create a landscape environment where mutualism between humans and plants can be achieved.

Abstract

Growing trend of urbanisation imposes challenges on the foundation of sustainability in the urban landscape. As a monitoring or surveillance mechanism, integration of urban informatics or big data mining into functions of a smart city is an essential, predominant tool for successful continuous enforcement of sustainability. Since traditional manual and automatic monitoring mechanisms are respectively lethargic and accelerated capital cost is required, a smartphone app which extracts and analyses such information shared by the urban population as a participatory tool is proposed in this research. The app will be sanctioned for big data mining of unsustainable development, malpractices and inefficiencies, and monitoring Urban Heat Island effect (UHI). Survey research was conducted to understand the perception of urban population on the importance of sustainability and to understand their intention to participate in information sharing via smartphone application and social media. Majority of the Gen Y respondents were in favour of subscribing to smartphone application as a method for them to actively participate in smart city mechanism to further enforce sustainability in their environment.

Keywords: Urbanisation; Gen Y; Surveillance; Urban Heat Island; Urban Informatics; Big Data Mining; Social Media

1. Introduction

Since the dawn of industrial revolution in late nineteenth and early twentieth century, rural population of MEDCs (more economically developed countries) migrated to urban areas on a quest to secure occupation in industrialised service economies[1]. However, by early 1950’s trend of rural-to-urban migration was shifted to LEDCs (less economically developed countries) where rural population migrated to urban areas with the intention of occupation (80 percent of global GDP was generated in urban areas[2]), better quality of life and education. Although urbanisation in MEDCs has declined since mid-twentieth century, with rapid urbanisation and growth of economies in LEDCs (Asia and Africa), 30 percent of the urban population by 1950s is expected to increase at a rapid growth to 60 percent by 2050[3].

It is further evident from figure 1 (appendix 1) that between 1950 to 2014, twenty eight megacities have emerged with an overwhelming population of 10 million
concentrated in each confined urban landscape while the majority of urban developments around the world have a population concentration of 1-5 million. However, providing necessary facilities for increasing urban population including dwellings, transportation, educational institutes, recreational spaces etc. results in the inevitable egregious use of urban landscape.

Thus, to meet increasing demand for urban spaces due to the exponential growth of urban population, a rapid decline in sustainable development was often observed which resulted in dire environmental repercussions, especially in the case of LEDCs where policies on sustainable development were not enforced due to miscommunication and corruption\(^4\)[5]. To state few examples; (1) modern buildings constructed without adequate approvals in the capital city of Sri Lanka - Colombo collapsed resulting in property damage, and a number of fatalities\(^6\), and (2) a partially constructed apartment complex which had been already occupied without obtaining occupancy certificate collapsed resulting in over seventy-four fatalities\(^7\).

The current growth of cities is twice as fast as available urban land area against its population and is expected to reach three times the global urban land area by 2050 based on current urbanisation trends\(^8\)[9]. Consequently, a requirement of adequate attention for land and natural resources utilisation towards sustainable development and future is imperative, whereas deficient management of urban expansion would lead to unsustainable consumption patterns, pollution and environmental deterioration. Hence, complying with objective eleven of sustainable development goals presented by the United Nations, governments should enforce sustainable cities and communities by implementing forward-looking policies\(^10\).

1.1. Surveillance and Monitoring

Subsequently, for successful implementation of such policies to be enforced sustainable cities and communities should be monitored or surveilled to avoid malpractices in urban landscape management - especially in the context of LEDCs with high corruption rates and inefficiencies in communication channels between community and administration\(^11\). Concepts of “smart cities” and ‘e-government’ popularisation in the late 1990s were inevitable being backed by the exponential growth of information technology (IT) to increase efficiency in functions of a city, i.e. integrating operations and services of a city with the aid of computation while disseminating information of these functions to the community\(^12\). In addition, while addressing inefficiencies in communication, the concept of “urban informatics” or “big data” was introduced which concentrates on gathering real-time information while providing a detailed spatio-temporal record on implemented functions via ubiquitous computing or ambient intelligence. Such techniques are being embedded in built environments, targeting better productivity and efficiency by reducing the communication gap between community and government administration\(^13\)[14].

1.2. Urban Heat Island Effect

The rapid growth of urbanisation results in an apparent increase in demand for dwellings. In a majority of developing countries (LEDCs)
Growing demand for housing is furnished by slums (one-third of the urban population in LEDCs lives in slums or informal dwellings by 2012[15]) which is occupied by lower or poor income class demographic segment. However, rapid growth in the rural-to-urban migration of lower-middle class and middle-class demographic segment has resulted in an increasing demand for formal housing projects which is often furnished via towering apartments (flats)[16]. Although these apartments effectively utilise land extent of confined urban areas, environmentally unsustainable structures contribute to the Urban Heat Island (UHI) effect. As further illustrated in figure 2 (appendix 2), it is evident that temperature of urban area is greater than that of suburban or rural areas as a result of UHI which would result in increased urban energy demand on air conditioners in buildings[17]. Although UHI could be mitigated by green roofs, cool roofs and pavements, light exterior structures and facades, reflective light exterior paint with high albedo effect etc.[18][19], monitoring of UHI is essential before commissioning, and progressive structural changes after commissioning.

In contrast, “big data mining” or “machine learning” is an expensive operation. When considering surveillance and monitoring of ethical practices to enforce sustainable cities and communities, IT infrastructure including server or data farms, sophisticated algorithms and monitoring equipment such as thermal sensors, PPM meters, CCTV etc., imposes a tremendous aggregate cost factor with regard to implementation of such systems, metro or country wide[20][21]. In the case of monitoring UHI, most popular data collection methods are the utilisation of drones with thermal imaging, satellite thermal imaging and surveys with thermal cameras which also imposes a tremendous aggregate cost factor for continuous data collection[22][23]. In addition, cost of managing such systems including staffing, training, infrastructure etc. would additionally be a tremendous cost. Hence, attention by governments and urban government bodies on such monitoring systems or smart cities as a whole is not significant based on cost factor, especially in the case of LEDCs which is an underlying reason for unpopularity of smart nations concept. Thus, this research suggests that it is essential to develop cost-effective monitoring tools for collection of data on both surveillance and UHI monitoring.

1.3. Next tenants of urban areas

When establishing smart, sustainable cities, it is essential to understand the next social cohort who would dominate in future urban townships and how they would react to the concept of smart cities. Although the majority of current urban dwelling owners belong to Gen X or Baby Boomer cohorts, it is evident that Generation Y (Gen Y - a population that was born after the early 80s) social cohort have currently invested in the urban property market. Research reveals that nearly 70 percent of the Chinese Gen Y cohort have invested in properties while current global average stands at 40 percent. However, pertaining to future trends, global property ownership of Gen Y social cohort is expected to be at 83 percent within the next five years[24]. Urbanisation by Gen Y in most parts of the world is inevitable by means of rental, inheritance or living with their parents – European countries being the exception where it is expected to decline[25] in terms of investment in outright property ownership by Gen Y.

1.4. Gen Y and Sustainability
In contrast to expectations of Gen Y social cohort being negligent, slothful and self-centered, many studies portrayed that Gen Y are more concerned on sustainability than other social cohorts. Being born in the early 80s, when environmental movements have reached maximum potential, it is evident that Gen Y was inspired and ready to grasp future sustainable challenges especially in the case of environmental challenges and climate change. For example, when analysing purchasing behaviour of Gen Y, it is evident that majority are concerned about the impact on sustainability such as emissions, carbon footprint, water footprint, life cycle cost of the product, fair trade and ethical practices of producer, child labour etc. In addition to consumer behaviour, rapid growth in participation for volunteering activities including environmental sustainability programs is observed within the Gen Y community in comparison with other generations. Hence, Gen Y’s healthy relationship with sustainability and the environment would provide positive opportunities to create smart, sustainable cities.

1.5. Gen Y and Personality traits

Additionally, Gen Y’s enthusiasm on sustainability is further fuelled by their firm belief on making a difference in the world (being radical) and their steadfast dedication and collaborative effort to create such grassroot activism (differences), which is also a unique trait of this generation. Being tech-savvy than other generations is another trait that is unique to Gen Y and certainly another essential trait critical in the integration of urban informatics to smart cities. One crucial aspect of Gen Y driven by being tech savvy and being radical is the intention of sharing articles and photographs of charities, and other volunteering events on social network pages belonging to Gen Y individuals, which is an underutilised big data source especially in the case of LEDCs. However, in the Sri Lankan context, two such social network communities are initiated for traffic violations and consumer rights violations that function to raise awareness which instead would have otherwise been utilised for data mining in administration purposes by government and regulatory bodies. In addition, it was hypothesised that concern on anonymity by Gen Y when sharing information is negligible.

Thus, it is hypothesised in this research that as next generation of urbanisation, Gen Y, would positively contribute to the success of sustainable smart cities backed by their firm belief to make a difference in the world and being a tech-savvy generation which would result in the successful integration of urban informatics functions in smart cities.

1.6. Smartphone application

As an attempt to incorporate Gen Y’s eagerness for radical change and sharing sustainable beneficence, a smartphone application (here on out referred to as “the app”) is proposed to be developed under this research for data mining in smart cities. This simple-to-operate app which runs on both Android and iOS platforms resembles the appearance of modern social media smartphone apps such as Instagram or SnapChat. User accounts are created which requires ethical disclosure before registration that focuses explicitly on data mining purposes of the app while users are provided with a short video clip to be introduced to functions and objectives of data mining via this app. Upon registration and logging in, users can capture photographs (including selfies) and apply creative filters before
publishing to their social media accounts while the app accesses location data and thermal (infrared) sensors of the built-in camera which is stored in remote servers (cloud) for mapping purposes. Cloud computing is proposed over traditional server farms based on capital cost effectiveness and to eliminate hardware failures.

1.7. Surveillance and Monitoring

Surveillance and monitoring of inefficiency, and unethical and malpractices in smart cities are evaluated by users based on intuition. Situation ranging from an illegal construction to a clogged drain witnessed by users is reported by sharing a photograph of the incident to their social media pages while the app access location data and geotags the shared photograph. Collected information including location data and the complaint along with the photograph is mapped, and a notification is issued to relevant authorities to initiate prompt action. Interactive access is granted for competent authorities to view complaints and respond with required feedback on their assessment of the incident, action to be taken and marked as “resolved” at action completion. Further, the app enables a user to access his/her list of previous complaints and action taken by the relevant authorities whereas, in case of a delay or neglect causing problem persistence, the user is encouraged to share current situation which would generate further notifications to the relevant authority. Thus, inefficiencies in monitoring unsustainable development and operation in smart cities are expected to decline with information generated through the app and the active participation of urban population while efficiently mitigating the capital cost of traditional monitoring methods, especially in the case of LEDCs.

1.8. Thermal Imaging and UHI

In addition, the app utilises Gen Y’s growing trend of self-portraits, i.e. “selfies” to analyse and map thermal readings of the urban area. Gen Y is enabled to capture and share selfies with thermal (IR) filter on their social networking pages where the app utilises the thermal sensor of the secondary camera within the smartphone to capture the thermal image of the surrounding environment such as monuments, buildings etc. The captured thermal image is further analysed to understand the thermal reading of the surrounding environment and mapped based on the geotag of the image. A dynamic database is expected with an increase in usage as real-time dynamic thermal reading data of the urban area footprint is updated on the map with the date on a different period of the year, month and day. Such thermal reading of built environment including buildings and monuments is interpreted as heat island effect especially on the vertical axis of the building and collected data could be utilised by city planners and landscape architects to reduce UHI effect in the establishment of smart cities. Capital cost-effectiveness in collecting thermal data on built environment through the app would especially benefit governing bodies of LEDCs. However, secondary camera thermal sensor which is currently utilised for infrared facial recognition is available at the moment on a limited range of smartphones and is expected to be integrated into a majority of smartphones within a few years with the growth of facial recognition. Although external IR add-ons to the camera are available in the market, willingness to purchase by Gen Y is hypothesised as negative in this research.

2. Methodology

2.1. Sampling and Data Collection
The sample of this study consisted of 324 respondents in Gen Y social cohort i.e. who were born after 1980. An open online survey (with 21 questions) was designed to gather data. Sample encapsulates 89 percent from LEDCs and 11 percent from MEDCs. When consider demographics of the sample; (1) gender distribution between female and male is 38 percent and 62 percent respectively, (2) 58 percent of Gen Y are already living in urban areas, and (3) 67 percent of Gen Y are planning to migrate to urban areas over the next 5 years.

2.2. Measures

Since the objective of this research is to understand Gen Y’s intention to participate in urban informatics to successfully establish smart cities, respondents were inquired on their “intention to use the app to monitor the sustainability of their living environment”. In addition, secondary questions were inquired to understand; (1) users’ perception on importance of sustainability, (2) current local government monitoring satisfaction, (3) lodged complaints on environment issues and unsustainable development being neglected, (4) willingness to share information on social media platforms, (5) ethical consideration in sharing information, (6) anonymity in sharing information, (7) number of smartphone users with IR sensors, and (8) willingness to purchase additional IR equipment.

3. Results & Discussion

It was evident from this study that majority of respondents (89 percent) were aware of sustainability and importance of sustainability in the built environment and urban landscape for a better quality of life. However, it is also observed that only 43 percent of respondents were equipped with the required know-how to convert their lifestyles and living environment into a sustainable lifestyle. 98 percent of respondents were in the view that local administration and government are not efficiently monitoring the sustainability of urban landscape and also mentioned that construction activities and landfills for future developments are conducted without proper monitoring, and an efficient system of tracking such activities is essential especially in the case of LEDCs. Further, a total of 301 respondents (93 percent) strongly agreed that lodging complains about such instances are a slow and long process. If legal action is required, the processing time can be tedious which is a reason for them not to pursue the complaint, whereas, respondents who have made complaints are in the perception that their complaints are neglected by relevant authorities as taking action on such complaints are being delayed or neglected. However, with an introduction of the app, users are part and parcel of monitoring and surveillance system in the smart city, and they enable to react to malpractices and inefficiencies in real time while enhancing the efficiency of monitoring and surveillance mechanism and reducing time to lodge complaints. In addition, increased response rate on initiating action is expected by users ability to make reminders of the same issue to the administrative bodies.

All the respondents were actively participating in sharing information, selfies and photographs on social media platforms and they all were in favour of sharing information on malpractices and unsustainable development. However, many respondents (54 percent) reflected their concern on selfies as their identity is thoroughly exposed. Although, sharing selfies with a thermal filter which only
illustrates thermal readings but not facial features were responded favourably by 91 percent of the respondents. 86 percent respondents declared that ethical considerations related to data mining on sharing information on social media are flexible if information from the app is utilised for enforcement of smart, sustainable nations while increasing their quality of life but not utilised to data mine for commercial purposes especially in the case of thermal imaging. Many respondents from Gen Y (67 percent) felt that they are radical and adventurous hence, low concern on the anonymity of information they share via the app is observed. However, an option to select between being anonymous or fully disclosed on user profile information was suggested as a necessity.

99 percent of the respondents were users of smartphones. However, when inquired about IR sensing ability, only 3 percent were unaware of the availability of such facility in their smartphones, and only 1 percent of the respondents were using smartphones with infrared facial recognition. Pertaining to the hypothesis, willingness to purchase additional IR equipment was observed as negative (96 percent) based on additional capital cost and concern on the requirement to travel with additional apparatus for thermal imaging purposes.

In line with the hypothesis, 86 percent would subscribe when the respondents were inquired on intention to use the app as they understand the importance of implementing sustainable and smart cities while acting as responsible citizens who are part and parcel of urban informatics in the future urban environment.

4. Conclusion

With the exponential growth of urbanisation, active and effective utilisation of resources and urban landscape based is imminent for sustainable future. Hence, development of smart cities with its functions being integrated with urban informatics to increase efficiency and productivity of resources and urban landscape utilisation is an essential development goal. Monitoring of such sustainable development for unethical and malpractices is quintessential to strengthen sustainable development goals in smart cities further. However, high investment in capital cost for traditional surveillance systems to extract urban informatics, is the underlying reason behind only a few megacities have incorporated urban informatics to its functions. Especially in the case of emerging economies such as India, Sri Lanka, Bangladesh, etc., lack of monitoring and high corruption have led to catastrophic anthropogenic disasters.

Hence, a smartphone application is to be introduced for data mining of unethical and unsustainable urban developments and malpractices by enabling growing urban population to integrate into participatory research. Users would share photographs of such issues, and a report is generated by the database, and relevant authorities would be notified. In addition, a thermal image of photographs is analysed to evaluate and map urban heat island effect of the surroundings which city planners and landscape architects could utilise when enhancing sustainable features in the smart city. Majority of the respondents understand the importance of sustainable smart cities, and they are willing to contribute to monitoring driven by radicalism and heroism of the next generation urban tenants, Gen Y. Thus, the majority of
respondents were keen to subscribe to the app while illustrating participatory urban data mining a success.

The Application Of Information Technology In Contemporary Landscape Design

Qing Mei

College of Architecture and Urban Planning, Tongji University, Siping Road 1239, Shanghai, 200000, China, People’s Republic of

Abstract

Landscape design is a work to coordinate the relationship between human and nature. It is an art accumulated in the process of human life activities. It is the result of summarizing and refining ecological, psychological, technological and cultural aspects. Information technology refers to all kinds of technology combinations that collect, transmit, store, process and express the information. It can extend the information function of human beings, and is an extension of human’s function of perception. At present, computer network technology, expert system, artificial intelligence, multimedia technology and so on are applied to landscape design.

In the first place, more information is needed for contemporary landscape design. It must pay attention to the information that reflects the time dimension of landscape preference. Any design ideas are established in the context of the development of the times and society. Secondly, the development of multimedia technology provides new technical support for landscape construction. The corresponding design concept is gradually applied to lighting system, pixel system, waterscape system and so on. Thirdly, virtual reality technology has expanded more creative space for landscape designers, and has a new impact on the creation of design methods.

Therefore, it is necessary to intervene in the information technology in the landscape design under the new era. The paper focuses on the analysis of information technology under the background of landscape design and landscape design theory, expounds the influencing factors of the information technology of the landscape design, analyses the Chinese examples of landscape design intervened by information technology, and points out its positive significance and development trend in the future, in order to produce reference and help to the landscape design practice in the future.

This paper is subsidized by NSFC project (No. 51678412) which is named as <Research on Technical System of “Downtown Factory” Community-oriented Regeneration in Yangtze River Delta Region>.

Keywords: Information technology, Landscape design, Multimedia technology, Virtual reality technology
1. Introduction of information technology background

1.1. The development of the information age

As early as 18 years ago, Massachusetts Institute of Technology professor Negroponte wrote a book to describe the possible digital future. In the book the people see the innovative way of life, and it is full of network. "Computing is no longer related to computers, it determines our survival," Negroponte said. The best way to predict the future is to create it.

Digital information bring people into a immaterial, movable, and intelligent era of information age. In a word, our daily learning, work, recreation, entertainment and other ways of life are all in the information. The human society has also formally entered the information society.

1.2. The development status of information technology in China

Information technology is developed on the basis of computer, communication and control technology. After several years of unremitting efforts, the information technology has developed to database technology, artificial intelligence, expert system, remote sensing technology, geographic information system, global positioning system, computer aided decision system, automatic control technology, monitoring technology, multimedia technology, computer network technology and many other applications. These technologies have been widely spread to people all aspects of life. Information is the big trend of the development of the world today, and it is an important force to promote economic and social change. Our society and urban construction are increasingly inseparable from the support of information technology, and the landscape design is also deeply influenced by it.

1.3. The necessity of integrating information technology into landscape design

Modern information technology mainly contains many contents, multimedia technology, 3S technology, computer aided design software, remote collaborative design, landscape simulation technology. At this stage, landscape design and construction is an important project of city development, can beautify city environment, reduce the pollution of the city function. In its construction process, the effective integration of modern information technology, the landscape design can be set up in advance space layout, more intuitively in front of people. For example, in the application of GPS technology and GIS technology, not only can we collect extensive information about landscape design and construction, but also analyze all kinds of information in garden layout.

In a comprehensive view of the history of landscape development, the application of technology in the process of landscape creation has always been a concern of people. In an era of rapid development of information technology, the importance of this problem is particularly prominent. In the field of landscape design, information technology has been widely used as a means and tool. Therefore, our work theories and methods are inseparable from the support of information technology. However, we have not paid enough attention to the impact and change brought by information technology to
landscape design. Facing the coming of the information age in twenty-first Century, how to give full play to the advantages of information technology to create a unique and powerful service landscape system? we may need to summarize its impact on the status quo, and predict its future development.

2. Multimedia technology and landscape design

2.1 Features of multimedia technology

Media or media is the carrier of information representation and dissemination, such as daily people's use of text, graphics, images, animation, audio and video technology, video and audio. These media are also called single media.

Liu Zili made a more specific definition of multimedia: the digital technology media appearing after modern media, such as radio, film and television, is called multimedia. Including computer and microprocessor.

Therefore, "multimedia" refers to the technology of synthetically using words, graphics, images, sounds, animations, videos and hyperlinks of network to enable users to get information by interactive way. Multimedia technology is essentially a systematic integration based on a completely new concept and guided by existing technologies, such as audio-visual technology, computer technology and so on. It is the crystallization of the comprehensive development of modern science and technology. The rapid development of modern Internet technology provides an efficient and new platform and more rich content resources for multimedia technology. Human-computer communication is the biggest difference between multimedia and traditional media, such as TV and stereo. While the Internet is added, the interaction between man and man, and the content of the media can be expanded.

The multimedia based information transmission method is compared with the traditional way. It has unparalleled advantages, which is determined by its characteristics. People exchange information with the outside world, relied on visual, auditory, tactile, olfactory. Information processing in the brain is also in a variety of media and multimedia technology will fully stimulate and mobilize the synchronous operation of these senses, using the information transfer mode of the "bandwidth" to avoid the information loss. So it can enhance the effect of information propagation, and it is a kind of comprehensive accord with human understanding and use of information media.

2.2 Development of multimedia art

Art has always been closely related to landscape. One art can provide diversified ideas for landscape. Secondly, landscape designers can learn rich forms of design language from the form of visual expression. Modern multimedia art has the characteristics of different form of art, which inspires the expression and thought of landscape design. On the other hand, multimedia technology is directly becoming one of the elements of modern landscape. Multimedia art, or new media art, mainly refers to the creation of computer and circuit transmission. It is an exploratory and experimental noncommercial technology created by digitalized tools and means. Its most distinctive characteristics are interaction and connectivity. The most important point of the
multimedia digital art is that it is different from other art forms. It is necessary to use digital technology in all or part of the process of creation. It is a new art form, which is based on modern media technology and digital science and technology, and integrates human art with rational perceptual thinking.

2.3 Multimedia technology and lighting system

LED -- Light Emitting Diode (light-emitting diode) is a semiconductor solid light-emitting device. In addition to its many advantages, it has gradually developed into an important lighting system.

LED as a display LED display technology has now been more mature in the advertising of various commercial advertising. With the rapid development of economy, the business media platform has almost all the corners of the urban space. Regardless of size or indoor and outdoor, business information is always wrapped around people. The application of multimedia LED in the display of city landscape is divided into two types, one is in the landscape space and architectural interface, such as the public space of city square construction interface LED display; on the other hand, LED displays have become independent elements in landscape space.

Firstly, it is attached to the LED display in the space of the landscape architecture. Nowadays, the skin of building is diversified. The LED display is helpful for the information expression of architecture, and at the same time, it is integrated with surrounding environment and landscape, reflecting the function of place.

Secondly is the independent LED display in the landscape space. Crown Fountain, as a public art work and urban landscape sketch, is undoubtedly loved by many people, so it can be said to be a successful urban landscape. It is located in the Millennium Park Square in Chicago, United States, with the designer of the Spanish artist Jaumes Plensa.

The crown fountain is different from the classical fountain, because the crown fountain is a modern city landscape art pursuing the ever-changing lights and images. The fountain at the bottom is black granite reflecting pools. The curtain wall is currently the world's largest TV wall. The artist took 1000 Chicago residents face. Each facial expression can stay for 5 minutes at a time, from smile to grimace until the last lip looks like an interesting contemporary strange dripping mouth, and the water column will spout, resulting in the illusion of spitting water from the mouth. The LED multimedia device takes the most advanced technology to occupy the most original fountain in Chicago Millennium Park. It is a harmonious artistic works produced by water, art and multimedia LED technology. (Fig. 1.)

Fig. 1. The technical application of the Crown Fountain screen
2.4 Multimedia technology and pixel system

CCTV media park is located in an open space in the CBD in Beijing. It will be on the visual image. So how to use media to make public space more public is a meaningful topic. (Fig. 2.)

The designer lifted the main space of the media park to the sloping field, and the pavement on the sloping land continued to use the concept of pixel in the environment design of the whole CCTV group, with the concept of "pixel source" as the design concept, and intensified the original design from OMA.

With the theme of "multimedia", the huge slope surface is covered by the new pixel system after the size variation. The system is alternately formed by the natural cover in pixels and the embedded grass grid around the pixels. In the planting plan of green space, the "coded information" is used as the language to express different information with variable lattice. Each pixel is a replaceable planting unit. By planting different shrubs or flowers, the color of each pixel is changed in a planned way, which makes the whole picture change continuously. In the new pixel system, the material and color of each point can be changed. This huge slope has formed a huge background, forming the role of the theme.

Fig. 2. CCTV media park's pixel system

2.5 Multimedia technology and waterscape system

One is the music fountain. The music fountain, which combines light, water and music, is the core of its technology. The programmable central processor can synchronize all kinds of water type performances, lighting changes and music performances, control programming software and work in general operation platform environment, so as to update the performance content.

For example, Chongqing music fountain is 380 meters long and is the first dry fountain in China. The music fountain is designed into 5 parts, both in the long road to enjoy, can also be close to participate. Especially in the last chapter of music rhythm is very romantic. The fountain is mainly controlled by the computer. The form, the music and the color of the waterscape are unified controlled by the processor, and then achieve the perfect combination effect of water, music and light. The most important feature of the musical fountain is that any sprinkler can be called a dancer. Under the control of computer program, it can be flexibly changed according to the music rhythm. At present, most musical fountain in China cannot be done yet.
Water curtain film. The laser water curtain technology appeared in the 80s of this century, consisting of a laser system and a water curtain system. Laser system is mainly composed of laser beam and laser control system. Laser control system can change direction, color and pattern change of laser beam. (Fig. 3.)

In the water film sprinkled by the water curtain nozzle, the beam formed a beautiful and fantastic effect. The laser water curtain film has brought strong visual experience to people, equipped with thousands of waterscape, and let people's thoughts freely run. It adds a new scene to the urban nightscape.

3. Virtual reality technology and landscape design

3.1 The development of virtual reality technology

Experts and scholars in the United States in 1980s put forward the concept of virtual reality. Many international experts and scholars began to research and focus on the role and advantages of virtual reality technology since 1990s, with the pace of development of computer technology and software system.

The use of computer technology to deal with the virtual reality technology, and to promote the application of virtual reality technology is more convenient and real. Therefore, virtual reality technology will be used widely in landscape design, which greatly improves the efficiency and, in addition to ensure the quality of landscape design.

3.2 The advantages of virtual reality technology and landscape design

The integration of virtual reality technology into landscape design can reduce the cost and improve the efficiency of the program. In the actual landscape design, we should fully consider all aspects of the content, not only to realize the effect of the design structure, but also to coordinate and match the surrounding environment and landscape design. Once we confirm the final design plan and make a large-scale modification, it will increase the cost. If the virtual reality technology is adopted to let the owners experience the scheme more truly, then the large scope modification can be avoided and the cost can be reduced. Therefore, in landscape design, we should improve and perfect the design. The use of virtual reality technology is to make landscape design more scientific and feasible. The virtual reality technology have more obvious three-dimensional features.
Virtual reality technology can increase the interaction between designer and owner. The landscape designer can expand or modify the details of the design according to the specific nature of the plan, so that the design scheme is more reasonable, and after that, the final design scheme is formed. In addition, although the current virtual reality technology can guide the construction, it can be more comprehensive and perfect display drawings. (Fig. 4.)

Fig. 4. Virtual reality technology helps designers communicate with owners

3.3 The application mode of virtual reality technology

Show the pattern. Virtual reality technology can be used in 3D or 2D, reasonably reflect the contents of landscape. This process may be unable to express landscape information and values, therefore, will show every angle of landscape and spatial detail, and then make the landscape design more scientific.

Supplemental mode. By using virtual reality technology to landscape design, general designer should actively communicate with the drawing designer, when there is a problem in the design process, to facilitate the timely solution, prompt and efficient implementation of the landscape design, and meet the actual needs of the design drawings. It will be easy to find existing problems in the design drawings, timely adjustment, and it avoids the problems in construction, combined with the landscape design and construction to achieve the perfect.

The model of public participation. The landscape design process, but also the implementation of decision-making in practice, and let the public participate in the actual in landscape design. The construction of team cooperation and coordination is necessary so that in the landscape design process, designer should actively investigate and adopt constructive masses that prompted the landscape construction to meet the needs of landscape construction.

4. Conclusion

Technology is the basis for the realization of the material composition and spiritual structure of landscape. It is the driving force for the development of landscape. Many landscape is the expression of technological existence. With the development of society, the influence of information technology on society will increase day by day. As a human respect for nature and coordinate the relationship between man and nature, the landscape design will gradually change and improve with the development of information technology.

Technical change due to the emergence of information technology, such as multimedia technology, virtual reality technology and so on to provide a broader perspective, rich material and new ideas for contemporary landscape designers, and the application of new design method and tool will inspire
designers to create the novel form of the landscape.

Abstract

The advent of shared bicycles has changed the habits of Chinese citizens in traveling and has also affected the behavior of citizens in using parks. The characteristics of shared bicycle gathering in and around urban parks can reflect the situation of citizens using city parks to a certain extent. Therefore, by analyzing the location data of shared bicycles, the spatial characteristics of tourists using parks can be explored. Taking the GPS location data of Mobike bikes measured on November 2nd and 4th of 2017 as samples, through the establishment of rasterization data and index weight analysis, the law of public use of parks after the promotion of shared bicycles was discussed. The main conclusions are as follows: (1) The number of different types of bicycles sharing different scales and different sizes of urban parks is different; (2) The changes in the number of shared bicycles entering and exiting the park and the impact of shared bicycle detention parks on the environment and order are analyzed; 3) Knowing the parks used by the citizens and analyzing the attraction levels of different urban parks for riding behaviors; this research method can assist planners to better understand the behavior of tourists under the background of sharing bicycles, and has important theories and practical value.

Keywords: Shared Bicycle; Big Data; Park

1. Introduction

Sharing bicycles is a breakthrough model innovation for the urban slow-moving system. While solving the last kilometer of the city, it is also setting off a new wave of green travel. However, as a new thing, many problems have arisen in the actual operation. Park green areas have become the hardest-hit areas for the proliferation of shared bicycles. In the Ching Ming Holiday in 2017, on April 3, the passenger flow during the peak period of Shenzhen Bay Park reached 300,000 people. The number of shared bicycles entering the park reached more than 10,000, far exceeding the normal flow load of the park\cite{1}. Whether urban residents can use green land in a convenient and fair way and enjoy the service value of green land is an important indicator to measure the maturity of urban development, the level of modern development, and the harmonious

\textsuperscript{1} IFLA World Congress Singapore 2018
relationship between people and land. In other words, the fairness and social enjoyment of such resources. Equality is the necessary path and important principle for urban development.

Geographic Information System (GIS) is a commonly used technical method in the current macro-research of various disciplines, providing a convenient and effective way for the study of urban green space and public services.

Based on this, this study is based on shared bicycle positioning data, using a GIS data analysis platform, taking urban green land as the entry point and tourist behavior as the research content, conducting relevant research and analysis on the research area, and trying to reveal the current status of urban green space distribution in the study area. Reachability and propose planning.

2. Study area overview, data sources

2.1. Research area overview

According to the information released by the Guangzhou Municipal Department of Transportation, as of July 2017, the city’s internet leased bicycles exceeded 800,000 vehicles, ranking the second in the country in terms of travel activity. Mobike bicycle users are relatively stable in both quantity and usage habits[2]. Therefore, the use of Mobike cyclist data to study the parking problem of shared bicycles in Guangzhou has certain typicalness and representativeness.

2.2. Data Sources

The research data collection method of this paper is to divide the city center of Guangzhou into a 200*200m grid, and use the grid center as the collection point, using the Mobike APP positioning service on weekends and working days in one hour intervals within one day. Acquire 24 times of data to obtain bicycle ID, GPS location, bicycle type, and acquisition time. The urban parks and road traffic data in Guangzhou in this study were sourced from the OSM (OpenStreetMap) online geographic database. The population density data in the neighborhood was derived from Baidu POI residential data and OSM online geographic database synthesis.

3. Analytical method

3.1. Spatial Database Construction

The research used Excel, ArcGIS and its data analysis software package to clean up the original data and select a valid and valid subset of data. Using the multi-ring buffer and spatial link analysis tools of the ArcGIS analysis platform, the number of bicycles in the 200m area around the park and the number of bicycles inside, the road length, and the density of the road network were calculated, and the comprehensive analysis and calculation of the nature of the park's green space, green area, and other factors were performed. The cumulative attraction coefficient of 201 urban parkland[3]. After normalizing the data and inputting the urban green space distribution map of Guangzhou City in ArcGIS, the urban breaks of all the urban green areas in the study area are divided into 3 levels according to the natural breakpoint classification method. Finally, the image is output, and the shared bicycle and...
park are judged as a whole. Time and space relations.

3.2. Time database build

Bicycle travel is greatly influenced by the weather. In order to reduce the impact of weather conditions on the research results, the characteristics of the day-long cycling activities with a predominantly cloudy condition and good air conditions were studied. The specific date was November 2. According to different collection times, the time distribution curve of the number of riders in the park on the day was obtained.

4. Cyclists' space-time characteristics

The spatial characteristics of riding behavior

The gravity of 201 urban green spaces in Guangzhou City was calculated and divided into first-level green space, second-level green space, and third-level green space according to the way of natural grading. The gravitational level ranged from low to high and corresponded to the intervals respectively. The specific data and spatial distribution were detailed. See Figure 1.

From Figure 1, it can be seen that different grades of urban green space in Guangzhou City are distributed throughout the region. From the data point of view, the total area of green space in the study area is 16.49 square kilometers, among which the level of the third-level green land reaches 5.21 square kilometers at most, accounting for 31.59% of the total area; the five-level green space is the highest level of gravitation, and the green space accounts for the least Only 6.71% of the total area is 1.106 square kilometers. These green areas are divided into two types: one is a large area, well-known, convenient transportation, easy to pick up the car parking, can provide more public services for tourists riding, including Yuexiu Park and Guangzhou Sculpture Park, Liuhua Lake Park The other category is a specific service group, densely populated, with frequent use of shared bicycles.[4] Such as the campus green space of the South China University of Technology and the green space in the university city. In addition, through the calculation of the number of shared bicycles in the park, it was found that the park with the most dense cycling behavior was Binjiang Park, which reached 30.86 vehicles/km2, of which the south of the park reached 70 vehicles/km2. In the park, the most popular parks for tourists are Liuhuahu Park, Guangzhou Sculpture Park, Pazhou Ecological Park, Nanxun Garden, Tianhe Park, and some riverside ribbon parks. Most of these parks are along the river and along the lake lanes, and have a beautiful ecological environment and a wide field of vision. However, many tourists have also derived uncivilized behavior. Observing from the GIS positioning, some shared bicycles are located on the banks of the river and the bottom of the lake (see Figure 2).

From the map, the first and second grade urban green areas are roughly divided into two types: one is a large area but is affected by a single traffic structure, a low road density, or a park management method, which is not conducive to riding and has not been adequate. Urban green areas that embody the value of public services include Haizhu Lake Park, Liwan Lake Park, Xiaogang Park, Huangpu Park, and Yantao
Park. Others are large-scale urban afforestation buffers around streets or highways, such as Baiyun District overpass. Under the green land and the Haizhu Wetland, the population density of this type of green land is relatively low and it is far from the densely populated core areas of the road network. Therefore, both in terms of positioning and practical role, the value of public services provided to tourists is limited.

By using bicycle data combined with three-dimensional maps of Excel software and Baidu POI data, with the park 200 meters of multi-ring buffers as the calculation scope, and through spatial connections and importing three-dimensional maps, the distribution of park shared bicycles within the scope of the study is obtained as follows.

(see Figure 3) From the figure, it is found that the distribution of shared bicycles in urban parks in Guangzhou is basically represented by rivers, and the number of bicycles in northern parks is generally higher than that in the south. Liwan District, Yuexiu District, and Baiyun District Park have the most densely distributed bicycles, while Haizhu District has relatively scarce and scattered green space resources, and the number of shared bicycles is also low. The level of accessibility is limited by the overall level of resource constraints and there is a large area. The scattered greenbelts under the overpasses and greenery along the streets have not been effectively used. It is necessary to expand and transform urban greenbelts of a certain scale and construct slow-moving green corridors.

4.2. Time characteristics of riding behavior

(see Figure 4) In order to more accurately determine the peak demand of tourists riding, to determine the maximum amount of sharing of bicycles, the study selected the highest demand for riding on the 4th of November for full-time analysis. As a result, it was found that the aggression of the day’s cycling behavior was not obvious from 00:30 to 7:30, and the connection with the park was not prominent. From 8:30 to 15:30, tourists are active in cycling, and from 15:30 to 16:30, the number of bicycles in the park is drastically reduced. This may be due to the fact that tourists leave too many bicycles in the park in the morning. In order to keep the park open, park managers will clean up. 17:30 to 22:30 form the last wave of night-time cycling activities, which may be a leisure activity for nearby residents. The maximum peak usage of the park was 3512 vehicles/minute on that day, with the peak of the early morning peak at about 11:30 and the peak of the late peak at around 17:30. At 15:30, the number of bicycles dropped sharply within a short period of time. Therefore, this time period is the heaviest time period for park cycling.

5. Conclusion

Through international comparison[5]. It was found that the parks in Chinese cities are large in scale and small in total number, and their spatial distribution is sparse. Such a function point requires people to pay more space to move to meet various needs, easily causing population and traffic aggregation in a short period of time, and increasing the amount of traffic., resulting in the phenomenon of shared bicycle explosions.
There is a serious shortage of per capita transportation space in Chinese cities, and sharing of bicycles to a certain extent exacerbates the originally intense urban traffic space.

The influx of shared bicycles creates problems for park management. Currently, most of the parks deal with this issue by prohibiting the sharing of bicycles, parking most bicycles at the main entrances and exits, and spending a lot of time and manpower on the park. Carry out clean-up, but allowed the battery car and tour bus that signed a cooperation agreement with the park to charge in the park. Many tourists complained and complained, and many tourists still ride the shared bicycle to enter the park secretly, causing serious conflicts. The explanation behind this shows that the lack of time and space in the current park planning and even infrastructure planning does not take into consideration the differences in use requirements and the lack of applicability to the planning of shared bicycle facilities.

Based on the above analysis, it can be found that cycling bicycle users in the park have different time and space characteristics. The planning of its parking facilities needs to reflect the humanistic care of urban planning.

There have been studies that have proposed a humanistic planning model based on space-time behaviors.[6], Stressing the adoption of data acquisition and analysis, focusing on living space planning, life time planning and resident behavior planning, understanding individual urban space behaviors, understanding urban issues from daily life, understanding residents’ needs from behavior analysis, and then identifying planning and construction. The key points are the sharing of parking spot planning, parking capacity planning and parking capacity management, optimizing the layout of parking facilities, and improving the efficiency and management efficiency of sharing bicycles.

For park planning, we should scientifically analyze the attractiveness of cycling and regular entrances and exits to determine the capacity of parking facilities. In combination with the user's riding habits, we can optimize the greenway route and set up a clear signage system. We should be able to use more on holidays. The intensive layout of parking methods forms a supply system that combines fixed-point centralized parking and scattered scattered parking to realize the balance between supply and demand in the diversion and park.

Abstract

Studies and projects dealing with environmentally efficient technologies for the management of rainwater flows already have a significant technical and experimental base, mainly in North American, European and Asian countries. In general, this technical production results in manuals, booklets, guidelines and technical information to make Best Management Practices (BMPs) which are additional and efficient technologies in urban contexts where water has become an environmental and socioeconomic problem due to climate change which affect the population year after year everywhere in the world.

Still in the international context, the insertion of the BMPs techniques assumed a retrofit position for the problems of urban drainage. With the additional function of the existing drainage systems, they allow the mitigation of the diffuse pollution caused by the superficial flows that bring with the polluting precipitations that follow the course of the drainage until they are launched in the natural water resources.

In Brazil, the absolute drainage system is predominant in most cities, as recommended by NBR9684/08. However, there is no oversight legislation for diffuse pollution and there are no legal parameters of permeability rate for road production.

Considering that the processes of production of urban and architectural projects have acquired an increasingly efficient technological support, through platforms that make the production and evaluation of efficiency parameters more flexible and accessible, this article aims to incorporate the advent of technology and information as a tool for mapping and identification of the urban built environment that present structural problems of rainwater drainage infrastructure, proposing to revert these problems through the installation of BMPs.

Thus, the development of a technological tool for the application of smart landscape infrastructure requires a change in mentality, of political support and in social education. The strategic purpose of the platform is to be adaptable to variations in inputs and outputs, given the mutability of cities and climate change. This platform induces the understanding of landscape design as an infrastructure that supports engineering techniques and the concepts of the natural sciences to develop technological and ecological solutions for cities in the production of socially fair, culturally rich and ecologically restorative urban spaces for all.

Keywords: Best Management Practices; Diffuse Pollution; Smart Landscape; Technology Modeling.
1. Introduction

The vulnerability of cities and communities around the world, to hydrological phenomena such as floods, means that the approach to storm water management in urban space is anchored in the proposal of mitigating strategies and adding to the current standardized drainage systems aiming to develop more resilient, smart and sustainable cities.

With a broad conceptual and scientific basis, the Best Management Practices (BMP) techniques are proposed as additional instruments of landscape architecture that through their organic composition matrices become efficient in capturing, retaining and managing urban rainwater. Therefore, decision-making in the implementation of this technology is still going through a slow and laborious process, except in countries of North America, Europe and Asia that have already made it more effective as an instrument of planning and management.

In Brazil, these technologies require, at first, a change of projectile mentality and that research and experiments developed be tested as solutions to cities in a more forceful way. Besides that, it is necessary that the political sector of management and territorial legislation promote behavior change, regarding the policies that govern the production of the urban space in order to combat the socio-environmental damages caused by the climatic changes that affect their communities.

As mentioned above, internationally, BMPs have strong productions in the form of manuals and technical guides. Among them, we have the Low Impact Development - LID\(^1\) (2010) by the University of Arkansas and Maryland Department of the Environment Stormwater Management Manual by the City of Portland\(^2\) (2016), which are a reference for defining the physical composition of organic matrices and their efficiency as a drainage infrastructure for urban stormwater.

BMPs as additional infrastructures and mitigation of urban storm water management in an attempt to make cities less vulnerable to climate change were also addressed by [1], [2].

Recently, water and sanitation, which are goals of the 2030 Agenda by ONU\(^3\), have resumed the discussion of the urgent need to reassess the issues of urban stormwater management.

This paper begins by addressing the BMPs as infrastructure of landscape architecture and urban retrofit. It then discusses how pollution has affected natural resources (e.g. the city of Fortaleza - Brazil). In order to evaluate in an exploratory way the possibilities of mitigation building an urban environment that present problems of structural and drainage infrastructure through the mapping of the site evaluating the installation of BMPs to mitigate the problems of flooding.

After establishing the place of intervention, algorithms that combine historical data with soil use patterns (e.g. occupation rate, soil waterproofing) and seasonal events as inputs of the technological tool for mapping flood points in urban space will be used.

2. Best Management Practices as a retrofit tool to urban drainage system.

Floodplains have been the most recurrent hydrological phenomena of the twentieth century [1]. With large-scale global urbanization, morphological transformations (e.g. occupation of protected areas, road construction, and urban infrastructure) eventually breaking in through the natural ecosystem cycles.

Historically, the chaotic production of urban spaces has treated urban drainage as an "accessory" to the urban land parceling [3], where much of this modern production happened by neglecting the biophysical bases and the natural processes of the landscape [4].

The increase of urban impermeable areas resulted in the reduction of the natural storage capacity of the flow [3]. With the increase of water volume accumulated in the soil, drainage systems were developed full of contradictions whose functions were the rapid capture of these waters to discharge it.

In this practice, it was the population and the ecosystem that faced the environmental costs of this urbanization [4], since with the increase of the downstream flow peak, floods became recurrent and affected especially the communities residing in lower levels near rivers and other water resources [3].

The movement to foster a new approach to compensatory urbanism in order to mitigate the environmental damages promoted in the construction of roads, dwellings and industrial areas, in an attempt to re-establish the quality of the environment [5], has become an emergency since when cities began to have countless socio-environmental damages resulting from climate change.

In order to break this questionable form of urban drainage production, the term "sustainability", which, despite being anachronistic, has been used to achieve new concepts aimed at stability through effective management and control [6], or less in predicting drainage infrastructure failure Fig.01.
For the development of sustainable cities, it is necessary that the approach to the production of the drainage infrastructure establishes resilient and compensatory measures that are proactive and that reduce and prevent flooding, as well as becoming an effective tool to reduce socio-environmental impacts [1].

Although urban drainage infrastructure proposals to promote resilient spaces are sometimes questioned, urban resilience becomes necessary [1].

Increasing the hydraulic efficiency of traditional drainage systems, adding to the already existing modular and adaptable systems that develop an interconnected green infrastructure through an adaptive three-dimensional design [1], makes possible to obtain a multifunctional drainage infrastructure, resilient and smart [3].

One of the challenges of contemporary urbanism is urban drainage, emphasizing that it is approach must be comprehensive and systemic, taking advantage of the architecture of smart and multifunctional landscape in the recovery of cities and the urban environment. However, it is necessary to understand the natural environment, built environment and urban infrastructure, so that new strategies are taken in favor of urban sustainability [7].

2.1. Urban Drainage and Community

The pollution of water, soil or air occurs through anthropic actions [8]. Urban environmental degradation is easily related to the production of urban sanitation infrastructure (e.g. combined system or absolute separator system).

Both systems present specific and structural limitations for effluent management (e.g. sewage treatment, or since they are developed as a monofunctional mechanism for the conduction and disposal of effluents, making them vulnerable to failures where they do not meet the demand for precipitation volume from climate change, or sanitary sewage from urban territorial densities.

In rural areas, the pollutants originate from the application of fertilizers and pesticides in plantations that through the infiltration into the soil ends up being transferred to the water resources [10].

Regardless of the scenario, urban or rural, the approach to the way the production of drainage requires attention since the pollution of water resources on a global
scale becomes something beyond an environmental issue, health problem and human economy [13].

The control of diffuse pollution requires management and implementation of control measures [11] so that socioeconomic and environmental factors stand out for the interests of land use in production for economic purposes only [12].

In Brazil, the problems of contamination of water resources caused by diffuse pollution are recurrent, due to the fact that this type of pollution load is not yet recognized by Brazilian legislation, nor is there any regulation and rate of permeability indexes for the production of roads, streets and sidewalks.

The predominance of the separate sewer system in Brazilian cities, as recommended by NBR9684/08, presents advantages and disadvantages4.

This type of system works as two systems, one for sanitary sewage management and another for stormwater management. Underpinned by the "hygienically safe" concept of drainage systems in cities, this concept needs reassessment. In Brazil, the sanitation infrastructure serves 82.8%5 of the population.

---

600,000.00\(^6\) linked to hospitalization expenses due to diarrhea, which is a disease related to potable water and urban sanitation.

Located in a semi-arid region, there is a rainy seasonality, where 90% of annual rainfall occurs in the first half of the year (DEHA-UFC)\(^7\).

After this period, the pollutant load deposited on the surface of its territory during the dry period of the year is directly dumped into the drainage pipes of the rainwater, without any treatment, a condition that is further aggravated by the clandestine connections that throughout its discharge sewage, eventually generating an effluent laden with polluting loads Fig.3.

2.2. Best Management Practices’s Implementation

The implementation of compensatory techniques as a way to mitigate urban spaces encompasses issues of environmental, social and political development.

The BMP model and it is dimensioning must correspond to the local criteria, since each urban context has it is own geomorphological characteristics and has it is evaluative criteria regarding the degree of toxicity of the effluents and environmental legislation [8].

In the implementation plan of the BMP matrices, the structural knowledge regarding the flow of the existing urban drainage network by evaluating the quality, the flow and the characteristics of the site, as well as its routes and the integrity of the internal drainage of the systems to their point of discharge⁹ is necessary.

In the densely populated urban context, the parameters that will make up the feed inputs come from the type of paving, the built density (e.g. buildings), the physical space and the surface drainage where it is flows will be verified in clean or paved soil.

The implementation of the smart landscape can be incorporated in the buildings, streets, sidewalks and open spaces with the objective of dividing the rainwater management function, delaying the failure of the traditional drainage system and treatment of surface water previously discarded in the water resource Fig. 4.

Fig. 4. Plan and implementation of retrofit of urban drainage network of urban rainwater.

With systemic planning it is possible to delay the saturation moment of the macro holing system [3], and for this matter, the strategy is to develop a preventive and corrective planning in the micro drainage

---

system in order to integrate it, composing a green infrastructure.

Taking into account that the BMP matrix has adaptable characteristics, which can be implemented before, during or after the production of the urban space, it is sizing and application typology are evaluated to reduce or minimize the environmental or structural problems of the site.

Nowadays, the processes of production of urban and architectural projects have acquired increasingly efficient technological support, where, through software, the evaluations of efficiency parameters have become smarter. The modeling of BMPs rainwater matrices aims to incorporate the advent of information technology as a tool providing technical composition information.

Through the transformation of the geomorphological, pluviometry, structural and territorial occupation data, algorithms for the digital platform allow real conditions for smart urban intervention.

3. Landscape Modeling data

The immediacy of anthropic actions on the environment, practiced, in many moments irrationally, aim at economic results in favor of socio-environmental values.

However, reversing the negative impacts of urbanization requires integration between science, technology and society.

The methodologies and strategies adopted in the production of cities should understand the conditions and characteristics of microdrainage and macrodrainage as a single and intrinsically connected system.

Smart cities are looking for ways to improve technology to facilitate the understanding of the city as a unique organism. In order to do so, point-to-point flooding inputs should be evaluated comprehensively to assess their cause Fig. 5 and 6.
In mapping the coverage radius, the platform identifies the conditions of the rated flood point and monitors the on-site BMP application conditions. For this, algorithms that combine historical data with land use patterns and seasonal events are used.

Inserting all radiuses of coverage’s inputs corresponding to the flood point on the platform generates fundamental structural information to promote the development of the intelligent landscape modeling network. From this data we evaluate how many BMPs are needed to supply the flow demand at that point. In addition to enabling the virtual positioning and sizing of each matrix in real time, allowing it to adopt storage strategies of composition of the green infrastructure.

The advantage of the intervention study with a broader scope is that in situations where it is not possible to intervene at the site, the platform evaluates the physical and geomorphological conditions covered by the radius of coverage, punctuating strategic and possible points for the matrices to be implanted, producing, a sustainable rainwater management network to reduce flooding at the critical point Fig. 7.

Supported through a landscape modeling technology tool that uses BMP arrays in the production of low impact infrastructure, the path to more smart and resilient urban space production becomes possible.

Another fundamental aspect of this tool to be highlighted is it’s adaptability of inputs. The strategic point is the conception of a tool that allows the updated variation of the inputs and output, being flexible to the data coming from the climatic variations besides accompanying the physical and structural transformations of the city and the urban natural environment.

Fig. 7. Modeling landscape process.

Based on the data resulting from the spatial and parametric evaluation of the site, the process of compatibilizing the BMPs (e.g. bioswales, rain gardens) to be implemented as a network of green infrastructure begins, assuming the technological function of the landscape in the mitigation and retrofit of the urban space.

In order to calculate the capacity of capture, retention and release of the effluents in the digital matrices, the possible volume to be stored at the storage substrate level will be counted. The size of the layers will be defined by the flow volume Fig.8.

- Variable Layer a: composed with hydraulic macadam or gravel nº 4 and 5. In this layer will be held the greater capacity of reservation.

- Variable Layer b: composed of simple graded gravel (BGS), which, because of its granulometry of stones of different strips, performs a reserve in addition to damping the effluent. In this layer will be performed the area complementing the necessary reservation capacity.

- Planting Substrate: This layer is not included for the reservation calculation. This assumption was based on the variability of the landscape design possibilities that are due to the climatic, spatial and social conditions of the site of implantation Fig 9.

4. Conclusion

The fundamental aspect for the transformation of a city into a sustainable city is the adoption of smart infrastructure in it is planning and management. However, it is necessary to change the mentality in all sectors that make up the urban organism, providing better living conditions for the citizen.

In Brazil, it is necessary to regulate urban water issues. Investment for sanitation exists, however, does not reach all parts of the population or all territorial expansion. In Fortaleza, public health problems are highlighted and can be even higher, because it is a coastal city, the contact of the
population is significant since it is part of the public leisure infrastructure. Therefore, the action by the public power to reestablish the adequate conditions of sanitation to the city and the community becomes an emergency.

Smart landscape architecture has a relevant function in mitigating urban problems, which through it is technology, facilitate and improve the urban landscape risk conditions of extreme natural events due to climate change. Nevertheless, it is application must be supported by innovative technology solutions to promote a more sustainable future for the city and communities.

Computational tools for stormwater management are currently restricted to specific site data, whether at the city, state, or country level (e.g., the National Stormwater Calculator). The rupture of this territorialism concept is an emergency, since the problems arising from natural phenomena are global, whereas, the excesses of one place, causes degradation in others on any scale.

Evidence Synthesis as an Urban Informatics Tool in Identifying Peri-urban Landscape Typologies at Cavite, Philippines

Cathe Desiree S. Nadal*

*University of Edinburgh, United Kingdom

Abstract

Peri-urbanisation has altered the present cultural and ecological environment in the desakota region of Cavite, Philippines. This process influences the tangible and intangible values attached to the region’s biocultural landscapes. Regardless of its physical and ecological impacts, the process needs evaluation in the case of its rapid effect in landscape production and alteration.

At present, a challenge for urban scholars is to provide a data structure to pieces of evidence that imply the effects of peri-urbanisation to Cavite’s landscapes. Being able to address this challenge can create provisions for planning and decision making at this rural–urban fringe. As a method of inquiry to develop the baseline for managing landscape influences of the peri-urban process, the researcher searched for critical findings done to explore the relationship of peri-urbanisation and the landscapes of Cavite, Philippines.

The research inquiry used a structured examination of pieces of evidence developed through a quick scoping review. This approach extracted information that shows spatial and ecological impacts of peri-urbanisation in the form of land cover representations. The composition of results was multifold and took off from studies from various fields – economy, agriculture, geography, anthropology, etc. Through the quick scoping review, the researcher hoped to create a baseline data gathering approach that can enrich Philippines' peri-urban data informatics.

The initial approach for the evidence scoping was the development of the text string protocol to collate pieces of evidence at selected electronic reference databases. It is used to choose relevant studies starting with the selection of geographically relevant references. To further screen the reference list, inclusion and exclusion criteria were added to create a reference list for analysis. This list was filtered and was used to answer the question, how does peri-urbanisation affect the biocultural landscapes at the outskirt regions of Philippine megacities? The result of the quick scoping review showed implications of peri-urbanisation as it identified possible landscape typologies found in Cavite. The resulting findings and analysis from the collation and screening process are relevant in creating a baseline for future
evidence assessment needed to identify the role of the landscape in peri-urban placemaking at the outskirts of Philippine megacities.

*Keywords:* cultural landscapes, peri-urbanisation, urban-informatics, evidence synthesis, quick scoping reviews

1. Background

The Philippines is highly-urbanised based on its population density. Singru and Lindfield (2014) support this notion by making a morphological analysis of the urban and rural population from 1980 to 2010. From the 37.2% population living in cities during the 1980’s, they saw the increase of 48.9% during 2010 as a vital baseline of the rapid effect of urbanisation in population growth. Getting access to urban cores brings more people closer to highly-urbanised cities and to an extent, affects its outskirt regions as well. In the same report, they emphasised this effect to the outskirts by showing the rapid population growth rate of 3.86% to one of Metro Manila’s most adjacent rural-urban region (RUR) of Cavite.

Peri-urbanisation happening in the RUR of Cavite alters the landscape character of Cavite’s upland, lowland, and coastal towns. The process restructures Cavite’s agricultural “hacienda” landscapes and the Spanish-organized plans of the “pueblos”. It also changes the geographically and ecologically significant habitats of the native flora and fauna. It is also essential for the highly-valued visual resources and as an origin of the indigenous customs, beliefs, and practices established by the different settlements that migrate towards the adjacent archipelagic core of Manila ².

Notwithstanding the alterations to the cultural and natural environment, peri-urbanisation also introduces variations to the landscape creating Roe and Taylor’s (2014) emerging cultural landscape patterns of the everyday.

The landscape patterns resulting from the peri-urban process in Cavite is arbitrarily written in academic publications as outcome of scientific research projects from other fields of study. These patterns can be pieces of evidence that supply spatial information needed to understand the peri-urban landscape phenomena in Cavite, yet has not been thoroughly investigated in landscape architecture research. This gap in landscape pattern data is consequently looked at as a critical aspect for further research inquiry.

A lack of peri-urban landscape overview at Cavite, Philippines calls for a fact-finding tool that can generate policy and management approaches for the sustainable future of its landscapes. For this type of research inquiry, snowballing literature reviews is typical, but is argued to create unstructured results that gather different references and lowers evidence gathering efficiency. Case study analysis is also ideal for fact-finding but can also be considered to form more evidence bias on the chosen case study results and can exclude some evidence that the researcher may or may not intentionally eliminate. In mapping evidences, the tool should minimize bias and should be structured ⁴ to increase the
confidence to its result. As a possible fact-finding tool, the evidence synthesis (ES) approach through the quick scoping review is applied to test its capability to retrieve and combine scientific information about peri-urban landscapes. In this paper, we follow the ES Approach as a peri-urban informatics tool for extracting and combining scientific information on topics related to the peri-urban landscape of Cavite.

2. Goals and Objectives

This study aims to collate peri-urban landscape information through evidence synthesis. This systematic evidence gathering technique is adapted from the NERC Quick Scoping Review approach where documentation of references becomes the source of meta-analysis. The following are the evidence gathering objectives:

- Interrogate methodologies and studies done to explore the ecological and cultural relationship of peri-urbanisation to the landscapes of Cavite, Philippines
- Create a structured list that maps pieces of evidence. This systematic map can form the general understanding/awareness of the peri-urban landscape character at the rural-urban fringe of Cavite, Philippines
- Extract contextual information that states the central issues leading to the changing landscape character of Cavite
- Create a landscape typology list based on the qualitative statements gathered from the final reference screening process

3. Methodology

The systematic search of academic literature started with the identification of vital elements used to structure the question. These elements are structured by applying the PICO Framework which contains the Population, Intervention, Comparison, and Outcome text strings that can be used to create the search strategy. These four elements were generated to define the literature search for the query, “What landscape typologies exist as pieces of evidence resulting to the altered ecological and cultural landscape valuation at the rural-urban region of Cavite, Philippines?”. Although serving as a guide, the PICO framework may not capture all the relevant database that contains pieces of evidence to support the query but is hypothesised as a useful tool in minimising biases and raising confidence in the literature list generated by the search string protocol.

Table. 1. PICO Framework used to arrange the Query Protocol
Boolean text operators combined the search term matches found to generate screening of literature searches from the PICO framework. These text operators helped in producing a list of literature from the electronic reference database, Google Scholar, last February 5, 2018. With the Boolean text operators, the text string protocol with the search syntax below was generated:

(Philippine* AND Cavite) AND effects AND landscape AND environment “peri-urban”

Because there is a limitation to human resources that are vital in reviewing the precision of the search string, the initial evaluation of search string protocol was presented in an Evidence Synthesis Workshop held in London last February 28, 2018. In this workshop, experts from the Centre for Ecology and Hydrology of the Natural Environment Research Council and other postgraduate participants identified nuances of the search whereby improvements of the search string went in order. In the workshop, a one-to-one consultation was also held to improve the search syntax and additional guidance on the procedure. Thus, a new search was rendered last March 8, 2018:

“(Philippine* AND Cavite) AND (landscape* OR environment* OR ecolog*) AND (quality* OR value*) AND (periurban* OR peri urban* OR peri-urbanisation OR peri-urbanization)”

Added in the search string is the geographic location criteria, “Philippines and Cavite”, to generate location-specific references.

From the 104-paper resulting from the search, four were initially removed for null content.
Inclusion criteria also include resource types that are considered good quality sources most of which are published journals, published PhD thesis and printed books. After setting the inclusion criteria, exclusion criteria were also generated. The exclusion criteria used were:

1. No data on the current landscape situation of Cavite,
2. No pieces of evidence that show the present peri-urban landscape character of Cavite,
3. No content that can be accessed and read for analysis,
4. Not in the English Language,
5. Unpublished work,
6. Duplicate copies of published work, and are
7. Quoted evidence from other published work; not primary evidence in the text.

83 literature were removed for further analysis leaving 17 relevant papers for review.

An assumption of the evidence review includes the confidence in the online database algorithm that can generate a well-selected reference list. Adding some research not selected during this search (i.e. published books that are not available online and other published journals not obtained by the search string protocol) is suggested in future searches for evidence enrichment.

From the 17 relevant papers that passed the screening criteria, an extraction database resulted in an information list of the landscape typologies discussed in the reviewed literature.

Each land cover column cannot be counted in duplicates per paper assessed, i.e. residential character evidence on one article, regardless of duplication and repetiton within the text, shall be counted as one in the tally chart. Therefore, the maximum number of results per category shall only be 17 which is the total number of final papers assessed.

After tallying the number of statements stating different land cover, the next step included the modelling of textual results into possible drivers, landscape forms, and landscape descriptions. The results are listed to be able to reclassify the types within the identified 11 land cover types. This approach enriches the list with a more comprehensive report of emerging landscape typologies.

4. Results and Data Analysis

11 major land cover types as guided by the Philippines’ landcover categorisation \(^7\) infers a representation of the 11 categories in peri-urban Cavite based from the 17 texts reviewed. The land cover
classification used in identifying land typologies were: Residential, Commercial, Protected Areas, Agricultural Areas, Infrastructure/Utilities, Industrial/Economic Zones, Idle Land, Transport Hubs, Institutional, and Uncategorized.

The landscape character based on 17 reviewed texts imply present attachment of migrating population to Cavite as a residential/settlement location. The driver of actors towards Cavite shifted the land cover from being highly agricultural\(^2\),\(^8\)–\(^12\). It also connects it to its present highly residential character dominated by new towns, gated subdivisions, and resettlement housing developments\(^8\)–\(^11\),\(^13\)–\(^16\).

Another highly relevant implication of the references reviewed is the attachment of Cavite to its industrial land-use by the appearance of business process outsourcing developments, export and manufacturing oriented economic zones. Being the second highly cited land cover character implies the close attachment of Cavite’s placeness to this type of industry. This type of land cover offers not just a driver of change to large plots of lands that were idle or once considered agricultural but also affect the periphery as it attracts services needed by the population working in the industries. As an effect, availability of food, shelter, and transport connectors are also being built within or near its vicinity.

Entirely a revelation was to see that Cavite is still closely related to its agricultural character as it ranked third in the number of evidence generated. Despite the desperate attempt to connect Cavite to its new market of migrants that live in settlement location within the region, some of the authors still closely associate Cavite to its “hacienda” plantation roots.

After gathering the 11 land cover classification from the Coding Extraction Table (See Table 2.0), some of the texts were then reclassified to create a more detailed Peri-urban Landscape Typologies. The researcher started with the results of the residential land cover types. The results were categorised according to two characteristic patterns: patterns of land management and patterns of spatial forms. The following were peri-urban landscape typologies coded from the residential text categorization:

<table>
<thead>
<tr>
<th>CODE</th>
<th>PERI-URBAN LANDSCAPE TYPOLOGY / CLASSIFICATION</th>
</tr>
</thead>
<tbody>

<td>Non-Government Organisation – initiated Resettlement Village Landscapes</td>
</tr>
<tr>
<td>P004</td>
<td>Necklace / Corridor-driven Landscapes of the Dispersed</td>
</tr>
</tbody>
</table>
The industrial texts were coded to reveal a possible landscape classification that is economic zone oriented and IT park oriented. With the labour character, quite distinct in these two development types, landscapes are also hypothesised to adapt to the needs of two types of employee and investor market.

Other landscape typologies reveal the following:

(1) Landscapes of the agriculture and aquaculture plantations;
(2) Landscapes of the old markets, massive commercial developments and the smallest “sari-sari” convenience stores;
(3) Landscapes that are driven by landform-dominated natural habitats;
(4) Amenity landscapes of the sports-initiated golf developments and leisure parks;
(5) transport-driven landscapes of various corridor types;
(6) landscapes of new and old town institutional nuclei; and the
(7) enveloped areas and the idle lands.

A total of 29 land typologies were initially considered by the researcher to move forward to mapping the peri-urban landscape phenomena happening in Cavite, Philippines.

5. Evidence Summary and Conclusion

Albeit the limited references demonstrating a more direct analysis of the changing landscape in Cavite, pieces of evidence from the field of geography, agriculture, economics, and urban studies indicate its effect. In the references scoped, the peri-urban landscape is contextualised in landcover types and not precisely according to its functions and uses as space and place. It may reveal the physical, tangible patterns, but lack a more intangible value characterisation as the attempt to ascribe meaning to the landscapes is not the primary goal of the kinds of literature reviewed. It, therefore, revealed an effort to ascribe attributions on what authors see rather than in what the stakeholders reflect upon or attribute to their landscape.

Relevant studies can be added to the reference scoped to support the landscape character codes generated. There is a gap in written publication seeing the landscape as a possible mirror of the effects of peri-urbanisation in the cultural and ecological environment. To answer the differences, more books that were not included in the online search and perhaps, a new Boolean operator may be used for a series of query to identify other possible unique references.

There is also difficulty in attributing landscape type per category as cooperation and further discussion with stakeholders and other tools to identify the landscape types can improve the typology list and improve the evidence base on this topic. A cross-examination and dialogues to enhance the search strings can, therefore, be done again to funnel more findings to support the coding approach.

Overall, Evidence synthesis can be a tool to generate answers to queries related to the landscape, but should be further supported by other landscape mapping tools and interventions to generate less bias and create a more grounded, well-evidenced result.

Abstract

Unwanted sound or noise can very much damage one’s psychological health like [1] hypertension, high stress levels, tinnitus, hearing loss, sleep disturbances and other harmful effects. Specifically, it can also pose physiological changes to wildlife like increased heart rate, body shifting and wastage of stored energy, panic and escape behavior, avoidance of habitat and unattractiveness to mate. From all of these, the need to study and preserve natural soundscape comes into play. Natural soundscape, as concluded by many scientific studies can provide a good escape from noise pollution in the metro, thus, preservation and conservation of natural soundscape as a biophilic approach in designing and planning urban designs tapped new urban informatics and methodological analysis beneficial for the modern age metropolitan.

[2] One of the perspectives of the evaluation of ecological significance focuses on the conservation of the biological diversity, an exemplary innovations is the use of acoustic recordings to monitor spatial-temporal wildlife activities. The chosen study site was plotted in a map using the triangulation network. A total of thirty sites were selected to conduct the bioacoustics recordings. Collection of acoustic samples lasted for 16 weeks. This interval allows the researcher to keep track of the bioacoustics produced by the presence of wildlife. The microphone selected had the capacity to capture the acoustic frequency range from 20 to 14,000 Hz which covers most songs and calls in the study area. The recordings were converted into digital formats for the quantification and analysis of the soundscape. After the researcher analyzed the forty wetland areas, the landscape assessment scaling index was determined by comparing the computed Simpson’s index and frequency and sound dynamics of the different areas. This landscape index are arranged using ten colors, red being the lowest soundscape level and white having the highest soundscape level. These colors correspond a particular Simpson’s Index value which can be used to assess a particular habitat area. Soundscape maps
corresponding each 16-week soundscape recording were then plotted to test the efficacy of the proposed health assessment index.

This study takes a scientific and mathematical approach in measuring landscape health using the researcher’s specifically-designed Landscape Health Assessment Index. It is strongly believed that through the strategic investigation of soundscape ecology, thorough exploration of ecological characteristics of sounds and their spatial-temporal patterns as they emerge from landscape can share considerable parallels of effects and changes within the landscape ecology. This study further investigates these changes and soundscape ecologies that may be beneficial to help study, assess, record and analyse landscape status and conditions that can be utilized as an important factor in creating, conserving, preserving, designing and managing ecologically significant areas. The focus of finding a new landscape measuring tool allows this research to come up with indices that can be applied to various ecological typologies and situations, thus, this new methodological approach of landscape mapping can be very beneficial in designing biophilic smart cities.

**Keywords:** Soundscape Mapping; Soundscape Preservation; Natural Soundscape; Ecological Services; Landscape Health Assessment Tool

1. Determining Standard Soundscape Level

To compare the efficiency of the proposed landscape standards for natural soundscape level, the researcher determined the benchmark that served as guideline for landscape health assessment. The target site was chosen through the investigation and selection of a healthy wetland and measured the soundscape present within that site. [3]

The traditional normal counting system was used first to assess the health of chosen wetland sites within the Cavite province and computed for its biodiversity using Simpson’s Diversity Index. The comparison include forty wetland areas and divided into two groups to come up with a strong claim and comparative soundscape levels. The results were then interpreted and compared to determine the average soundscape level produced from a healthy wetland. This numeric standard will be used as a guideline to assess the thirty selected sample study area and produced the soundscape map to help analyze the condition, problems, needs and probable solutions to the anthropogenic noise present within the adjacencies of the site.

The following steps were meticulously conducted by the researcher to determine the standard soundscape measure / level a particular healthy wetland can produce.

![Fig 1. To determine the standard soundscape level of a healthy wetland environment, forty wetland environments were located and compared. This step allows the researcher to assess and compare results in various factors and analyze these results](image-url)
to derive the target landscape health assessment index.

Fig 2. Locate the healthiest wetland environment by examining the present tree species and compute for biodiversity using Simpson’s Diversity Index. This step provided the researcher the knowledge about the certain acoustic level or sound dynamics a particular wetland can produce. By locating the healthiest wetland, the researcher determined the standard and maximum acoustic level that can be produced.

Fig 3. The soundscape level were recorded from the samples of different wetland environment to determine the degree of loudness and or softness (pertains to sound dynamics) of biophony a particular wetland can produce. The study of different wetlands with different health status allowed the researcher to compare and analyze clearly the existing and varying sound dynamics among these wetland environments and determined the related intervening factors.

Fig 4. The standard soundscape level produced by the healthiest wetland environment was recorded and used the numeric output as a basis of a natural soundscape produced by a healthy wetland.

Fig 5. The two healthiest wetland environment were compared in terms of their soundscape levels in order to verify the determined standard acoustic level after the investigation and comparative analysis.
2. Instruments Used:

This research study was conducted at Brgy. Marulas and Tabon II, Kawit Cavite and a degraded wetland with adjacent underutilized parcels of lands were chosen as the target site for this investigation. The site was plotted in a map using triangulation network. This mapping system was used since the site is large in scale and is normally used for surveying big areas.

A total of thirty (30) sites were selected to conduct the bioacoustics recordings. Most of the target areas of the site were a collection of underdeveloped parcels of lands and wetland edges with small number of woodland areas and riparian areas. The middle of wetland areas and adjacencies like commercial, residential and institutional establishments were also surveyed and recorded.

Acoustic samples were collected during Saturdays and Sundays from the 29th of August until 18th of October, 2016. This interval allows the researcher to keep track of the bioacoustics produced by the presence of wildlife. The chosen weekend dates were strategically investigated and carefully examined without severe weather conditions to minimize the background noise of the sounds produced by the environment. At each 30 areas within the site, an acoustic recording was deployed. The recording technology used was powered by Omnidirectional boundary microphone (Model 330-3020, RadioShack Co.). [3] The microphone selected had the capacity to capture the acoustic frequency range from 20 to 14,000 Hz which covers most songs and calls in the study area. Each acoustic unit was set to record 3-min duration, three times in the morning during 5:00, 6:00 and 7:00 am, and another three times during the evening, 5:00, 6:00 and 7:00.

[4] The recordings were converted into digital formats for the quantification and analysis of the soundscape. Since the maximum frequency range of the microphone was 14 kHz, it was necessary to digitize the sound samples at a sampling rate to avoid aliasing. Each recording was divided into six 30-s sound clips. The first 2 clips and the last one were removed and only the 3 middle clips were analyzed. This was done to minimize interference due to mechanical sounds and other hindrances.

Fig 10. The product of triangulation network of the selected 30 sample study areas.

3. Statistical Tool Used

[5] The researcher used the formula Simpson’s Diversity Index to determine the healthiest wetland environment among the ten wetlands sample found at Cavite Province. Through the use of this formula, the wetland with the healthiest assessment in terms of biodiversity was set as the standard wetland and its soundscape level was recorded and compared to other healthy wetland environment from the two studied groups.

[6] Since the Simpson’s formula is widely used for measuring habitat diversity, it is also a good measure to determine the healthiest wetland from the sample by taking into account the present species and the
abundance of each species. Furthermore, Simpson’s Index ($D$) measures the probability that two individuals randomly selected from a sample will belong to the same species (or some category other than species). There are two versions of the formula for calculating $D$, either is acceptable but consistency should also be considered. The value of this index ranges from 0-1 which indicates that the greater the value computed, the greater the diversity present.

4. Presentation of Results from the Gathered and Computed Biodiversity Index of the Forty Wetland Areas

The forty wetland areas were located and studied by the researcher in order to determine the standard soundscape level a particular wetland habitat can produce. These chosen forty wetland areas were compared using their biodiversity characteristics via Simpson’s Diversity Index, Simpson’s Index of Diversity and Simpson’s Reciprocal Index. Here is the presentation of the gathered results from the landscape biodiversity assessment using the traditional counting system method.

See Table 1. Biodiversity of the Forty Wetland Areas using Simpson’s Index

Table 1 shows the computed Simpson’s Index using three indices: Simpson’s Index, Simpson’s Diversity Index and Simpson’s Reciprocal Index. Each index has different analysis and interpretation. For the Simpson’s Index, the lower the value computed, the more diverse the environment. For the Simpson’s Diversity Index and Simpson’s Reciprocal Index, the higher the value, the habitat is considered as more diverse.

Results showed that habitats from swamps area had the lowest Simpson’s Index with 0.06 index followed by another swamp area with 0.01 index. The third and fourth most diverse habitat was comprised with marshland areas with index of 0.12 and open water with 0.15. On the other hand, the wetland areas like riverside had the lowest index of 0.35 and for the shallow water, an index of 0.23. The interpretation for Simpson’s Diversity Index and Simpson’s Reciprocal Index also indicated the same results with swamps areas as the most diverse habitat followed by wetland areas and open water respectively. Areas at the riverside and adjacent to open water ranked last, respectively.

According to the survey and inventory conducted among the 40 wetland areas, the swamps also had the highest number of recorded trees with a total of 37 trees species, followed by marshlands with 34 recorded trees species and 29 trees species were tallied from all the open water areas. Riverside areas had 13 trees species present at the site while the shallow water had 10 total recorded trees species.
5. Presentation of Results from the Gathered Soundscape of Forty Wetland Areas

See Table 2. Results of the Recorded Soundscape of the Forty Wetland Areas

After the soundscape of the forty wetland areas were recorded, the analysis of each significant sound materials were converted to digital format and analyzed using Spectrum Lab, a sound analyzer and visualizer software. As shown from the table, swamp areas garnered the highest soundscape level with frequency of 2500-4000 Hz and soundscape dynamics of 58-64 db and a total of 68 soundscape recorded activity. It was followed by marsh areas with frequency at 2500-3500 Hz, sound dynamics of 48-52 db and a total of 63 soundscape activities. Marshlands were followed again by open water areas with the highest frequency of 2000-2500 Hz and sound dynamics of 46-50 Hz and a total of 55 recorded activities. The riverside ranked next with a frequency of 1500-200 Hz, 29-33 db and 53 recorded aural activities. Lastly, the shallow water areas with a frequency of 1500-2000 Hz, 15-23 db and 36 tallied aural activities.

After the researcher analysed the forty wetland areas, the landscape assessment scaling index was determined by comparing the computed Simpson’s index and frequency and sound dynamics of the different areas. This landscape index are arranged using ten colours, red being the lowest soundscape level and white having the highest soundscape level. These colours correspond a particular Simpson’s Index value which can be used to assess a particular habitat area. For instance, a particular wetland area produced a 31-35 db of soundscape dynamics, its colour pink (Scale 5) has a particular correspondence which tells something about the area’s health. Through the recordings of these soundscape present in particular site, landscape healthy assessment can now be conducted in a much faster and more efficient way.

Figure 12 shows that the colour scheme of the proposed landscape index has a corresponding value of the Simpson’s Index of Diversity. Remember that as the value gets higher, the more diverse the habitat is, thus, the healthier the ecosystem can be.
This proposed landscape health index were applied to the target site. Using the 30 sample study area with varying typologies and wetland environment, the researcher determined the status of the landscape health and determined which areas have high soundscape level to integrate in the final design.

Figure 14. Application of landscape health index to the 30 sample study area. Second recordings.

Figure 15. Application of landscape health index to the 30 sample study area. Third recordings.

6. Application of the Proposed Landscape Health Assessment Index to Landscape Design and Spatial Planning

One of the cores of the study is to find easier and more efficient way of assessing landscape health through the use of present nature sounds. After studying forty wetland areas and deriving the proposed landscape health assessment index, the researcher was able to determine on how to possibly apply the index to multiple disciplines, especially in landscape and spatial planning.
Figure 16. Application of the proposed landscape assessment index. Determination of areas with good soundscape activity.

Figure 17. Application of the proposed landscape assessment index. Determination of areas with moderate soundscape activity.

Figure 18. Application of the proposed landscape assessment index. Determination of areas that need to improve vegetation of native tree species.

Figure 19. Application of the proposed landscape assessment index. Determination of areas that need overall habitat improvement and re-vegetation.

Figures 16-19 shows how the proposed landscape health assessment index was applied in the chosen target site.

Figure 16 discusses how to areas with good soundscape activity can be utilized into actual landscape spaces. Using the index, a sample landscape plan was specifically designed to listen and maximize the surrounding soundscape potential of the vicinity of the area. Figure 17 shows which area has moderate soundscape activity that can suggest how designs should focus on preserving and improving the site’s soundscape potential. Figure 18 on the other hand, shows which areas require immediate improvement of vegetation and introduction of more native tree species while Figure 20 suggests which areas need overall habitat improvement and re-vegetation.

See Figure 22. Sieve Analysis Designed to Determine Natural Soundscape Potentials and its Preservation and Conservation Measures

7. Conclusion

This research study mainly focused on the preservation of natural of soundscape using landscape architecture standards and landscape design. After a series of compilation of case studies, online researches, bioacoustics recordings and finalization of site development plan, the researcher concluded that the preservation of the natural soundscape can be summarized into three parts namely soundscape management through vegetative studies, integration of mimetic biophony and reduction of noise stress levels through landscape elements and design.

This study takes a scientific and mathematical approach in measuring landscape health using the researcher’s specifically-designed Landscape Health Assessment Index. It is strongly believed that through the strategic investigation of soundscape ecology, thorough exploration of ecological characteristics of sounds and their spatial-temporal patterns as they emerge from landscape can share considerable parallels of effects and changes within the landscape ecology. This study further investigates these changes and soundscape ecologies that may be beneficial to help study, assess, record and analyze landscape status and conditions that can be utilized as an important factor in creating, conserving, preserving, designing and managing ecologically significant areas. The focus of finding a new landscape measuring tool allows this research to come up with indices that can be applied to various ecological typologies and situations, thus, this new methodological approach of landscape mapping can be very beneficial in designing biophilic smart cities.

With the use of the Proposed Landscape Assessment Index, the researcher was able to come up with multiple design strategies and spatial planning standards that will not only be beneficial in both preserving and conserving natural soundscape but also to design a soundscape park that helps users on how to train their ears with the natural soundscape present around them. The immense benefits of soundscape to human have been a subject to several studies, and although this research does not necessarily focus on that, the researcher highly believed that the Index can provide multi-disciplinary actions not only in the field of landscape architecture and urban planning but also to health and nutrition, policy making, environmental ethics and law, ornithological and bioacoustics studies and many more.
8. Recommendations

In order to further improve this research study on soundscape preservation, the researcher recommended the following:

1. Provide more related literature focusing on the reduction of noise stress levels using both architecture and landscape architecture designs in order to design a multitude noise reduction strategy and scheme.
2. Conduct an in-depth analysis and research on the effects of amplification of biophony to different wildlife species.
3. Discover other good sources of biophony such as amphibians and reptiles in order to further study the elements of soundscape ecology.
4. Apply the proposed landscape strategies and designs in a more diverse and busier urban environment.
5. Conduct a more specialized and detailed landscape elements proposal focusing on the hardscape materials installation and construction like the floating bridges, constructed grasslands and the proposed specialized stone walls.
6. Integrate the conceptual framework to other design application, especially in form finding and form composition, in order to prove the effectiveness of the proposed framework.
7. Study on other bird species present not only in the province of Cavite but also to the other bird congregations found in the Philippines.
8. Record more biophonic samples from different parts of the Philippines in order to standardize the proposed landscape health assessment index.
9. Provide a more specialized plant list focusing on the proposed planting design with deflecting, absorbing and reflecting vegetation buffer.

Assessment of Online Public Opinion on Historical Gardens: A Case Study of the Humble Administrator’s Garden in China

Yuan Li, Xianfeng Li

Department of Landscape Architecture and Ornamental Horticulture, China Agricultural University, No.2, Yuanmingyuan West RD, Haidian DIST, Beijing, 100193, PR China

Abstract

This paper presents an assessment framework to transform online public opinion on Chinese historical gardens into sentimental and topical indicators for rethinking and enhancing practices of public participation. Web crawlers were employed to gather online comments, and two natural language processing technologies, including sentiment analysis and topic modeling, were used to transform these comments into indicators for subsequent analysis. The Humble Administrator’s Garden (HAG), which is a time-honored Chinese traditional garden and a world cultural heritage site in China, was selected as a case study for demonstrating the effectiveness of the proposed framework. In terms of 16092 comments collected from Chinese famous travel review sites, the assessment results illustrate key topics with different sentiments as well as summarize issues about management and tourists’ experience. This framework can help policy-makers and landscape architects in potential decision-making in relation to the HAG, and is expected to be widely applied as a bottom-up strategy to assess public opinion in the ex-post evaluation stage of design and management approaches in the context of historical gardens.

Keywords: historical garden; social media; public opinion assessment; text mining

1. Introduction

The tourism industry and economic development are becoming increasingly significant in terms of historical gardens and its related conservation strategies. The design projects of such historical gardens usually require economic, social and environmental foundations. Although the title of “world heritage” can help to increase the number of visitors towards heritage sites dramatically, the issues concerning conservation, design, and management can be caused by different factors, due to the fact that local communities, policy-makers, and the public have different desires and expectations intended for historical gardens.

The general public have a tendency to focus on the economic and environmental presentation of these historical spaces. While they can be directly or indirectly influenced by the historical landscape, cultural heritage and some other prominent features of these gardens by searching related content through social media. Associated with local communities, the social media users’ comments and perceptions can contribute to
a relatively holistic evaluation of the historical gardens, as these informations would be more objective and unbiased [1]. Successful implementation of such landscape design projects depends not only on the practical and theoretical feasibility but also predominantly on the support from the public, who ultimately pays for and would be affected by these projects. Consequently, the public opinions are of vital importance for the conservation and restoration of historical gardens, and the public satisfaction play a significant role in association with ex-post evaluation and public participation. In addition, the assessment of public opinion should be taken into consideration in the overall design and restoration of Chinese ancient gardens. While, the complexity of such projects and diverse interests of the tourists can lead to some difficulties in the successful evaluation of public opinion.

Most of the researchers usually use questionnaire surveys to collect and measure public opinions on landscape design projects [2]. However, these traditional survey methods are regarded as costly, time-consuming and disturbing [3, 4]. Meanwhile, the general public might be reluctant to share and express their views and opinions in some cases, either due to lack of enthusiasm and related professional knowledge or for their concerns about the potential adverse impact of their comments. The above mentioned issues could distract the public interest and demands in the process of professional design and decision-making, and could ultimately affect the public participation and the development of democratic views [5, 6].

Recently, with the flourishing of social network services, the public have grown accustomed to record and share their views and opinions online, and the social media platforms thus highlighted a new opening for collecting and assessing the public opinions [1]. Social Media became a very essential tool in our life. The interactions among social media users can respond to external events by viewing individual comments, which could also be considered as a vast and distributed network of sensors [4]. As a consequence, this paper used two natural language processing technologies, including sentiment analysis and topic modelling, which mark-up an assessment framework to transform unstructured online public opinions into sentimental and topical indicators for reconsidering and improving practices of public participation.

2. Methods

The public opinion study regarding the user-generated contents can be augmented by using different data mining technologies, especially sentiment analysis and topic modelling. Textual data can easily be account for the dominant part of online comments of the social media sites. Although these data sets are of high-dimension, sentiment analysis can shape them into an emotional measurement. That is to say, the sentiment orientation (e.g., negative or positive) of an online comment can be determined, by providing an indicator to help measure public satisfaction [1]. As well, the intellectual structure of an extensive collection of text messages can be uncovered with the help of topic modelling. Therefore, this data mining technology can extract significant topics of the public opinion on a particular issue.

Based on above mentioned techniques, the whole assessment framework included three parts: data collection and pre-processing, sentiment analysis, and topic modelling. The processes were mainly implemented in Python, and R. For demonstrating the effectiveness of the proposed framework, the Humble Administrator’s Garden (HAG) was selected as a case study, as it is a time-honoured Chinese traditional garden and a world cultural heritage site in China.
2.1 Data collection and pre-processing

The online comments related to the HAG were collected from three different Chinese travel sites (i.e., dianping.com, ctrip.com, and mafengwo.com). Python was used for the coding of web crawler program in order to collect all online comments which were published in the time period between April 1, 2014, and March 31, 2018. Finally, 16092 online comments were acquired in order to satisfying the research purpose of the current study.

Unlike English texts, Chinese texts do not separate words with spaces in sentences, therefore, segmentation played an essential role at the beginning of mining process of the Chinese text. In this article, the segmentation tool called Jieba, (which is an open-sourcing Python library) was used to segment words from the collected online comments. Some comments were having different unimportant words, such as citations, hyperlinks, and locations, which might have adverse impact on sentiment analysis. Due to their specific patterns, these insignificant words were filtered out by using regular expressions.

2.2 Sentiment analysis

In this paper, the sentiment value (SV) for each online comment in the overall collected data were determined by a lexicon-based sentiment analysis algorithm [7]. Three types of words are correlated to the sentiment of a sentence: attitudinal words (AW), degree words (DW) and negation words (NW). Explicitly speaking, attitudinal words express the emotions or attitudes, as they determine the sentiment of a sentence; the existence of degree words and negation words can modify the sentiment of a sentence. In the lexicon-based method it is essential to establish attitudinal word lexicon (AWL), degree word lexicon (DWL) and negation word lexicon (NWL). The final AWL in this article was constructed of two widely-used AWLs (including Hownet and National Taiwan University Sentiment Dictionary), and it consisted of 3443 positive attitudinal words and 9097 negative attitudinal words. DWL and NWL were both inherited from Hownet, which included 224 degree words and 23 negation words. In addition, each attitudinal word were given a sentiment value (SV_d) for representing its sentiment polarity, each degree word were given a modification coefficient (MC_d) in order to amplify or diminish the sentiment value of an attitudinal word, and each negation word were used in order to invert the sentiment value of an attitudinal word.

The sentiment value of an online comment was calculated in a sequential manner. In the first step, the comment was divided into different clauses in terms of the punctuations. In the second step, it was tried to search for attitudinal words in each clause. When an attitudinal word was found in a clause, then we further proceeded for searching degree words and negation words between this attitudinal word and the previous attitudinal word. Later on four rules (Table 1.) were established in terms of the relative positions of the three kinds of words, in order to assign the modified sentiment value (SV_m) to the attitudinal word [7]. In the next step, the sum of all the modified sentiment value of attitudinal words was considered as the final sentiment value of a clause. In the last step, the weighted average of all clauses in a comment was regarded as the final sentiment value of the whole comment. If the sentiment value of a comment was less than zero, the comment could be considered as negative emotions, otherwise it could be considered as non-negative (neutral or positive) emotions.

Table 1. Rules of sentiment value modification
2.3 Topic modelling

Topic modelling can help to classify and organize comments into different representative topics so that researchers could better understand what people have said about a specific object. It is an extension of frequency analysis, which uses a statistical algorithm to uncover the underlying intellectual structure and extract semantic information of document collections. We used Latent Dirichlet Allocation (LDA), which is one of the most common topic models. The main idea of LDA is that it assumes a document which is comprised of multiple topics, and each topic is composed of terms in a fixed vocabulary [8]. For example, an article about historical garden conservation may include two topics, “cultural landscape” and “heritage protection.” Words in relation to cultural landscape, such as “culture”, “traditional” and “history”, may appear in the “cultural landscape” with high probability; while words in relation to heritage protection, such as “stakeholder”, “assessment”, “protection” and “legislation”, may appear in the “heritage protection” with high probability.

In this paper, by conducting sentiment analysis, the whole online data were categorized into two groups according to sentiment polarity (i.e., negative or non-negative) of each comment. Then, both of the comment groups were analysed by using the topic modelling in order to summarize and interpret their main themes respectively. The R package, “lda,” was used for the modelling process, and MS Excel was used for the supplement of processing statistical data and plotting figures.

3. Results

3.1 Overall analysis

According to the calculation, the overall average sentiment value was 1.76, and 2231 comments were considered as reflecting negative emotions, which were only accounted for 13.6% of the whole collected data. The temporal analysis of the whole comments presented that the HAG is a continuously hot topic in social media (Fig.1 and Fig.2). The monthly average number of the online comments regarding the HAG was 335, including 289 non-negative comments and 46 negative comments. Also, there were about 12 peaks during the period of 48 months, and they can be partially caused by holidays, seasonal landscape and local activities.

![Fig. 1. Temporal trends of the online comments (Apr. 2014- Mar. 2018)](image-url)
3.2 Synthesized “topics” on the HAG

After sentiment analysis, all of the online comments were categorized into two groups: negative comments group and non-negative comments group, and two topic models were established for fitting these groups. Table 2 illustrates the first twenty topics which have a relatively higher proportion, and the terms presented in these tables are the ten most frequent words of each topic. As the data was collected from Chinese websites, all the words in Table 2 were translated from Chinese to English. In order to make sure the results can have more detailed information, the keyword “the Humble Administrator’s Garden” was removed before modeling process. Based on our related findings of the HAG, we identified the subcategories of different topics by manual examinations of the two groups respectively. The interpretations of these subcategories of the topics are explained as follows:

3.2.1 Topics in the non-negative comments group

The first subcategory is about the status and identity of the HAG. For instance, Topic P8 contains words like “China,” “world,” “cultural heritage,” “tourist attraction,” “famous,” and “culture,” and thus addresses the importance and cultural significance of the HAG. Topic P20 contains words including “four famous-,” “Beijing,” “Suzhou,” ”honoured as,” “classical” and “famous garden.” Note that some other Chinese traditional gardens like “The Summer Palace,” “The Lingering Garden” and “The Chengde Summer Resort” also appear in this topic. It indicates that the social network users tend to compare the HAG with other famous gardens when expressing their views about the HAG.

The second subcategory emphases on the history and culture of the HAG. Topic P3 includes two names of famous Chinese scholars like “Xianchen Wang” and “Zhengming Wen.” These names are highly related to the HAG: Xianchen Wang was the owner of the HAG, and Zhengming Wen was the designer of the HAG during the Ming dynasty. Topic P5 contains “Ming dynasty,” “middle part,” “architecture,” “west part,” “layout” and “water,” and addresses the historical layout of the HAG.

The third subcategory is related to the tourists’ feeling and experience when visiting the HAG. Some of them were highly appreciating the Chinese culture and design techniques of the HAG, such as “beauty” and “Kun Opera” in Topic P7, “the ancients” and “wisdom” in Topic P10. Others were expressing their impression of the HAG, such as “quite large” in Topic P4, “beautiful” in Topic P9.
The fourth subcategory is about the characteristic of the traditional landscape in the HAG. Some tourists discussed the seasonal changes of the landscape, such as “lotus,” “summer,” “bloom” and “winter” in the Topic P12, and “rain,” “heavy snow” in the Topic P16. People also discussed the architecture of the HAG, with words like “pavilion,” “small bridge,” “rockery,” “landform and waterscape,” “flowers and trees” and “garden” in the Topic P15 and P19.

The fifth subcategory focuses on the garden management of the HAG. In this subcategory, some topics discussed the content of buying a ticket, such as Topic P1 contains “ticket price,” “low season” and “peak season”; Topic P6 contains “identification card,” “queuing,” “online” and “booking.” In addition, Topic P2 contains words like “explanation,” “tour guide,” “free” and “introduction,” and it addresses tourists’ experience about the service of guided tour in the HAG.

The last subcategory is about the travel recommendations which are shared by related tourists. Topic P18, which includes “morning,” “holiday,” “fewer people” and “seven o’clock”; Topic P26, which includes “tour guide,” “explanation,” “history,” “follow” and “knowledge.” Both of the topics address advices about how to have a better experience in the HAG respectively. Also, topics in this subcategory present some worthwhile tourist attractions near the HAG, such as “museum,” “must see,” “nearby” and “Lion Grove” in Topic P13; “Pingjiang Road,” “Guanqian Street,” “walk” and “bus” in Topic P17.

### 3.2.2 Topics in the negative comments group

According to the topics, the negative comments in this group is related to two factors. One factor is the tourists’ expectation gap. Topic N14, N17, and N20 address the disappointment from over-high expectation or the comparison between the HAG and other Chinese traditional gardens, with words like “not worthwhile”, “Summer Palace”, “disappointed”, “imagination”, “ever seen”, “Beijing”, “Lion Grove”, etc. Topic N15 and N16 focus on the influence of weather condition, with words like “winter,” “influence,” “weather,” “pity,” “raining,” “summer,” “unfortunately.” Topic 21 contains “place,” “real,” “pity,” “time,” “cannot go,” and thus it presents the negative feeling regarding the traveling schedule.

Another factor is about the management and service of the HAG. Topic N6, N11, N13 and N19 discuss the price of the ticket, with words like “ticket,” “not worthwhile,” “cost-effective,” “too expensive” and “price.” Topic N1, N4 and N12 focus on the number of tourists, with words like “too many people,” “holiday,” “stagger visiting time” and “suggestion.” Topic N2, N5, N10, N22 and N23 focus on the service in the HAG, with words like “tour guide,” “explanation,” “buy a ticket,” “queuing,” “telephone number,” “customer service,” “bad” and “attitude.”

In addition, some topics also involved the content of the garden’s landscape, history and identity, although with a relatively neutral tone. For example, Topic N3 contains “elegant” and “pavilions”; Topic N7 contains “China” and “four famous-”; Topic N8 contains “beautiful scenery”; Topic N18 contains “Ming dynasty.” But there are no words with significant positive emotion can be found in these topics.

In conclusion, Table 2 illustrates the key terms and proportions of the major topics in the non-negative group and the negative group respectively. According to the results, stakeholders can easily understand the factors which have different impacts on people’s
attitudes about the HAG and the importance of these factors.

4. Discussion

4.1 Implications for the HAG

The Humble Administrator’s Garden is one of the famous historical gardens of China and is highly significant in many aspects, including history, culture, environment, and tourism. As a consequence, it is of vital importance to assess public opinion about the HAG. This paper illustrates that the HAG is an increasingly attractive topic to the social media users. More and more people are willing to express and share their experience and views regarding the HAG online.

The sentiment analysis presents that only a small part (13.8%) of the social media users show negative sentiment. As a world heritage site which has been built for more than 500 years, the HAG is still welcomed by the tourists, and it is well-maintained. Hence, the results of our study is relatively cheerful for the scholars, managers, and policy-makers.

Topic modelling of negative comments group and non-negative comments group revealing the major concerns of the social media users about the HAG. The topics of the non-negative comments group illustrate that people tend to focus on the HAG from six aspects: prestige and identity of the HAG, history, and culture of the HAG, tourists’ feeling and experience, characteristic of a traditional landscape, garden management and travel advices. These contents are also crucial for the conservation and development of the HAG. Meanwhile, the topics of the negative comments group show the most critical issues which have adverse impacts on the HAG, such as tourism consumption, crowd control, public service, etc.

4.2 Implications for related design and conservation project

Public participation is critical for policy-makers to deal with public projects. This research can help to better assess the public opinion on the management and design regarding historical garden. Some basic suggestions are shown as follows:

(1) Administrators and policy-makers should encourage people to express their views, appeals, and attitudes on the online platforms related to the discussion of historical garden projects. The existence of social media creates a convenient platform for the interaction among the general public, government and project managers. Social media can also contribute to building the awareness of public participation, and it is a more effective and economical method for scholars and policy-makers to collect and assess public opinion than traditional public participation methods. However, the effectiveness and accuracy of this method have to be based on a large number of participants, so it is necessary to encourage more individuals to join in this online approach.

(2) As the conservation and development of historical gardens are long-term work, monitoring online presence of these gardens should be a meaningful task. Historical gardens have been and will exist for a long time. Hence they often have a long-term influence on the society. The public satisfaction and attitudes of famous historical gardens usually vary with time and space. As a result, monitoring and studying historical gardens via social media seems to be the only effective way to measure the variations of the public opinion at the macro level.

4.3 Limitations

Although the user-generated contents from social media can be regarded as an alternative
approach which can help to provide rich information and save money, these data can be skewed because of the existence of selection bias, which means that the data are only collected from the social media users who can afford internet-enabled devices, and have enough leisure time to share experience online. Nevertheless, the analysis results in this work do reveal useful knowledge due to a large number of users.

In addition, the lexicon-based sentiment analysis algorithm in this paper is not well performed when processing ironical comments, so the accuracy of sentiment analysis is hopeful to be further improved by using the more sophisticated algorithm.

5. Conclusion and Future Work

The traditional Chinese gardens were initially been shaped and dominated by elite culture, and thus the public’s everyday-life experience was prone to be neglected [9]. With the progress of democracy, understanding the public opinion is becoming increasingly crucial for the conservation and restoration of historic gardens. Due to urbanism and tourism trends, different historical places are facing different challenges regarding economic, social and environmental impacts, but social media provides a down-top strategy to address these issues from a public perspective. This technology also contributes to promoting the sharing of information between policymakers and the public: government and scholars can gather and analyse people’s own views and experience which are available on the Internet in order to better understand public attitude and needs in time, and individuals can have access to the latest policies and strategies related to historical gardens via social media easily and rapidly.

As such, this paper presents an assessment framework to transform subjective public opinion into sentimental and topical indicators for rethinking and enhancing practices of public participation. By analysing online public opinion on the HAG, this study provides a more democratic and effective method to uncover how Chinese social media users think about the famous world heritage site, which is significant in the post-evaluation stage of design and conservation projects.

Resilience Design Of Shallow Mountain Greenway Infrastructure Based On Safety Pattern Of Rainwater

A Case Study On The Design Of Shallow Mountain Avenue In Shijiazhuang, China

Junming Feng, a Yi Shi, a Yunyuan Li a*

a Beijing Forestry University, NO.35, Qinghua East Road, Haidian District, Beijing, 100083, China

Abstract

The relationship between urban construction and natural ecology is complicated. With the development of plain cities gradually spreading to shallow mountainous areas, the impact of this relationship has become even more far-reaching. Greenway is an early urban infrastructure in the shallow mountainous areas, therefore, it is important to study the effect of the flood control system in the construct of greenway landscape under the perspective of rainwater safety pattern. Combining with the planning and design practice, this article draws a comprehensive flood prevention strategy of defense, delay, storage and discharge, at the same time combined not only the analysis platform, practical exploration but also with macro-micro collaborative plan and design. Firstly, the ecological sensitivity of the study area was analyzed by GIS software, and the corresponding sensitive focal point distribution was obtained. Secondly, with the ecological restoration pattern and several steps to mitigation the rainfall, the overall planning and layout of infrastructure was combined with the site; finally, analyze the specific solutions, the corresponding runoff elimination results were obtained by SWMM simulation. We hope that we can draw a flexible greenway landscape model, while improving the functionality of the Greenway landscape to bring more resilience ecological impact.

Keywords: flood safety; shallow mountain; greenway; resilience design
1. Introduction

In recent years, the urbanization movement has developed rapidly. Many cities have already broken through the expansion of the current city area into surrounding areas. Take the North China Region as an example (This study focuses on the geomorphology, therefore, the limit scope of the North China mainly includes Beijing, Tianjin, Hebei Province, Shanxi Province, Shandong Province and Inner Mongolia Autonomous Region), during the process of development, many thorny problems like residence, transportation, and so on. are solved in highly efficiency, therefore, there also pay the cost of deteriorating ecological environment and insufficient landscape performance, etc. Such of this problems mentioned are specifically embodied in the following aspects:

1.1. Urbanization extends to shallow mountain areas

The North China is located in the middle of the eastern edge of the second largest geomorphological terrace in eastern China. It has several types of mountainous like terrain, hills, plateaus, plains, and all other mountain types. It is a typical area suitable for construction and live. There have been many urban construction activities (such as Beijing and Baoding) since ancient times. However, with the development of the new era of urban development, related pressure like housing and transportation are increased, the traditional urban area can no longer satisfy the needs of the future, so lots of cities tend to set the shallow mountain area as a new area. Such as the "Beijing Urban Master Plan (2004-2020)", while delimiting the scope of shallow mountains, it also make a master plan for the development of shallow mountain areas.

Shallow Mountain, as a connecting zone between mountainous and plain ecosystems, has obvious regional characteristics compared with other regions, and has the advantages of various geomorphological features of plains and mountains. It is more suitable for urban construction and also good for enriches the urban landscape. The more importantly, it has difference in the distribution of natural resources, horizontal and vertical, all of this are resulted in a higher biodiversity of adjacent environmental systems than in other areas. Therefore, the development of cities needs to increase the emphasis on the habitat sector. In addition, shallow self-sustaining thresholds in shallow mountain areas are easily affected by human activities and are difficult to recover normally once they have been destroyed by humans.

1.2. The urgently contradiction between rainstorm and flood safety area

The shallow mountainous areas of northern China are located in the mid-latitudes and belong to the temperate continental monsoon climate. There have obvious season differentiation, less annual rainfall and with a serious shortage of water resources. Due to the location of the subtropical high-pressure ridges, rainfall is highly concentrated in 2017. Rainstorms are mainly concentrated in flood seasons from July to August. Precipitation in flood seasons accounts for 45%-65% of the whole year. Floods and floods occur along the mountainous areas. Among them, Yan mountain and Taihang mountain are concentrated areas of heavy rain in the region, and can easily form flood disasters.
and enter the south of the plains, posing a serious threat to water security in the south of the plains.

1.3. The greenway has a functional-ecological double bond

The Greenway was first used by Whyte in 1959 and gradually became realistic construction in the subsequent development. Most literature approved that the Boston Park System completed by Frederick Law Olmsted in 1867 was a pioneer in the practice of greenery, its related discussion and research also provides guide for this research. Firstly, there are abundant landscape resources in shallow mountain areas, such as forests, wetlands, rivers, farmland, and so on, which are important constituent elements of the urban landscape in shallow mountain areas, and they are also rich in beautiful environment, abundant resources, and numerous historic sites, so there is enormously in the potential development. Secondly, as a linear element linking patches in different regions, it also improving the regional ecological connectivity.

2. Research object and significance

2.1. Research object

Taking the landscape design of the Shallow Mountain Avenue in Luquan District from Shijiazhuang as an example (Fig. 1), the site is located on the west side of the City and between the western mountainous region and the main urban area. The total length of the green road is 46.7 kilometers, surrounded by surrounding mountains and rivers. The greenway is based on the municipal roads and will become a green line space that run through the vicinal shallow mountains.

2.2. Research significance

The research and design are based on the shallow mountain ecological base site for greenway landscape construction. It is hoped that the urban landscape can be expanded in the elastic landscape area and new sustainable construction strategies can be provided. It has the following effects:

As a linear greenbelt, the greenway can connect large-scale public greenbelts and natural greenbelts around the city at the municipal level. It can serve as an ecological corridor through the connection of green patches; at the urban level, the shallow mountain greenway can effectively maintain
and improve the shallow mountains’ eco-environment, perfecting the greenspace system structure of mountainous cities®, effectively communicating the energy conversion between the suburbs and promoting the circulation of the urban ecosystem; In the view of the practicality of rainwater management measure, China has proposed the concept of “sponge city”® by absorbing and introducing from foreign advanced concepts and practical experiences to solve urban stormwater disasters, especially about the LID facilities. Many water problems, such as the shortage of water resources, the drop of groundwater level, and the loss of habitat of aquatic organisms, all of what can help to solve the problems of rainwater flooding; Judging from the landscape entertainment, shallow mountain greenways can use the advantages of terrain to create a linear landscape sequence by coordinating multidimensional spatial perspectives of plains and mountains. In addition, the service function of the city can be improved, and a new type of shallow mountainous area can be created that is in line with the mountainous terrain and is fully functional.

3. Flexible mitigation methods for rain flood

Through research and analysis, the project will build a flexible sponge greenway system in defense, delay, storage, discharge parts.

3.1. Defense Methods

Considered the ecological restoration of terrain, firstly enhancing the ability of self-circulation and self-regulation through the current enhancement of vegetation, classifying the mountains according to the characteristics of the mountains surrounding the greenway, and then combine different types of The mountain body (the near natural hill, the artificial interference mountain, and the barren mountain) is targeted for repair. The specific measures are as follows:

In the rehabilitation of near-natural hills, the main focus is on ecological conservation, adding vegetation at the same time, enriching the level of vegetation communities, establishing measures to maintain the sustainability of the mountain; for the artificially disturbed mountains, Through the arrangement and management of the greenway function in the design, human activities are regulated to reduce interference, and ornamental plants are mainly added in the node area; For the barren mountain areas, there are many impacts of piedmont runoff and flooding, and this is combined with many Layers of ponds, rain gardens and other buffer facilities to slow down the mountain runoff and improve the ecological safety factor.

3.2. Delay Methods

The construction of the rainwater retention system achieves the effect of delaying the flow of water, which is the key of the study. First of all, the elevation data in the shallow mountain areas surrounding the greenway are extracted from GIS, and the water collection analysis is performed on this basis to obtain the water collection point. Then choose a watershed with better and longer water points, and set up a series of rainwater retention facilities (rain gardens, submerged green spaces, etc.) to form a good water landscape (taking the northern forest water section as an example. Fig. 2.3). At the same time, in conjunction with the specific design of the station and
the venue, rainwater landscapes can be set up at important sites or venues that require a high degree of landscape viewing, and the height difference can be set to form a dynamic rainwater landscape.

![Image](image1)

**Fig. 2.** The water collection analysis in the north part of the Shallow mountain greenway.

![Image](image2)

**Fig. 3.** The water collection pattern in the Shallow mountain greenway.

The specific process for rainwater flood mitigation in the design is as follows (taking the northern Wanghe River as example. Fig 4). When the rainstorm comes, firstly, the natural mitigation is carried out by supplementing planting quilts, ponds, and rainwater gardens. The ecological grass-groove ditch and underground culvert will re-dispatch the water and concentrate the excessive amount of rainwater to the flood discharge channel on the east side of the road section. Here, the excavation of small-scale waters increases the scope of flood discharge, and finally the rubber dam is used to adjust the flood discharge flow rate. Finally relief the pressure of downstream flood discharge.

![Image](image3)

**Fig. 4.** The delay methods of rainwater in the north part of the Shallow mountain greenway.

### 3.3. Storage Methods

The main purpose of the defense and delay strategy is to mitigate the rain and flood pressure. In addition to the synergetic relief pressure, the storage strategy can also form a dry and wet type landscape through the distribution and utilization of rainwater. In the water storage system, firstly, we use LID facilities (such as rain gardens, sinking green areas, etc.) to channel rainwater to form a preliminary retention effect, and then combine the ecological grass-grooves and underground culverts on both sides of the lane to drainage water into the existing anti-seepage treatment. In the channel, the rubber dam is used to allocate landscape water with different elevations, and the reservoirs and underground pipelines in the nodes are properly supplemented (Fig.5); in the landscape system, the design is based on different seasonal characteristics of drought and humidity to form the landscape space, and the plants are selected. The plant should have the characteristic which can resistant to
long-term drought and short-term flooding. Aquatic plants such as Ceratophyllum demersum, Nelumbo nucifera and Eichhornia crassipes are used in the deepwater area. The shallow water areas are mainly emerged plants, and the vegetation buffer zone is mainly planted with wet plants such as Iris pseudacorus, Lythrum salicaria, Cyperus, and so on.

3.4. Discharge Methods

The relevant design for site drainage is generally connected with the impoundment of water, the main purpose of which is to ensure that safe discharge could achieved in the event of excessive rain and flood during the rainy season. The design incorporates a variety of sponge-like landscape infrastructures such as rain gardens, temporary flood discharge water bodies, etc. Rainwater gully, pipe culverts, etc. are used to regulate and divert rainwater, so excess rainwater is gradually discharged. The discharged rainwater is mainly used in two aspects. On the one hand, it is discharged into the green space nearby. In the course of the water flow, wetland plants, stones and other materials are used for rainwater purification, eventually reaching a certain standard as irrigation water or landscape water; on the other hand, when the rainfall is too excess to storage nearby, the rainwater can not normally used in the site area. At this time, it is necessary to use the municipal facilities to discharge the flood, and finally ensure the safety of the rain in the shallow mountainous area.

4. Design and analysis calculation

The design of the elastic sponge greenway in this study mainly uses LID facilities to control stormwater runoff. In order to accurately quantify the effect of stormwater runoff control, a stormwater management model (SWMM) was used for simulation studies to provide data support for the stormwater runoff control effectiveness of the sponge greenway. The section of the Huangyan Village to Wanghe Huangu section of the Luquan District is selected as the study object (Fig.6). The section has a total length of approximately 3.1 km and a total area of 46.1 hm² (including roads), of which the LID facility has an area of 123267
m², accounting for 26.7% of the total area of the section. The study area was generalized into 6 sub-water catchment areas. Sponge greenway development model and traditional greenway development model were established in the area. Using the SWMM model, the simulated return period was 5 years, 10 years, 20 years and 50 years. The statistics of the total amount of external runoff are receiving from two development modes (LID development and traditional development). Finally, peak flow, and peak present time were calculated (Tab.1). The layout plan for the specific LID facility in the study area is shown in the figure.

5. Results

This study analyzes the climatic characteristics and geographical features of the typical shallow mountainous areas in North China, combining the development background of urbanization to summarize the importance of the application of the current elastic greenway landscape. From the perspective of rain-flood security, a number of studies have been combined to propose the idea which constructing an elastic greenway landscape as an infrastructure, and to guide specific designs. The discussion of this study mainly includes two stages which include the rainwater flood control and the LID design and specific layout: In the regulation of rainwater, four steps of defensive-delayed-storage-discharge are used to achieve the mitigation and regulation of different rainfalls; In the elastic
design and layout, through the construction of a rainwater regulation system for specific rainwater storage and utilization, combined with the results of the SWMM stormwater runoff simulation, it is concluded that the elastic sponge greenway has significant results in reducing stormwater runoff and delaying peak present time. Compared with the traditional greenway development model, the sponge greenery under this research design method has obvious advantages in rainwater storage and adjustment, and has certain application value and promotion potential in urban shallow mountain areas in North China. It is hoped that the multi-functional greenery will be used as a landscape infrastructure to make the shallow mountain area more flexible. In the end, it will not only protect the entire city, but also provide a more reliable basis for other related construction.

Symbiosis with Rivers:
Guangzhou Urban Renewal Plan through Phased Strategy of Ecological Restoration

Zhang Menghan\textsuperscript{a}, Liu Jingyi\textsuperscript{b}, Tan Li\textsuperscript{a}, Tan Minghao\textsuperscript{a}, Jiang Xin\textsuperscript{a}, Li Xin\textsuperscript{a}\* 

\textsuperscript{a}Beijing Forestry University, No.35 Qinghua East Road, Beijing, 100083 
\textsuperscript{b}South China Agricultural University, No. 483 Wushan Road, Guangzhou, 510642

Abstract

Though being born because of the river, destruction of river system in Guangzhou seems inevitable in the process of rapid urbanization when massive rivers were “over-engineering”, and even disappeared. Consequently, urban water systems can hardly cope with environmental problems such as floods.

Taking Guangzhou's intrinsic and unique features of urban river network conditions into consideration, this study tend to propose an ever-changing urban renewal plan that is symbiotic with rivers. Through on-site investigation and cases study, an exploration aiming to bring the covered river to light again through landscape strategies is proposed through in three main phases, and regional renewal is ensured to implement in a large scale, which make city's space reactivated. Meanwhile, humanistic landscape on riverbank of architectural culture heritage protection and leisure space construction are involved in integration method.

\textit{Key Words}: Over-engineering, Phased Strategy, Sludge Transformation System, Ecological River Restoration, Rejuvenation of Public Space, Green Infrastructure
1. Background: The Changes of River System and Waterfront Environment in Guangzhou

Owing to historic reasons and special circumstance of modern China, the evolution of river management in Guangzhou is unique compared to most cities. As a well-known oriental sea port and the starting point of the “Marine Silk Road”, Guangzhou was born because of its location on Pearl River System. The tributaries of Pearl River named "Chong", which were densely distributed throughout the city, represent the most characteristic kind of rivers in Guangzhou, forming the backbone of the city's water system. With a small amount of water, they were natural waterways directly connected to major rivers. In the urban area, there are 238 rivers with a total length of 913 km, which merge into Liuxi River, Baihe River and Pearl River. And they employed an important influence on regulating water levels because of being affected by tides.

Fig. 1

1.1. The Period of Rivers’ Cultural Development

Throughout its long history, these rivers, as well as their environment, have been closely connected with people’s daily lives, because they shoulder not only the city’s task of flood management, irrigation and shipping transportation, but also the back lanes of residents' lives, such as taking water, washing, daily traveling and even recreational activities. Thus, instead of a merely beautiful natural landscape, the urban riverfront is a unique cultural landscape, which has shaped the urban spatial pattern of style for more than 2,000 years. For example, East Hao Chong, once a moat in the Ming and Qing Dynasties, has gradually formed a commercial center along the river at the end of the feudal society, supporting the development of business.

Fig. 2

1.2. The Period of Rivers’ Traffic Decadence

However, in the 1910s, with the modern urban city-building movement, Guangzhou began to demolish the ancient city walls, constructed a great variety of municipal roads, which eventually became the main transportation system. As a result, the traffic function of the rivers began to degenerate even gradually disappeared, signing an evident trend of transport declining, nevertheless, they did not lose their main function as the drainage channels. The development of the city was slow and orderly, and the rivers, with high quality of purity, at that time still played an important role in the urban ecosystem and residents' lives.

Fig. 3

1.3. The Period of ‘Over-engineering’ Rivers

After the 1950s, with the rapid development of the city’s economy and the population growth, because of the disordered construction and management of the surrounding areas along rivers, the intensive buildings altered the original
natural bank form of the river, weakening their capacity of flood discharge. Consequently, the riverfront repeatedly experienced guilt during rainy season. In order to solve the problems, Guangzhou reformed the urban drainage system from natural embankments to upright rigid embankments under the guidance of the idea of flood control at that time. There is no doubt that destruction of river system seems to be inevitable in the process of rapid urbanization. Moreover, Massive rivers were ‘over-engineering’, especially when Guangzhou in an all-round way started to unify the open channels into underground channels with city roads on its cover. Those open channels with slate were changed to underground channels with reinforced concrete box culverts, as we can see in Xiguan Chong and Yudai Hao. What caused more serious problem is that the pollution of industrial and domestic sewage discharged into rivers was increasing, so the rivers in the central city become black and odorous as sewage pipes for the city.

1.4. The Period of ‘Disappearing Rivers’

After the 1970s, especially the beginning of the Reform and Opening-up in 1979, Guangzhou entered a new period of booming development and its urban area has expanded dramatically. Thus the urban landscape has undergone major changes in the rapid increase in population, traffic jams, and the emergence of viaducts. However, the deterioration of the riverfront water environment was still intensifying. The environmental problems and traffic pressure brought about by the abnormal development of the urban construction have caused more rivers to lose their original ecological functions and landscape environment. As a result, many rivers in the city have gradually disappeared such as West Hao Chong, Yudai Hao, Lizhi Wan and many other rivers have been replaced by underground culverts. Only the effluvial East Hao Chong flows on the ground with the high-rise buildings around, with scarce slate road left over from history. The original bustling life scene disappeared and the river have almost been forgotten by the world. There is no longer the scene of ‘clear creek and green space’ everywhere and Guangzhou lost its ‘Water City’ feature. What’s more, the quality of rivers are becoming increasingly polluted and blocked. In 2016, the rivers that did not reach the standard of water quality accounted for 88.79% of the total. Consequently, urban water systems can hardly cope with environmental problems such as floods.

Since the 21st century, more and more people have improved the awareness of the rivers’ importance to the urban ecology and living environment. However, the contradictions between gray infrastructure and green infrastructure are particularly prominent. There are two core problems of the rivers’ status: the decline of the urban water system and the decline of urban space. The former, caused by being covered, has resulted in serious water pollution and weak capacity of flood management. The latter, plenty of negative activities such as illegal possession and garbage dumping, has led to the monotonous urban space without regional features and vitality. Thus it is against this background that we have started this large-scale project of comprehensive renovation of rivers.

Fig. 4
2. Objectives: The Concept Based on the Idea of Resilience

Taking Guangzhou's intrinsic and unique features of urban river network conditions into consideration, this project seeks to find a solution based on the idea of resilience by establishing ever-changing urban renewal places that is symbiotic with rivers. The city’s adaptation to disasters should reflect the temporal dynamics. The traditional engineering measures dealing with flood only with a single function of defense, or simplex ecological remediation, resulting in waste of urban space and resources.

Our plan is proposed to improve the construction and development of the cities built downstream along the river by solving the problems both under covers and on urban surface. The water flow plays a role of transporting sludge to the confluence or estuary considering time effect. A system aiming to transform sludge into humus is constructed underground, which will also provide opportunities for the renaissance of urban green space. After uncovering, various possibilities were re-introduced into the city and the waterfront areas became the basis for activating the urban space once decayed. Except for protecting cities from flooding it also has the function of revitalizing the public space and improving the eco-environment. Moreover, it is also an optimal strategy of balance between the tense land use and the protection of natural ecology.

3. Methods: Three Main Stages and Ecological Technology

Through on-site investigation and cases study, an exploration aiming to bring the covered river to light again through landscape strategies is proposed through in three main phases:

3.1. Stage I: Restoration Plan Both on the Urban Surface and Underground

In the first stage, in order to form the foundation of ecological and cultural river restoration, reconstruction is divided into two parts: the treatment plan on the urban surface and underground. On the one hand, underground excavation is conducted locally to form a stagnation space, where sludge is transported to by the process of river's automatic force. Then biogas power generation is used to convert concentrated sludge into humus. On the other hand, at the beginning of the restoration of the river, we ought to find waste space and potential areas on the ground to build some pocket parks. And electricity generated by that process of biogas could partly supply public infrastructure. The sludge transformation system is constructed underground since oxygen is exposed through openings of equipment on the ground, which will also provide opportunities for the construction of green space and the renaissance of urban public space. After uncovering, the purified sediment can be used directly for the construction of the revetment, as the foundation of the new waterfront space composition. So there is no doubt that it is an efficient way to restoring ecosystem of the rivers.
3.2. Stage II: Uncovering and Diverse Treatment of Revetments

In the second stage when the regional sludge water system has basically been constructed, the large amount of sludge under the cover plate would gradually transform into soil containing humus, which will become the foundation of the new waterfront space composition after opening the cover plate. Obviously, the river will become visible, evoking the public environmental awareness. In particular, it is necessary to consider the status and adopt targeted methods to reconstruct revetments for different levels of urban density.

While uncovering sufficient space for the urban ecosystem, the comprehensive rectification of riverfront must first adopt diverse treatment of revetments according to the specific conditions of different rivers, making the river line richer in both morphology and function. Because the revetment of river is not only a defensive line to ensure the safety of watershed, but also an important component of the waterfront landscape and spatial utilization. Modern ecological technologies are used to design different riverbeds and revetments including semi-permeable fabric-formed concrete channels, tubular mesh fabric growing containers and gabions in limited estuary water level change areas, different ways to form a high ecological potential green infrastructure that has flexible functions of flood control, as well as meets the needs of various animals and plants. For example, in the downtown area, where the space is relatively confined with over-engineering revetment, semi-permeable fabric-formed concrete channels and multi-level platforms with tubular mesh fabric growing containers are set up in order to meet the flood control requirements. Only by this way could we weaken the rigid coastline to form an interesting waterfront with various needs such as hydrophilicity and recreation. In different circumstance, there is wide range for ecological restoration of the river, especially on the outer edge of city. For the treatment of such river banks, the design mostly uses natural grading treatment with natural materials such as rubble, wooden piles and gabions to stabilize slopes, and sometimes it also includes tubular mesh fabric growing containers to form a flexible ecosystem with functions of flood control.

3.3. Stage III: Reactivating urban space with Diverse Possibilities and Technology of Water Purification

In the third stage, in the case that single landscape could be easily eroded by the construction of other lands, aggregation and transformation is necessary in the contemporary context rather than tearing apart river and city. The new functions replaced the original monotonous blocks, giving the blocks diverse possibilities, consequently the old city's space being reactivated. Meanwhile, humanistic landscape on river bank of architectural culture heritage protection and leisure space construction are involved in integration method.

There are three representative types of revival spaces. Cultural rivers, as the first type, are mostly located in the old urban area of the city with an attractive style of historic neighborhood, surrounded by a great
variety of historical and cultural resources. There are massive scenic spots such as Morning Tea Market, River Museum, Outdoor Café, Street Corner Garden and so on. The second type called rejuvenated rivers, located in the developing part of urban area, have a lot of opportunities for the development of commerce and entertainment industries. The industrial transformation and activation of public space will make it the central area of future urban vitality, as we can see in City Terrace, Waterside Theatre, Water Steps and Bridge Park. Because of being located in urban fringe areas and important ecological nodes, the third type named ecological rivers have plenty of room and flexible space. Through Silt Garden, Rainwater Pond, Suburban Wetlands and Popular Science Park, in the future, they will become important regional eco-corridors or ecological parks.

Fig. 5

Water purification in the river is another important, long-term ecological mechanism for the comprehensive renovation. Plant purification is a common method: combining the requirements of the landscape, a combination of aquatic plants with highly effective purification is planted in the river fluvial to achieve the effect of adsorbing and degrading river water pollutants and purifying sewage. Since many rivers in the city are tidal rivers, the water level varies greatly with the tide of the Pearl River. In order to solve the impact of water level changes on wetland plants, ecological floating beds have been widely used for planting aquatic plants. The ecological floating bed is free to rise and fall as the water level changes, and it can respond well to tidal changes. Moreover, aquatic plants, semi wet plants and damp-tolerant terrestrial plants preserve the natural environment and waterfront habitat as much as possible. Through the purification of water quality, the rivers in the central urban area have changed from stagnant water to live water, and the river water environment has been improved.

Fig. 7

Fig. 8

4. Methods: Regional Renewal Strategy in a Large Scale

In a large-scale planning, the regional update strategy is also conducted through three main phases: taking Guangzhou’s unique terrain and surrounding mountains into consideration, in the first phase, while starting ecological restoration of mountains, the sewer network is constructed as the foundation of all other process of ecological restoration.

Most of the rivers in central Guangzhou have lost their navigational functions, however, they are still the city’s ‘blue line’ in the psychological of the public. So in the second phase, we clearly defined the control area of rivers and the band-shaped green space reserved for the rivers. The control area of rivers could not only act as the natural site for the construction of the urban ped-bike system, but also guide the public to intimate contact with the waters, establishing dialogues and exchanges between the ‘blue line’ space and the greenway system.
In the third phase, various possibilities were re-introduced into the city and the waterfront areas became the basis for activating the urban space once decayed. Ultimately, the riverfront environment can serve city life in a more extensive scope. In return, river network regeneration can benefit from the urban space revival.

Fig. 8, 9, 10

5. Results: Unique Space to Rebuild Close Relationship Between Waterfront Environment and Urban Life

Once as a real ‘water city’ being born in water and living in water, the river network in Guangzhou is widely distributed everywhere just like lanes, so the rivers are original place where the residents have live for thousand years, which employ an indispensable influence on their life-styles, however, after decades of urban development, the rivers have become no longer relevant to everyday life in urban city. The rivers are not only an important component of the urban ecological environment, but also a stage for the urban life. So the improvement of the riverfront environment is not only a simple ecological restoration or scenic construction of rivers, but also a repairing process of the relationship between city and river.

Taking social concern of riverfront improvement into consideration, urban riverfront remediation should fully measure the functional orientation, cultural inheritance, and life style of the surrounding urban area, so that it will become a space truly correspond to Guangzhou’s flavor, carrying local life-styles. For example, if the houses along the riverbanks of East Hao Chong, once a moat in Guangzhou with a long history, were almost demolished during the renovation, the living space pattern of this area, which was rich in old Guangzhou, will disappear. In terms of the protection of urban life forms, the complete construction is often irreversibly destructive. While preserving selective part of the residential area and it will be transformed into an integral part of the riverfront green space. The existing neighborhood and unique urban life will continue, which should be a better choice to create more vitality with the temperament of Guangzhou.[3] Eventually, far from reverse to river as it used to be, the vitality of the waterfront environment will redirect the urban life facing the river, rebuilding the close relationship between waterfront environment and urban life. It is bright future prospect to contrive a beautiful vision of harmonious co-existence between people and river through the phased rejuvenation strategy of ecological restoration, exhumation and spatial integration.

Fig. 11

6. Enlightenment of Constructing Green Infrastructure Based on Ecological Restoration of Rivers in Guangzhou

As we can see in restoration of rivers in Guangzhou, there is no doubt that the implementation of green infrastructure in the process of rapid urbanization is bound to encounter unimaginable difficulties, but it also contains unprecedented opportunities. I would like to conclude the enlightenment of constructing green infrastructure.
In urban construction, we must strictly protect existing key natural ecological areas that have not been destroyed through forward-looking planning. Next, we must seize the opportunity of urban development to explore a series of potential urban space construction and restoration of natural functions through creative means. In particular, it is necessary to consider the combination with the urban status and adopt more targeted strategies and methods to reconstruct green infrastructure for natural, semi-natural, productive areas, suburban expansion areas, low-density and high-density urban core areas.

Moreover, the updated space with renewal of urban area could constitute green infrastructure with internal connectivity and systematic natural ecological functions, which would be compatible with the spatial and functional characteristics of modern cities. It is not merely a natural space, but also an efficient ecological framework for ensuring sustainable social and economic development, and an optimal strategy of balance between the tense land use and the protection of natural ecology. Some single landscape strategies can easily make the land eroded by the construction of other land. Instead, a compound urban strategy should be adopted to focus on the vitality and development potential of the multi-functional space, clearly defining a mixed proportion of land uses.

In addition, the green infrastructure in the urban environment must be protected by artificial means to make it more efficient, reduce its existing vulnerability, and rely on the continuous development of advanced technologies and engineering facilities to enhance the functional efficiency of the green infrastructure.

The last but not the least, the construction of green infrastructure needs to solve the problem of short-sightedness, which only exists in the immediate future, which prevails in the process of rapid urbanization. It fully recognizes that its ecological role is played gradually, but its functional effect is long-lasting and low-cost. It will be a long-term development strategy and long-term ecological mechanism for the “green modern city” in the future.

The Spatial Landscape Characteristic of the Traditional Impounding Lake System in Jiangnan Region

Zhang Xi, Wang Xiyue, Wang Xiangrong

Abstract

As a significant category of traditional agricultural landscape, the impounding lake system was widely distributed in the south of China historically, which formed a typical vernacular landscape through thousand-years evolution. The study takes Jiangnan region as the research area, lying in the south of the Yangtze River, with both plains and hills scattering in. From the perspective of landscape architecture, several typical impounding lakes of Jiangnan region in the history are chosen as research objects by consulting ancient books and chorographic maps. Firstly, the relationship among the impounding lake system, the environmental background and the traditional city is discussed at the macroscopic level. Further, the paper summarizes forms of impounding lakes at the macro level and landscape elements at the micro level. The multiple functions of the impounding lake system are analyzed in three aspects: economy, ecology and culture. The purpose of this paper is to draw the attention of scholars who study in related discipline to focus on the traditional impounding lake system in China. Simultaneously, use ancient water management methods and apply them to the resilient landscape construction of modern cities.

Keywords: Landscape Architecture; impounding lake system; spatial landscape characteristic; Jiangnan region; resilience
1. Introduction

The impounding lake system is a typical category of Chinese agricultural landscape. As agricultural landscape occupies most of Chinese territory [1] and embodies diverse geographical environment as well as long agricultural history spatially, it is the core component of vernacular landscape. Vernacular landscape reflects the natural and cultural characteristics of specific regions, including not only natural landscape, but also the landscape derived from dwellers’ production and daily life through history [2]. Settlement landscape in architecture is the main aspect of current vernacular landscape study in China, while the connection among natural landscape, agricultural landscape and settlement landscape is often overlooked.

Because of various topographical and hydrological characteristics in vast territory, agricultural landscape emerges different characteristics. Long-distance diversion canal system is mainly used in northern China, but impounding lake system in southern China. As a typical hilly agricultural landscape, traditional impounding lake system is widely distributed in Jiangnan region historically [3](Figure 1), and forms unique regional feature. Jiangnan region lies in the south of the Yangtze River, with both plains and hills scattering in. Flash floods brought by abundant rainfall along with uneven precipitation lead to complex agricultural issues [4]. Therefore, a large amount of traditional impounding lakes were built in history for flood control and irrigation. But most of them have gradually disappeared because of urban sprawl or the policy of reclaiming farmland from lakes. The paper selects typical impounding lakes in Jiangnan region including Chishan Lake in Jurong, Lian Lake in Danyang, Jian Lake in Shaoxing, South lake in Yuhang, West Lake in Hangzhou, Guangde Lake and Dongqian Lake in Yinxian as research objects for comparison, in order to summarize the spatial landscape characteristics of traditional impounding lake system, which can put forward proposals for resilient urban landscape construction in Jiangnan region and maintaining of landscape diversity in China.

2. Formation and Development of the traditional impounding lake system in Jiangnan region

From the Spring and Autumn Period to the Western Han Dynasty, water conservancy construction focused on the development of large-scale irrigation channels in the north of China. Although the impounding Lake also developed during the Western Han Dynasty, it mainly concentrated in Hanzhong, Nanyang and Runan region. Until the Eastern Han Dynasty, the eastward movement of political center led to economic development in the southeast of China, combined with the natural conditions of the hilly areas in Jiangnan region, so the traditional impounding lake system that is suitable for such environmental conditions was built in Jiangnan region. In the Southern and Northern Dynasties, the continuous war in the north gives rise to a large number of population moving southwards, which accelerating the process of economic development in the south and further development of impounding lake construction. Until the Song Dynasty, rapid growth of population in Jiangnan region resulted in insufficient arable land. People changed lakes and mountains into
farmlands, so the number of large lakes in Jiangnan region is significantly decreased. On the contrary, the number of small lakes which are suitable for mountain irrigation increased.

3. The spatial landscape characteristic of the traditional impounding lake system

3.1. On the macro scale

The vernacular landscape pattern in Jiangnan region was formed by the long-term mutual superposition of agricultural landscape, natural landscape, and settlement landscape. Therefore, it is particularly important to discuss the mechanism among the impounding lake system, the environmental background and the traditional city, which can be spatially characterized.

First of all, the ancient water system organically connected the impounding lake system with the environmental background and the traditional city. The traditional impounding lake system in Jiangnan region is presented as a “catchment-impounding-flow” resilient structure. The "catchment" process starts from the water source in the environmental background, which can be divided into two types, the rivers and the mountain stream. The "impounding" is the adjustment and storage of the water by impounding lakes. The "flow" includes drainage and diversion system. In the dry season, the lake water can be used for agricultural irrigation, water supplement of canals and urban water system (Figure 2). Moreover, it can be drained into rivers or ditches through overflow system to ensure the security during the flood season. For example, Dongqian Lake impounds the water from surrounding mountains. The lake water flows into Zhongtang Canal, Qiantang Canal, Houtang Canal and Xiaoxia River respectively through the four sluices of Mozhiyan Sluice, Dayan Sluice, Qianyan Sluice and Meihu Sluice, then irrigates farmland through the water network of the Yindong Plain. In the flood season, the lake water is discharged into the Fenghua River or the Yong River [5].

Secondly, taking into account the distance between the impounding lake and the city, the impounding lake system can be divided into two types: the near city type and the far from city type (Table 1). The traditional impounding lake system usually has a variety of functions such as agricultural irrigation, flood control and water supplement for canals and cities. The far from city type is mainly used for agricultural irrigation. Take for example Guangde Lake and Dongqian Lake, which respectively irrigated in the Yinxi Plain and Yindong Plain. The near city type is more suitable as a sustainable source for urban water system because of its distance advantages, such as West Lake in Hangzhou. In the Tang Dynasty, six wells were built in Hangzhou city convenient for diverting water from West Lake [6]. The study found that in the near-city type impounding lake system, there are mainly two kinds of positional relationship between the city and the impounding lake: the city is located between impounding Lake and river, such as Jian Lake and West Lake, the city and impounding lake are separated by the river, such as Nan Lake, Lian Lake.

3.2. On the intermediate scale

The impounding lake system has obvious landscape features, which are closely related to the natural condition.
According to the location, impounding lakes can be divided into three categories (Figure 3) with different levees alongside the lake: The first category of the lake uses intermountain depressions to construct in the valley with multiple mountain streams as the water source, such as Dongqian Lake and Chishan Lake (Figure 4). This type of lake has only a partial arrangement of levees at the gap between two mountains. The length of the levee is short, which greatly saves construction volume. For example, Dongqian Lake has a total of 9 levees (excluding 2 separation levees), whose total length is only about 2,550 meters, of which the longest Fangjia Levee is 819 meters long. The second category is built in the plain area that is backed by mountains. The levee is semi-enclosed and has a relatively long length. Taking Jian Lake as a case study, the total length of three levees is 59,400 meters, of which the shortest one is 4,700 meters long[7]. The water sources for second category lakes are mostly several mountain streams, such as Guangde Lake, Jian Lake, South Lake and West Lake (Figure 4). The third category of the lake is built on lowland with full-enclosed levee, such as Lian Lake, which uses Malin Stream as the only water source (Figure 4).

According to the lake structure, the impounding lake can be divided into two categories: simple and complex. Because of the different lakebed elevation and the dredging activities during the evolution of lakes, separation levees are often built in impounding lakes. The simple-type lake (Figure 5a) is a single lake with no separation levee, such as Chishan Lake and Guangde Lake. The complex-type lake is divided into two or more parts by separation levees. Some of complex-type lakes have no difference in height (Figure 5b). Their separation levees are made of silt from the dredging project. This not only saves the cost of moving the silt out of the lake, but also separates the lake to make dredging much easier [5]. Examples for reference include Dongqian Lake and West Lake. Another type of the complex lake, such as Jian Lake and South Lake, is composed of upper and lower lakes (Figure 5c), and is separated by separation levees to accommodate the difference in lakebed height. This will save the construction volume of levees alongside the lake, and at the same time reduce wind waves against levees. In addition, some of lakes have undergone several changes between simple-type and complex-type due to the development of water conservancy technology and different needs of different periods. As a typical example, Lian Lake changed from simple-type to complex-type after many times of siltation and renovation. Later, the lake was converted into a simple-type structure, because its upper lake was occupied by farmland in Ming Dynasty.

3.3. On the micro scale

There are two approaches to form the traditional impounding lake system: one is storing water by levees at the place where the runoff converges, and the other is building levees alongside natural lakes to expand the impoundage. These two approaches embody the process of interaction between artificial construction and natural environment. With the development of engineering technology and the ever-increasing spiritual, religious and aesthetic needs of humans, the impounding lake system has become increasingly mature. In addition to the lake itself, the complete traditional impounding Lake system also includes water management infrastructure and landscape infrastructure.
The water management infrastructure consists of levees, islands, sluice gates, weirs, covered drains, wells and etc. Firstly, the levee and the island constitute the spatial framework of the impounding lake system. According to different functions, the levee can be divided into levee alongside the lake and separation levee in the lake. The main use of levees alongside the lake is to store water, including three forms of partial levee, semi-enclosed levee and full-enclosed levee. The irreplaceable function of separation levees is to accommodate the difference in height and reduce the scour by flowing water. In addition to the most common linear separation levees, cruciform separation levees have also emerged. South Lake is divided into 4 parts by the cruciform separation levee [8](Figure 7), with mulberry trees planted on it to strengthen the levee and get maintenance costs by leasing land. The wooden piles excavated from the site of South Lake illustrates that the method of building levees was still used today by drilling the row of wooden piles down into the ground to strengthen the foundation, and then filling the soil. The silt produced during the dredging process can also be mounded into islands. There are countless mounds in South Lake. The higher one is more than ten meters high and the lower one is only a few meters high. The Reed Mound and the Wild Duck Mound are named after lush reeds and numerous wild ducks respectively [9]. It can be seen that the artificial islands in the lake constitutes abundant small ecosystem, which not only has ornamental value, but also brings certain ecological benefits to the water system. Secondly, the irrigation and drainage facilities, such as sluice gates, weirs, covered drains and etc., serve as key nodes in the water management system in order to establish links between internal and external water systems. For example, Dongqian Lake impounds from 72 streams in the southeastern side of the mountain (Figure 6 shows the direction of main streams). Nine levees are mounded at the gap between two mountains on the northwest side, and two separation levees between the two sides of the lake where has the shortest distance. Seven weirs are still in use, except for Limu Weir and Meihu Weir that disappeared with Mei Lake. The lake water is discharged into external water systems including Zhongtang Canal, Qiantang Canal, Houtang Canal and Xiaojia River through the four old sluice gates [10]. From the spatial analysis, settlements around Dongqian Lake are close to the water source, namely on the plains of the lakeside or both sides of the watercourse. And some of settlements are also distributed on the open flats near weirs and sluice gates, named after these water infrastructures. It’s convenient for management and maintenance of these facilities. For example, Qianyantou Village, Mozhi Town, Dagong Village, Dayan Village and Guojiayi Village are located near Qianyan Sluice, Mozhi Sluice, Huxin Levee, Dayan Sluice and Guojiayi Sluice respectively.

The landscape infrastructure consists of a series of landscape elements including temples, pavilions, towers, bridges, stone tablets and etc. Take South Lake (Figure 7) as an example. These landscape elements are often built in the lake (on separation levees and islands), on the boundary of the lake (on levees alongside the lake) and around the lake (where has broad view), such as Fuhu Pavilion on the cruciform separation levee in the lake, Dizang Palace, Shiliang Pavilion and Youfei Pavilion on the northern levee, Sanxian Memorial Temple, Tiancao Temple, Sanguan Palace and Sanyi Palace on the eastern levee, Anle Tower on the top of surrounding Anle Mountain,
Dongxiao Palace on the western mountain around South Lake and Guanyin Pavilion on the cliff of Xiafeng Mountain. Wang Shaozhen, a poet, wrote “The trees flutter in the wind. You can overlook the lake here and see Dongyue Temple through the fog”, which reflects Guanyin Pavilion is a lovely location overlooking the lake with comfortable environment. Meanwhile, from the perspective of Guanyin Pavilion, visitors can overlook Dongyue Temple at the foot of Phoenix Mountain. These landscape elements are often used to define the scope of impounding Lakes. It is recorded that South Lake was served Sanguan Temple as the eastern boundary, Xiafeng Mountain as the southern boundary, Shanyu Port as the western boundary, Shiliang Pavilion as the northern boundary, Dongyue Temple as the southeastern boundary, Sanxian Temple as the northeastern boundary, the wilderness as the southwestern boundary and Shimen Bridge as the northwest boundary. (At that time, the upper South Lake has been silted up). Eight stone tablets were set up to define the lake boundary.

4. The multiple functions and values of traditional impounding lake system

4.1. Economic value

The traditional impounding lake system is a paradigm for harmonious development between humans and nature in Jiangnan region. As an important form of land use in the agricultural landscape, impounding lakes take full advantage of natural resources, in order to ensure the sustainable water supply for agricultural production, figure out the problem of crop drought caused by uneven seasonal precipitation in Jiangnan region and promote the prosperity of agricultural economy. Apart from the agricultural function of irrigation, the ecological function of water supplement for canals is also worthy of attention. For example, after the middle period of Tang Dynasty, the north part of Jiangnan Canal (from Zhenjiang to Wuxi Wangting) used tidal water of the Yangtze River as the source in summer and autumn. In winter and spring, if tides cannot flow into the canal, Lian Lake water became the source of canal. In order to ensure the normal operation of the shipping industry, sluice gates and weirs were established to control the impounding and discharge [11]. There is an old saying that “If the water level of Lian Lake is dropped by one inch, the canal’s will rise one foot”. In the course of mutual adaptation between humans and nature, the distinctive agricultural landscape in Jiangnan region is finally formed.

4.2. Ecological value

The traditional impounding lake system also has considerable ecological value. It is interconnected with regional water system to form the water adaptive landscape through resilient deployment of water resources [12]. Thereby, disruptive natural events such as flash floods caused by uneven seasonal precipitation in the hilly Jiangnan region are figured out. With the long evolution, levees and islands mounded in dredging process promotes the natural formation of secondary wetlands, which provides habitats and eco-corridors for local wildlife. This helps to improve the diversity and stability of the ecosystem.

4.3. Cultural value

After satisfying the basic material living conditions, the impounding lake also serves as a vehicle of the cultural creation for spiritual needs. Thus the traditional impounding lake system has an extraordinary vernacular cultural value.
representative case is West Lake, which still retains the natural beauty of lakes and mountains and profound cultural significance currently. West Lake attracted a lot of literati in history. They left plenty of famous poets, ancient books and paintings. Bai Juyi, a poet in the Tang Dynasty and prefectural governor of Hangzhou, dredged six wells and formulated the corresponding impounding lake management system. Meanwhile, he wrote the Qiangtang Lake Inscription (West lake was called Qiantang Lake in ancient) which includes renovation strategy and relevant issues, and carved the inscription on stone by the lake. These cultural and artistic creations have promoted the inheritance and development of vernacular culture. He also left famous verses, such as “The scenery of the lake is too enjoyable to leave, and the most lovely is the White Sand Levee canopyed by poplars.” and “I do not want to leave Hangzhou and go home, half of the reason is the picturesque West Lake.”

5. Discussion

In the dynamic evolution over thousands of years, people continuously influence on nature under the premise of respecting nature. The interaction between nature and humans has formed the vernacular landscape with regional uniqueness and landscape diversity. Satisfying the needs of production, spirituality, religion and aesthetics, these landscapes are also spatial reflection of formation and evolution of regional characteristics in history. However, with the acceleration of globalization and urbanization, people no longer respect nature and work with nature. Vernacular landscape of China gradually shows a trend of homogenization and simplification. Therefore, an overall and in-depth study of vernacular landscape is of great significance.

The analysis of the agricultural landscape, which is the core component of the vernacular landscape in China, will provide the basis for the maintenance of the diversity and uniqueness of vernacular landscape. Although some of traditional impounding lakes have disappeared, natural and cultural relics can still be found in the preserved impounding lakes, ancient books and chorographic maps. Teasing out the relationship among the impounding lake system, the environmental background and the traditional city, and summarizing the resilient mechanism of the traditional impounding lake system, helps to provide reference for resilient urban landscape in Jiangnan region in the future.

Landscape Resilience: Research on Landscape Process and Strategies of Water-Level-Fluctuation Zone in the Three Gorges Reservoir——Case Study of Gaoyang Town

Jiang Xin, Wang Sijie, Wang Xiangrong

Abstract

Water-level-fluctuation zone in the Three Gorges Reservoir is the most typical artificial fluctuating zone in China, with a vertical drop of 30m. It is faced with huge ecological and social problems caused by flooding (great variety of the water-level). So it has been a worldwide problem that how to protect it ecologically, utilize it scientifically and develop it healthily. In the perspective of landscape resilience, taking the water-level-fluctuation zone of Gaoyang as a case, the paper attempts to make analysis of the land-use, hydrological situation and summarizing its characteristics and problems (ecological environmental deterioration, traditional customs and habits absence, farmland and public facilities disappearance). Then the paper puts forward a resilient solution from three aspects of ecological restoration, industry recovery and local cultural renaissance to study its landscape planning strategies.

The project is located in Gaoyang town, whose location is at the mid-south of Xingshan county, Hubei province. Gaoyang town, with profound cultural background and over one thousand years history. What’s more, Gaoyang town was the last town moved out from the Three Gorges Reservoir Area because of the rising water level. Many problems are caused by flooding. The first problem is the ecological problems, such as the water loss and soil erosion and biodiversity loss, should be solved urgently. Secondly, the traditional customs and habits would lost as the rising water level flooded the ancient town and a large number of immigrants had to move out. In addition, Gaoyang town faced huge challenges because a lot of farmland and public facilities had been flooded. Therefore, how to promote rural landscape under the influence of the hydro-fluctuation belt and make it a healthy and sustainable development is the real question we ought to face straightly.

The paper puts forward a resilient solution that is using the existing "riparian zone" flood area, the change of water level forms a series of differences in the "ladder". Ecological restoration of riparian; Planting seasonal vegetable crops; Extension Agricultural ecological cycle system; Giving full play to the advantages of fishery. At the same time, the "ladder" provides a series of green open space for the residents, diverse landscape level changes which create the residents to carry out rich folk festivals, and become a link between the residents and the reconstruction of the close relationship between the river.

The paper is expected to construct resilient framework of water-level-fluctuation zone landscape planning strategies of Three Gorges Reservoir Region. These resilient measures make regions quickly recovered and develop sustainably after a devastating natural disaster.

Keywords: landscape resilience; biodiversity loss; flooding; water-level-fluctuation zone; Three Gorges Reservoir
1. Introduction

Since the completion of the Three Gorges Dam in 2006, large swaths of land have been flooded, forcing millions of people to relocate and creating a large area of water-level-fluctuation zone. The water-level-fluctuation zone refers to a special area where the flooded land around the reservoir periodically exposes to the surface of the water due to the fluctuation of the seasonal water level formed by the reservoir operation plan. Water-level-fluctuation zone in the Three Gorges Reservoir is the most typical artificial fluctuating zone in China, with a vertical drop of 30m. It is faced with huge ecological and social problems caused by flooding (great variety of the water-level). Therefore, how to make a flexible ecological protection and urban development plan to realize sustainable development in the water-level-fluctuation zone has become a worldwide problem.

Resilience is defined as "the capacity of an ecosystem to tolerate disturbance without collapsing". Resilience is conferred in human and ecological systems by their capacity for recovery and future adaptation, as well as the given ability of humans to anticipate and plan for the future using these knowledge. There is increasing awareness that a greater understanding and emphasis of ecosystem resilience is required to reach the goal of sustainable development. In the perspective of landscape resilience, taking the water-level-fluctuation zone of Gaoyang town, Hubei province as a case, the paper attempts to make analysis of the land-use, hydrological situation and summarizing its characteristics and problems. Then putting forward a resilient solution from three aspects of ecological restoration, industry recovery and local cultural renaissance to study its landscape planning strategies.

In terms of the research on hydro-fluctuation belt (fig. 2.), some countries or regions such as the North America, Europe, Australia, Japan started early and relatively, obtained rich research results. In the early research, the interlaced zone located in the water and land ecosystem is called the "riparian belt" (the concept of riparian belt and the hydro-fluctuation belt is similar in early times). Throughout the study abroad, it mainly concentrated in the wetland ecological restoration, vegetation restoration and reconstruction, riparian zone ecosystem management, the influence of land use of riparian zone, vegetation succession, etc. In the end of the 20th century to the 21st century, with the establishment of the Three Gorges Dam and the formation of the Three Gorges Reservoir area, the water-level-fluctuation zone in the Three Gorges Reservoir became a research hotspot, scholars mainly made researches from solving ecological environment problems, land resources utilization, reconstruction of ecological system, plant planting, etc. For example, Ren Wei (2016) studied the landscape characteristics of the hydro-fluctuation belt zone in Yunyang, Chongqing. The study classified the land usage, and put forward the plan of landscape planning based on it. Deng Cong (2010) pointed that fluctuating zone ecosystem is a open-ecosystem, the stability of its ecosystem and the security of landscape is essential for the whole reservoir ecosystem. Fu Juan (2015) made a survey...
of water-level-fluctuation zone along the Xiangxi River of the Three Gorges Reservoir, the floristic composition and plant community diversity were reported. The research stated that species richness, community diversity, evenness and dominance represented the pattern of gradually increasing and then declining. The hydrological conditions appeared to be the important reasons of vegetation composition. Some exploratory studies have been carried out on tourism landscape planning and design. Bao Wen (2012) studied the development and administration of tour landscape in water-level-fluctuation zone of the Three Gorges Reservoir area, the study pointed that the tourism resources and landscape had huge change before and after Three Gorges Dam construction, which made great damages to local tourism resources. Then putting forward solutions to revitalize tourist industry. But there is a lack of research from the perspective of landscape resilience. Because the landscape research of the water-level-fluctuation zone is a multidisciplinary subject, it also lacks cases consideration from comprehensive aspects of ecology, economy, social, culture.

2. Background of Gaoyang town

2.1. Transition history of settlement

Gaoyang town, with 1026 years history, is famous for the Chinese distinguished figure named Wang Zhaojun and is also called as ‘the hometown of Zhaojun. Local villagers have the custom of worship Wang Zhaojun. Gaoyang town is the vital transportation hub as it closes to the Xiangxi river. Gaoyang town is the center of politics, economy, culture and transportation of Xingshan county in the eighties and nineties of last century as the blocks expended quickly and the town expended along the Xiangxi river at that time.

In early October 2006, the Three Gorges Dam was filled with 156 meters of water, and the ancient town site of Gaoyang sunk into the water. Only parts of the historical sites with low water level appeared on the surface. Gaoyang town was renamed Zhaojun town and the existing more than 1,000 years of ancient town—Gaoyang in fact disappeared underwater forever. The concrete dam was built after the construction of the reservoir. However, the accidents that the collapse of the dam took place frequently because of the unstable foundations and river erosion. The hydro-fluctuation belt was finally abandoned because of the reason above and also because the town lacked its own character (fig. 3.).

2.2. Hydrological analysis

In the Three Gorges Reservoir area, the height of riparian zone that smaller range is about 3 to 10m, then the largest of it is up to 30m, with 349 km² of the area. In the flood season, from Jun. to Sep. the water level is 145 meters. From Oct. To Dec., in the storage period, the water level rises to 175 meters. From Jan. to May, in the flood period, the water level slow down to 145 meters. The water level holding in 145 meters is about 110-120 days, and in 175 meters is for about 35-40 days (fig. 4.).

The water level drop of 30 meters will enable the formation of a large area of the Three Gorges Reservoir Riparian zone.
Because the most of the town is located in the river flat of the both sides of Xiangxi River and Gengjia River in the elevation from 155 to 165 meters. By the water level is 175 m in the Three Gorges reservoir, Gaoyang's main street and municipal facilities almost all flooded. In addition, Gaoyang town is located at the the tail section of Xiangxi river which belongs to the Three Gorges Reservoir Area. Geological problems such as soil erosion, landslides and mudslides always take place because the force of engineering activities and the changed environment.

2.3. Problems caused by flooding

Many problems are caused by flooding. The most serious problem is the ecological problems, such as biodiversity loss, water pollution and eutrophication, soil erosion and vegetation damage, should be solved urgently. As mentioned above, the the water level fluctuation season in water-level-fluctuation zone violate natural drought-flooding law, when the most hot and humid season comes, the heavy rains are frequent at the same time, will lead to great changes in terrestrial ecosystems, especially to plant communities. Therefore the ecosystem is quite fragile. In the other hand, before the formation of the water-level-fluctuation zone, the vegetation on both banks of the reservoir area is a natural ecological barrier, which has some function of interception and filtration of pollution from the reservoir bank, especially agricultural non-point source pollution. Nitrogen, phosphorus, etc. carried by surface runoff are equivalent. A part of it is digested and absorbed by vegetation to prevent it from entering the reservoir water body. After the formation of the water-level-fluctuation zone, these functions will basically be lost, and more pollutants will enter the water body, leading to an increasing degree of eutrophication in the reservoir area.

Secondly, Gaoyang town faced huge challenges because a lot of farmland and public facilities had been flooded. Residents were forced to migrate from old Gaoyang town to other districts and most of the houses, roads and the public facilities had to be dismantled because the floods from the reservoir. Compared with the old town before, the land area of the town shrank and the residents lacked the necessary public facilities and public space. The figure 5 shows that 82% buildings are flooded and 130000 people are removed. As a result, 30% of the industry is affected and incomes are reduced by 20% (fig. 5.).

In addition, the traditional customs and habits would lost as the rising water level flooded the ancient town and a large number of immigrants had to move out. With the process of urbanization, the construction of Gaoyang town, like other towns in China, is facing a serious problem of assimilation.

Therefore, how to promote rural landscape under the influence of the water-level-fluctuation zone and make it a healthy and sustainable development, maintaining the unique historical culture of Gaoyang town at the same time, is the real question we ought to face straightly.

3. Resilient Strategies

Because the water level is constantly floating, the strategies must be resilient. So the study puts forward a resilient solution
that is using the existing "riparian zone" flood area, the change of water level forms a series of differences in the "ladder" (fig. 6.). Ecological restoration of riparian; Planting seasonal vegetable crops; Extension Agricultural ecological cycle system; Giving full play to the advantages of fishery. There are 4 layers in the "ladder" including folkway layer, fishing layer, crop layer and plant layer from low to high. The floating trails (folkway layer) are set on the river close to the flooded houses. Residents will recall the history when they get close to the folkways ladder, which also create many kinds of public space for people’s activities along the river banks. The fishing ladder’s altitude will change along with water level where people can fish and cultivate aquatic products on it. These activities and hygrophyte planted around the fishing ladders aim to build open waterfront space. The local crops and seasonal vegetables planted on the ladders are supplied to residents and the ladders create a scenic riverside landscape. The chosen hygrophyte can filtrate and settle nutrition, pesticide and microorganism. It is significant for water purification and conservation of water and soil of the water-level-fluctuation zone. At the same time, the "ladder" provides a series of green open space for the residents, diverse landscape level changes which create the residents to carry out rich folk festivals, and become a link between the residents and the reconstruction of the close relationship between the river.

The whole system can fluctuate according to the change of water level, so it can produce different landscape effect. In summer, the water level is the lowest, so these ladders will distribute in a stepped vertical shape. In spring and autumn, the stairs located on the middle of the water-level-fluctuation zone will float because of the rise of the water level. After that, all the floating stairs will constitute a larger activity platform where people may have a spring outing or dry the grain. All the stairs will float and constitute the largest platform for festival and folk custom activities during the winter when water level is the highest.

3.1. Ecological restoration

Due to the periodic inundation of the river, the vegetation conditions in the area are very poor, mainly with wild shrubs and herbs, and the ecological balance is destroyed. Plants are the vital part of both ecosystem of the water-level-fluctuation zone and the sightseeing of riverbank. They are beneficial to reduce soil erosion and purify the water which contribute to the species diversity eventually. Therefore, the water-level-fluctuation zone need to consider the purification function of the community configuration and species selection for the formation of wetland vegetation, and establish an interception and distribution system for the sewage generated in the extension zone of the wetland belt, evenly distribute the runoff from farmland and cities into the nursing belt to fully utilize the wetland system. The purification function achieves a better effect.

Plants growing on the water-level-fluctuation zone spread as the plaque (just like our boat like stairs), which is helpful to plants growth when they are drowned. The plants also spread in four band like district along the water-level-fluctuation zone according to the altitude. Therefore, this system imitates the four natural band like
district. The plan designs four different plant stair districts according to the different altitude and grow ecological vegetation, cash crop, grain and hygrophilous vegetation in each district.

According to the different site environment condition, the suitable seedlings need to be chosen for aquatic or for terrestrial. Current research shows that plants suitable for the water-level-fluctuation zone in the Three Gorges Reservoir include Taxodium distichum, Taxodium ascendens, Myricaria laxiflora, Glyptostrobus pensilis, Populus deltoids, Carya aquatica and so on[9]. In the plan, these plants are applied. In addition, management technologies including seedlings treatment, timely construction, reasonable close planting, drought resistance, and cultivation are also very important.

3.2. Industry recovery

In ancient times, Gaoyang town was an important port of Xiangxi River Basin. The agricultural products, tea and medicinal materials produced in Gaoyang town were transported from here to the outside. In modern times, Gaoyang town has also achieved certain development with its abundant agricultural and forestry resources, mineral resources and hydraulic resources. Therefore, industry recovery is the key to drive the economic prosperity of Gaoyang town. This system plans to plant local crops and vegetables seasonally in the ladders. Sow seen in spring, when the water level is low, harvested after a period of growth in summer or autumn, and when the water level is highest in winter, the area is submerged. In addition, the system uses the lower layer to develop fisheries products.

The baskets are placed below the decks and float freely as the water rises. The output value of the primary industry of Gaoyang town will improve through the revitalization of agriculture and fishery.

Moreover, the terraced landscape formed by the system will become a unique landscape in Gaoyang town, and the rural tourism can develop greatly with the help of the historical and cultural influence of Zhaojun's hometown.

3.3. Local cultural renaissance

The ancient Gaoyang town was once a city with a long history and a rich culture. As the water flooded, many historic sites were also permanently submerged under water. Only in summer, when the water level is lowest, some historic sites and buildings will appear above the water. So at the lowest level, the system set up a historical route to tell people that there used to be a beautiful old town. At the same time, cultural revival is also reflected in the heritage of festival activities and customs, the large floating plates formed on these decks can be used as places for folk festivals and cultural displays.

In addition, the response to culture is also reflected in many aspects, such as the cultivation of native plants, the application of native materials and so on, using these physical space environment to convey a rustic atmosphere. The excellent cultural traditions of the area evoke people's feelings for the ancient town that has passed away.
4. Conclusions

Because of the flood disaster, the Three Gorges area has a lot of negative effects, and many ancient villages are disappearing. How to improve the landscape in the area scientifically and rationally is an important aspect of landscape resilience. With the help of a simple, low-interference way to realize harmonious coexistence of human, society and nature, promoting the region's ability to respond to disasters, even transforming these bad conditions into favorable factors, is the embodiment of the landscape resilience. Through the case study of Gaoyang town, the plan creatively puts forward the resilient solution, which will have a positive influence on the planning of the other towns in the Three Gorges Reservoir area.

Abstract

The urban riverside region is the area with abundant natural landscape resources and human landscape resources in urban open space. Nowadays, most of the riverside region has problems of unreasonable use of space, lack of features, etc. With the continuous development of the city, the demand for urban open space is constantly improving, the renovation of the city riverside area is imperative. This paper introduces the concept of urban renewal, starting from the factors of land use, function, culture and ecology, so as to draw a set of universal theoretical system in the area of urban river area renewal, and guide the healthy development of urban riverside region renewal activities. Taking the Beijing Zhuanhe Riverside area as an example, the paper hope to make reference for the future renewal of the urban riverside region.

Keywords: City; Riverside Region; Renewal; Urban Design

*Corresponding author: Qing Lin, E-mail: lindyla@126.com.
1. Research Background

With the development of China, urban renewal has gradually become a hot topic. And as a part of the urban renewal, uniqueness of urban riverside area updated is often neglected. The riverside areas of the city are often rich in natural and human landscapes on account of its nature close to river, which also create the sophistication of their environment. Therefore, how to deal with the various relationships such as traffic, landscape and function in a limited land area during the renovation process is worth exploring.

2. The challenges confronted by the renewal of urban riverside area

2.1. Problems left over by history in riverside region

On the basis of its good water transport conditions, most planners choose riverfront area as an industrial and warehouse space at an early stage of urban construction. So the regional transportation infrastructure is relatively developed. With the development of landway transportation, the riverside area gradually declined, which caused the dilemma of the current riverside area. Firstly, it is the damage to the river ecosystem; Secondly, on account of historical reasons, urban waterfront areas are isolated by main roads, railways or industrial zones, so it purpose is single; the space of riverside region is introverted and relatively isolated organization system lacks close contact and communication with other areas of the city\(^1\). However, as the rare scenic resources in the city, how to make the riverside region a place for leisure and recreation of the residents by means of renovation is a huge challenge confronted by renewal of riverside region.

2.2. Absence of riverside area characteristic

In the process of urban renewal, on account of ignorance of the background differences in different regions, most of the riparian areas today exists problems such as weak connection with rivers and poor identifiability. At the same time, the single design method has resulted in except slight differences in the landscape of riverside area. How to carry out in-depth excavation of local history, culture and regional features through transformation and renewal is another major challenge for the renewal.

3. The strategy of riverside region renewal

3.1. Renewal meet function

As a whole, riverside regional function should be coordinated with the overall urban functional layout of the city. As a relatively unique area in the city, riverside area is a complete system itself\(^2\). Therefore, the upgrading of the riverfront area requires a reasonable functional layout. Dismantle and reconstruct buildings with inappropriate layout such as wasted wharfs and warehouses, increase the public space in the riverfront area and satisfy the residents’ daily recreational demands; At the same time, it is necessary to govern intensive urban land traffic, underground transportation and water transportation, alleviate the serious division of the interior sections of the riverside area.

3.2. Improve and upgrade landscape

As adjust function, the utilization of riverside resources is also very important. Riverside landscape can be shaped by combining riverside landscape belt with landscape nodes. Because of the continuity of riverside landscape belt, different landscape sequences can be formed by combining the landscape nodes. In addition, the whole riverside landscape belt and landscape nodes are connected in series by the means of the slow traffic system to form a complete landscape system. It can penetrate into the interior of the entire riverside area. This enhances the overall landscape while also facilitating the residents in the area.

3.3. Shape and demonstrate regional characteristics

The riverside area tends to be the starting point of the urban construction, so the riverside area is also the place where the historical culture gathers. The architecture and landscape with urban geographical features are the embodiment of urban characteristics. However, the traditional forms cannot be simply copied or scaled up under demands of new function and space requirements, we should conduct in-depth research on local history and culture characteristics. Therefore, when the riverside area is updated, it should be combined with era characteristics to create urban design elements with practical and cultural characteristics.

3.4. Protection ecological environment

The renewal design of the old riverside district takes the improvement of the ecological environment of the riverside area as the precondition. Otherwise, the riverfront area will not attract people and investment and its updated design will lose premise. Therefore, in the renewal of urban riverside areas, we must make full use of the principles of landscape ecology to restore and manage the ecological environment, including the governance of water pollution, softening of hard revetments and establishment of ecological corridors along the river. Only in this way can we restore and protect the fragile ecological environment of the urban river.

4. Update content of urban riverside region

The renewal of urban riverside area includes the contents of general urban renewal: the construction of building with unreasonable function layout and the large-scale renovation of urban roads; Rectification of aging buildings and public service facilities. At the same time, it also needs to pay attention to ecological protection and the construction of riverside public space. Overall, riverside area updates contain:

4.1. The governance and restoration of water body

Carry out restoration of water body and govern polluted urban water body; Conduct desilting of water body and restore natural connection and mobility of natural water system; Remould hard bank of the river and restore natural revetment; Plant waterfront plant groups and improve self-purification capacity; Implement construction of sponge

city and strengthen absorption ability on rain.

4.2. *Restore and utilize waste land*

Carry out ecological remediation on waste and polluted land; eliminate potential safety hazard on site and cultivate plants with high adaptation to restore natural ecology of waste land.

4.3. *Improve green space system*

Carry out pergola construction along with river. At the same time, increase urban green space by the means of remove and transformation and other methods to form green space pattern of “green dot, green line and green surface”.

4.4. *Increase public space*

Through governance of illegal occupation of public space and demolition and other methods, increase public spaces in riverside space to satisfy demands of residents’ daily leisure and recreation.

4.5. *Improve traffic condition*

Tease road system in riverside system to buffer traffic jam. Carry out avenue transformation for those long and lack of shield. Increase public transportation system and parking system.

4.6. *Transform old residential areas*

Carry out environment transformation on old residential areas; strengthen construction of public service facilities inside areas; improve residential environment and offer ready service for residents.

5. *The methods of urban renewal and its application on riverside region*

In accordance with definition in the *The old city of Beijing and its Juier Hutong neighbour* authored by Wu Liangyong, renewal mainly includes three aspects of contents as following: 1) transformation, reconstruction or redevelopment refers to completely get rid of certain aspects in current environment and its purpose to expand space and increase new content to improve environment quality; 2) rehabilitation refers to reasonable adjustment and utilization of current environment, generally indicating partial adjustment; 3) conservation refers to protect on current state of owned conservancy value without alteration basically.[5]

In the riverside renewal process, the three means corresponds to three renewal models: demolition and transformation type, governance type and protection type. In the riverside renewal process, the three modes are normally co-existed. The demolition and transformation refers to remove and rebuild buildings and zones unable to adapt to era demands such as industry, warehouse and shack-dwellers to re-motivate vitality of riverside region. The governance type includes governance on water body and improvement of overall regional environment. The protection type refers to protection on historical construction and exploration on history and culture.

6. *The concept renewal of Beijing Zhuanhe riverside region*

The following part will combine with actual survey on Beijing Zhuanhe riverside

---

region. Targeting at survey results, propose conceptual plan on renewal of this area and hope to provide references to the renewal of urban riverside region in the future.

6.1. general situation of the area

The survey scale is located in the Zhuanhe riverside area in Xicheng district, Beijing, which was founded in 1955-1963. Zhuanhe river started from Gaoliang bridge in the west to Northern moat in the east. In 1905, when Zhan Tianyou built Beijing-zhangjiakou railway, set up Xizhimen station, which made Zhuanhe river re-channel to north direction and lay the foundation for the current Zhuanhe river. On account of long age of construction, large number of unit compounds existed in the area. On 1st, July, 2014, shutdown of Beijing-zhangjiakou railway and the holding of Beijing-Zhangjiakou Olympic Winter Games brought huge opportunities for renewal of this region. (Figure 1)

6.2. The renewal of Zhuanhe riverside region

The conceptual renewal this time is to target satisfying comfort level of slow-traffic system, build green network and improve overall regional environment quality. At the same time, in virtue of transportation junction of Xizhimen and regional advantages of Northern second ring, improve regional internal functions, stimulate regional vitality and form public space with regional characteristics.

(1) Land utilization

The internal area in this region is dominated by residential areas and it exists large shanty towns. The transportation facilities occupy large floor areas. The Zhuanhe river flow through internal areas and greenbelts are distributed in line along with Zhuanhe river. Therefore, in the renewal design, dismantle areas without historical conservation value as well as inferior building quality such as shanty-towns in accordance with requirements of urban planning. At the same time, rebuild greenbelts with inferior current environment quality and low use ratio. Meanwhile, on account of shutdown of Beijing-zhangjiakou railway and vacancy of Beijing North Station, a part of transportation facilities have been adjusted. By means of reconstruction and re-developments and other methods, it is aimed at making these areas re-play significant role in the overall development in Zhuanhe region, undertake new urban function and become crucial urban areas. (Figure 2)

(2) Combing the traffic
The internal road system in Zhuanhe river area is relatively complete. However, on account of existence of Beijing-Zhangjiakou railway, severe segmentation exists in eastern and western side of this region and it failed to form a complete riverside slow traffic system. In addition, long age of construction, some narrow problems, devoid of shield and severe road occupying phenomenon result in low comfort level and poor cross experience of current roads. It adopts three-dimensional transportation to solve this problem in the design process to guarantee integrity of slow traffic system. In the process of renewal design, initially solve the problem of breaking points in the riverside slow traffic system, because walkway is unable to pass through Beijing-Zhangjiakou railway. Meanwhile, set up riverside sites to enrich level and structure of hydrophilic trail. For problems existed in the urban roads, carry out transformation on green improvement to promote cross comfort level. Moreover, it adopts the method of peaking shift parking to buffer traffic jam caused by on-road parking of vehicles. (Figure 3)

(3) Urban function
The functions of urban riverside area is generally oriented by residence, business, work, leisure and recreation. Among them, residence function is considered as one of the main functions of Zhuanhe river area and owns strong vitality until now, so it should be strengthened. At the same time, this area is the close neighbour of Beijing old town and possess convenient traffic locational conditions, so business function as the main regional function should be developed. What closely related to business is the function of business office. Therefore, in renewal design, install certain quantity and scale of business office function in the riverside area to improve economic values in this area and gather popularity. It is an obvious tendency for cultural recreation function in current riverside area, so build a series of entertainment, popularization of science and cultural facilities as the important means to build the cultural images in this area.

(4) Landscape construction

“Water” and “green” are the elements symbolizing nature in the city. The “water” and “green plants” demonstrates strong oneness. The combination of water and green create the landscape of “blue water, green belt and blue sky” so that the riverside landscape owns more pleasant hydrophilic breath\(^\text{[6]}\). Consequently, in the renewal design, pay attention to shaping riverside green belts. In accordance with differences of surrounding environment and landscape style, divide the linear green spaces of entire riverside area into riverside ecological section, urban leisure section and neighbouring residential section. (Figure 4). In addition to this, set up railway heritage park, residential park and so on combining sectional background. (Figure 5,6,7)

(5) Ecological protection

From the angle of landscape ecology, “plaque-gallery-matrix” constitute basic

---

form of ecological system\cite{7}. The ecological system in riverside area equals to gallery in the landscape ecology, which tends to be the most frequent intersection between human activities and natural ecological system. Consequently, in the renewal design, it adopts a series method of water body purification, increase phytocoenosium in riverside area and soften original river bank with plant material.

(6) Feature construction

The extraction of regional characteristics is carried out embracing railway culture. From construction of Beijing-Zhangjiakou railway in 1905 to its shutdown in 2014, as its Beijing starting station, Zhanhe river region witnessed the development of Chinese railway career. With the construction of Beijing-Zhangjiakou high-speed rail, memories on Beijing-Zhangjiakou railway will be reserved as its regional memories. Therefore, in renewal design, utilize space of demolition to set up railway heritage park. Meanwhile, install railway culture museum to commemorate Beijing-Zhangjiakou railway on active service for over one hundred years. It reached the purpose of shaping local characteristics though this simple method and play the active role in improving economic and cultural development of the entire Zhuanhe river region.

7. Conclusion

With urban development, urban renewal is carried out. In comparison with general areas, the riverside areas are normally restricted to more elements. As a result, the renewal of riverside region will take the characteristics into consideration such as natural environment, historical humanism and economic society, choose renewal strategies and methods suitable for this area to restore vitality in riverside region and re-play its role in the urban development.

\textsuperscript{b} Beijing Forestry University (No.) 35 E(ast) Qinghua Road Haidian District,Beijing 100083 (zip code) P.R.China

Abstract

With the construction of sponge city in China, the limitation and disadvantages of the construction of sponge park are also highlighted. The excessive focus on the LID system and the management of the rain water have contributed to the sacrifice of the “artistic quality” of the park construction. This paper analyzes and summarizes the traditional Chinese landscape design and the LID system and takes Longquan Lake Country Park as an example to discusses a design strategy of effective combination of the two, providing guide for sponge city afterwards.

\textit{Key words:} China, Landscape Architecture, Resilience, Chinese traditional landscape Design, LID system;

1 Introduction

With the construction of Sponge City in China, cities have accumulated experience of dealing with problems of stormwater from practice. In the process of construction, problems like "excessive reliance on the rain collecting function of the green system" and "the unbalance of art and science" emerged.[1] This reflects that although the construction of the sponge city has achieved fruitful results, our country is still lacking a set of effective and compatible method of combining it with Chinese traditional landscape design. It is the core of this research that how to meet the function of rainwater management in the construction of sponge city, while meeting Chinese traditional aesthetic standard.

Due to the fact that researches on the Low Impact Development system(LID system) in China are mostly focusing on urban area, the
rain-flood management strategy of green space in the shallow mountain area lacks scientific guidance of the design level. Owing to climate change, urban expansion, disturbance of human activities and many other negative factors, vegetation in shallow mountain area get strongly damaged, which caused a series of water problems such as the overall degradation of the ecological environment, soil erosion, water shortage and water pollution. Therefore, choosing Longquan Lake Country Park which located in the shallow mountain area of Shijiazhuang city, Hebei Province has important research value.

2. Design Strategy Combing Chinese Traditional Landscape Design Method with LID System

According to reports from ministry of housing and urban-rural development, 62% of cities have experienced varying levels of flooding all over the country in 2008-2010. In recent years, heavy rainfall hit Guangzhou, Shenzhen, Nanjing, Hangzhou and many other cities. Especially extremely rainstorm in Beijing on 21th, September, 2012 led to severe water and traffic paralysis in the city and even mountain flood debris flow and other natural disasters in local mountain area. Even so, Chinese classical imperial palaces and gardens were even capable of rapid drainage, surviving from getting flooded, which thanks to its perfect and mature drainage system.

2.1 Overview of Chinese Traditional Landscape Design

Deeply influenced by the geometry stemming from ancient Egypt, western gardens emphasized numbers and geometry, which represents for human’s conquest of nature. Different from it, Chinese ancient people learned to dredge rivers, make mounds as well as stone-layout from time to time, forming the theory of ‘harmony between man and nature’. It became the general principle of Chinese world view and culture ever since. Chinese literature devote particular care to learning method of ‘ profound harmony of human inner feelings and the secular world’ and ‘who excels reads as many as ten thousand books and travels as far as ten thousand miles’. Chinese painting conform to the creation way as ‘learning from nature, merge nature with artist’s inner feelings’ while having ‘art is that between likeness and unlikeness’ as artistic state and evaluation criteria. Under the influence of literature and painting, Ji Chen summed up the concept and pursuit of Chinese garden in the book Art of Garden-building----‘Though it is done by man, it looks like the way it is from the very beginning’. This request that the creation of manmade landscape not only needs to take nature as the prototype but also needs to recreate nature on the basis of natural law and merge with poetic idea.
The Summer Palace is a typical example. In Ming & Qing Dynasties, imperial court put forward a series of measures to solve the stormwater problems: built up levees along Yongding River to hold back large floods; regulated floods from shallow mountain area through imperial gardens in western hills area; used river system to prevent waterlogging and so on. Placed in western hills area, the Summer Palace combined hydraulic engineering and gardening together by the excavation of river at the north part. The resulting earth volume was used to make mounds and to extend the real hill in site. Functioning as drainage system for the mountain, the west Taohua gully was expanded at its water outlet part. After completion, the Kunming lake reservoir works as stormwater management facility as well as irrigation water source. Furthermore, it transports landscaping water for the Winter Palace, provides places for practicing navy and also provides entertainment and tourism places for people. Through the test of time and floods, the treasure left over from the Ming & Qing Dynasties is enough to prove its great aesthetic value and its abilities working as stormwater management system.

2.2 Overview of Low Impact Development System

Rapid urbanization has brought great economic development to China, but also brought about a series of urban problems. The impermeable hardscape of large area, the backward of urban infrastructure such as drainage facility and flood control facility, the depletion of groundwater, and extreme weather brought heavy rains to cities has brought more and more serious floods. To solve this problem, Chinese ministry of housing and urban-rural development compiled the Sponge City Construction Technology Guide—Low Impact Development of Rainwater System Build(try out)(Guide), which referring to American LID system theory and practice experience and consideration of the situation of China.

According to Guide, LID system uses the sunken green space, permeable pavement, seepage pond and seepage to ensure the rainwater seeping into the ground; uses the sunken green space, green roof, water storage tanks, rainwater tanks to store rain water, realize the recycle and reuse of rainwater; uses biological detention facilities, wet ponds and rainwater wetland to reduce runoff and pollution. All of these work as one to form an intact low impact rainwater management dealing measure. Rainwater runoff that exceeds LID system’s ability to hold will be discharged into the urban rainwater sewer system, which enables rainwater drainage in off-peak periods and alleviated the pressure of the urban rainwater sewer system. Thus it can be seen that LID techniques of ‘infiltration, retention, storage, purification, use, drainage’ not only ensure the control of rainwater at the source, midway and end but also restore the natural cycle of water in large degree.[5]
In addition, combining techniques like SWMM and GIS enables us to evaluate and calculate the relevant statistics of stormwater management effectively, which benefits to both the guidance to the construction stage and the analysis and summary after completion.

2.3 Contrastive analysis of Chinese Traditional Landscape Design and LID System

Although both Chinese traditional landscape Design and LID system regulate stormwater, but there are differences in construction objectives, emphasis and technical measures between these two.

‘Harmony between man and nature’ is the core of Chinese culture. Aesthetes Li Zehou summed up the Chinese landscape garden art as ‘naturalization of human and humanization of nature’. The reason why Chinese gardens are called natural landscape garden is that it is an art that being poetic and it takes the natural landscape as its model and combining landscape painting and landscape poetry form into being. Both of them pay attention to ‘feel like’ rather than ‘look like’. They are the product after the observation and experience of nature, combined with the author’s inner thoughts and emotions. After thousands of years of accumulation, simulation of nature led to Chinese traditional landscape Design’s variety. Thus it has a deep understanding of how does nature system works. Chinese traditional landscape Design pays a lot of attention to comb the landscape structure, make abundant variety of spaces and give it poetic meaning on the basis of site condition. Thus it’s artistic quality is self-evident. In the process of construction, stormwater has already be controlled and managed.

LID system focuses on solving the problem of stormwater. Different from traditional stormwater management system, LID system emphasize that rainwater is a resource, not a waste. Applying LID system techniques of ‘infiltration, retention, storage, purification, use, drainage’ can ensure the control of rainwater at the source, midway and end as well as realize the natural hydrological cycling of rainfall. The construction mode is based on the guidance of scientific evaluating method. It evaluate site and give guide for design at earlier stage and reevaluate after construction for adjustment and design afterward. In a long term, it is beneficial to the progress and development of stormwater management technique. It’s scientificity is self-evident.

But it is not hard to see in practice that it is difficult to control and manage stormwater accurately simply by using traditional Chinese landscape design as the guidance basis; it is guarantee the aesthetic characteristics under the guidance of LID system. Scientificity and artistic quality are the two important attributes of landscape architecture. The artistic quality can’t guide the construction of landscape architecture in
nowadays by itself, while the pure engineering science can not completely represent the whole landscape architecture. This is the starting point of this study.

3. Practice in Longquan Lake Country Park

This paper combines the Longquan lake country park project in Luquan district, Shijiazhuang city, Hebei province, research in combining Chinese traditional landscape park construction method with low impact design of the drainage system of the development of specific methods and patterns. Situated in in urban shallow mountainous areas in northern China, Longquan Lake Country Park takes the the drainage pressure both from urban internal area and urban shallow mountainous areas. In addition, the annual rainfall in North China is less than normal and the rainfall is concentrated. Rainstorms frequently occurs and the annual evaporation is large. This causes serious flood and water shortage. There is a pressing need for applying stormwater management system to the construction of country parks in urban shallow mountainous areas in northern China.

3.1 Construction of Landscape Structure and Water Circulation on Macro-level

Based on the traditional Chinese landscape theory, the overall structure of landscape architecture of the planning site is done. The design delimit water body and watershed according to the landscape planning, then work with techniques of LID system to realize natural circulation of rainfall.

The project firstly conducts a comprehensive field survey of the site and uses ArcGIS to deal with the site surveying and mapping documents and then designs the topography. The design follows the principle of "adapting to local conditions" according to the traditional Chinese landscape theory, using traditional gardening method to deal with topography and making full use of it’s characteristics in site to make
delicate and natural waterscape. Smallest earth volume is used to make various landscape as much as possible.

When heavy rains comes, it will serve as rainwater infiltration and detention system to manage rainfall and floods. When the rain exceeds the load, it works as as a transmission system to transport surplus rainwater to the middle district for further storage. 3) middle district: Gullies are enlarged fully. The resulting earth volume is used to make main hill at north side of this district. The large water body here is not only the basement of rainwater storage system, but also the core water body for rainwater storage for the whole park which holds surplus runoff coming from west and three gullies district. 4) east district: The existing water bodies in the site are kept, and the gullies of the terrain are properly combed to form the wetland landscape.

While combing the landscape architecture, the rainwater circulation can be constructed. Each district has its own water cycle during normal rainfall period while they work as one during heavy flood period to store rainwater coming from inside and outside as super sponge. Planning evaluates the rainwater (table 1, 2) and adjust the water area of this park. Chinese traditional landscape design also emphasizes the principle of ‘always know where is the water come from and where it goes to’. The water system of the site is connected, and the elevation of water level from east to west gradually decreases. At the end, the water system of the main water body is connected with the eastern water channel by three point water surface. When the amount of
precipitation on the spot exceeds the ability of the site to hold, the surplus rainfall will be discharged into the water channel through the three point water surface and then imported into the municipal pipe network. The rainwater drainage system of the park is established and it effectively avoids the disadvantages of "over-reliance on the rainwater harvesting function of greenbelt system" during the construction of sponge city.

Tab 1 Rainwater Storage Calculation

3.2 Construction of Landscape Terrain and Rainwater Control on Middle-level

Handling the waterscape and landscape further. Applying LID system techniques of ‘infiltration, retention, storage, purification, use, drainage’ to ensure the control of rainwater at the source, midway and end.

On the basis of macro landscape structure, the terrain is further combed. The topographic trend and slope changes are arranged to effectively avoid unorganized rainwater flow, and control the flow velocity and flow direction. The surface runoff in the green space is organized and collected through linear negative terrain, such as gully and valley. In the larger part of the water flow, design increases the block stone or even the stone mountain to prevent soil erosion. The adjustment of the water form also combines with the rainwater organization of the green space: For example, in the area where the rainwater is concentrated, the inlet will be enlarged and used as the rainwater alluvial fan to relieve the impact of the flow on the soil. After fully combing the terrain, the road system of the park will be constructed. Using Permeable pavement, the road system will be used as the linear element of the rainwater infiltration system in the whole park. The rainwater after the first infiltration of in the green space will be organized by terrain and flows into the road system. In the process of transport by road it get secondary infiltration.

Rainwater falls onto the site will be absorbed to some degree, and the part that does not being infiltrated will enter into the grass ditch. The grass ditch has a certain
retention effect on the rainwater and can lead the rain to infiltrate again. In the area where the rainwater is collected intensively or connected with squares, the grass ditch will be partially enlarged to form a rainwater garden and the rainwater can be retained to a greater extent. According to the requirement of water catchment, the construction of grass ditch will be combined with road system-----along either side of the road or on both sides. The establishment of the grass ditch has further improved the construction of the park rainwater retention system.

3.3 Construction of Micro-topographical Features and Rainwater Management Point on Micro-level

The design of landscape nodes is considered with LID techniques. The microcirculation in the whole system is realized by rainwater garden and sunken green space, which effectively combine the landscape and popularization value of green space.
storm reaches the breaking point, the rainwater will be drained into urban rainwater pipe network. At this stage, the rainwater infiltration system and rainwater retention system are completely constructed.

On this basis, the rainwater purification system is constructed. The rainwater purification system chooses suitable purification method and uses physical, microbial and biological method in combination in accordance with their different characteristics and purifying effect. Microbial method is the way that microorganism plays a major role as a decomposer to decompose and absorb in Eutrophication material. But after two months, the effect will significantly reduce. Therefore, microorganisms need to be released regularly for specific water quality conditions. Its advantages are that it is bioenergy and low power consumption and it can absorb in COD, ammonia, total nitrogen, total phosphorus and SS efficiently and effectively. Biological method include aquatic plant planting technique and animal habitat creation technique. Aquatic plant planting technique is the way that plant plays a major role as filter, cleaner as well as major constituent element of a park landscape. In this project, 16 kinds of aquatic plants are selected. The planting area reaches over 30% of the area of the whole garden so that landscape effect can be ensured while acting as an excellent filter for ecological purification. Animal habitat creation technique is the way that animals function as the moderator of ecological environment. The weakness of this way is that it has slow effect, the choice of biological species should be paid attention to when designing. Through the combination method of ‘aquatic plant-animal habitat construction-microbial investment’, contaminant like SS, N, P, COD in the water can be reduced shapely. It can even improve the quality of water as V to the quality as VI while improve the level of dissolved oxygen in water. In urban runoff pollutants, SS is often associated with other pollutant indexes. Therefore, SS is generally used as the control index of runoff pollutants. In this project, the total removal rate of SS can reach over 60%. Aquatic plant ponds are put in part of water bodies to purify water while serving as landscape elements that improve the landscape effect of waterscape.

At final stage, the rainwater utilization system is constructed. Water-saving irrigation is used as main irrigation method in this project. Water-saving irrigation is an irrigation measure that maximizes the product of yield using minimize water, which has the characteristics of water saving, energy saving, labor saving and high water quality. The water bodies in this park serves as sources of irrigation and the irrigation area basically covers the whole park. According to the evaluation of precipitation rainfall capacity, water retention capacity and irrigation water capacity, when rain
Future Resilience

4 Summarize

This paper studies Chinese traditional landscape design and LID system and draw a conclusion that there are different emphasis and difference in guiding the park construction. In practice, the combination of the two shows a certain degree of fracture. Thus this paper proposes to a new design method that combines them together which can provide reference for subsequent sponge city construction, guide to create a strategy that conforms to the Chinese traditional aesthetic idea and alleviate urban rain flood pressure. By considering of these three levels, Longquan Lake Country Park effectively avoided the phenomenon of designing first and managing rainwater later. While ensuring the landscape effect and manage stormwater scientifically, it can provides reference for construction of stormwater management system in country park.

1. Study on the Construction Method of Habitat-Type Urban Forest under the Background of "Keeping White and Increasing Green" in Beijing -Taking the Hengjiezi Urban Forest as an Example

Xuejing Yu, Qu Shi, Xiong Li*

Beijing Forestry University, (No.35 East Qinghua Road, Haidian District, Beijing 100083 (zip code), China

Abstract

In order to improve the living environment and build a biophilic city, Beijing Administration began to cancel some non-capital functions. By using the means of “keeping white and increasing green”, illegal buildings were demolished to get a reserved land or for greening and serve as people's livelihood or to leave a flexible space for the future development of Beijing. In this context, Beijing will continue to start a large number of urban forest construction pilot projects to promote urban ecological quality and enhance the public satisfaction of accessing greening areas. This paper takes the Hengjiezi Urban Forest as an example to explore the habitat-type urban forest construction method based on biodiversity researches.

Habitat-type urban forest is built with the purpose of improving urban ecological environment and improving biodiversity by creating habitats for animals and plants and breaking through traditional supremacy of human rights and advocating the idea of equality of life rights. The design will be based on water, topography, plants, travel routes and architecture strategy and will try to create a habitat-type urban forest construction model through the comparison with the traditional greening mode. By means of the dynamic change of water level control, visitors flowrate control, travel routes control and so on to meet the resilient demand.

In the design phase, the animal and plant target species are selected, then the aquatic habitats and terrestrial habitats are classified according to the ecological habits of these target species. For aquatic habitats, the habitats are created based on the food chain system for benthic animals, amphibians, fishes and birds in a stratified pattern. For terrestrial habitats, the habitats are created based on the feeding, nesting, evasion habits of target species in a stratified pattern. Based on urban forest requirements on local tree species, a seedling table is figured out. Then according to the control of plant patch scales and proportions and the collocation of vertical
structure, 27 types of habitats are superimposed, so as to attract the expected target species. Finally, the whole process is digitized and simulated to get a dynamic growth model.

**Keywords**: Urban Forest, Habitat Construction, Resilience, Biodiversity

---

**2. Introduction**

With the constant acceleration of urbanization, it is increasingly difficult to see animals in cities. It is urgent to discuss the new green space construction mode of harmonious coexistence between man and nature under the background of ecological civilization. [1]

As a typical representative of large cities in developing countries, Beijing has to face the contradiction between economic development and ecological restoration. “Keeping white and increasing green” is one of the important measures to relief the function of the capital of Beijing. Referring to other types of land outside the planning green space, after the removal of the illegal construction, it is not possible to determine or implement a permanent plan in the short term, first through the way of greening to improve urban residential environment, reserve space

---

**3. Plot analysis**

The research plot is located at the intersection of the southeast fifth ring road and the Beijing-Shanghai expressway, which belongs to the ring belt of Beijing Country Park, with a total area of 62.6 hectares. There are many comprehensive parks, country parks and golf courses around the site, and all the functions in the area are relatively perfect. The site is composed of old factories, abandoned buildings and idle land. The whole terrain is relatively flat, and there is a current canal across the land. (Fig. 1)

Fig. 1. Site location picture.

---

**4. Planning strategy**

The research aims to improve the biodiversity and create a relatively complete food chain system, so as to create a natural habitat suitable for the survival and development of a large number of animals. [2] To establish and update aquatic and terrestrial ecosystems, to form a resilient and self-regulation mechanism, to play an important role in urban ecology of forest and biodiversity. Finally, create a habitat mode for more living creatures. [3]
4.1. Water strategy

According to the study, there is a positive ratio between the level of biological diversity and the meandering degree of the water system. With the increase of the sinuosity of the water system, the marginal effect will be increased correspondingly, which makes the wetland form more diverse, the wetland function is greater, and the biodiversity will be improved accordingly. [4] The best patch shape is the circular core, the curved boundary and the finger-like protuberance in favor of the propagation of species. The area of the island in the wetland is below 3000 square meters, and the length and area of the island is high, so the island should not be too large, and it is best to control between 0.9 and 1.4 per hectare in the water area. Therefore, the sinuous water system and small scale islands are more suitable for habitat creation.

In the traditional garden design, the hard edge and the bottom of the pot are used, and the water level is constant and easy to manage. The boundary of traditional water body is changed to bending and folding, using soft revetment, combined with the rich underwater topography, change the bottom to the natural type bottom at the same time, to form a hierarchical seasonal aquatic habitat. [5] Finally, create a winding, varied water system. (Fig. 2)

3.2 Topography strategy

The traditional gardens adopt the gentle terrain, the wind environment is single, and the space is changed. The first starting point is "man". Therefore, the design avoids the enclosed, dark, humid environment, convenient for tourists to visit. This environment is not suitable for biological survival, so this strategy is to create a more complex finger-like terrain in this area, add the terrain elements such as hole and low-lying land, and form the local wind circulation, builds a small environment of complex and diverse. From the point of view of biological equality, it is a safe haven for many species. At the same time, we should consider the experience of tourists, rationally set the terrain trend, and provide a variety of environments with non-interference and harmonious coexistence with other creatures. (Fig. 3)

3.3 Plants strategy

In the plant strategy, different from the previous methods of artificial afforestation, the size and area of the patch were regulated by mixed mode, tree layer for large patches of 50-80 strains, 20 to 50 strains of medium-sized
patches, small patches of 5-20 strains, build with the same tree with different age. The shrub layer is 10*20 for large patches, 10*10 for medium-sized patches and 5*10 for small patches. Irregular staggered of the edge of the patches, forming a natural and beautiful boundary. Small patches are used near the edge or landscape nodes. Large patches are used in combination with the background forest, and the rest is the medium patches. The ratio of large, medium and small patches is 3:5:2. (Fig. 4)

Fig. 4. Plants strategy picture.

3.4 Travel routes strategy

In the garden specification, the road density is 200-380m/hm², so the tourist system is relatively perfect, but the animal habitat factors are not taken into account, so that the habitat patch is divided by the park roads, and the patches are relatively broken. This strategy will reduce the density of road to the first 100 m/hm², have at least half area will focus on core habitat for animals reserve, provide habitat for creatures to the greatest extent, and offers visitors must pass the sightseeing tour line.

3.5 Architecture strategy

Building will use the original ecological natural materials decorative facade, height control in two layers of the following, shall not exceed the height of the tree, and control of building construction, make buildings blanking in terrain backlighting. While satisfying people's comfort in architecture, they avoid the sight of animals, making animals more comfortable in the environment and not being disturbed by artificial facilities.

5. Specific design

Based on the detailed design of the aquatic habitat and land habitat, the planning strategy reconstructs the relatively complete biological habitat, thus improving the biodiversity in the area. (Fig. 5)

Fig. 5. site-plan.

4.1 Aquatic habitat

4.1.1 Habitat creation for benthic animals

Benthic animals are visible animal communities living in the bottom of water bodies. The base should be dealt with first. Except such as silt soft substrate, still need to set up rock and other solid substrate. And plant the aquatic plants that benthic animals like to attached, such as reed and calamus, increased vertically aquatic habitat area,
and plant roots can firm bottom, to provide habitats for climbing and burrowing benthic animals. It also provides important shelter for benthic and small fish to avoid predators.

Proper feeding sources for benthic animals, including suspension and sediment. In order to ensure a good environment for planted aquatic plants. To some extent, it can reduce the impact of fish crabs on the growth of wetland vegetation by adding some barrier facilities, such as metal mesh. (Fig. 6) Fig. 6. Benthic animal habitat.

4.1.2 Habitat creation for amphibian

Amphibians is a kind of typical wetland animals, this study will use the dead branches into the shallow water area, is used to control the water flow and provide shelter, shade, climbing media and food source for amphibians and other creatures. For the base layer, it can artificially create some small habitat cave, and improve the richness of underwater topography. Through the understanding of the growth habit, various amphibian species are distributed in different Horizontal layers, with an average depth of about 0.6m. The water system is designed around the different sizes of the mudflat, to provide a appropriate land habitat for amphibians. (Fig. 7) Fig. 7. Amphibian habitat.

4.1.3 Habitat creation for fish

The creation of fish habitat is also an important part of the aquatic habitat. It is mainly by adding the complexity of water system structure and the diversity of hydraulic conditions by placing rocks or stones in the base. (Fig. 8) Fig. 8. Fish habitat.

The space between the stones is a shelter for aquatic organisms, often consisting of three to nine boulders, spaced less than a meter apart. At the same time, grow the plants which fishes like to eat, such as hornwort, hydrilla, eel grass, etc. In the end, the fry will be artificially injected into the habitat to enrich the whole fish ecological chain.

4.1.4 Habitat creation for bird

The aquatic habitats are designed for wading birds and swimming birds, According to their habits, the distance between people and targeted are set up

First of all, wading birds are migratory birds, not suitable for swimming, living in marshes and water edge, to get food from the bottom, from the mud, or from the ground. It is usually found in inland lakes, ponds,
estuaries, reed swamps, paddy fields and coastal marshes. The breeding habitat is mainly reed cattail marsh, the viewing distance is 50-100 meters.

At the same time, according to the birds' habits, the plant community types are mainly planted with Salix matsudana, Pagoda tree and other tall trees to form the upper wood structure of the plant community, to provide tall trees for wading birds to reproduce. Select the plant with higher height to provide a foothold for wading birds. For example, birds such as heron and ibis require a higher proportion of shallow water, submerged plants and Floating plants to cover 40% to 60% is more suitable. (Fig. 9)

Fig. 9. Wading birds habitat.

Secondly, it is very important for aquatic plants to provide food for migratory birds. At the request of the water body, the habitat of the duck species should not exceed 2 m, mainly in the shallow water area (water depth of 10 to 30cm). Open water (canopy density of emergent aquatic plant less than 10%, water depth less than 0.5m) is within 50% of the water area, and the higher the better. [6] He vegetation coverage rate of the habitat between 50% to 75% is better, among which the shrub coverage rate is 30% to 50%, the emergent aquatic plant coverage rate is 40% to 70%, the tree cover is 0-10%, and the water surface is 25%. The water depth of 0.9m is suitable for some inverted tree trunks. 300-500 square meters pond is more suitable for inhabit.

At the same time, the choice of plant community types and waders classes are similar. Choose Salix matsudana or populus tomentosa as the dominant species of trees, with lacebark pine, Chinese ash and other trees. Provide shade for the birds. At the same time, abundant herb layer and aquatic plants provide good habitat conditions for the birds, so as to facilitate the hunting and hiding. For example, the mandarin duck is a typical migratory bird, which mainly lives in rivers, lakes, ponds, reed swamps and paddy fields. A pair of mandarin ducks raised 6 small mandarin ducks for 12 hectares of habitat, including water, direct habitat space and buffer green space 3 habitat types. The watercourse area that attracts the mandarin duck is at least 30 meters wide.

4.2 Terrestrial habitat

Terrestrial habitats are different from aquatic habitats Due to insects, small animals, songbirds, and scansorial birds, they are scattered throughout the park and symbiosis with other animals.[7] Therefore, independent habitats cannot be determined for specific populations.
The target of this research focusing on the most important terrestrial habitat factors, according to the target of the habit of feeding, nesting, avoid, combined with the Beijing native plant resources development list, to obtain the land habitat nursery stock table. Fig. 10. The tree patches layout picture.

According to the control of patches scale and proportion, the layout of tree patches was obtained. (Fig. 10)

According to birds' habits, the proportion of evergreen and fallen leaves increased to 4:6. [8] (Fig. 11)

Fig. 11. Evergreen and fallen leaves proportion picture

According to the animal's demand for habitat, nine planting patterns were divided, which combined with evergreen leaves to create 27 habitat types to attract target species. (Fig. 12) (Fig. 13)

Fig. 12. Habitat layout picture.

6. Summary

In a word, the actual situation of land and surrounding area should be fully considered in the specific design, and the local flora and fauna, climate, soil and other conditions should be fully studied. Through the rational design of aquatic habitats and terrestrial habitats, the food chain system is well constructed and a stable resilient ecosystem is formed, which is able to cope with the change of external environment and to form a resilient habitat-type urban forest with the aim of increasing biodiversity. Fig. 13. Habitat type picture.
Acknowledgments

Firstly, I would give my sincere gratitude to Prof. Xiong Li, Beijing Forestry University, who has provided help and guidance for this paper. As my graduate supervisor, he gave me comprehensive guidance so that I could complete this study.

Second, I am extremely grateful for my classmates who helped me to finish this project.

Last but not the least, my gratitude also extends to my family who have been assisting me all of my life.

This work was supported by National Natural Science Foundation of China (Grant No.31670704).

Suitability of the Conservation and Development of Traditional Villages in Western Zhejiang Province: A Case Study of Shen’ao Village in Tonglu County

Chen Yuxi

First affiliation, No.35 East Qinghua Street, Beijing 100083, China

Abstract

Construction of beautiful villages has become sweeping across the whole country in recent years. However, the phenomenon of similar appearance of each village must be avoided in rapid construction. There’re many regional traditional villages in western Zhejiang province, which are valuable to explore the suitability of villages’ construction. This paper writes from two development stages of villages and discusses suitability of construction taking Shen’ao village in Tonglu county as an example. We are supposed to put forward some valuable inspiration to the maintenance of regional traditional villages in western Zhejiang province with the analysis of suitability both in historical development and process of protection.

Keywords: traditional villages; suitability; conservation; development; regional

1. Research Background

1.1. Historical Background

Village is a basic inhabited form and living unit of human, which has various of morphological characteristics and evolution path under different natural and social environment. China has massive traditional villages with long history and rich cultural remains. Ministry of Housing and Culture of China started a survey on Chinese traditional villages together with other institutions in April of 2012. There have been four batch of 4157 villages listed in the Directories of Chinese Traditional Villages in the nationwide. These villages are not only in wide distribution and different types, but also continue growing and developing today, which have a great research value [1].

Regard as precious wealth of the interaction between people and nature, traditional villages are getting a great deal of attention on their preservation and development with the upsurge of ‘beautiful villages’ constructions in recent years. However, there comes different kinds of problems. Suffering from a series of impacts on the process of urbanization, traditional villages face the problems of natural disasters, with the internal decay and over-transformation at the same time. Discussing the future resilience and suitability of traditional villages means a lot. We hope to control the trends of development of traditional villages effectively through methods of landscape architecture. Meanwhile, it will contribute to the sustainable development of villages and the large scope of ecological environment through studying on the relationship between villages and the nature.
1.2. Traditional Villages in Western Zhejiang Province

The distribution of terrain in the Zhejiang area has a theory of ‘seven mountains, one water and two fields’. The whole terrain is sloped from the southwest to the northeast. The southwest of Zhejiang is more mountainous and the north is in the plain [2]. The unique geographical conditions form a variety of village types. Zhejiang has 401 traditional villages and the western Zhejiang area has 56 of them [3]. Traditional village of western Zhejiang located in the transition zone between hilly and plain. These settlements have innate good conditions whose geography position fits the natural environment, closely related to water and has good landscape pattern as the basement construction. These kind of villages usually hold significant regional characteristics with profound historical and cultural heritage. Nowadays research on traditional villages in western Zhejiang province most stays on spatial distribution of large area [2], clan culture [4-5], historical landscape [6], case analysis [7-8] and so on, which are distribution and summary of history one-sided. This article started from Shen’ao village, a typically traditional village in western Zhejiang province, tries to evaluate the development of the village combining the history and status quo of protection and explore the suitability of development process at the same time. Hope to provide reference for the construction practice of protection and development of traditional villages in the western Zhejiang province.

2. Shen’ao Village in Tonglu, Western Zhejiang Province

2.1. General Situation of Shen’ao Village

1. Location

Shen’ao village located in Jiangnan town, Tonglu county in Hangzhou, Zhejiang province. Shen’ao is in the north of western Zhejiang (pic. 1), whose southwest is 15.5 kilometers from Tonglu County, and the northeast is 56.6 kilometers from Hangzhou.

2. Natural Condition

Shen’ao village is located on the south bank of the Fuchun river, at the intersection of the hilly and plain. It has great water source conditions in which the water network is densely distributed. The climate of Shen’ao is mild and livable with rich precipitation. The northeast side of Shen’ao village is Mount Huangshan and the Lion mountain and the southwest side of the village is the Qian mountain. Longmen mountains are in the southeast. Tong Creek and Hou Creek flow through the northeast and the southwest of the village. Tong Creek is a tributary of the Fuchun River, charging with the function of flood discharge and drainage. Hou Creek is also called Zi creek, which is more narrow relatively with good scenery of pastoral [9].

The water system in the periphery of the village is superior obviously, and landscape view is totally different of the two stream.
Moreover, it is convenient for the usage of water on both sides of the village (pic. 2).

3. Cultural History

Shen’ao village is a clan settlement of Shentu’s family. The family of Shentu has a long history with vast branch. South of Tonglu is one of them in a tributary of Zhejiang. Shentu’s family moved to Tongxi (Today’s Shen’ao) in the early Southern Song Dynasty according to the records.

2.2. The Research Value of Shen’ao Village

Settlements in western Zhejiang area have a long history, in which some counties like Tonglu, Chun’an, Jiande, Quzhou were established tracing back to the previous of the Three Kingdoms. Lots of buildings remain intact in some villages of western Zhejiang because of the long history and safe geographical location. Shen’ao village is famous for its abundant remains of ancient buildings and techniques of water control by the wisdom of old people in the area. As the first batch of villages which is included in the national directory of traditional villages in western Zhejiang, protection work of the village carried out earlier, discussing its suitability and resilience of construction and development in the future have certain guiding significance (pic. 3).

3. Suitability of Conservation and Development of Shen’ao Village

3.1. Suitability of Conservation and Development of Traditional Village

Construction of traditional villages is a result of taking multiple factors into account such as natural conditions and social conditions, which is an important part of the developing history of them. Traditional villages are not stagnant. Their protection and development should conform to the needs of villagers’ daily life, bear the important task of economic development in villages and towns. Therefore, villages cannot be separated from the continuous construction process. At the same time of social progress, urbanization and industrialization have brought new problems to villages, such as the loss of population and culture, the blind construction and so on. We propose the suitable construction helping to maintain the unique regional features of traditional villages in the historical flood under such a situation. The develop process of traditional villages is summarized to two stages, historical construction and future utilization. How to build the village, repair the environment and make a long-term planning reasonably in these two stages is the key of ‘suitability’, to
balance the relationship between nature, human society and the land in the development.

The ‘suitability’ in the process of historical construction of traditional villages means adapting and respecting. The traditional villages are usually good in Fengshui, because their location and construction following the local conditions to some extent, respecting the nature and using the nature properly at the same time. Their development complies with the change of society, however, it needs to be discussed whether it is appropriate to adapt to the society all the time.

The ‘suitability’ in the process of development and utilization needs more ‘moderate’. The current study tends to attribute the present problems of village protection to similarity. However, some villages have a certain similarity in both culture and environment within a specific range of area, coupled with the limited of development conditions and engineering ability, will be easy to form a similar visual experience at last. Therefore, planners have to learn the situation correctly. Appropriate development of the traditional villages should be moderate, respecting the growing track of villages themselves and rationally expanding the structure and texture of predecessors’ work, so as to maintain regional characteristics of traditional villages.

3.2. Suitability of the Process of Historical Construction in Shen’ao Village

1. Construction Adapts to the Environment

1.1. Adaptation of the Site Selection

People have been in awe of nature since ancient time, as the site of the settlement is adapt to natural environment. There is a proverb called ’high and do not close the hill with enough water, low and do not near water with ditch prevention [11]’, using the nature rationally and defending the safety of human themselves.

The development of Shen’ao village is typical. People can’t control effects of natural disasters in the absence of high construction ability those years. High water levels of Tong creek during the rainstorm period will inevitably bring security risks. The early Shen’ao village located in the southwest where is the highlands, and then gradually expanded to the northeast because of social development and growing population.

From the perspective of the current development form, Shen’ao village is located in a relatively gentle land between lowlands and hills. The site selection following the traditional Chinese geomantic omen theory, which called "negative Yin Yang, facing the water and against the mountain". These kinds of topography and water conditions are also conducive to the healthy development of villages.

1.2. Adaptation of the Construction

Shen’ao village is surrounded by two creeks. The southwest one called Hou creek is
excavated at the early stage of the village construction, which can divert the flood properly. The existence of these two streams basically controls the development scale of the whole village.

It’s inconvenient for villagers to deliver water by open channel because Shen’ao village is higher than the surrounding water system in altitude. The villagers excavated an 800-meters underground channel in the upstream side of Tong creek, guiding water into the village. The culvert is arranged with a certain interval "Aokou" (generally 3-4 meters deep), providing water for residents. People started building their houses along this underground channel and gradually came up with the first street in Shen’ao (Pic. 4). The water system and its facilities guided the formation of the village structure in Shen’ao directly. The location of the water facilities in the village such as drainage ditch, wells, ponds and the structure of buildings and streets are all interrelated (Pic. 5). Shen’ao village is a model of Chinese traditional settlements construction. The theory of planning water system at first and then conducting construction is still of significance.

As for the project of house construction, it’s easy to get the based building materials like wood and stone because Shen’ao is located in the hills and near the mountain. We can find the left beam structure of buildings in the Ming and Qing Dynasties, which are usually big with beautiful carved (Pic. 6). Stone is also very common being used in the building facades and street paving (Pic. 7).

2. Construction Adapts to the Culture

The traditional Chinese local society is connected with blood ties [12], and the geo is an expression of blood. Shen’ao village is an example of it. The patriarchal clan system was the basis of residence and city...
construction system in the long history as the mainstream of each system in ancient China. Ancestral hall of Shentu has a prominent position in the settlement, the village of blood ties of Shentu. It controls the volume of the settlement on the plane, the architectural form and orientation around the ancestral hall together with other rooms, and determines the layout of the street space (Pic. 8).

Ancestral hall of Shentu which also called Youxu Tang is the most important building in the whole village and located at the pond near the entrance to the village. Front square of Youxu Tang became the most popular public space of the village. Room is a place for family members holding big events and storing the farm implements, and also a symbol of the development and strength of the family [1]. Shentu’s family has eight Rooms (Room1 is centered on the Front Room while Room2 is centered on the Rear Room). We can find that all the Rooms are distributed along the Old Street first. The reason may be that the infrastructure of the Old Street is the earliest and the most completed of the whole village. Although Room6 and Room7 have many people, they are mostly located next to another main street called Houju Road because of the late development.

These eight rooms and their respective control ranges determine the regional scale of ancient village. The patriarchal clan system is the intangible planner of this kind of traditional village. The formation of the settlement is adapted to the clan culture. In addition to the overall control of the patriarchal culture, the village will be affected by the surrounding existed regional culture in the process of development. With the development of society, the social culture in different periods will be reacted to every corner of the village.

Shen’ao is in the ancient Yanzhou area, near Anhui province. Prosperous merchants from Anhui in Ming and Qing Dynasties made Huizhou culture greatly influenced Jiangsu and Zhejiang area. Buildings of the village are most with white wall and grey tiles, corbel-steps above the roof (Pic. 9). The form of settlements space leading by surrounding buildings is similar to Huizhou architecture, which usually has a closed courtyard and tall walls enclose a family (Pic. 10). The internal space is open and public space is centered on the courtyard (Pic. 11).
Architecture is the embodiment of village construction’s adaptation to the social culture as a living fossil. The existing buildings in Shen’ao are the combination of Anhui architecture and mountain residential buildings in western Zhejiang [13]. Architectural features of different periods are clear and easy to find, including the modern village built by rural residents.

3. Value to the suitable construction in the future
In modern society, the so-called "social and cultural adaptation" has been abused. With the expansion of village construction, the increasing self-consciousness of villagers and their demands for life lead to the low quality spontaneous construction, which is difficult to control and undermine the overall appearance of whole village. Therefore, the suitable construction of future village should learn from the advantages of historical construction, planning before extending the range of village, respecting to the natural landscape pattern and the original village texture, arranging infrastructure and public space reasonably. What’s more, people should also extract cultural elements of Zhejiang architecture and use them into the future construction.

3.3. Suitability of the Process of Development in Shen’ao Village
According to the statistics of the yearbook data of Shen’ao village, the population of the village declined significantly in 2012 over the past ten years and reached the minimum in 2013 [14]. It is also in this time that the government carried out a series of protection and renovation projects for Shen’ao village, and started the future plan of traditional village protection and utilization. People can see the benefits immediately. The suitable protection and utilization of villages directly led to the return of human.

1. Suitable Position
The background of villages’ development in western Zhejiang are similar. Although every traditional village has its own characteristics, the difference is very small. Marketing highlights which added forcedly by people are contrary to the moderate planning rules of traditional village, destroying regional characteristics of villages.

Good family in Jiangnan, which is the position of Shen’ao village, seems simple but appropriate. The protection and utilization works used their own strengths, respecting for the history and renovating the ancient architecture, ancient water system as much as possible. These old structure is the basis for villages’ own development and tourism for ancient village in the future. The protection works firstly meet the needs of the daily life and production of the villagers in the function assignment, and then the new format. Although there are lots of visitors all the day in the village, the atmosphere of life is strong.
and dynamic. The protection and utilization of traditional villages is working for people living in villages. Children are the future of villages and towns. We can see the future of Shen’ao village through the bustling scene of the village library during holidays.

2. Suitable Renovation

![Image](image1.png)

Pic. 12 The ancient village and skyline after the control of appearance

Traditional villages have been destroyed in different degrees during the long history, so the restoration project is the most important part of the development process. Shen’ao village is reasonable and appropriate in the repair project, which is mainly reflected in the renovation of buildings, water system, paving, walls and so on. Classify the current buildings according to their quality, which could be concluded into three development modes, service, culture and benefit, and each one adopts different repair measures. In addition to the restoration of ancient buildings, Shen’ao village is not forced to transform the built farmhouse into an archaize building, but it takes the way of overall style control to make the village remain the mark of every social development stage (Pic. 12).

Shen’ao village is like a micro Jiangnan. People can see ponds and wells while walking in the village, reminding them of the underground flow. In order to maintain such geographical features, restoration of river system seems to be important. The ancient water system in Shen’ao village consists of five parts, which are creek, pond, Ao, canal and well. The water system of "two creeks, one Ao and three canals" remains to this day. The most important thing of water system restoration is the protection of water quality, repairing nodes and the management of the whole system.

The street space is composed of street and building facade, which is the most direct space to experience a traditional village. The protection and utilization planning restored the original pavement pebble of several streets. As for the building facade, planners adopted different measures of restoration according to different periods of construction and building materials, neither seeking for the new things nor imitating the ancient (Pic. 13, 14).

![Image](image2.png)

Pic. 13 Repair of building facade at the entrance of Xingsu Tang

![Image](image3.png)

Pic. 14 Comparison of old street before and after restoration
3. Suitable Landscaping

The landscape here mainly refers to the design of plant configuration, landscape elements, structures and so on. The traditional village has formed a mature vein of landscape itself and it is not suitable for excessive addition. Shen’ao village focus on the public space around Aokou and Tang to enhance the original landscape. People use stacked stones as planting bowls planted with native plants, creating a pleasant landscape environment. The structures in the site are basically retained, and people repaired the wooden structure of the original gallery frame in the meantime. Material of new landscape elements are also using local materials as far as possible (Pic. 15).

![Pic. 15 Gallery frame after the renovation](image)

3.4. **Suitability maintains regionalism of Shen’ao**

The protection and development project of Shen’ao village is the model of the combination of protection of original authenticity and inheritance of living state [16]1. The suitability is mainly embodied in the adaptation of the village construction, suitable for positioning, moderate repair and development and so on. Respecting for history and inheriting from the historical experience, adhering to the "endogenous development" internal growth theory, people protect the village context of growth ultimately and maintain the regional characteristics of traditional village.

4. Summary

Western Zhejiang is hilly, there are nearly half of traditional villages’ altitude less than 150 meters, and mostly located in the mountain plains like Shen’ao village. The location of Shen’ao village is adapted to the natural environment. Its ancestors took methods wisely towards water system, which adapts to the geographical and geological conditions of ancient villages. Moreover, the development of ancient villages is suitable for multiple cultural evolution. As a traditional village, Shen’ao village has taken a moderate restoration and landscaping plan under an appropriate target, the protection and utilization of the project is very effective. Through the analysis and summary of Shen’ao village, suitable construction will be an effective and sustainable development mode to maintain the regional characteristics of the west Zhejiang area.

The two aspects of "historical construction" and "protection and utilization" appear to be time oriented. However, they interact and restrict with each other in the practical process, so as to achieve the harmonious unification of material environment and traditional culture.

Suitability is actually a combination of adaptation and moderation. For the "historical construction", it is more like a process of summary and learning, and the suitability focus on adaptation. Utilization is the theme of the development of traditional villages. As the social background of modernization and industrialization in recent
years, we can always find similar elements from various practical cases, thus the "suitability" principle focus more on moderation, respect, conform to the historical site, and maintain the growth force of old villages.

The problem of "hollow village" is very common in the current rural development. Proper restoration and construction will let people come back to those areas, which will also bring the growth of construction land, and new suitable construction is needed again. In this respect, the analysis of suitability will play an important role in the process of historical construction in Shen’ao village. For new construction, the social and cultural background are sustainable growing in inheritance. We cannot blindly build as the old mode or the extremely new in order to be different, people need to make a connection between the history and future. That’s also called the construction of the landscape between the past and the future in the space-time continuum, protecting each unique landscape unit and taking it as a cultural reference attribute [17]. The proper protection and development of traditional villages should respect the history, conform to nature, undertake the future, and contribute to the sustainable development of the earth's ecosystem.

Acknowledgments
Knowledge and understanding come from the observation and love of life. In the process of writing this article, I would like to thank my dear parents, teachers and classmates for their care and help.

Abstract

The connotation of botanical garden has been expanding with the developing process of urbanization in China. It’s an effective way to define the new role of the botanical gardens by Green Infrastructure theory. This paper summarize the planning and designing methods for Chinese botanical gardens combined with infrastructure system. It elaborate the botanical garden planning and design methods on the basis of green infrastructure system from the macro and micro views.

Keywords: Green Infrastructure(GI); Botanical Garden; Low Impact Development(LID); Biodiversity

1. Introduction

In late 2017, the country’s urbanization rate has reached 58.52% [1], with more than half of the total population living in towns, cities or suburbs. The city sprawl leads to a fragmentized and isolated natural system and the dotted city pattern surrounded by pasturesland is sliding into reverse. Those are bringing numerous city problems [2]. Therefore, for a long period to come, how to build a poetically ideal inhabitation will become the primary concern. As an effective solution, Green Infrastructure is playing a crucial part in city construction. Botanical garden, an important part of urban green space, serves the function of scientific research, science popularization, and recreation etc. [3]. The distant urban space forces people to consider how to integrate botanical garden into Green Infrastructure and how to optimize its diversified functions.

2. Green Infrastructure

Green Infrastructure means a net made by connections between natural space and other open spaces. The net contributes to preserving ecological value and function, keeping air and water clean and doing good to humans, wild animals and plants. It is a natural life support system as well as an ecological framework which serves environment, society and economic health [4].
2.1. The Origins of Green Infrastructure

In the 1860s, Olmstead’s connection thoughts about park and open spaces and the idea of establishing ecological protection and management network to decrease the fragments of ecological areas had a significant influence on academic field. Based on the two thoughts, two new theories were formed. One is to build connected parks and integrated green space system to protect human’s profits. The other is to establish a natural protection net to protect biodiversity and species’ habitats. The two new theories evolved the lead wire of modern western Green Road Campaign and ecological framework of Green Infrastructure.

In 1984, UNESCO put forward the idea of establishing ecological infrastructures resembling Green Infrastructure in Man and The Biosphere. In 1990, during the Green Road Project in Maryland, Green Infrastructure firstly appeared as one of sustainable development strategies. In May, 1999, PCSD issued the work report named Creating A Sustainable US in 21st Century, in which the concept of Green Infrastructure was brought forward. Since then, the concept of Green Infrastructure was spread across the US, the UK, Canada and many other countries.

2.2. The Components and Functions of GI

2.2.1. The Functions of Green Infrastructure

The principal function of Green Infrastructure is ecosystem service. It means humans attain profits from eco-system. The profits could be concluded as supply service, support service, adjustment service and culture service.

The supply service includes food and material resource supply, fresh water supply, groundwater formation, biological genetic resource supply, erosion prevention and soil fertility protection, noise prevention and biological control etc. Support service includes urban wildlife habitat support, the biodiversity production and protection, the soil formation, photosynthesis and nutrient cycle. Adjustment service includes regulate local climate, decrease drought and flood disaster, air therapy regulation, carbon sink, water purification and circulation, pollination, pest control, detoxification and decomposition of waste. Culture service includes recreation, keep physical and mental health, provide tourism and local scenic spots, aesthetic experience and inspiration, cultural values, provide information, adaptive management, stress free life and urban agriculture etc.

2.2.2. The Components of Green Infrastructure

Green Infrastructure is composed of hubs, links and sites. Hubs mean large natural areas without external interruption. Provides starting and destination points for wild animals and plants. The size of it varies with hierarchies. It mainly include large ecological protection reserves, large public land, working lands, and large parks etc.

Linear ecological corridors collectively refer to links, which forms an integrated system by connecting hubs and sites. Links has a crucial impact on the stimulation of ecological cycle, the guarantee of eco-system health and preserving biodiversity. It mainly includes landscape link corridor, eco-protection corridor and natural greenbelt etc. Sites means niches and recreation sites in a large natural area. Its size is smaller than hubs.
but could provide habitats for animals and ecological nodes for humans in case hubs could not connect links. It not only supplements hubs and links but possesses ecological and social value.

3. Botanical Garden and Green Infrastructure

The concept of botanical garden originated from western in where people make scientific researches, science popularization and take a rest by means of collecting and protecting numerous internal and external species.[8]

3.1. The Development and Construction Status of China Botanical Garden

3.1.1. The Development of Chinese Botanical Garden

There were a long history of plants-collection in ancient China, but strictly speaking, the botanical gardens that conform to the scientific definition have only begun to be constructed under the influence of western countries in modern times. Until the founding of PRC, there were only 8 botanical gardens in China. After the establishment of the PRC, on the initiative of Chinese Academy of Sciences, government renovated and built total 36 modern botanical gardens. After the reform and opening up, the construction of China's botanical gardens has been booming. Up to now, there has been more than 200 botanical gardens in the whole China, which are affiliated with different departments such as gardening, forestry, agriculture, pharmaceutical, and scientific research etc.[9]

With the development of Chinese society and scientific technology, botanical gardens present different features in different periods.

In general, the development of modern Chinese botanical garden could be divided into four phases: before 19th century, mid-19th century to mid-20th century, after 20th century and nowadays. Because of the change in social needs at each stage, botanic gardens have adapted to the functions of the times under different mainstream thinking.

3.1.2. Current Situation and Inadequacy of Contemporary Chinese Botanical Gardens

Currently, except most large and medium size cities, many prefecture-level cities have begun to build botanical gardens. The development of the Chinese Botanical Garden has not been more than 100 years,
shorter than most western countries. It’s difficult for China to obtain the achievement, but there are still many problems as follow.

1) Self-enclosed system fails to maximize eco-efficiency

Constructed as an independent ecological patch, the traditional botanical gardens have not formed a well relevance with the surrounding natural systems. The exchanges of matter, energy and genes only occur within the park for its relatively closed system and has little impact on the regional ecosystem. As an isolated ecological plate, ecological performance has not maximized, and it is not conducive to the improvement of regional ecological pattern[10].

2) Focus on own functions singly

The diverse and complex functions play an important role in improving the status of green space in urban development[11]. However, the functions carried by most botanical gardens still remain in a series of traditional functions such as collection display, popular science research, and leisure recreation[12]. And these single traditional functions have not formed a perfect system for each other and cannot adapt to the rapid development of urbanization.

3) Imperfect popular science system and outdated display mode

At present, the popularize knowledge activities of botanical gardens in China mainly include the following types: festival activities with the theme of seasonal flower viewing, various kinds of popular science exhibitions, lectures, and practical training that are held in indoor venues. These activities have a single and outdated pattern and do not form a good integration with the park’s natural landscape environment. As a result, the interactive activities of popular science activities are reduced, and the subjective initiative of visitors cannot be fully mobilized.

4) Similarities in form and lack of own characteristics

At present, most of the Chinese botanic gardens do not have their own characteristics except the geographical position of natural climate characteristics reflected by the floristic characteristics and garden style, and the primary and secondary relationships between the affiliated parks and scientific research[13].

5) Low biodiversity

Currently, China’s most botanical gardens only display 300-500 species of plants. A few of the parks can reach 6000-8000 species, and there are only 39 botanical gardens with more than 1,000 species (including varieties). The total number of planted and cultivated plants in the Botanic Garden of China is about 20,000, while the UK Kew Garden has 55,000 plants. Plant types are the basis of botanical gardens, and its richness or not reflects the level of botanical gardens. Therefore, enriching plant species is a top priority for the construction of Chinese botanical gardens[14].

3.2. Integrated into the Green Infrastructure System—Functions Extension of Botanical Gardens

3.2.1. New Requirements for Botanical Gardens with Contemporary Social Development

Sustainable development, environmental protection, and the coexistence of man and nature, these important topics have brought significant development opportunities for the construction of today's botanical gardens.
The botanical garden has become a hot spot for urban environmental construction and has risen to a strategic level. It has gradually developed into a comprehensive urban park integrating plant collection and display, popular science education, nature protection, and recreation[15].

However, with good opportunities in external development, the construction of botanical gardens is also facing many challenges. It overtakes more social attributes and needs constant adjustment to meet the needs of modern urban cultural life[16]. This article argues that the role of botanical gardens in the current rapid urbanization process should meet the following requirements:

1) Fully integrate into the regional green infrastructure network.

The botanic gardens, as a region with high diversity of species in the city, should pay attention to the connection with the urban green space during construction, and enhance the connectivity and integrity of the urban green space system, and use the Links as part of the regional ecological chain[17] to improve regional ecological efficiency and the regional green infrastructure system.

2) Improve the functions of leisure and recreation.

The particularity of the botanical gardens in terms of base sites, management systems, etc., allows them to have a great advantage in the basic research of plants and cooperation. However, with the change of public demand and aesthetic awareness, the botanical garden, as part of the urban park green space, should enhance its ornamental nature and provide the public with adequate recreational functions.

3) Advance science popularization system.

The science popularization system mainly consists of two aspects. The ways of popular science display and popular science facilities.

The ways of popular science display should be flexibly set according to the tourist groups of different ages, including gardening theme activities and exhibitions, and online popular science education[18]. The science popularization facilities should keep pace with the times on the premise of guaranteeing complete facilities, and introduce emerging technologies, such as the construction of digital botanical gardens[19], adapting to social needs with the process of innovation.

4) Highlights regional features.

The botanical gardens should reflect the regional landscape features and the urban features. The exhibition will focus on the display of native plants with regional features and will not blindly introduce foreign plants. It should pay more attention to the traditional landscape pattern, space composition and plant community collocation, express the local plant landscape and spatial characteristics.

5) Enhance the biodiversity of urban ecosystems.

While ensuring the diversity of plants and animal and microbial are enhanced, and consideration should be given to creating habitats for birds and other animals. The stability of plant communities provides a stable living environment for animals and microorganisms. As the same, animals and microbes also provide guarantees for the healthy development of plant communities[20]. The construction of habitats also enhance the popularization and appreciation of the botanical gardens.
The new requirements raised by urbanization process for the construction of botanical gardens coincide with the appearance of green infrastructure in contemporary China.

Botanical gardens are diverse in scale and form, and cloud play an important role in the construction of a green infrastructure network. Large-scale botanical gardens can serve as hubs for ecological protection in areas such as conservation of biodiversity, providing recreational space, and alleviating negative effects in cities. Liner botanical gardens can be used as Links connecting green spaces to form regional green space network which further improve the urban ecosystem. Small botanical gardens can serve as sites for enhancing biodiversity and recreational functions.

4. Botanical Garden Plan Based on Green Infrastructure System

Two dimensional analytical programmes are put forward in this paper to achieve the integration of botanical gardens into GI system. One is that botanical gardens are planned as macro constructions and designed as micro constructions between hubs and links. The other is to make botanical gardens as micro construction of sites, part of GI system.

4.1. Botanical Gardens as Hubs and Links

4.1.1. Botanical Gardens Built as Hubs and Integrated into GI Network (as a Part of Macroscale)

In general, only larger botanical gardens could play the role of hubs and each such botanical garden covers in excess of 200 hectares. The crucial to make these botanical garden hubs influential is the construction of links. Three methods are usually adopted to construct links.

The first is to choose proper sites where natural linear elements could be used to make links. Rivers, forests and farmlands are the most common natural linear factors. Shanghai Chenshan Botanical Garden is the typical botanical garden constructed with such method. It covers an area of 207 hectares. To make linear connections throughout the garden, designers use the natural riverways in the garden center and form an open space network which makes botanical garden connect DianShan Lake east and She Mountain west (Figure 4-1).

The second method is to build artificial links to connect external hubs or natural links. Artificial links refer to streams and forest belt which connect surrounding natural areas in the garden.

For example, Bai Caopo Forest Botanic Garden covers 350 hectares and is located in the center of the regional green circle. The green circle system covers Taiyuan City, the ecological barrier in the north of Jinzhong City, Xiashan Suburban Forest Park, Tian Longshan National Forest Park, Wu Jinshan National Forest Park, large forest and farmlands. Bai Caopo Forest Botanic Garden is a key joint in it. Designers form a regional open space by connecting approaching natural forest landscape and other surrounding landscape patterns (Figure 4-2). In addition, greenways in the garden are regarded as important part of city greenways. City greenway system is perfected by integrating garden greenways (Figure 4-3). It makes greenway system as a way to create
The third is to make botanical gardens as external part of hubs. It needs designers to consider the overall city green land system fully, such as Beijing Botanical Garden, which was regarded as the extended part of Xi Mountain to Beijing ventilation corridor (Figure 4-4).

4.1.2. Design Botanical Gardens as Links and Integrate into GI Network (Macroscale)

The botanical gardens which serve as links are rare in China. The most typical one overseas is Chicago Botanical Garden, part of the northern branch corridor of Chicago River (Figure 4-5).

4.1.3. Design Botanical Gardens as Hubs and Links in Microscale

Serving as hubs and links, the microscale of botanical gardens promotes self eco-service function by a series of measures such as perfecting original functions and composite functions, promoting biodiversity and so on.

1) Improve the original function & Develop the composite function.

Once enhance the popular science function and regional characteristics, the functions of botanical gardens serving as green facilities can be strengthen. For instance, Chenshan botanical garden in Shanghai uses new measures like opening interactive experiential science activities for different crowds and Xianhu botanical garden in Shenzhen constructing digital garden acquiring great social impact. In addition, botanical garden will overtake some new functions adapting to the city development, such as the function about water system. Chenshan Botanical Garden pays attention to collect the natural precipitation, comprehensively manage the waters for building recycle waters, purified and rational system.

2) Cultivate Biodiversity

Biodiversity includes landscape diversity, species diversity, and genetic diversity. It could be realized by means of cultivating various habitats, application of native species and few interferences from humans.

In the case of BaiCaopo Forestry Arboretum in Jinzhong, Shanxi province, the site belongs to unique loess erosion landform, there are many loess hill, platform, ridge and tableland (Figure 4-6). Therefore, we can take full advantage of various terrains to cultivate a multiple ecotype on the basis of the forest and analyze the landscape pattern to design the functional layout and leisure place. These layouts reflect the design principle that respect the characteristics of the site (Figure 4-7). The vegetation selection has formed relatively stable forest structure through the construction of local native plants.

4.2. Botanical Garden as Sites

Affiliated to different apartments, the botanical gardens used as sites mostly belong to education, medicine and forestry with small size [24]. Constrained by outer environment and the scale, the botanical garden can’t involve too much biological processes while connecting with central control point and links. So the key of bringing into green infrastructure network for sites turned into making the full use of every functions and overtake more functions to sustain the system. Sites just like the botanical gardens used as central control point and links, mainly constructed by
comprehensive functions, science-capacity building, local characteristics and biodiversity.

5. Conclusion

It’s an effective way to define the new role of the botanical garden by Green infrastructure theory. This paper summarize the planning and designing methods for Chinese botanical gardens bringing into infrastructure system. It elaborate the garden planning and design methods on the basis of green infrastructure system from the macro and micro views. It is hoped that this research will provide a new idea for the planning method of Chinese botanical garden and provide a reference for solving the existing problems in Chinese botanical garden.

How to Construct Country Parks with the Aim of Improving Biodiversity—Taking the Planning and Design of Longquan Lake Country Parks as An Example

Wang Meilin, a Xiong Li.a,*

Beijing Forestry University,(No.)35 East Qinghua Road,Haidian District,Beijing 100083(zip code),China

Abstract

With the acceleration of urbanization, cities are facing ecological imbalance and environmental crisis. Artificial habitats are a serious threat to the existence of natural habitat, resulting in a rapid decline in biodiversity. It is necessary to consider how to improve this serious situation through landscape architecture design to improve the urban ability of self-restoration. After expounding related concepts such as natural and habitat construction. Taking the planning and design scheme of Longquan Lake country park in Shijiazhuang City, Hebei Province, China as an example, this paper discusses the ecological mode of country parks with the aim of improving biodiversity in the elastic range of the transition between cities and nature, and constructs a relatively complete ecological chain. It provides some practical experience for the formation of stable and diversified urban ecosystem.

Key words: Biodiversity; Naturality; Habitat Creation; Longquan Lake

1. Introduction

Urban biodiversity is the material basis for the sustainable and stable development of the city, and has an important significance for the sustainable development of the city. City is a semi-natural ecosystem dominated by human beings, and its biodiversity characteristics are different from those of natural ecosystem.

As urbanization continues to heat up, biodiversity rapidly decreases. According to surveys, more than 15000 species worldwide are on the verge of extinction, faster than any previous geological period.[1] Artificial habitats (such as concrete roads and buildings) destroy natural habitats that are suitable for wildlife survival, and the area of habitats for organisms to depend for survival is extremely reduced and habitat conditions are severely destroyed. This is one of the important reasons for the loss of biodiversity in urban cities.[2] In addition, environmental, pollution, alien species invasion, simplification of agricultural, forestry and animal husbandry varieties, global climate...
change etc. Are threatening the survival and development of organisms. This series of reasons are closely related to the interference of human activities. Therefore, in the urban ecosystem, how to solve the human development and biodiversity protection is the general problem discussed by a lot of planning and design workers and ecological researchers.\[3\]

2. Relevant research

Some scholars have studied urban biodiversity from the perspective of theoretical framework and problem causes. Qizheng Mao is discussing the problems of urban biodiversity research in "Progress of Urban Biodiversity Distribution Pattern". Miller Jr. analyses the causes of homogeneity of biodiversity in his paper "Thinking about Biodiversity and Experiences of species Extinction". Yirong Deng puts forward the ideas and strategies of biodiversity restoration in a regional scale in the “Approach and case study on Urban Diversity Restoration”, which takes Haizhu Ecological City in Guangzhou, China as an example. Patrick Mooney selected birds as ecological objects in the study of Bird Habitat use in Lower Fraser River Basin of Canada, to study whether habitat types and habitat groups will affect the local bird species level. In the exploring of regional biodiversity restoration and experiment research, Hui Liu made a relatively complete experimental study on the improvement of biodiversity on a small scale in the Experimental study of Habitat Construction.

To sum up, the previous researches, on the one hand, a lot of attention has been paid to the pattern of urban diversity and the problems on a larger scale. On the other hand, the study of the urban regional scale and biodiversity of small scale itself is deeper. However, the exploration of the transition part between different scales is very rare. It is difficult to know how to realize the relative integrity of the control system in the actual process, and the transition region between the city and the nature is less explored. The author will discuss the related contents below.

3. Research ideas

If the process of moderate and orderly development of biodiversity is understood as the complete adaptation to the natural process without artificial interference, there will be no way to discuss to improve biodiversity. Planning and design is a man-made process, we should regard man as a factor in the natural system. Based on this understanding, to increase biodiversity to an appropriate and more stable level is either to choose the operational process that humans respect nature to limit human negative impacts on the environment to a smaller extent, or through guidance, to promote the natural system towards a benign cycle of planning and designing.\[4\]

Based on the above discussion, the author discusses the combination of two ways to promote the biological diversity in the medium and micro scale. The two main objects of urban biodiversity decomposed are plants and animals. In order to study the systematic and correlation between them, the concepts of naturality and habitat construction are introduced here.

3.1. Naturality

Means the degree of naturalness. The concept of naturality refers to the distance or similarity between real vegetation and their natural state. The greater the human interference, the greater of impact or destruction of vegetation and sites, the lower
of the degree of their naturalness and the farther away from their "climax community" or "potential natural vegetation". The difference between the current vegetation status and the primary (or potential) forest vegetation status in a given region can be evaluated and quantified by an assessment of naturality.[5] On the basis of correctly recognizing the regional naturality grade, it is hoped that the purpose of promoting succession can be achieved by planting a suitable number of specific tree species to lay the foundation for the improvement of biodiversity for the status quo of vegetation in different succession stages.

3.2 Habitat creation

Habitat (or biotope) often refers to all the environmental factors required for all activities such as the survival and reproduction of a species. For animals, it is a place to provide food, shelter, protection and other necessary living conditions for their individual, groups or community in a certain stage of life, which promote their various life activities. [6]

The creation of biological habitat is a complex process, creating and regenerating high-density living space in the object environment, especially considering the bottom living environment of "ecological pyramid". To create a diversified living environment, that is, to preserve the most basic living environment on the biological chain, which makes the advanced organisms have a rich food base. Therefore, habitat construction needs to consider all levels of components in the food chain. Only by building an elastic system with self-regulating functions can achieve the stability of the biodiversity environment and promote the appropriate communication between human beings and nature.

Combining the definition of habitat in ecology and from the angle of landscape architecture design in microscopic scale, the author defines the connotation of habitat construction. That is, through the spatial elements of water, terrain, vegetation to affect ecological factors which influence the survival of animals and plant growth, such as water, light, heat and so on, to create a spatial organization displaying the natural internal order, to provide suitable site conditions and growth succession space for living organisms.

Combining the planning and design scheme of Longquan Lake country park in Shijiazhuang City, Hebei Province, this paper will expound the ecological strategy and construction mode for the purpose of improving biodiversity during the process with medium control and micro design.

4. Planning and Design of Longquan Lake Country Park in Shijiazhuang City, Hebei Province, China

At the beginning of the project, according to the actual situation of Longquan Lake area in Shijiazhuang (Longquan Lake area locates in the shallow mountain area of West Mountain), referring to the relevant practical strategies and experiences and the comprehensive analysis, the design team draws the objectives and requirements that should be met in the planning and design of Longquan Lake country Park in Shijiazhuang City.1) On the basis of mastering the natural succession law of the zonal plant community in Shijiazhuang, taking the catalysis succession as the means, the plant diversity in the region can be directly improved, and the animal diversity can be promoted indirectly.2) Creating a relatively complete food chain system in the design area, creating natural habitats suitable for the survival and development of a large number of animals, establishing and renewing aquatic and terrestrial ecosystems,
and forming a flexible and sustainable self-regulation mechanism. Make the forest and biodiversity play an important role in urban ecology. Then, I will select the typical links and sections of the project to make a key statement.

4.1 Plant planning strategies for generating succession

The site belongs to the regional geography and climate conditions: located in the eastern edge of the Eurasian continent in middle and low latitudes, close to the Bohai Sea, of the Pacific Ocean, and belongs to the temperate monsoon climate. The seasonal variation of solar radiation is remarkable, the ground high and low pressure activity is frequent, the four seasons are distinct, the cold and heat are distinct, the rainfall is concentrated in the seasons of summer and autumn. The dry and wet period is obvious, the summer and winter is long, while the spring and autumn is short. The regular succession process is shown below.

![Fig. 1. A Natural succession Picture.](image)

Design team analyzes naturality of site status based on GIS technology. The site naturalness is divided into five grades, the roads and villages without vegetation layer did not enter the succession process for the greatly interfered of artificial intensity; the part of cultivated land and the residential area with higher green quantity also belonged to the stage of not entering the succession process at all for the greatly interfered of artificial intensity. The third layer is grass and shrub stage, and the present situation is in the middle and late stage of the shrub community succession. The xeric Bothriochloa ischaemun is dominant, and the shrub is sparse in the community, and the main is chain, lespedeza and wild jujube. The current succession stage of artificial forest is in the early stage of tree stage. Seedling afforestation and sowing afforestation are included, while the species is relatively single, the artificial side cypress, cork oak, the young tree forest of acacia in domain, the main shrub is chain, lespedeza and wild jujube. The herbaceous plant is dominated by the bothriochloa ischaemun; Finally is the natural secondary forest, in the middle stage of trees succession, partly by artificial seeding forest succession, and mainly for platycladus orientailis, associated with cork oak, acacia, pistacia, main shrubs for thorns chain, lespedeza, and herb for Chinese wildtype. It is hoped that the site status stage which is not completely in succession stage, middle and late stage of shrub community succession and the middle and late stage of Arbor succession stage will be guided to the middle stage of Arbor stage succession. It is suggested to supplement quercus variabilis, robinia pseudoacacia, populus davidiana (Arbor) leaves white wax, thin bark wood, amorpha fruticosa, yellow prickly rose, cotinus coggygria, clove (shrub) big awn oil (herbaceous) and so on.

For the present stage of Arbor stage, it is suggested to be guided to the last stage of Arbor stage and to supplement quercus variabilis, robinia pseudoacacia (aracia pseudoacacia) leaflet white wax, yellow thorn rose, cotinus coggygria, clove (shrub) big oil awns (herbs) and so on.

In the above way, aiming areas with different succession stages, the species and quantity of plant communities are controlled, which to some extent catalyze their relatively natural growth, which is a long-term process that needs intermittent operation. According to different regional conditions, different types of living environment for different species can be guided and to shaped, which has a far-
reaching impact on the subsequent planning and design.

Fig. 2. A Natural level picture.

Fig. 3. A Natural Succession Schematic diagram.

4.2 Habitat planning and design strategies for biodiversity enhancement

In order to improve biodiversity, a relatively complete food chain is needed. Firstly, based on the common species of animals and plants in Shijiazhuang, and combined with some rare species, target species are identified. Biodiversity is based on habitat diversity. Therefore, according to the ecological habits of the target species and the types of space to be constructed, the designer, according to the preferences of different species, forms a flexible material space through the controlling design of the natural elements such as water body, topography, plant to construct habitat environment with varieties. As the east of Longquan Lake, (100.6 hectares) is planned as a wetland area in the upper part, which is the most abundant biodiversity, with comprehensive ecosystem function and highest productivity ecosystem in nature that is chosen to elaborate in detail.

According to the common species of animals and plants in Shijiazhuang and some rare species, the target species are determined, and then the habitat is created layer by layer according to the food chain system. Limited by space here, birds are selected as the research object to be focused on for narration. Birds are at a higher level in the ecosystem, and there is evidence proving that bird diversity can represent the overall biodiversity.

Fig. 4. A network diagram picture.

Based on the study of common birds in Hutuo River wetland section of Shijiazhuang, the birds were divided into waterfowl and non-aquatic bird after the sufficient study on original habitat birds. From more than 80 species of water birds and 63 species of non-water birds, 20 species of waterfowl and 15 species of non-aquatic birds, which are most suitable for survival in the eastern wetland, were selected as target species. They will be expounded separately in the below.
4.2.1 Aquatic bird habitat construction

The construction of aquatic bird habitat is considered deeply from two aspects: habitat range and planting design.

The determination of habitat range is affected by many factors. For example, the target species of game birds, represented by the Duck family, are mainly foraging in shallow water areas with a depth of 10-30 cm, and are active in waters with a depth of 1.5-2 m, while the target species of wading birds, represented by Crane family, are mainly taking meadow activities within 15 m offshore, nesting and resting in the shrubbery. General waterfowl can bear the distance of 50 m from the outside disturbance. Finally, the design team selected the depth of water, the range of coastal activities and disturbance distance as the selection index of the habitat range of waterfowl, and selected 11.4 hectares of habitat area of the eastern waterfowl by the superposition of the three indexes.

Secondly, considering the related indicators of planting design, after a period of investigation and research, designers found that aquatic plants will provide food and necessary rest and hiding space for waterfowl, and its coverage will determine the livable degree of waterfowl in the water area. Waterfowl require a higher proportion of shrubs, herbs and low tree coverage to provide an environment for nesting and rest on shore within a range of 15 meters of inshore activity; Waterfowl require less floating leaves and floating plants in the waters. Otherwise, it will affect its take-off and landing. The inshore plants should be able to provide shelter for the waterfowl and provide visual guarantee for the bird. To sum up, aquatic plant coverage, Arbor and shrub coverage of inshore activity and plant height were selected as the main influencing factors.

According to the area of habitat distribution of waterfowl after screening, combined with the function and landscape layout of the park, we divided the habitat of waterfowl into the following six regions and controlled the coverage of aquatic plants, the coverage of Arbor and shrub, and the height of plants as follows.
4.2.2 Establishment of habitats for non-aquatic birds

Similarly, the construction of non-aquatic bird habitat will be discussed from two aspects: habitat range and planting design.

The design team studied a series of relatively microscopic conditions, such as terrain slope changes can also cause plant species and community structure changes, thus affecting the bird’s habitat, of where require a certain slope of 30-40%, terrestrial bird requires 15% -35% as preferred; Selection of non-aquatic bird habitat influenced by disturbing distance mainly by road; Wetland water margin planted at least 30M wide waters connected of formed plaques, which provide channels from terrestrial habitats to aquatic habitat through a variety of plants grouping for birds. Therefore, the terrain slope, disturbance distance and water access patch are taken as the selection index of the habitat range for non-aquatic birds, and the three indexes are superimposed to screen 8.9 hectares of habitat for non-aquatic birds.

The planting design selected soil richness, community structure, tree height as indicators. The abundance of ground cover plants will affect animal activities (including insects and soil microorganisms), ground moisture and bird feeding sources, which are important factors affecting the habitat of birds. The community structure of bird habitat was divided into Arbor shrub herbaceous type, Arbor herbaceous type, shrub herbaceous type and herbaceous type according to different collocation of Arbor and shrub. The proportion of different community structure and community structure in habitat affects bird life; the proportion of different height trees in habitat greatly affects the suitability of bird habitat.

Through the control of the above indicators, the designers divided the non-aquatic bird habitat into the following six areas.

5. Summary

On the basis of quoting and discussing related concepts, this paper takes the planning and design of Longquan Lake country Park in Shijiazhuang City, Hebei Province, China as an example to discuss the ecological construction model of country parks with the objective of improving biodiversity in the elastic range of the transition between cities and nature that is, respecting the laws of natural succession and speeding up plant succession by appropriate catalytic means. At the same time, create a relatively natural habitat as much as possible. According to local conditions and the biological needs, especially the birds, put forwards the corresponding zoning construction indicators, set reasonable allocation of animal and plant species and disturbance control to build a complete
ecological chain and to form a stable and diversified urban ecosystem as well as provides some practical experience. However, the restoration and protection of biodiversity is a gradual process, which requires long-term unremitting efforts to achieve positive results.

Acknowledgments

Thanks Professor Xiong Li, Beijing Forestry University, who has given this article a great deal of valuable advice and assistance. In addition, I would like to express my sincere thanks to Professor Zhandong Li, Associate Professor Peng Yao and Lecturer Chensong Lin of Beijing Forestry University for their strong support and help.

Study on Landscape Construction Strategy in Urban Piedmont Area

Yuan Jing\textsuperscript{a}, Li Xiang\textsuperscript{b}, Liu Lipan\textsuperscript{c}

\textsuperscript{abc}China Academy of Urban Planning & Design, Chegongzhuang Xi Lu #10, Haidian District, Beijing 100044, China

Abstract

China is mountainous and watery. Traditional Chinese urban planning emphasizes the layout and relationship of mountain, water and city. The idea layout of city is surrounded by mountain and water, which make city and the natural environment can take advantage from each other. The piedmont area is a special region of the city, which is the boundary and transition zone between city and natural environment. The land use of piedmont area is diverse, including urban construction land, rural settlement, farmland, woodland, water systems. The piedmont area of city is an important space of living, production and recreations with outstanding landscape and ecological values.

At present, rapid urbanization leads to the urban expansion and the area of residential and industrial land in the piedmont area increasing. However, the vegetation is reduced, the natural hills are destroyed, the traditional villages and farmlands are gradually disappearing, the landscape characteristics and ecological functions are impaired. The piedmont area need specific measures and means to restore its landscape and ecological value.

The paper take the piedmont area of Mount Qingyuan in Quanzhou, Fujian Province as an example, to analysis its landscape change process; to summarizes the landscape pattern, landscape structure and landscape characteristics of each stage; to analysis the landscape decade and ecological destroy problem led by urbanization and industrialization. Furthermore, this paper put on the landscape development strategies: (1) According to the characteristics of the environment, restoring landscape security pattern in the piedmont area; (2) Based on the historical characteristics, protecting the piedmont area historical landscape heritage; (3) combined with the development needs, renewing the landscape of urban and rural in the piedmont area.
Keywords: landscape architecture; the piedmont area; landscape ecology; landscape heritage; landscape renewal

1. Introduction

1.1. Definition of Urban piedmont area

China is mountainous. Topographically undulating areas such as hills, mountain and plateau account for approximately 66.7% of the land area. Alluvial plains between mountains with flat terrain, fertile soil, and abundant water resources are the common sites for urban development and development. The construction and development of the city will inevitably interact with the surrounding natural hills. There is a certain transition area between the city and the natural mountain. It belonging to the ‘Piedmont Area’. This area has a topographical characteristic that gradually transitions from the plain to low hills and mountains.

1.2. Traditional Chinese Landscape City System

The rich mountains and waters in China have given birth to traditional landscape aesthetics and culture. Ancient Chinese literati admired nature mountains and water landscape. Nature environment were places where they healed depression and felt physical and mental freedom. In the past thousands of years in China, most of the local officials were literary men. They brought their profound inspiration of nature into the cities that they created.

At the same time, Feng Shui theory also have significant influence on location and construction of ancient Chinese cities. The idea Feng Shui Pattern is a basin-shaped landscape unit that is oriented mainly from north to south and surrounded by the four sides with triple mountain enclosure(Fig.1). The Feng Shui planner chose the location and layout of the city based on the location, layout and direction of the mountain and water system. It has created a relationship of ‘symbiosis, coexistence, co-prosperity and co-pleasure’ of mountains, water, city and people. The Feng Shui pattern has a positive effect on agricultural production and ecological balance. [1]

Fig. 1. The ideal Feng Shui structure Source: Yang Liu, The research of Fengshui Theory And The Building of Ancient Shanshui Cities.

1.3. The relationship between city and nature

Urbanization and industrialization has caused changes in the relationship between urban and natural landscape, leading environmental problems. In recent decades, China has undergone rapid urbanization. Traditional urban-rural relations have changed. Construction land in urban have a significant growth, eroding the natural and
rural land around city. The open space and green space in piedmont area has decreased. The landscape heterogeneity and biodiversity has decreased, the ecological environment is destroyed and the beauty of traditional landscape has disappeared.

The relationship between urban area and natural space is one of the important research topics in urban planning, landscape architecture, landscape ecology. Howard E. put forward the idea of ‘garden city’, a multi-core system that cities surrounded by rural and natural area in this pattern. The transition area between urban and rural areas consists of low-density residential and garden belts. He hoped to integrate nature and agricultural area with city organically, to solve the urban development problem, such as environmental pollution brought by industrialization and urbanization, the uneven distribution of population and jobs, and the income gap between rich and poor. [2] Olmsted F L. A believed that the natural environment in city was a necessary condition for alleviating urban congestion after the industrial revolution and people could relieve their emotions in beautiful natural space. He planned and designed the Boston Emerald Necklace Park System to bring nature to city.

In the middle and late 20th century, urban ecology has developed and provided valuable spatial planning principles. Ecological restoration measures such as urban ecological networks could improve the degraded nature in cities. Urban ecological networks consisting of patches and corridors have been valued. Green corridors could link up large-scale forest or greenways, active woodland and natural patches, large parks, river corridors, green belts marginal habitat, small urban parks, and agricultural lands within and outside urban area [3]. This might help enhance the city landscape and ecological functions. In 1996, the United States issued Charter of New Urbanism against urban sprawl, eroding farmland and green space and advocated smart growth city. Is has inspired urban zoning control planning which divide planning area into natural zone, rural zone, sub-urban zone, general urban areas, urban center zone, urban core zone and special districts(Fig.2). The control guidelines were proposed by special characteristics and land use for each division and emphasized the use and control of transition areas [4]. In 2013, Singapore government put up their urban planning goals as ‘the city in a garden’. The implementations have involved increasing the natural protected areas and parks within and around the city, and enhancing urban biodiversity [5].

2. Site Analyses

2.1. Overview

The study site is in Mount Qingyuan, Quanzhou. Quanzhou is a well-known historical and cultural city in China, with a developed culture relating to ocean communication. The traditional culture there have originated from the integration of different countries and regions. There are various religions competitively developing in Quanzhou.

Quanzhou has maintained its historical landscape elements, such as ancient city of Quanzhou, Mount Qingyuan, Ming River, Luoyang river, traditional architectures and villages, etc (Fig.3). Quanzhou also fully embodies the spatial pattern landscape characteristics—a city surround by the rivers and mountains, also facing to the bay.[6]

Fig 3 Quanzhou historic landscape  
(Source: a and b from Quanzhou ancient architecture)

b. Mount Qingyuan

Mount Qingyuan is a Scenic and Historic Area of China because of its magnificent natural and cultural landscape, with a long development history. The rich number of stone carvings and the multi-religious displays coexisting in the landscape. It reflect the spatial characteristics of the ancient city's famous mountains that are blended and developed by traditional geographical culture, inhabited culture and religious culture[7]. In addition to the variety of natural.

Fig 4 Mount Qingyuan scenic and historic area
(Source: the first two photographed by author, the latter from the cellular network)

c. Study Site

Study Site is located in the Mount Qingyuan Scenic and Historic Area. It borders on the ancient city of Quanzhou in the west and Mount Qingyuan in the east. It is located in northeast area the Mount Qingyuan Scenic and Historic Area and belongs to tertiary protected area and closes to the core area of the park. It is the transition zone between the city and mountains(Fig.5).

Fig 5 Bitmap of study area
(Source: Left-bottom map from the Master Plan of Mount Qingyuan Scenic and Historic Area.)
2.2. Evolution of urban landscape of Quanzhou

The landscape pattern of city has undergone three phases (Tab.1)[8]. In this process, the study area have changed from a purely natural landscape into the semi-natural landscape, and eventually into a urban-rural landscape.

Tab 1 Evolution of city-scenery pattern

<table>

<th>Stage III: Urban-rural Landscape</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Phase I</strong></td>
<td><strong>Phase II</strong></td>
<td><strong>Phase III</strong></td>
</tr>
<tr>
<td>Old City facing famous mountains</td>
<td>Cityscape connected</td>
<td>Surrounded by the City</td>
</tr>
<tr>
<td>After many times of city expansion, Quanzhou, as an existing ancient city, has turned into such a situation --- facing mountains across the field. The Hu Bo Garden area is dominated by nature-idyllic landscapes, with scattered villages throughout. A landscape painting of crisscross footpaths between fields and that of a red wall and cooking smoke are presented. The combination of the city and the landscape has formed the landscape features of this famous city with the famous mountains, in a relatively independent status.</td>
<td>In the 1990s, with the rapid economic development of Quanzhou, the urban and rural construction volume rapidly increased and its scope continued to expand. The city has already developed to the foot of Mount Oiu'an. The villages around the scenic area, including the Hu Bo Garden area, have expanded outwards in an unordered manner, crowdedly within the mountains and forests. The unreasonable architectural heights within the Hu Bo Garden area and the modern means of transportation like railways have disrupted the natural sequence of &quot;mountains, fields, and cities&quot; between the ancient city and the scenic spot, and cut off the landscape connection between the mountains and the city.</td>
<td>After the 21st century, with the rapid development of the Beifeng Group, the pastoral scenery area of the original ancient city surrounded by three mountains gradually changed into the Mount Quanzhou three-facedly enclosed by Quanzhou City. Due to the unique geographic location of the Hu Bo Garden area and the improvement of traffic conditions in recent years, towns and villages have shown a joining trend. The uncontrolled spread of villages has further squeezed the ecological area, and the traditional city-mountain structure is facing to a huge impact.</td>

2.3. landscape changes of the study site Area

**Stage I Natural Landscape**

Since the Quanzhou government moved to site known as today during Tang Dynasty, the study site was initially developed, which was based on natural landscape.

**Phase II Nature-Rural Landscape**

After the Tang Dynasty, the Study Site area was further developed. Several natural villages were built alongside the mountains along with the initially development of agriculture. The Study Site area gradually evolved into a nature dominated landscape [9]. This change added to the spatial level of the urban landscape, and changed into a city-field-scenery landscape pattern.

**Stage III urban-rural Landscape**

After the 1990s, the process of urban sprawl was accelerated. The establishment of the Mount Qingyuan Scenic and Historic Area led to a development of the Study Site area. The original villages rapidly expanded, and modern transportation facilities flooded into the area, leading to such a condition where the pastoral community is constantly
suffering from operation, forming a contiguous development of the city-village and a fragmented landscape pattern of ecological area. As shown in Fig 6 of Evolution of the Study Site from 1921 to the present

![Evolution of the Study Site area (1921-2017)](Image source: the bottom map from Google Maps; the picture self-made)

2.4. Site Analysis of the study site

a. Low natural ecology and poor quality

Ecological area is fragmented: patchy forest land scattered along the western side of the Qiyunshan Highway, weed lands mainly distributed in the open space around the community, and no contiguous large areas of grassland within the planned area. (Fig 7)

![Ecological Area Distribution of Study Site](Source: Baidu Street Scene and the rest self-painted)

The quality of large agricultural area is low. The garden is mainly distributed in the north-eastern side of the Tianbian Community, and is mainly dominated by longan orchards. The farmland is mainly distributed on the west area of the Tianbian Community and on the northwest area of the Huanqing Community in which there mainly grows fruits and cash crops. The nurseries are mainly distributed on both sides of Huabo Road. (Fig 8)

![Eco-spatial area distribution of Study Site](Source: Baidu Street Scene and the rest self-painted)

Unordered construction and land use the construction of the study site area is considerable confusing. Village land, urban land and scenic land are mixed together. There are large-scale factory buildings, communications facilities and other large base stations inside the village. In the communities of Houmao and Huanqing, there are driving schools and other urban sites. The original traditional buildings were replaced by modern three-story buildings and various large-scale factories. The disorderly factory expansion continued to swallow the communities and the surrounding natural landscapes, which resulted in the destruction of the original landscape style of the villages and the deterioration of the overall landscape quality. (Fig 9)

![a Tianbian Community  b Huanshan Community](Image source: the bottom map from Google Maps; the picture self-made)
c Huanqing Community  d Houmao Community  e Renfeng Community
Fig 9 Current Statuses of Communities in Study Site
(Source: Photographs from Baidu Street View, others self-painted)
b. Disorder development of the community and lack of public space
There are relatively few lands in different types, such as public venues, social welfare land, and kindergartens. Slow pace of retrofitting led to the lack of internal infrastructure and the inability to meet the daily needs of residents. The internal public space in the community is affected by the compact layout of the original buildings, by the small building separation, and by the lack of rational planning for the newly-built buildings. As a result, the public space within the community is squeezed and residents have less space for their activities. At present, there are two types of public space within the community, namely, the space before the ancestral hall, the former land open space, and the newly built public facilities. But a small area and little recreational facility are the problems. (Fig 10).

a Former land open space  b space before the ancestral hall  c Village committee space  d Street style
Fig 10 Aerial view of Study Sit

c. The landscape of the community cluttered in low quality, and lack of integrity and coherence
Community settlement landscape is more natural with many changes in street space. Their scale is pleasant, but the biggest problems are that the relatively narrow space and their flat style landscape. The Study Site buildings retain relatively complete ancestral halls, and its old buildings still retain the traditional style and interior features. However, due to the roughness of the later renovation and maintenance, the new building styles are not uniformed. That is to say, the form of facade is disorderly, and scale is out of control. The open space of the Study Site area is packed with area in various dimensions and forms such as the space before the ancestral hall, a square, a green space, farmland, and water channels. However, because of traffic and facilities, the public functions of the site are not prominent, and the unused space is not fully utilized. Community plant landscapes have been investigated and found to be rich in species and especially outstanding in native tree species. However, due to the lack of green space and the lack of corresponding plant designs, plant communities and their levels are monotonous, so it is lack of landscape appreciation. (Fig 11)
3. Strategy for development of piedmont area in Mount Qingyuan

3.1. Protecting the ecological-agricultural area and Improving the ecological environment of the community

As a rigid boundary between the core preservation area and the three-grade preservation area of Mount Qingyuan Scenic and Historic Area, the tourist road is also a clear boundary between the ecological area and the agricultural area. The strict protection clauses of the key preservation zone ensure the ecological safety of natural secondary forest and other important historical sites. The area outside the road includes a small amount of woodland, farmland, longan orchard plots, nursery plots and the urban and rural areas.

According to the defined policy space and the land use status in the piedmont area, constructing the area’s ecological security pattern based on the anti-planning theory [10] is the basic research of defining ecological protection space. In term of the characteristics of Mount Qingyuan’s piedmont area, the study of ecological security pattern includes two aspects: water system and catchment corridor protection and biological habitat protection. Water system and catchment corridors protection area consists of the existing rivers and the reformed catchment corridor, which is simulated and modified on the basis of DEM elevation model, and the safety level is determined according to the different ecological functions. The analysis of biological habitat protection is studied in two aspects: vertical analysis and horizontal analysis. Vertical analysis, which can be calculated by the spatial superposition technique of GIS to get the histogram of the suitability evaluation results, includes the analyzing of elevation, surface cover, slope and other factors to determine the habitat, distinguishing the most suitable habitat for the species, and use it as the "source" for the next step analysis [11]. Horizontal analysis is based on the law of spatial movement of focal species, and establishes resistance range to simulate the movement range to determine the ecological safety space outside the source. Ecological security pattern of piedmont area is superimposed the analysis results of water system and catchment corridor protection and biological habitat protection. The result shows that the low-level ecological safety area mainly contains the southeast side of the study area and the buffer area of the catchment corridors, canals and ponds. The mid-level ecological safety area mainly contains the orchard plot in the middle of study area. The high-level ecological safety area mainly contains the farmland, the small grass land, the orchard plot and the constructed area of some villages.

a. Analysis Result of Water System and Catchment Corridor Protection  b. Analysis Result of biological habitat protection  c. Analysis Result Ecological security pattern

Fig 12 Ecological Security Pattern of piedmont area
The corresponding ecological protection strategy can be made according to different levels of ecological security pattern:

1. Setting up the negative list of construction project and activity in low-level ecological security area, and strictly prohibits all construction and development activities.
2. Defining the positive list of project types in mid-level ecological safety area, controlling the total amount of construction, guiding local residents to grow special economic crops, increasing amounts of plant species and improving species diversity.
3. In high-level ecological security area, encouraging local residents to grow trees, grass enhance the proportion of ecological area and agricultural of piedmont area.
4. Encouraging local residents in built-up area to build gardens and three-dimensional afforestation at their roof and balcony to improve the quality of residential environment.

3.2. Shaping public space, formulating policies and guiding style recovery.

The village streets are small and the public space, as the only open space besides the ecological and agricultural area, is the key point of the restoration of the traditional style in village. In research site, the main village public space is the temples and the ancestral halls. The temple space in the traditional settlements in Southern Fujian is the substantial carrier of the folk belief culture. As a social form, the temple sacrificial organization affects the organization and production of the settlement space by the way of the residential integration [12]. There are dozens of temples and the ancestral halls in the piedmont area of the Mount Qingyuan, and the temples and the ancestral halls have an inseparable relationship with public spaces. The typical forms are the ancestral hall - the stage type and the ancestral hall - the square (or basketball court) type.

a. The Ancestral Hall - The Stage Type  b. The Ancestral Hall - The Square (or basketball court) Type

Fig 13 The Typical Public Space Forms in research site
(Source: photographed by author)

The frequency of using public space by village residents is closely related to the spatial quality. Taking the public space of Tian Bian community as an example, the front square of the village committee attract many villagers due to the banyan as the center with tables and chairs. Almost no villager stays at the western stage and basketball court in the community owing to no trees and facilities. There are plenty of rain for all the year around and hot summer, which leads that residents’ spontaneous activities around the fig is very common in the research area. In addition, public facilities are an important to the residents’ activities. According to the different types of public space and the needs of residents' activities, it is necessary to transform public space. The corresponding strategies are as follows:

1. Planting shade trees with tree box set seats and tables and other furniture, Meeting the needs of the elderly villagers.
2. Increasing different types of sports facilities, including fitness equipment and amusement facilities to provide space for young people and children.
3. The pavement and decoration need to match the colors and symbols of traditional style in Southern Fujian.

By transforming and reshaping, the public space, as the core of the village, will take the lead in restoring the traditional style and providing more high-quality activity space.

3.3. Activating historical relics and making flexible use of historical buildings in various ways.

There are very rich natural and cultural heritages in Mount Qingyuan Scenic and Historic Area, but there are no high-level historical relics in this study area according to the resources investigation of scenic spots. However, through the site reconnaissance, there are dozens of historical buildings in Southern Fujian style as well as the temples and ancestral halls that is the center of village’s public space. Due to the urbanization process, many residents migrate to the city. Residents no longer repair old houses, so that some historical buildings are in an abandoned state.

Fig 14 abandoned historical buildings (Source: photographed by author)

Southern Fujian culture is an important part of Chinese traditional culture, which has great influence in Taiwan and Southeast Asian countries. Mount Qingyuan, as an important natural and historical cultural heritage in China, deserves more attention to protecting the historical buildings in the piedmont area.

Historical buildings are distributed in every village of study area, establishing flexible and diverse protection policies and promoting the operation mechanism of protection in every villager is necessary. The corresponding strategies are as follows:

1. Delineating a certain protected area according to the scale of historical buildings and the condition of the surrounding sites as a historical and cultural area.

2. Enterprises and individuals are encouraged to protect, renew and redevelop historical buildings and historic cultural areas under the premise of a village style guidance clause, so that operators can get long-term benefits, which can upgrade the industrial and commercial diversity of scenic area.

3. On the premise of retaining the architectural characteristics of South Fujian and not destroying the original appearance of the building, the abandoned buildings are encouraged to be rebuilt and
developed creative industries and tourism industries under the premise of a village style guidance clause, which are able to enhance location value to achieve profitability and achieve self-balance of project funds.

4. Searching for way of combining protection and development that the environment of historical buildings and cultural features can be more effectively protected and utilized, showing the artistic value of historical buildings.

Acknowledgments

Thanks are due to Director Wang Bin who leads the project team of General Plan of Mount Qingyuan Scenic and Historic Area and the project team of Scenic and Historic Area Detailed Plan of Pedimont Yuan in Mount Qingyuan for providing information of the two projects that our paper is based on.

Abstract

The world is witnessing an unprecedented acceleration in climate change. Enhanced global warming is disrupting climate patterns across the world leaving Small Island Developing States (SIDS) particularly at risk. Demographic patterns are changing and there is an inexorable movement of people from rural to urban areas across all countries of the world, including SIDS. While cities are therefore becoming denser, research and literature points concludes that few are sufficiently resilient to cater with changing climate patterns; an example is Port Louis, the capital city of Mauritius in the Indian Ocean.

In last 20 years, Port Louis has witnessed flash flood episodes that have claimed human lives. While upgrading has been undertaken to Port Louis’ drainage systems as a response, the city is still heavily plagued by rainwater accumulation. Other cities in SIDS have also witnessed similar drastic events, and moreover face the dilemma of how to promote sustainable development while aspiring to pro-actively enhance the future liveability of their cities. Environmentally-responsive landscape architectural design offers the promise of renewing ties between people and nature. This paper examines this scenario, and proposes a conceptual framework to promote resilience, liveability and sustainability in the city of Port Louis through design. The paper explores principles, key dimensions and drivers of landscape architectural design and how they can be integrated within the existing structure and planning framework in Port Louis. The findings of this research, presented in this paper, contribute to addressing the dearth of literature and research on this topic pertinent to Port Louis and Mauritius, offering an exemplar for resilience and liveability scaffolding in cities of SIDS. This paper also offers policymakers and stakeholders with an extra dimension to consider for future urban development planning in SIDS cities.

Keywords: Small Island Developing States; Mauritius; Liveability; Sustainability; Biourbanism; Landscape architecture

1. Introduction

The world has entered a new urban era where the planet’s ecology is being significantly influenced by human activities. A core agent is cities whom cause significant environmental impacts triggering a real need for eco-friendlier systems capable of scaffolding sustainability, liveability and resilience [1]. Although urbanization brings unique challenges, it is evidenced that other serious challenges and concerns arise. Improving the ecological
functioning and resilience of urban systems remains therefore central. As posited by Elmqvist et al [2], urban investments in ecosystem-based adaptation and green infrastructure can contribute positively to human and animal well-being and liveability in cities.

The city of Port Louis, the capital of Mauritius, recently witnessed flash flooding episodes and has been plagued by rainwater accumulation and ponding. This environmental pattern is increasingly commonplace in all Small Island Developing States (SIDS) [3], which are vulnerable due to their lack of preparation and logistics to deal with such situations.

SIDS were first recognized as a distinct group of developing nations at the United Nations’ Conference on Environment and Development in June 1992 [4]. The Barbados Programme of Action was adopted in 1994 to assist the SIDS in their sustainable development efforts [5].

For Mauritius, enhancing sustainable development and enhancing future liveability in its cities is therefore a primary concern.
Urban ecology evolved internationally in the 20th century as being a potential solution for improving sustainability and liveability in cities [6]. Authors like Steiner [7] and Ndubisi [8] have asserted that ecologically motivated landscape architecture and site design, such as the Sustainable Sites Initiative [9], is good practice.

Port Louis has attempted to respond to this theory by seeking to enhance sustainability and reduce flood concerns through contemporary design and landscape management mechanisms and initiatives. The flood episode of 2013, being one major effect of climate change experienced by Mauritius so far, demonstrated the urgent need to address sustainability, liveability and resilience nationally.

2. Background

When Mauritius was first colonised by the Dutch between 1638-1710 they established a harbour at the southern village they named ‘Grand Port’. Urban planning for Port Louis, the capital city of Mauritius was led under French colonisation from 1715-1810, and then under the British until independence in 1968. The French approach was to favour large alleyways and to maintain a lush canopy. Their designed infrastructure satisfactorily sustained the Port Louis population of around 6,779 inhabitants in 1968. However, today Port Louis accommodates a population of 155,226 being a demographic increase of 2,290%. The city witnessed this exponential increase in population without expanding its basic infrastructure services. Coupled with the effects of climate change, sandwiched between the Signaux Mountains and the Indian Ocean, this rapid urbanisation has brought forth numerous concerns in terms of city planning. Key climate change risks and impacts for Mauritius are summarised in Table 1 of which Port Louis is located in the Marine ecosystem type (as seen in Figure 5) wherein all impact factors are pertinent.

Table 1: The main climate change-related impacts on the main ecosystem types in Mauritius. Source: [10].
The contemporary post-independence government response to Port Louis’ urban planning has been haphazard with little comprehension of the historical drain and creek system in the city and their capacity to handle the huge volume of runoff because of the major urbanisation adoption of non-porous surfaces.

With urban sprawl, there has been a rapid reduction of the French-established green areas in the city. Today it is showcased by the PORLWI Collectif that Port Louis encompasses around only 16m² of green space per capita, a figure well under the 35m² as recommended by international standards [11].

Green space loss in favour of built fabric expansion has brought forth numerous issues specific to Port Louis including:
- an increase in the urban heat island effect that is also affecting Port Louis’ economic footprint [12];
- a reduction in air quality [13];
- a reduction in physical and accessible public open space; and
- a reduction in the natural rain water absorption potential contributing significantly towards flash flooding [14].

3. Resilience

With rapid urbanisation in Mauritius, urbanization has amplified the sealing of the drainage basins and conventional engineering work in river valleys (eg. riverbed straightening and narrowing) there increasing the threat of urban floods throughout Mauritius [15], as seen in Figure 4. Port Louis particularly experienced this situation in 2013, as seen in Figure 3. The 21st century has witnessed augmented flood threats due to global climate change with intensified urbanization and extreme weather events [15]. Majewski [16] has argued that extreme meteorological and hydrological events are increasing in frequency. However, the manner in which cities and towns have planned, used and developed land is also another cause exposing populations to coastal and river flood risks.

The European Union Floods Directive (2009), introduced alongside a requirement of integrating flood risk management and hence the coexistence with water, is one of the preferred approaches. Some of these measures include the implementation of:
- flood protection efforts;
- sustainable rainwater harvest approaches; and
- application of underground and surface water management in drainage basins.

Majewski [16] has claimed that other measures should include:
- warning systems and hydrological and meteorological prediction;
- educating how to decrease risk of property damage in flood-prone areas; and,
- evacuation and protection plans.

Figure 5: Elevation of Port Louis, Mauritius, by www.FloodMap.net. Source: http://www.floodmap.net/Elevation/ElevationMap/?gi=934154, accessed 1 March 2018.

4. Liveability

The separation of city and nature was previously a predominant characteristic of urban architectural designs [17]. This philosophical approach is hazardous and costly because it disregards a city’s natural processes and separates human living from nature. Allam [14] and Grant et al [18] argue that the more the disconnected humans are from nature the more individuals do not understand the link between healthy cities and healthy ecosystems. Today, it is acknowledged by scholars that landscapes associated with infrastructure and buildings can accommodate multi-functional layers of vegetation and soil controlling surface water, providing wildlife habitat and food,
and keeping the city cool as contrast to its long-perceived ornamental and Gardenesque values [18]. Grant [18] further argues for the need for panoramic, trans-disciplinary thinking and co-ordinated action to enable a grey-to-green transformation of cities, to enhance the liveability of these places to its citizens.

Numerous researchers are increasingly trialling new methods to analyse cities to assess and measure their liveability [19]. However, it remains difficult to define ‘liveability’. While some researchers’ claim that liveability is tied intrinsically to physical amenities such as green space and parks, others supports its connectivity to economic dynamism, career opportunities, cultural offerings and human safety for a family to co-habitat in. However, the most important conclusion is that liveability is connected to infrastructure and sustainability issues [19].

The decision of forming a balanced relationship between the city and nature is crucial.

5. Sustainability and Maintainable Solutions

Because of the larger flood threats in the European Union, the member states have responded in implementing strategic programs and such should also be the case in Port Louis. For instance, the programs of Making Space for Water (2005) in the United Kingdom, and Room for the Rivers (2006) in The Netherlands, seek to increase river valley retention capacity as well as improving drainage basins together with enhanced co-ordination of spatial planning and flood protection. These strategies emphasise integrating sustainable water management and urban planning in areas far from simply the riverbanks (improved rainwater retention for decreasing flood threats) and urban waterfront zones (which offers direct protection from floods).

Three primary trends currently dominate management of urban waterside areas which include [20]: riverbank urbanization and urban revitalization of downtown waterside areas; sustainable land management allowing enhanced retention capacity and using construction forms which adapt to changing water levels; and, environmental revitalization of river valleys.

Table 2 offers a synthesis of key ecological design strategies that could be applied in Port Louis to better negate climate change risks and threats as well as increasing the urban liveability and built environment quality of this rapidly growing urban landscape.

| Table 2: Key Ecological Design strategies pertinent for Port Louis, Mauritius. Source: adapted by the authors from [21]. |

5.1 Planning guidelines and regulations in Port Louis

While there are numerous documents outlining parameters for urban development in Port Louis, the enforcement of guidelines remains a local challenge. The contradictory nature, or difficulty of clear interpretation, of planning codes across various planning documents further accentuates this issue.

This creates a leeway for haphazard development, and provides opportunities for developers to maximise their land use for increased economic profitability while disregarding the development’s impact on
their immediate surrounding. Allam [22] confirms that there is a mismatch between planning documents and the demographic boom of 330% in the last century.

The confusing guidelines coupled with a lack of guidelines enforcement has enabled approval of various projects that contributed to the flash floods of March 2013; namely the construction of buildings on classified rivers and streams; the KFC building, Air Mauritius Parking, Rogers Parking, Garden Tower and Hawkers Palace [23]. Those developments however do not abide by the Mauritian Forests and Rivers Act 1984 river buffer requirements [24]. Figure 6 illustrates development along the Ruisseau du Pouce Stream where the capacity of drains has been reduced.

6. Landscape Architecture and Ecosystem Functions

Five principles of ecosystem functions include recognition that: urban areas or cities are ecosystems; cities or urban areas are heterogeneous; cities or urban areas are dynamic; cities or urban area biophysical and human components interact; and, biophysical processes are crucial in them [25].

The first principle provides the basic theory of contemporary urban ecology. It indicates what needs to be included for explicitly addressing urban systems. The urban ecosystem concept embraces the deepest urbanization levels and the addresses the function and structure of exurban fringe [25]. The other principles relate to the specific implications of the first principle. Hence, the first principle has been discussed in this paper.

6.1 Cities are Ecosystems

Cities and urban areas are ecosystems as they have interacting physical and biological complexes. Therefore, one should not consider that ecosystems are stringently homeostatic, self-maintaining and fundamentally closed entities [26]. These assumptions are not invoked by the definition of core ecosystem. In simple terms, an ecosystem relates to the interaction between a physical complex and a biotic complex [27]. This definition remains the core motivating contemporary research and application by Jax [28].

Cities contain organisms, people and light, water, soil, air and physical regulators as day length and temperature. Biotic complex are also present in cities which have complex social structures [29] and these include institutions [7]. Machlis et al. [30] claim that the sumptuousness of social interactions and structures are the heart of
the inclusive conception which they refer to as the ‘human ecosystem framework’. In the same vein, a city’s physical complex is not only made up of native soils and substrates and existing or emerging non-managed animal populations and vegetation, but contains covered or highly modified soils, introduced or maintained vegetation, paved surfaces, utility infrastructure, roads and buildings as well. Hence, in contrast to agricultural or wild ecosystems, the urban ecosystem has additional complexities [31].

The precise scenery of the novel structures contributing to the biotic and physical complexes in a city may be perceived as conservatories to the concept of basic ecosystem [27], rather than violations to the definition [32]. Because urban ecosystems comprise new human artefacts such as infrastructure and buildings and new land forms, an additional complexity layer is emphasised as the ‘built’ component. Therefore, cities are human ecosystems with built, physical, social and biotic components that interact with one another ([33; 34]. Any spatial arena containing interacting biotic and physical complexes is an ecosystem. In addition, smaller ecosystems may be found in larger ecosystems and this remains important in the application of ecological insights in landscape design [7].

6.2 Implications for Ecological Design

The interactions of the built environment, social structures, physical conditions and setting and organisations happen through information flows, organisms, energy and matter [25].

Van der Ryn and Cowan [35] define ecological design as ‘any form of design which reduces the environmentally destructive impacts by integrating itself with living processes’. It assists in connecting the scattered efforts in ecological restoration, ecological engineering, sustainable agriculture and green architecture and other fields. Urban design, technologies, buildings, transportation system and land uses are some of the reasons that give rise to ecological problems. Ecological design should be able to understand patterns which connect to nature and hence it remains important to work outside mainstream disciplines for seeing matters in larger contexts. Landscape architects need to foster integration between urban ecosystems and designs to save scarce resources for future generations [2].

Malaysian architect Ken Yeang [36], argues that there is a need to: apply ecomimesis being designing by imitating ecosystems; include environmental bio-integration; imitate the functions, structure, and processes of nature as in their ecosystem; not misled by technology; not assuming that if a building yields a high rating in green-system rating it is successful; and, recognizing that ecosystems contain both abiotic and biotic constituents acting in the biosphere.

These principles help in creating a sustainable city by reducing waste, creating healthy social relationships, decreasing noise pollution, increasing accessible open green spaces, enabling healthy and greener buildings, decreasing indoor and outdoor pollution, ensuring fewer toxic...
transmissions, and increasing energy efficiency [36].

7. Potential Solutions

7.1 Urbanization of riverbanks and urban revitalization

The main argument for revitalization was that areas had become a barrier separating cities and towns (humans) from water spaces as well as negating visual and emotional access to rivers in providing breathing space in swarming cities. Januchta-Szostak [37] have highlighted that successful revitalization projects in port districts demonstrate the social and landscape potential of riverside regions. The primary aim of urban waterfront transformation was to reintegrate riverbanks with the urban fabric (with respect to their function and composition) and scaffolding investment zones with outstanding landscape attributes. The sudden rise and interest in waterside parks, squares and boulevards being a showcase for cities and towns prompted a need to invest in active flood protection systems in profoundly built-up downtown zones that could be turned into attractive areas for residential and recreational integration, such as London’s Thames Barrier Park [30].

7.2 Construction attuned with the changing water levels

The necessitation of new types of flood-proof land management and construction techniques and practices to allow infiltration of flood water has been acknowledged as enabling the need for ensuring space for increasing flood water and inevitable expansion of cities [38]. There is a need to establish safe evacuation routes while considering the dynamics of rising waters. In addition, the need for quality zoning to enable adaptation to the rising water and intensity and direction of flood water flow based on planning of flood risk maps that would simultaneously allow shaping landscape architectural designs closely with water [20]

Pilot projects, such as in Littlehampton and Peterborough in the UK, demonstrate innovative rainwater management systems in urban areas enabling flood protection as part of Long-Term Initiatives for Flood-risk Environments (LIFE) initiatives [38]. In these cases, flood risk maps were the foundation for new urbanized shaping approaches enabling periodic floods mitigating and acceptance of the need to enable natural environmental processes and engineering.

7.3 Urban rainwater management

The key to preventing urban floods is to reduce surface runoff since its volume increases considerably when large urban surface areas are sealed. The USA and several EU member states have recommended adoption of the Sustainable Urban Drainage Systems (SUDS) that mimics environmental processes that occur naturally including infiltration, detention and retention [39]. These Systems help to decrease pollution levels and rainwater runoff from the urbanized zones.

Rainwater management in SUDS may be classified into 3 stages [20]: collecting and transporting water; water distribution and retention for reuse; and, evaporation and
infiltration. SUDS stages stress the purification of rainwater runoff via natural properties of the vegetation and ground. Thus, water needs to be clean in any composition so as to be socially and visually attractive [20]. Therefore, there is no need to conceal purification processes from the public. Moreover, the water-plant ecosystem serves as a recreational purpose and help in ecological education of the inhabitants [40].

7.4 Recommendations to local planning guidelines

Based on the review of current guidelines and regulations in Mauritius, it is noticed that guidelines are outdated, and addendums do not cater for environmental impacts of climate change. For example, the Design Guidance Policy, part of the Mauritius Planning Policy Guidance 1 [41], is more than 14 years old. It is also recommended that guidelines are designed in a more contextual fashion for both Urban and Rural areas. The Planning Policy Guidelines 6 [42], does this well by imposing strong regulations on Heritage. This needs to be expanded outlining desired activities, development and regulations at street block level. Further, there is the strong need for enforcement of urban guidelines and regulations. Numerous bodies across various Mauritius ministries currently issue clearances, which work in conflict from each other. There is a need for a centralized committee at municipal level for the review of all developments prior to the issuance of development permits at municipal level.

8 Conclusion

This papers explored sustainability and liveability through the five principles of the ecosystem. The first principle which showcased urban areas as ecosystems and the implications for ecological design were emphasized. This was particularly important for Mauritius, as being part of the SIDS which hosts a unique fragile ecosystem.

The need for a resilient fabric was emphasized due to the local challenges of Port Louis through the advent of climate change; and its impacts on weather patterns. The issue of flash floods which impacts on both economy and society were discussed and solutions were offered that tallies with ecological and sustainable methodologies.

Urban planning policies and guidelines relating to Port Louis was reviewed and recommendations were made to decrease the risk of flash floods. It was further argued that urban ‘green and blue infrastructure’ could play a fundamental role in enhancing the adaptive capacity of coping with climate change [2].

Altogether, the proposed recommendations are aimed to ensure that appropriate policy anchors into governance and practice to ensure urban densification to prevent urban sprawl; conserve and enhance nature; ensure proper planning for climate change mitigation; and, support a more efficient policy for urban disaster management.
Acknowledgment

The authors are grateful for the assistance of Urban Planner Laurence Goder, for reviewing the Mauritian Planning Policies and Guidelines outlined in this paper, and would like to acknowledge the contribution of an Australian Government Research Training Program Scholarship in supporting this research.

Abstract

Is it possible to envision the city today without sustainable development?

In Western Europe, we put a large part of our energy in the protection of resources in order to reduce the effect of climate change, especially the extreme heat in the city centers, and to develop resilient cities in the face of natural disasters. We also work hard on social development and on generating melting pots between generations and origins. With these goals in mind, we, as landscape architects, with our large scale projects, are part of the solution. But, as nature has proven, large impacts on our environment often come from the sum of a large number of little simple changes. Nature provides ‘low tech’ answers, so, what can we learn from it? Fighting high level summer temperatures in our living spaces today is simple with smart \textit{technological} solutions. But, it is just as simple and efficient with low tech \textit{natural} solutions, like storm water management, evapotranspiration, wind use? These solutions represent no energy costs. And they are reliable, even during a large power failure, this type of design continuing to function no matter the circumstances. Scientific experimentation in Lyon, France (but also elsewhere), has already proven that a planted street (trees and bushes) is 4° Celsius cooler than a mineral street nearby.

In each project, we have to choose between the use of “pre-invented” industrial solutions, often with a high need of technical maintenance, or the use of locally adapted solutions, needing little maintenance, except observation, cleaning and gardening. In order to answer the city’s needs and be as efficient as industrial products, we must dedicate more time to designing our public spaces, adapting solutions and designs to the spaces being refurbished. Using these “natural” solutions will change the face of our cities, the atmospheres, the social networks, as well as the way we organize / share work. We will need more and more ‘city gardeners’. These new ‘gardeners’ could be local citizens, just as they could be members of the city’s extended garden department. In any case, more ‘gardeners’ also mean more social exchange and more social appropriation of public spaces.

This thinking is illustrated in projects developed in the Lyon suburbs, where a number of projects are being renovated. The refurbishment of large settlements from the seventies (associated with social housing) in the North of Lyon, integrates as basic design requirements, green infrastructure, storm water management and biodiversity strategies, wind orientation studies, as well as a structural analysis and thermal scan of all existing buildings. This doesn’t forego the economic or the mobility analysis of the project. In another neighborhood, East of
Lyon, raingardens and green spaces colonize the city center further preparing the area to climate change. The question is not to confront a smart life for smart cites, with a ‘slow’ and simple life for sustainable human installations, but just to choose the best solution for each situation.

Keywords: climate change, low tech design, storm water management, green infrastructure, city gardeners, Lyon

1. Introduction

The projects presented hereafter, all of which are located in the Lyon suburbs (France), stem from the will to first and foremost review the urban, as well as the social organization, planning and design of a commonly found constructive typology in France: the ‘grands ensembles’. These ‘grands ensembles’, projects developed mainly in the 60’s and 70’s, are large scale social housing projects that were spread over entire sections of unused or abandoned city areas, outside main city centers.

Today, they have become matrices for an urban and social renewal, accompanied by a strong drive for inner city landscaping, that take into account future global warming questions and rainwater management. In the last years, these ‘grands ensembles’ have met with a large increase in their population (due to higher demography, real estate speculation, etc.). But most thankfully, they also benefited from the existence of ‘vacant’ spaces, yet to be constructed.

The original urban configuration of these ‘grands ensembles’ is precisely what can be used today to adapt new urban refurbishment, reconciling natural space and density demands, automotive and soft traffic infrastructure, social and residential housing. This reconciliation of interests and functions is mainly possible through the introduction of a mixed typology of spaces. For example, streets and avenues invariably integrate trees, rainwater gardens or ditches as well as melliferous plants, where there were none, or new urban constructions are built with the obligation to integrate central and permeable planted patches or even green roofs.

A part (more or less important, each according to individual city’s political policies) of these newly created publics spaces are today submitted, in France, to public consultation and are followed either by local residential action (public space management taken over by actual residents or future newcomers), by educational team management from surrounding schools, by the use and handling of spaces for non-profit associations or even artists within the scope of a biennale or other artistic manifestation. For these reasons, these spaces must remain, despite having to be of easy upkeep, a source of collective well-being and of sharing (sharing stories, experiences, uses and functions, even production (allotments for vegetable or fruit growing), etc.).

The following examples illustrate the history of the evolution/transformation of existing 'grands ensembles' neighborhoods, through the implementation of major green infrastructures, mostly (but not always) managed by local authorities but always adapted to each context, each area (streets, avenues, parks, central green spaces, fruit and vegetable patches, etc.). These major transformations are made possible by the French Agence Nationale pour la Rénovation Urbaine (ANRU), a national public aid and subsidy program to
help various cities deal with the renovation of whole sectors of their inner cities.

Shared wisdom (sensus communis): term initially used by the Romans, meaning humanity and sensibility as well as common sense. Indeed, wisdom can be translated as the common sense of the common folk. It is the wisdom born from immediate and practical knowledge. This is a common and collective cultural heritage. Our work in Vaulx-en-Velin and Rillieux-la-Pape, suburban residential cities, Northeast of Lyon (the Greater Lyon conurbation accounting for around 1.5 million habitants) aims to reclaim this notion of “shared wisdom”.

Fig 1 - The 55 municipalities of the Greater Lyon area. In green, city of Vaulx-en-Velin. In yellow, city of Rillieux-la-Pape.

2. Vaulx-en-Velin _ THE EVOLUTION / TRANSFORMATION OF DIFFERENT CITY NEIGHBORHOODS USING SHARED PUBLIC SPACES

Since the 1960’s, Vaulx-en-Velin has been expanding from an old rural community to a residential suburb complete with working factories. Pressed by the urgency of housing shortages, the 60’s urban planners applied rather typical mainstream theories to all of France’s developing territories, unfortunately, regardless of context, cultural or historical preoccupations. This period saw the introduction of “platform” urban planning, consisting mainly of social housing, surrounded by large empty “green spaces” built on old orchards, farmlands and wetlands. Today’s designers and planners are most likely to search for all remaining traces of this past, both historical and social, in order to elaborate the city’s new urban landscape. The goal being to reintroduce and reinterpret different aspects of the old landscape through new public spaces but with a shared vocabulary (orchards,
vegetable patches, meadows, rain gardens, etc.)

Three examples successfully demonstrate this process within the city, a city which has grown from 21,000 habitants to more than 47,000 habitants since the end of the 1960’s.

The project’s renewal was based, throughout, on a strong partnership between the different territorial protagonists.

Fig 2 – The location of 3 urban renewal projects in Vaulx-en-Velin

This neighborhood’s refurbishment included the design and construction of new streets, squares and urban parks, as well as parking lot reconstructions, the creation of communal gardens and the arrival of new shared common spaces, etc.

Two squares in the heart of this neighborhood (each of 3,000 and 1,600 m²) now offer new public spaces devoted to conviviality as well as allow for the planning of community events and activities.

A new urban park now provides multiple answers to space sharing: children’s playgrounds, mini sporting grounds, specific theme gardens, multiple use large green spaces, and more intimate green spaces, etc.

The non-profit association “Vaulx Jardins” manages garden allotments that remain at the inhabitants’ disposal through a ‘Management Service Agreement’ signed with the Vaulx-en-Velin local authorities.

The association considers these garden allotments as community meeting places and relaxation areas with the primary aim of respecting all users and the environment.
Using agro-biological gardening methods, the residents participate in the embellishment of their own living environment contributing to their neighborhood’s newfound identity.

The association informs and educates local gardeners, and at times, the public, on all types of natural techniques enabling the development of many cultural and educational activities for all ages.

To answer growing concerns in the fast growing environments of our cities, France, as early as 1970, put in place new urban legislation allowing for large zones to be development with public or private funds (or both) for the betterment and the renewal of all city territory. Still largely the model in use in today’s public urban planning, Vaulx-en-Velin’s City Hall sector is but another example of the implementation of an Urban Development Zone.

Began in 2010, the project consists mainly of green infrastructures and rain gardens (small and large units, as well as large units with overflow outlets), using permeable materials (evergreen pavement for parking spaces, water treating rainwater gardens, etc.).

Novelty of the project: most of the underground water treatment is made through the tree substrate.

Early on, in researching the future design for this new zone, it was found that existing plants growing on the nearby riverbanks had an inherent capacity to support droughts as well as floods. These plants were capable of surviving in polluted environments by means of a rainwater filtration process. It became obvious that this knowledge would mold the future neighborhood’s landscape and the plant order within the project. The plant selection was then based on the physical properties of the substrate and the plants' root filtration capabilities.

**2.2 The City Hall Urban Development Zone (2010–2022) – 11 ha**
Plant nurseries and universities were associated with one another. Piezometers (instruments needed in the fine water pressure measures) and probes were installed at the same time as the vegetation was planted. The aim of these water pressure surveys was, and are still today, to study the water cleaning results of the plant species as well as their growth.

Fig 5 – Blooming rain garden plants

Fig 6 – The rainwater management of all local streets in the urban zone is exclusively alternative via rain gardens or ditches. This sector’s construction ended in 2015.

Not far from the City Hall Urban Development Zone, stands another renewal project, the Barges neighborhood. This project stands among other smaller projects in the city with similar ambitions: these are ‘warn out’ areas that have outgrown their initial functions and need to open up again to new urban populations and uses.

As often in occupied areas, the Barges renewal project was the object of a public inquiry and dialog sessions with the local residents early on.

Adjoining the newly designed public spaces, a center for Youth and Sport activities secured a certain amount of use for these new public spaces, located far from the more
urban city center. The sports center’s users and the local residents were at the heart of all concerns while designing the project.

The desire to densify our urban areas for sustainable development purposes need not only touch large agglomerations. When opening up a neighborhood such as the Barges, it must be associated to concrete development projects that reinforce the initial political will to create new functions and uses in these areas. Timid as they may be at first, these development projects, whether housing or public facilities, need to be backed. This was the case with a neighboring lot construction. An auto-building project, for residential use, was introduced in the Barges urban landscape, built by the ‘Chamarel’ association, a group of retired seniors searching to live in a shared coop building with shared principles. Among these principles, one finds certain common needs:

- **Cooperation**: Collective and regulated management of all aspects of the project, and later, the living spaces.
- **Ecology**: Construction and operating rules in compliance with sustainable development norms.
- **Civic rights**: Open living spaces, available to all groups, in keeping with the pursuit of a locally active lifestyle (associative, cultural, etc.)
- **Respect of individual lifestyles**: Controlled relationships between private life and collective life in respect with secularism.

As for the vegetation choices, the plants here are reminders of Vaulx-en-Velin's past involved in fruit and vegetable farming, and are at the heart of the project. A drawn shape upon the square's new concrete surfaces represents a huge thistle to remind the inhabitants of their city's past. This floral motif is reused in the street furniture.

![Fig 7 – Corten steel screens engraved with the thistle motif](image)

![Fig 8 – Rainwater garden](image)
This project aimed to implement specific plant species to allow the development of biodiversity. The introduction of bird houses also contributed to reclaiming biodiversity. The general maintenance of the project is incumbent upon the city but the nearby activity center also plays a role.

The reintroduction of a small tree-filled grove (representing the historical forest of this site), of rain gardens and swales, planted for rainwater management purposes and made up of permeable materials (evergreen pavement for parking), and plants like native tree species and blossoming hedges of mixed varieties, recall a rural image for the new square.

3. **RILLIEUX-LA-PAPE** – THROUGH A NATIONAL URBAN RENEWAL PROGRAM, GREAT UNIFYING GREEN INFRASTRUCTURES

The New City of Rillieux-la-Pape, built in 1960, is today one of many registered municipalities in France’s national Urban Renewal Plan, a plan which includes numerous housing rehabilitations but also
demolitions and future constructions. The establishing of this sort of territorial Urban Renewal Plan allows cities to rethink the ‘grands ensembles’ neighborhoods and their city’s own framework in general, most notably through the prism of the city’s urban nature.

At the same time, Rillieux also wishes to develop an Eco District Label within this program, as well as a Cit’ergie Label (the Cit’ergie Label being the implementation of certain measures destined to municipalities that are willing to continually improve their policies concerning sustainable energy consistent with ambitious climate targets).

Two examples to illustrate the evolution/transformation of a city, having gone from 10 000 residents to more than 30 000 residents since the late 1960’s:

The city of Rillieux-la-Pape is stretched over many different districts that, with time, have stopped being connected. It is especially the case with its New City district, a ‘grand ensemble’ neighborhood dating back to the 60’s and 70’s, concentrating within its territory most of the city’s population. Rillieux suffers today from these divisions among its neighborhoods, whether they be physical or social. An Urban Renewal Project such as this one, with the help of public funding from state or local government, offers new opportunities for this city to face its two major challenges: the renewal of ties between the different districts and the transformation of an old city into a new sustainable one, that will counter urban heat islands, reintroduce urban biodiversity and work to better its public spaces.

Fig 12 – City of Rillieux-la-Pape: a green belt to surround the city’s differences in altitude – a New City district constructed halfway between a natural balm and farmlands
that would cross the city from East to West, using the image of a flowing river with areas expanding into varied spaces for different uses.

The park was thus conceived to become a grand unifying space. It offers on one hand a large scale meeting space for residents, and on the other, playing areas, sporting areas, and easy access kitchen gardens. It is the foremost component of the new green space policy, mixing green infrastructure, natural green spaces and/or nearby proximity spaces. If these green spaces’ main mandate is to cater to leisure or recreational activities, they also serve as a biodiversity reserve or even a fruit and vegetable garden.

Non-motorized transportation options are reinforced: a bicycle path, today partially existent, is completed and redrawn across the southern stretch of the park (1.4 km), while a pedestrian walkway is entirely created across the northern stretch of the park (1.3 km).

**Fig 13 – City of Rillieux-la-Pape: Local Urban Masterplan – In red, the former reserved area for a future roadway**

**Fig 14 – The location for the future Linear Park**

**The basis for the ‘Coulée Verte’ or Linear Park: a reserved area indicated in the city’s local urban masterplan, devoted to become a future roadway stretching from East to West.**

An urban study, covering the entire city of Rillieux-la-Pape in 2014 (Study team: Eranthis/Notus), and the Urban Renewal Project, under way since 2008 (and prolonged for the another 15 years), concluded with the suggestion to overlap a new green infrastructure framework atop the city’s actual urban frame, the main component, at the heart of it all, being a large ‘Coulée Verte’. This ‘Coulée Verte’ was renamed the Linear Park: a large park.
The park’s first steps in its construction in 2017 coincided that year with the Lyon Contemporary Art Biennale. As a marker for its debut and a way to involve residents beforehand, a local artist was able to take temporarily over parts of the park, his intervention consisting mainly in planting Damas rose bushes.

The idea was that at a further date he would be able to produce and collect the rose water once the rose bushes would attain a certain maturity. It is through a residents’ association, in charge of pruning and caring for these bushes that his work goes on each participant already invested in the park’s future.

These new ‘city gardeners’ are very much the different neighborhood’s habitants. They meet regularly around a common activity: the caring of the rose bushes.

On the park itself, specific actions were sought in order to recover cooler air in the city, to reinforce urban biodiversity, to manage rain water and to federate citizens’ gatherings, at little cost.

This concerns:

- the peeling off of existing ground top surfaces made of a bituminous mix (parking areas, streets, access roads, etc.) to replace them with grass covered zones, bush and perennial areas, trees, a bicycle path, etc.
- the planting of an additional 250 trees (to add to the 150 existing...
trees), a great variety in plantation species (30 different in all), some flower varieties, some fruit varieties, to attract, as much as possible, birds and bees.

- the introduction of sporting plains, playgrounds, community barbecues, green amphitheaters and natural solariums
- the expansion of existing kitchen gardens (a total of 2 500m²) to unify collective sharing actions, to ensure the caring by the habitants of public spaces, etc.

Project management: Eranthis landscape architects, Notus and JASP architects and city planners.

Developing green and blue infrastructures, searching for civic participation.
In 2014, the newly voted in municipal team wished to hold a holistic discussion at a communal scale particularly concerning its green framework. It was on this notion, the green framework, that their territorial project was based upon, putting forth the landscape as founding principle, a transformation instrument for spaces and practices, a levy to change the city’s New City image.

The Urban Renewal Project searches to put forward natural and recreational environments forging ahead on the existing green framework in order to develop a true network of theme related parks (urban, natural, agricultural, sporting, recreational, etc.) with one logic in mind: a structural human flow for the municipality’s identity and its economic development.

The city’s changing image and the social and urban diversity
The Alagniers neighborhood is the oldest part of the New City District. It suffers from a negative image due mainly to its poor architectural development (dilapidation, strong morphology issues, etc.), to its increasing impoverishment and to its absence of social diversity. When coming from Lyon, it is the gateway to Rillieux. In this geographical context, the renewal program is a benediction for any image changing initiative.

The river and its ‘affluents’ / the structural nature
The Alagniers neighborhood is restructured around three North/South ‘green affluents’ (the ‘river’ being the earlier cited Linear Park, chap. 3.1), and constitutes the first foundation in the implementation of new functions and uses.

These affluents constitute a certain continuity between the city’s natural balms and the Linear Park. They insert themselves, and actively participate, in the new green transportation plan: bus, bicycles, etc.
They allow for a better enhancement of area buildings and main public facilities in the urban landscape (newly renovated existing tower, etc.).

- resident workshops (exchange times, brainstorming and debates)
- residents’ association brainstorming workshop (work done on collective memories, change adaptation, etc.)
- other urban renewal project visits and an exchange network between residents at the Greater Lyon scale
- friendly exchange moments between district associations and public housing authorities. These rather festive moments are ideal for everyone to exchange concerning the Urban Renewal Project and to materialize short term actions.

Civic participation from local residents to deploy Urban Renewal Projects, to set up urban experimentation zones.

The city’s political project team put in place an intervention methodology adapted to each type of project and to the desired degree of participation.

They applied for each sector:
- ‘walking’ general diagnosis and exploratory walks to account for daily management and environment needs
- street level publics consultations in front of buildings, or door to door consulting, to gain information on uses (questionnaires concerning public recreational facilities for example)

Fig 24 – The green ‘affluents’ that irrigate the Alagniers neighborhood

Fig 25, 26, 27, 28 – City ‘gardeners’!
4. Conclusion

Our city’s new ‘intelligent’ urban planning and designs are today conceived in terms of the more essential criteria, more basic, simple to put in place. Among these criteria, one may find:

- The planning and designing of cities while anticipating and adapting to risks and climate change
- The preservation of water resources and the guarantee of quality and efficient management
- The preservation and enhancement of soil biodiversity and natural environments
- The promotion of heritage sites (architectural and natural), of regional history, of city and neighborhood identity
- The implementation of urban, landscaping and architectural quality projects
- The favoring of active mode transportation (bicycle, skating, etc.), community transportation and all alternative means of transports
- The implementation of common guidelines for mutual coexistence and solidarity
Soil and Water Bioengineering as Natural Based Solutions

Abstract

Soil and Water Bioengineering: is a discipline than combines technology with biology, making use of native plants and plant communities as construction material for protecting soil and contribute to restore degraded environments.

It can be summarized that initiation of vegetation is a good way of providing various ecosystem services such as erosion protection, aesthetic value, habitat provision and balanced local climate without neglecting water management issues. Soil and Water Bioengineering are Natural Based Solutions offer sustainable solutions to cope with climate change mitigation and adaptation challenges and are effective not only in normal but also in extreme situations. In this context we are working on the ECOMED Project.

The ECOMED project aims at supporting and promoting the specialization level of the Soil and Water Bioengineering sector in the Mediterranean ecoregion. The Mediterranean particularities are related to the aridity of the climate and the selection of both plant material and planting techniques.

Canal Artía Irun-Spain-One of the works to be analized by SCIA SL in ECOMED Project G. Vasco P. Sangalli AEIP EFIB
The ECOMED project is co-funded by the Erasmus+ project of the European Union and the project consortium includes academic entities and enterprises, from 8 different countries (Italy, France, FYROM, Greece, Portugal, Spain, Turkey and United Kingdom). The use of the accumulated experience within the sector is a featured element into the sector specialisation process strategy.

1. **Introduction**

The ecological crisis issued from the human activity ant its risk push us to find solutions that go through the understanding of the laws of nature and its principles, the stop of the ongoing degradation and the mechanisms of restoration. As a society, we are experiencing a period of uncertainty, in which we perceive that the solutions could come from finding a balance within our environment based on the sustainable management of our ecosystems, the restoration of their functionality and services, and the use of nature-based construction systems such as soil- and water-bioengineering techniques.

Soil and Water Bioengineering: is a discipline than combines technology with biology, making use of native plants and plant communities as construction material and erosion control in degraded environments. The term "Engineering" refers to the use of technical and scientific data for constructive, stabilization and erosion control purposes and "bio" because the functions are related to living organisms, mainly native plants with biotechnical characteristics and with the purpose of restore ecosystems and increasing the biodiversity.

There is growing recognition that nature can help provide viable solutions that use and deploy the properties of natural ecosystems and the services that they provide in a smart, engineered’ way. These nature-based solutions provide sustainable, cost-effective, multi-purpose and flexible alternatives for various objectives: Technical, ecological, landscape integration and socio-economics. It can be summarized that initiation of vegetation is a capable way of providing various ecosystem services such as erosion protection, aesthetic value, habitat provision and balanced local climate without neglecting water management issues. In this context we are working on the Ecomed Project.

The ECOMED project aims at supporting and promoting the specialization level of the bioengineering sector inside the ecoengineering in the Mediterranean ecoregion. The Mediterranean particularities are related to the aridity of the climate and the selection of both plant material and planting techniques.

The Ecomed project is co-funded by the Erasmus+ project of the European Union and the project consortium includes academic entities and enterprises from 8 different countries (Italy, France, FYROM, Greece, Portugal, Spain, Turkey and United Kingdom). The use of the accumulated experience within the sector is a featured element into the sector specialisation process.
strategy. This strategy can be articulated from different perspectives:
- By analysing the sector current needs, strengths, weaknesses and opportunities.
- By analysing existing soil and water bioengineering works.
- By improving the existing design routines and protocols.
- By reinforcing the sector by a know-how transfer strategy (generation of new interactional schemes and dynamics within the sector).
- By generating an improved syllabus and sector specific training modules.
- By generating a plant database adapted to the bioengineering Mediterranean sector and needs.

2. Methods and Materials

2.1 Study Area

The Mediterranean ecoregion in Europe should be a priority in the efforts implemented in mitigating soil and land degradation (Cerdan et al., 2011). The ecoregion is extremely susceptible to erosion, floods and landslides because of its natural characteristics that include the semi-arid climate, sparse vegetation, many dry lands and steep topography (Davidson 1991, Palmer, 2017; Zaimes et al., 2012). The Millennium Ecosystem Assessment (2005) estimated that 10–20% of drylands are already degraded. Furthermore, scientists have stated that approximately 12 million hectares of drylands are degraded each year (James et al., 2013).

This ecoregion has been inhabited by humans for thousands of years. The impacts of the human activities in the region are evident with the many unsustainable agricultural lands and the few remaining patches of natural ecosystems (Pearce, 1996; Tal, 2010). The natural and frequent wildfires of these ecosystems should also be a major concern (Shakesby 2011). Burnt bare areas have very high erosion rates especially after torrential rains (De Luis et al., 2003; Pausas et al., 2007).

The socio-economic changes of the past century in the ecoregion have led to the frequent abandonment of agricultural fields that have also increased susceptibility to soil loss (Ries, 2009). Finally, the forecasted changes in climate for the ecoregion that are increased precipitation intensities along with prolonged droughts should be considered in management plans and in the use of vegetation. Increased soil erosion, floods and landslides in the Mediterranean ecoregion should be expected in a region where these phenomena already cause serious socioeconomic problems (Giupponi and Shechter, 2003).
Overall the soils of this ecoregion have been developed under unique natural and anthropogenic drivers. This uniqueness means that to achieve soil sustainability the strategies used need to be suitable and adaptive to the region. The Soil and Water Bioengineering should be adapted and are likely to fail soil sustainability in Mediterranean (Lagacharie et al., 2017).

A set of soil and water bioengineering works scattered over the Mediterranean ecoregion are being selected for their analysis. This is a crucial feature within the Ecomed project strategy. The scenarios or work typologies included within the set of selected works are slope scenario, fluvial scenario and coastal scenario. Besides, some failed works will be selected for their analysis and discussion. The collected information both from the field work and the analysis of bioengineering projects and works will allow an effective proposal of improvements at different levels of analysis which are design, construction, monitoring and training. The preceding scheme will support the specialization process of the soil and water bioengineering sector in the Mediterranean ecoregion.

2.2 Materials

To promote and specialise the soil Bioengineering sector for the Mediterranean ecoregion new material and tools need to be adapted or developed. For the new material and tools to be applicable in the Mediterranean, the accumulated experiences of the ecoregion within the soil bioengineering sector need to be identified, analyzed and utilized. These experiences are the basis of the new material and tools being developed and are being mined with four different ways: a) understanding the know-how transfer within the sector, b) analyzing existing soil bioengineering works, c) generating new interactional schemes and dynamics within the sector and d) by improving existing design methodologies and developing new design routines and protocols.

A survey of the existing curricula related to soil bioengineering of the educational institutions in Mediterranean was conducted that was followed by a thorough analysis. Another survey of specific enterprises related to the soil bioengineering and geotechnical sectors was conducted on the major current needs to improve the sector specialization level. Specifically, 2-3 experts from big companies were asked questions in regard to how to best specialize Soil and Water Bioengineering in the Mediterranean. These surveys provided the feedback on the know-how transfer of the soil bioengineering sector currently in the ecoregion.
2.3. Results

One of the advantages of soil bioengineering works is the use of plants and/or parts of plants. As these materials grow, they further enhance the protection of soil loss and erosion that is provided initially by the inert materials (e.g. soil, rock, timber) that are used in combination with the living building material. The growth of the living plant material ensures the long-term sustainability of these works. As the living material is heavily dependent on the climatic condition, bioengineering structures are characterized by their semi-empirical nature. This is why it is necessary to compare between the original and the current state and the different stages of the construction site in terms of biodiversity, soil evolution, plant anchorage, ecosystem resilience, etc. The work analyses should also be complemented with the additional comparisons with two reference scenarios. Initially a site without any soil bioengineering intervention will be used as a pre-operational site. Afterwards an end-point reference where the targeted restoration objectives are well reflected will be utilized. With the first comparison we will be able to assess the intervention benefits and the work performance. With the second comparison we will be able to assess the progress of the restoration objectives fulfilment and the pace at which the restoration objectives are being achieved. This is carried out since pre- and post-construction evaluations can measure the change or the impact of the intervention, but the level of success can be judged only relative to a reference system (USDA-NRCS, 2007).

In addition with most experiences, examples and methodologies originating from different ecoregion (primarily the Atlantic and Continental) testing and examples from the Mediterranean ecoregion are necessary. With the Mediterranean climatic condition substantially different from the Atlantic and Continental condition successful ecoengineering interventions from the ecoregion are analyzed. Therefore, the ECOMED project is reviewing existing soil bioengineering works from the entire Euro-Mediterranean region with some being selected to be further analyzed. The idea is to provide successful case-study engineering interventions but also “failures” that could be transferred and utilized in different areas of the ecoregion with similar problems. This type of information is currently missing for this ecoregion and the generated and analyzed case-studies will provide information required to meet the needs for the professional specialization and to better understand its effective and efficient applicability in the ecoregion.

Restoration of Dunes. El Saler. Spain A. Vizcaíno AEIP EFIB

The apparent gap between universities and enterprises in many scientific fields requires the better and more effective collaboration of the two. Therefore, the ECOMED project is generating new
interactional schemes and dynamics within the academic and professionals of the sector. The first step was to invite the companies, enterprises, agencies and organization that work or deal with soil bioengineering for each country of the partnership to participate in the online questionnaire that addressed the needs and existing gaps in the soil bioengineering sector to further promote it in the Mediterranean ecoregion. This allowed to evaluate the opinions of the enterprises in regard to the design, construction, maintenance and monitoring of works but also the educational and professional expertise in the sector. Additionally, after the completion and analysis of the questionnaires, the partners in each country hosted Focus Groups to further discuss the results of the questionnaire. These activities will fill the current scientific gaps and generate a knowledge transfer network involving the Mediterranean stakeholders. The development of such a network will promote soil bioengineering in the ecoregion.

Soil and water Bioengineering are sustainable tools to improve resilience against soil loss and soil degradation.

2.4 Conclusiones

The Ecomed Project want:

- To promote an innovative and more effective teaching and learning in Soil and Water Bioengineering in Mediterranean Areas.
- To generate a sector specific theoretical and practical syllabus essential for the specialization process of the Mediterranean Ecoengineering sector and more specifically the soil and water Bioengineering sector.
- To create new alliances and dynamics between Mediterranean research and education centers and Soil and Water Bioengineering enterprises.

Experiments on Flowscapes

Dr. ir. Inge Bobbink

Faculty of Architecture and the Built Environment, TU Delft, Julianalaan 134, 2628 BL Delft, The Netherlands

Abstract

For the last five years, graduates within the master track of Landscape Architecture at TU Delft’s Faculty of Architecture and the Built Environment have been working on the theme of “Flowscapes”. In the graduation guide the theme is explained as follows: “Flowscapes, explores infrastructure as a type of landscape and landscape as a type of infrastructure. The hybridization of the two concepts seeks to redefine infrastructure beyond its strictly utilitarian definition, while allowing landscape design to gain operative force in territorial transformation processes. Through focusing on landscape architectonic design of transportation, green and water infrastructures, the studio aims to develop innovative spatial armatures that guide urban and rural development and represent their civic and cultural significance. With movement and flows at the core, landscape infrastructures facilitate aesthetic, functional, social and ecological relationships between natural and human systems. The studio seeks a better understanding of the dynamic between landscape processes and typo-morphological aspects; here interpreted as flowscapes. Flowscapes projects put Landscape Architecture Education Delft at the interface of Urbanism, Architecture, Civil Engineering, Environmental and Spatial Planning.”

In this paper the theme will be discussed by comparing two graduation projects situated in two different deltas: “The Haringvlietdam, a beautiful coastal landscape, part of the Rhine-Meuse delta” in the Netherlands and “The Living Estuary, a study to develop landscape spatial adaptive strategies by integrating water, ecosystem and anthropomorphic-dynamics in the estuary of the Volta Delta” in Ghana. The focus of the paper is on the method developed and applied in the graduation work. What do these projects have in common? In what way are they different and what can we learn from them in terms of understanding landscape architecture as an integral design discipline, in relation to the theme of flowscapes? A discipline that relates space to place and uses design as an operative force to steer adaptive and sustainable territorial transformation processes.

Keywords: Flowscapes; dynamics; integrating natural and human systems; biodiversity; climate change; flooding; a living delta, future resilience.
1. Introduction

Deltas are dynamic areas where river branches meet the sea. These rich ecosystems, have attracted, and still attract humans as deltas provide food, water and a good trade position from which to conduct trade. According to Meyer [2014] four-evolutionary phases for delta regions can be distinguished. First, the phase where landformation is dominated by natural forces. Second, human interventions and settlements begin to influence the natural dynamics on a modest level with the help of technology. Third, water management knowledge developed by the state which enables large scale structural interventions to regulate the delta system. And fourth, a delta in which a new balance between the different layers (natural, cultural and urban) of the delta system is introduced, creating a sustainable living delta.

Most of the delta’s in the western world and in Asia are urbanised and refer to phase two or three. Only a few delta’s in the world, especially in Africa, are still intact even though people live there. They can be categorized as belonging to phase one. The degree to which urbanised deltas are managed and how high the safety level is, differs substantially. In all cases, exploitation over years of urbanisation, intensive farming and industrialisation causes land subsidence, loss of wetlands, coastal erosion, salinisation and loss of biodiversity. Subsequent to this path of exploitation, more measures are required to maintain or increase the established safety level. A better appreciation of the damaging impacts of climate change requires amending this traditional, exploitative approach. Controlled urbanised deltas need to transform towards a more open system, balancing urban, cultural and natural dynamics in order to create a sustainable, living delta landscapes. In other words there is a need for measures that minimise anthropogenic impacts of coastal protection structures on ecosystems and that might even offer possibilities to enhance ecosystem functioning. [Borsje, 2010]

Since landscape architecture is the discipline which works and thinks with processes, landscape architects should get involved to and guide coastal engineers in again making living in the delta attractive and inclusive. As stated by a colleague from Delft: "The landscape is considered as a process rather than as a result. Natural and social processes constantly change the landscape, making the dynamics of the transformation a key issue in research and design. The design is considered to be an open strategy, aimed at guiding developments, no blueprint design. Projects play a role as an open-ended strategy, as in staging or setting up future conditions." [Nijhuis, 2013].

In this paper two students projects, both situated in a delta are discussed. Both projects work on the idea of transforming an existing delta to a living delta (phase 4). One project deals with the Dutch delta, probably the most regulated and safest delta in the world and the other project is about the Volta Delta in Ghana, a scarcely cultivated African delta. Both delta’s face large changes in the coming years. The Rhine-Meuse delta needs to move towards the fourth evolution step to regenerate dynamics and enhance the delta as an ecosystems. Concepts such as ‘building by or with nature’ that utilizes the forces of nature to strengthen natural, economic and living conditions are discussed. Building with nature not only implies that ecosystems
should suffer as little as possible from flood protection measures, but also that natural processes should be incorporated to strengthen the coast. [Brand, 2014] In the end the building with nature approach looks for integrated and flexible solution by making use of natural processes in such a way that meets the need for infrastructure while creating the opportunities that benefits both, for the economy and ecology sectors. [De Vriend and Van Koningsveld, 2012] The transformation of the Volta delta towards the forth step is needed not so much because the delta lost its natural dynamics but due to serious coastal erosion problems and rapid, uncontrolled urbanisation.

The approach of the two projects to reach the goal of generating a sustainable living delta is different. Not only due to the different starting points of today’s delta, but due to economic and political differences as well as access to water management knowledge. In the Dutch case the state takes more or less the lead, there is an awareness and funding to change the delta towards phase four. In the Ghana case, nothing is certain, measures for coastal reinforcement are taken without an awareness of the full consequences for the region and informal urbanisation is occupying more and more of the delta’s terrain. The awareness of the need for change towards a more sustainable approach is not yet present in Ghana, though the potential of the Volta delta as a living landscape is better places than the Dutch delta.

2. The Haringvlietdam, an operative landscape

The delta works in the Netherlands are world renowned for their construction of dikes, dams, sluices, and storm surge barriers that shortened the coastline of the Rhine-Meuse delta by 700 km. The works were declared finished after almost fifty years, in 1997. During the construction it was realised that by building the delta works, the natural system was drastically altered. During the process of building and in response to public pressure, the idea of a closed structure which restricted the sea was already altered.

Fig. 1. Oosterscheldekering, an open barrier construction (sea on the left of the barrier) photographed during flood tides. The Netherlands. © maritimnieuws, RWS

The Oosterscheldekering, a 4 km long barrier, one of the elements of the whole plan was changed into an open construction, that only closes under adverse weather conditions. In this way, the saltwater marine life behind the dam is preserved and fish can continue, while the land behind the dam is safe from the water when needed. The Haringvlietdam, an earlier build part of the Delta construction and subject of one of the discussed projects, consists of a closed dam which divides the water flow into fresh and salt water and can be considered a linear technical structure, a typical engineered element.
Maria Potamiali explores in her graduation project how the Haringvlietdam dam can be transformed into an operative landscape infrastructure. To get a grip on the site and to understand the processes she mapped the natural dynamics and processes of the tides, the wind, the waves, the erosion, the sedimentation and the biotics in the area. Followed up by understanding and drawing their interrelations and the changes in the system due to the construction of the dam. From this research, design principals for the Dutch coastal zone were formulated. The forces of wind, waves and tides could be used for the creation of barrier islands to protect the coastline were the dam to be opened. Making islands could be achieved by placing an underwater barrier and stimulating natural processes to redistribute sediments towards desired locations.

The new islands also work as a buffer to reduce wave energy. Behind the dam the intermediate space, between the existing new and old dikes, could be transformed into a new intertidal area by dike realignment.

The tidal activity due to the opening of the dam, creates conditions for saltmarsh development and once saltmarsh vegetation is established sedimentation enhances the heightening of the zone, naturally. This mechanism can be identify as an adaptive strategy to sea level rise, that at the same time reduces wave energy, improves the stability of the dike and enhances biodiversity. With regard to ecosystem engineering, this mechanism can be applied both at the barrier islands as well as at the dam.

In addition to the creation of new islands, which on the long term can become a building site for temporary housing, saltmarshes, mussel and oyster farms, windmills and tidal turbines positioned in the dike became part of the design. Whenever the
design principles were projected and transposed onto the site, the ideas were discussed with an civil engineer and altered as necessary. In this design-by-research-project, the intention was primarily to create an attractive, safe, site-specific liveable delta landscape. As Maria states in her report, “The design should be considered as an open end slow process towards an adaptive coastal self-sufficient region”. The constructed dam became part of an operational infrastructure playing a new role in a sustainable delta, a flowscapes.

Fig. 6. The Haringvliet landscape, where natural islands and technical structures work together. © Maria Potamiali

The graduation project of Ayu Prestasia aims to develop landscape architectonic design principles for future adaptive strategies that integrate water, ecosystem and anthropic (human) dynamics in order to enhance the spatial quality and livability in the Volta Delta. System adaptability in this project refers to the definition of resilience by Holling [1973] as the ability of a system to absorb change and disturbance without changing its basic structure and function or shifting into a qualitative different state. It could also include the ability to self-organise change in the social ecological systems [e.g., Holling 1996, 2001; Levin et al. 1998; Carpenter et al. 2001; Folke 2006; Wu & Wu, 2013]. In a vulnerable natural area, such as the Volta Delta, and vulnerable civilisation development strategies and design interventions should gradually provide from erosion are deforested and used for firewood. Due to the erosion, almost 50% of the inhabitants, that have settled both on the coastal shoreline and in the inland delta, experience flooding. Both, humans and natural values are threatened by these changes. Coastal protection in the form of dams and groynes have been recently installed without a long-term, comprehensive planning and don’t provide the protection for the delta as a whole. Rapid informal urbanisation is moving into the delta.

The Volta delta is still (compared to the Haringvliet dam area) a dynamic environment, forming the interface between the Volta river and the Atlantic ocean and providing significant natural values for many species. Nevertheless, by constructing a dam in 1965 tens kilometers upstream, a reservoir was created (the largest lake made by humans), mainly to provide electricity for the aluminum industry. Downstream sediments since then have significant reduced by 90% which, together with sea level rise and the associated change to coastal currents, causes severe coastal erosion. Moreover, the mangroves that protect the banks of the river

3. The Volta delta, a Living Estuary

The Volta delta is still (compared to the Haringvliet dam area) a dynamic environment, forming the interface between the Volta river and the Atlantic ocean and providing significant natural values for many species. Nevertheless, by constructing a dam in 1965 tens kilometers upstream, a reservoir was created (the largest lake made by humans), mainly to provide electricity for the aluminum industry. Downstream sediments since then have significant reduced by 90% which, together with sea level rise and the associated change to coastal currents, causes severe coastal erosion. Moreover, the mangroves that protect the banks of the river

The graduation project of Ayu Prestasia aims to develop landscape architectonic design principles for future adaptive strategies that integrate water, ecosystem and anthropic (human) dynamics in order to enhance the spatial quality and livability in the Volta Delta. System adaptability in this project refers to the definition of resilience by Holling [1973] as the ability of a system to absorb change and disturbance without changing its basic structure and function or shifting into a qualitative different state. It could also include the ability to self-organise change in the social ecological systems [e.g., Holling 1996, 2001; Levin et al. 1998; Carpenter et al. 2001; Folke 2006; Wu & Wu, 2013]. In a vulnerable natural area, such as the Volta Delta, and vulnerable civilisation development strategies and design interventions should gradually provide

from erosion are deforested and used for firewood. Due to the erosion, almost 50% of the inhabitants, that have settled both on the coastal shoreline and in the inland delta, experience flooding. Both, humans and natural values are threatened by these changes. Coastal protection in the form of dams and groynes have been recently installed without a long-term, comprehensive planning and don’t provide the protection for the delta as a whole. Rapid informal urbanisation is moving into the delta.
opportunities over time for the environment and people. The project aims to optimise the potential of the ecosystems to cope with the challenges of the estuary, to work together with the water dynamics create safe condition for living and to improve its economic values. Therefore, a mutually supportive relationship between nature and people needs to be established. Interventions should involve active participation of local inhabitants and stakeholders to increase the resiliency towards changes in the systems. To do so three steps are taken, investigation, scenario building, and implementation. First, a deep investigation of the delta is conducted to identify the relation between natural and human processes through time is identified. Methods such as the layer approach and cross-reference mapping, are used to look into the different relations between water dynamics, ecosystem dynamics and anthropic dynamics. Design experiments are conducted to find design principles that enhances the interrelations between the different dynamics in a way that they can enhance the delta as a living system.

Secondly, scenario’s, that elaborate on spatial changes in the region over 50 years are detailed and put on paper. They help to identify certain turning points in the development of the delta and point out significant elements which have a large impact on change.

The comparison of the three extreme scenarios is used for further experimentation to formulate a feasible and desirable strategy on the regional scale of the delta. With the help of design experiments, the determined variables are combined and their influence on the spatial dimension is studied.
Thirdly, design principles generated from the first step are implemented into the design strategy at the regional scale and are spatially and in its materiality elaborated at the scale of the neighborhood. The principles of ecosystem services are used as an assessment tool to guide and transform the implementations (design interventions) and to realise the sustainable development goals.

The three water, ecosystem and anthropic dynamics are integrated into a dynamic spatial design that only works if the balance between them is maintained. In addition, new programmes, such as tourism, new wetlands, and fish farming provide opportunities for income and increases the land values, they need to become part of the system. Zooming in to different areas in the region made clear that, by zoning through the implementation of new infrastructure or adjustments on existing infrastructure (water, greenery and road structures) different kinds of circular systems can evolve on site. By encouraging and educating systems thinking, residents hopefully understand that they are, and need to be, part of the living delta, the flowscapes.
4. Conclusion

Since landscape architecture is the discipline that works and thinks with processes, time, and through scales and can communicate with the help of drawn visions, landscape architects are key players (helped by many other experts) to steer delta’s towards balanced livable environments for all species. The two delta’s, differ substantially given their different geographical locations. The Dutch delta as of 2018, is a product of an overregulated and by the government-controlled system. Money and awareness is present and once a consensus is found which also satisfies the different interests of farmers, fishermen’s, nature lovers and the water board the transformation can begin and can be monitored. The methods used by Maria generate an exciting possible future where anchor points, like the dams that create the barrier islands, are designed in such a way that they enhance and accelerate specific processes on site. By thinking in terms of a slow process, people living in the area can adapt to the new, much more dynamic conditions. The case of the Ghana delta is different since climate change is live-threatening due to the vast speed of the coastal erosion. Moreover, many other problems of livelihood are at stake. By visiting the site, we learned that nevertheless wildlife and forestry NGOs are nevertheless present in the area, they are working with the people and teaching them how to live with all that the delta has to offer in a more integrated way. Ayu expanded this strategy in her design in such a way that people not only invest in themselves but, at the same time, become part of the living delta system. Again in a slow but constructive, adaptive (open to changes) process. In the project, the idea of people and nature benefiting from each other is strongly presented by proposing different circular systems in different zones. The interaction between people and the landscape is, in the case of this project, inseparable and could, if successful (let’s allow us to dream), become a showcase for all future delta’s. Both projects are striving towards the evolutionary phase 4 of a delta, creating a sustainable living environment, a true flowscape.

Research on The Method of Resilience Urban Design Based on The Eco-oriented Development Model ——Taking Jiulongpo West City in Chongqing, China as an Example

Mao Feng\textsuperscript{a}, Wanmin Zhao\textsuperscript{a}, Tao Zhang\textsuperscript{b}

\textsuperscript{a}Faculty of Architecture and Urban Planning, Chongqing University, China
\textsuperscript{b}College of Architecture and Urban Planning, Tongji University, Shanghai, China

Abstract

In rapid development stage of urbanization, China's urban construction has made great achievements, but the extensive development lacks eco-friendly concept, has result in continuous deterioration of the human settlement environment, and the weaker ability of cities to withstand disasters. Under the global trend of advocating a resilience city concept, the eco-oriented development mode gradually raises concerns, how to achieve urban resilience by dealing with urban and external ecosystems has become a hot topic. This paper taking Jiulongpo new city in Chongqing China as an example, based on Geographic Information System, explore the framework of the urban design based on the concept of eco-oriented development. The details are as follows: Firstly, through the digital elevation model and horological model to build landscape protection pattern; secondly, green ecological network pattern is constructed based on remote sensing data and minimum resistance model; thirdly, the method of analytic hierarchy process is used to construct land sensitivity pattern by overlaying multiple factors; fourthly, construct historical and cultural heritage protection pattern through cultural value assessment; finally based on the four major patterns and various elements, conduct all kinds of city systems design and spatial pattern layout, to achieve the purpose of maintaining the health of ecosystems, protecting animal migration routes and large habitats, passing on cultural heritage, and improving the quality of human settlements.

Keyword: Eco-oriented development model, ecological safety pattern, resilience city, urban design;
1. Introduction

In recent years, China has paid more and more attention to the restoration and protection of the ecosystem. In December 2015, the Central City Working Conference put forward the framework of "energetically carrying out ecological restoration ", Emphasizing the construction of ecological civilization, based on the principle of "respecting nature, complying with nature and protecting nature", and implement a strict ecological environment protection system which shaped the protection measures of green development mode and life style. The mountainous cities have special natural and geographical features which differ from the plain cities. Blind urban expansion causes fragmentation of ecological space in mountainous cities, severe destruction of mountain water resources, instability of ecosystems, and frequent natural disasters. Based on the concepts and design methods of the green infrastructure (here in after referred to as "GI"), this paper propose the ecological strategic framework , control various elements from the perspective of active defense and flexible control, and build a multi-scale, multi-functional, multi-target composite ecological network to guide the urban construction, aiming to maintain the health of the ecosystem, protect the migratory path of animals, and improve the quality of human settlement.

2. The core of Eco-oriented Development Model: GI

GI is a network of natural life support systems consisting of a hub and a link. Elements include natural open spaces such as water systems, wetlands, woodlands, greenways, parks, farms, and pastures. The core concept of GI is to emphasize the active involvement of natural ecology in land use, pay attention to the overall regulation of regional urban space from the evolution of macroeconomic structure, and create a sustainable human settlement environment by constructing a sound regional open space system[1]. GI network is the ecological framework and strategic premise for human beings to carry out urban and rural development and construction activities. It can comprehensively manage natural life support systems at different scales (river basins, villages, cities, and communities) and has been considered to be able to guide efficient and sustainable urban spatial development[2, 3].

The Boston necklace planned by Frederick Law Olmsted was considered as the origin practice of greenway. He integrated the broken and scattered open space into a continuous recreation line. Eliot Charles later inherited Olmsted's design philosophy and put forward the theory of "survey firstly before planning", providing scientific methods of greenways and open space planning[4]. Warren Manning proposed an environmental planning model based on the superposition of survey results and basic data analysis. Then Ian Lennox McHarg developed a multi-factor overlay
analysis method\cite{5}. Phil Lewis created a landscape analysis method that can identify natural and cultural resources, and proposed the concept of “environmental corridor” with multiple elements and complex functions. Richard TT Forman elaborated on the relationship between spatial structure, pattern evolution and ecological processes of landscapes, and provided a method for assessing the health of ecological processes using landscape pattern indices, further improving the technical method green networks construction. With the development of GIS and RS technologies, the extraction and recognition of data, the construction of evaluation systems and the overlay analysis have become more sophisticated and complicated. The global environment deterioration caused by urbanization has attracted widespread attention. In urban design and regional planning, Europe and the United States have gradually paid attention to the ecological service function of the green infrastructure and the supplement of the gray infrastructure. The green belt construction in Berlin, Germany, is an important means of controlling urban sprawl and serving the daily recreational functions for urban residents. The East London Development Strategy proposes to construct the London Green Network, through the integrated use of land resources from the aspects of ecological security patterns, recreational preferences, regional cultural context, and open space. The Mawland's Green Print program developed\cite{6} a Green Infrastructure Assessment (GIA) method through evaluating regional resource value and ecological service value to plan and protect multi-scale green space, and present an intuitive natural space value and protection map for government, land managers, planners, residents, and social groups. Subsequently, many cities in the United States started the green print program and managed urban internal-external natural environments through graphical language. At this point, the green infrastructure planning basically forms the methodological path and research paradigm: integrating basic data, analyzing key ecological elements, identifying and constructing ecological networks\cite{7,8,9}.

3. Urban design based on the concept of eco-oriented development——case study of Jiulongpo new city

3.1. Characteristics of ecological environment in Mountainous Cities

The mountainous green space system formed by mountains, waterways and green areas has a high level of naturalization. It is the basis for safeguarding regional ecological security and supporting urban and rural areas for overall planning and sustainable development. Compared with the plains, the mountainous region has more complex natural environment features and ecological processes. The dramatic changes in slope and degree of undulation, the complex multi-element ecological network base (mountains, rivers, ravines, valleys, etc.) can all be considered as large-scale habitat patches and corridors for material energy transfer), and larger spatial heterogeneity, make the ecological environment of
mountainous cities complex, changeable, in the state of low risk resistance. There is a staggered distribution of urban construction and green spaces. Ecological processes and patterns are extremely heterogeneous and complex in spatial distribution. Based on the characteristics of mountainous urban ecosystems and landscape patterns, this study used the principles and methods of GI to establish a GI network through the evaluation of mountain, waterway, green protection patterns and land use ecological sensitivity.

3.2. basic information of Jiulongpo west city

Jiulongpo west city with an area of 360 square kilometers is located in the valleys between Jinyun Mountain and Zhongliang Mountain, on the west side of the Jiulongpo District in Chongqing, and south to the Yangtze River. The topography gradually decreases from north to south. The site is dotted with rivers, lakes, reservoirs and wet spots, dense forests. The Current land use area of Jiulongpo west city is 37.6 square kilometers, and the land layout is more fragmented and scattered.

3.3. build landscape protection pattern

1) mountain protection pattern

Mountain is an important landscape feature of Mountainous City, and also a large habitat source and passage for indigenous animals and plants to live and migrate. Therefore attention should be paid to the maintenance of mountains and continuity. According to the elevation and slope data, identify and divide the landform types in the study area. Strictly control the range and buffer scope of the mountain and avoid the ecological cycle chain break.

Importing 1:5000 contour topographic maps of Jiulongpo west city to GIS for surface analysis and reclassification. The mountain protection zone is defined as an area with a terrain slope of more than 20% and an absolute elevation of over 500 m where strictly control development and construction activities and guarantee green cover and cliff line form. Slope protected areas are defined as areas where the terrain slope is greater than 8% and less than 20% and the elevation is greater than 300m where control the development strength and the height of buildings.(fig1,2)

2) water way protection pattern

In mountainous watershed, topography and topography directly affect the pattern
Future Resilience

and horological response process of water system. The supply of surface runoff in mountainous cities mostly comes from rainfall. A small amount comes from the supply of groundwater and high mountain snow melt. The water network is densely covered, the water system structure is complex, and the types of water bodies are diverse. Based on horological analysis, the water flow direction and confluence accumulation are analyzed to determine the surface water flow path and watershed units. Finally, the Strahler-Horton water classification method was used to classify and classify the internal water network of the site. The dominant water system is a well-established waterway with a fixed amount of water under long-term rainwater scouring, such as a river, stream. Semi-dominant water system refers to staged water storage, with the potential to form a fixed river channel, such as potholes, gullies, etc. Recessive water system refers to the lowest level of the water transfer network, which is not easy to form the waterway point. The higher-level catchment points are the most frequent areas for disasters and the most conducive to collecting and infiltrating rainwater for landscape design. According to the regional characteristics and planning requirements, the water system network for protection and restoration is delineated.(fig3)

In the GIS, the DEM elevation overlay road status and construction land information are integrated into integrated terrain. In GIS, the road status and construction land information are integrated into terrain. The horological model was used to combing the runoff to calculate the network structure and grading of the river network within the site. The higher the level, the larger the catchment area, the greater the amount of water, and the more important the horological and ecological functions. Considering that the hidden water system contributes little to the restoration of the site's horological processes, and the entire water collection network is preserved, it will lead to the fragmentation of the construction land and facilities construction. Therefore, only the water level of more than 4 levels will be reserved.(fig4,5)
3.4. build green ecological network pattern

Because of its poor connectivity and low carrying capacity, broken landscapes cannot provide effective ecological service functions, and thus have negative effects on the biological survival, ecological security, and sustainable human environment. The design path is as follows: 1) Identification of source patches based on relevant indicators (area, NDVI, nature reserves, biodiversity, ecosystem services) refers to areas where natural habitats that are less subject to external disturbances and which play a central role in ecological services. 2) Identifying corridors through the minimum accumulation resistance model, setting the calculated resistance surface for various types of ecological elements, and simulating potential corridors. 3) Establishing an evaluation system based on ecological importance assessment factors and building a multi-level ecological network.

We put Landsat TM Remote Sensing Image of Jiulongpo west city 2017 into Envi for Land Use Map and NDVI Index. Core patch is a collection area where the landscape plays an ecological role. Only patches that reach a certain area and vegetation coverage can meet the selection requirements of core patch. Put land use maps into GIS and identify core patches based on vegetation indices and scale thresholds. Comprehending relevant research literature and expert advice, we set multi-factor integrated weights as costs, including land use type, vegetation coverage level (directly affects the degree of difficulty of corridor restoration) and terrain relief (direct impact on animal and plant migration routes). Then we identify ideal ecological corridors from the perspective of protecting species migration paths through the minimum resistance model. Finally, a green ecological network pattern of "Nine Cores - Twelve Corridors" was formed. (fig6, 7, 8, table 1)
3.5. *Eco-logically sensitive zoning*

Eco-sensitivity reflects the ability of regional ecosystems to resist, adapt, and recover when they face natural or artificial disturbances, that is, under the same external forces, the possibility of ecosystem degradation in different regions. Eco-environment-based assessment of ecological sensitivity can effectively identify key ecological locations and provide a basis for rational land use layout, so as to avoid irreversible destruction of natural resources in the mountains and waters by blindly expanding and to ensure the sustainable development of human settlements in the mountains. The ecological sensitivity analysis steps are as follows: 1) Select ecological sensitivity factors by reviewing relevant data, expert consultations, field surveys, and grade the single factors. 2) The evaluation factor judgment matrix is established by the Delphi method. The weights represent the importance of the evaluation factors to suitability. 3) Using GIS to visualize single factors first, then multi-factor stacking according to weight values to finally get ecologically sensitive partitions.

According to the regional characteristics of Jiulongpo west city in Chongqing, five evaluation factors for elevation, slope, water body, vegetation and natural disasters were selected. The factors are divided into five levels according to the degree of importance. The AHP method will be used to weight the scores and superimposed in the GIS to obtain ecologically sensitive zoning, which guide develop management and control strategies for districts (table 2, fig9).

3.6. **cultural heritage protection pattern**

Based on the field survey data and historical and cultural data inside the site, the key districts such as historic districts and historical heritages are identified and buffer zones are established. The least resistance model is used to identify corridors and finally form a cultural network. Cultural and ecological networks are superimposed and finally formed a strategic development framework. **Conclusion**

Mountainous cities have the features of complex terrain, dense water networks, broken landscape patches, and frequent disasters. Rapid urbanization construction neglects the destruction of landscape features, interferes with and disrupts ecological processes, leading to serious imbalances in urban ecosystem cycles and
deterioration of human settlements. Based on the planning methods of green infrastructure, this paper extends the connotation of ecological elements, proposes urban regional spatial development frameworks and strategies from the five aspects of mountains, waterways, green ecological network, ecological security patterns and culture analysis. Recovery of the Geological Landscape as a Successful Geotourism Site in Gunung Keriang, Kedah by Implementing the Landscape Analytical Framework based on Ian McHarg Ecological Method.

Muhammad Adam Zakaria, Faridatul Akma A. Latif (Dr)

Abstract

Today, serious degradation of the geo-heritage has lead by technological development, economic and population growth and social changes in most parts of the world. These occurrences have encouraged many researchers and nature-lovers to a greater appreciation of this fragile natural environment and have resulted in numerous studies conducted in order to conserve it. The nature conservation is only related with the protection of biodiversity, but it is quite clear that conservation of other existing both abiotic and biotic nature also should get more much responsiveness. Geo-heritage may result in a wide range of impacts. This study is to identify the literature review of the recovery of the geological landscape in Gunung Keriang and to prepare the inventory-analysis for documenting the uniqueness of Gunung Keriang landscape geo-characters towards successful geo-tourism site. The methodology used in this project included (i) Ian McHarg’s Ecological Inventory Method and (ii) Strategies and design guidelines for successful proposed design. This study showed that several key success factors for sustainable conservation which includes the level of the stakeholders’ awareness, participation and appreciation towards heritage values and its economic potential and enforcement of legislation or policy would bring toward the success of the geo-tourism. Embracing this fact, and recognizing its implications for the nature, innovative public education programs and promotional activities will discourage the massive quarrying and the disoriented cultural-spatial design on site. Indirectly, the strong genius loci and successful ecosystem can be implemented. The last sections of the study show how the present practice of environmental designers preclude the generation of ideas towards successful geo-tourism in Gunung Keriang, Kedah. In conclusion, this knowledge on successful geo-tourism should be embedded in any geological landscape design as to prevent disoriented natural-spatial design on site.

Keywords: geological landscape; geo-tourism; and geo-heritage
1. Introduction

Making geodiversity significant to people, where they live and how they live, is crucial for successful geo-conservation. The need for its conservation and appreciation of the benefits can be delivered to society (Tilden, 1977 and Anderson & Brown, 2010). Unfortunately, numerous rare features in the geological landscape, have been destroyed and no longer can be treasured by visitors. The awareness of environmental change and its impact in geodiversity, will help us to make better and more informed decisions about the upcoming of our environment. It is very challenging to make policy and legislation work for geo-conservation.

The loss of identity and distinctiveness character of precious geo-sites contributed by the uncontrolled development plan. The new design will create a good visual quality of the geological landscape, but sometimes it may not consider in preserving the geo-heritage value. Our future generation will lose their appreciation towards geological landscape and the distinctive character of their value.

Disturbance of the rocky shore flora and fauna, including reducing their abundances, diversity, and reproductive output, shifting their size structure, and altering ecosystem functioning are harmed by the visitor activities, such as collecting, trampling, and rock turning. However, the active mineral site management and restoration can be synchronized on a landscape scale, the susceptibility of isolated habitats and species populations in geological landscape can be reduced and additional ecosystem services can be provided (English Nature, 1999).

The main objective of this study is to identify the literature review of the recovery of the geological landscape in Gunung Keriang and to prepare the inventory-analysis for documenting the uniqueness of Gunung Keriang landscape geo-characters.

2. Literature Review

2.1. Geo-tourism & conservation

The concepts of geo-tourism have significantly well-known in the last ten years. According to David Newsome (2016), the geo-tourism terminology is the education-based tourism that using the geological heritage resources. However, the geological heritage resources must base on the vivid characters of the geological features that differ from other places. Scientific, aesthetic, recreational and cultural value are the examples of attribute that can identify the vividness between two or more the geological landscape. The Table 1 below are the definition of each attribute.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scientific value</td>
<td>Geological data or the history of geological feature development</td>
</tr>
<tr>
<td>Aesthetic value</td>
<td>The pleasant view and its landscape surrounding</td>
</tr>
<tr>
<td>Recreational value</td>
<td>Suitability of nature landscape to become the recreational area</td>
</tr>
<tr>
<td>Cultural value</td>
<td>Local or tourist behavioral toward the site</td>
</tr>
</tbody>
</table>

Table 1 Definition of vivid character of the geological landscape (Source: David Newsome, 2016)

The initial definition of geo-tourism define as a practice of tourism that its concentration are on geology and landscape. An appreciative of earth sciences through gratefulness and educational, will promote promotes tourism to geo-sites and the safeguarding of geodiversity (Hose (1995, 2000). Visiting the geological features, the
usage of geo-trails, identification of scenic view point, guided tours, activities surrounding of the geological landscape and the existence of information center are the examples of program that can be adapted to achieve hose’s believes (Dowling & Newsome, 2006; Newsome & Dowling, 2010).

2.2. Geo-tourism in Malaysia

In 2007, Malaysia declared the island of Langkawi, one of the wonderful geo-sites as its first geo-park. Mt Kinabalu in Sabah and Gunung Mulu in Sarawak are part of geo-site that listed in world heritage. The outstanding caves and karst formations in the middle of mountainous rainforest make Gunung Mulu National Park as one of the famous spot for the geological lover. The conventional geological resources that own by this landscape have significant and growing function the in industrial expansion of Malaysia and entire the world. Hydrocarbons, minerals, clays, rocks, soils, water, sands, gravels, and salt are examples of the geological resources that can be found (Dowling, 2009).

2.3. The development of geological features for geo-tourism

In 1997, state government gazette Maliau Basin Conservation Area as a Protection (Class 1) Forest Reserve due to the existence of a rounded sedimentary basin in central Sabah. Two approaches have entirely used by Malaysian Geological Heritage Group in this type of development. The first approach is using the support system that already practice and taking benefit from the geo-tourism area. A thorough study was delineated to map and characterize accessible geological sites at Kinabalu Park in Sabah (Badang, 1990). Planning the development at a specific site that has the vivid geological landscape character was done as the second approach. Each site provided with the purpose of educating tourist through research and development activities focusing on mapping and categorization.

2.4. Principles of successful geo-tourism

There are many vital characteristics to form a geo-tourism. Dowling (2011) described the principles of geo-tourism as follow;

1. geologically based
2. sustainable
3. educative
4. locally beneficial
5. generates tourist satisfaction

The first three characteristics are measured to be crucial for a geological landscape to be reflected as geo-tourism while the other characteristics are observed as being required for any tourism.

3. The impacts of geo-tourism

Beneficial (good) and adverse (bad) are can be at any tourism as its impacts. New development and employment opportunities for community offered by the geo-tourism as a sustainable industry. Income growth, job opportunity, divergence and infrastructure expansion are also the range of the economic benefits that can be generated for them (Greiner, Stoeckl, and Schweigert, 2004).

4. Methodology

4.1. Ian McHarg ecological inventory method

This method extracted from “An Ecological Method for Landscape Architecture”. This method provides three filters namely physical, biological and
cultural that must take into consideration during the site inventory and analysis stages.

### PHYSICAL
- Topography
- Surface drainage
- Geomorphological
- Climatic factor
- Skylight shadow

### BIOLOGICAL
- Plant communities
- Wildlife
- Ecological sensitive area

### CULTURAL
- Land use
- Land ownership
- Circulation
- Edge condition (visual study)

Table 2 Ian L. McHarg, “An Ecological Method for Landscape Architecture,” Landscape Architecture (1967)

4.2. Observation evaluation

Identifying primary user group at site is essential to adopt the successful geo-tourism on site through the user participation. The author will interview the user about their activity-facility need for their satisfaction experiencing the site.

5. Results and discussions

5.1. Ecological inventory method

5.1.1. Site physical context

5.1.1.1. Topography

Two method used in order on identify and analyst the topography in Gunung Keriang which are slope analysis and elevation profile.

**Slope Analysis**

Observation has made on site. Based on the imaginary from google map, a slope analysis map delineated. From the map, shows that Gunung Keriang surrounded with flat terrain. The flat slope is suitable for any development while the steep slope is strictly prohibited for any development unless there were thorough research on development impact that will develop.

<table>
<thead>
<tr>
<th>Slopes</th>
<th>Colour</th>
<th>Slopes range (percentage)</th>
<th>Development order</th>
</tr>
</thead>
<tbody>
<tr>
<td>flat</td>
<td></td>
<td>0%&lt;15%</td>
<td>Suitable for any development</td>
</tr>
<tr>
<td>medium</td>
<td></td>
<td>&gt;15%&lt;25%</td>
<td>Can be developed based on needs</td>
</tr>
<tr>
<td>steep</td>
<td></td>
<td>&gt;25%</td>
<td>Strictly prohibited for any development</td>
</tr>
</tbody>
</table>

Table 3 Slope range
The highest peak of Gunung Keriang from the ground was 217.92 meter. Landscape analysis was carried out using the landform classification by Tanot Unjah & Ibrahim Komoo (2005). The classification is an identification of landform according to rock type. From the elevation profile cutting section of Gunung Keriang, classification of landform based on types of rock. Two type of rock in the area are carbonate sedimentary rock and clastic sedimentary rock. The observation made by referring the view towards the cardinal direction which are north, east, south, and west. The landform representing different type of rock are shown below.

5.1.1.2. Geomorphological

Field Sketching

Topographic sketches of landforms for each 180° have been made referring the cardinal direction. From these sketches, the rock condition can be observed and classified in detail. The north-south, east-west, and south-north are obvious as much have been covering by vegetation compare to the west-east side.
This data is gathered from Jabatan Geologi Malaysia. In their report that included in Rancangan Malaysia ke-9 has identified the level of safety of development for Gunung Keriang. The extremely dangerous zone clearly can be seen, mapped at the edge of Gunung Keriang.

Regular inspection of each cave entrance to prevent unwanted things happen

5.1.1.3. Hydrological

Macro Scale

The macro scale hydrological map shows the presence of stream channel flow from outside to the site channel and from site to the outside channel. The importance of this study is to restore the stream corridor and rejuvenate the boundary edges along the streamline.
Micro Scale

The presence of water bodies at site can be seen from the micro scale of hydrological map. The landform of the Gunung Keriang is one of the factors that influence the water flow from the catchment area that is the highest ridge to the lower levels. The rainwater flow in all directions from the peak of Gunung Keriang and channeled to the nearby water body. It is an indicator of high biodiversity existed on site. It is a potential to provide exciting site visit here. However, this area only can be allowed for minimal human activity to flourish the flora and fauna in Gunung Keriang.
The water element that can become one of the support element in design.

The existence of water flow at the ground of Gunung Keriang.

The water stagnant due to improper storm water management.

5.1.1.4. Climatic factor

The average for the annually rainfall is 2805 mm occurring at the site which the local temperature is 26.5 Celsius.

Accordingly to the graph above, the lower precipitation is at January month with the 45 mm of the average rainfall.

For the average temperature at Gunung Keriang is 26.5 Celsius, January is the hottest month in every years. The lower temperature in every year is in January which is 25.7 Celsius.
The 79.5% humidity or the lowest humidity can be identified in March, June and December. Humidity is affected both weather and climate as well as global climate change and also affects indoor environment, understanding it can help you determine the best place locate recreational area and suitable activities on site.

The sun path is significantly influencing the flow and the volume of the pedestrian. The activity attractiveness also is controlled by the shadow fall on ground. Based on the information collected, in the morning, most of the shadow is falling on the west side of Gunung Keriang. This causes less comfortable for the user who entered the Gunung Keriang from East side for recreational activity in the morning.

In the afternoon, the conditions of the area are uncomfortable. The shadows of the open space are getting reduced and people are started feeling uncomfortable. They only can rely on matured trees shades. To solve it, the open space must be planted with the large diameter trees that can provide shades during afternoon.

In the evening, the shadow conditions of the area are interchange with the morning sun path. The previous temperature rise is back down and people can use as an area of open space for them to relax and as a recreation area after a hard day’s work at the east side of Gunung Keriang.

However, the different shadow that falls from the Gunung Keriang to the ground shows that this site always provided with sun shading based on the existance of matured trees.
Matured trees with wider branches provide shades at this park.

Natural shade from the trees fall to the playground area.

Road side trees also function for giving shades to pedestrian.

Hawker that always attracted to the comfortable area for their business.

5.1.2. Site biological context

5.1.2.1. Plant communities and wildlife

Various flora and fauna can be found on site. The table below shows the detail of the significant wildlife and plant species that can be identified.

<table>
<thead>
<tr>
<th>NATIVE &amp; MATURER TRES</th>
<th>Common Name</th>
<th>Scientific Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tekoma</td>

</tr>
<tr>
<td></td>
<td>Monyet</td>
<td><em>Macaca fascicularis</em></td>
</tr>
</tbody>
</table>

Table 4 The detail of the significant wildlife and plant species that can be identified at Gunung Keriang.
5.1.2.2. Ecological sensitive area

An ecological sensitive area (ESA) is a designation for a natural area which needs special protection because of its landscape, wildlife or historical value. Three keys of aspect that take into consideration which are, plants distribution, wildlife distribution and the proximity of hydrology. The overlap of those three keys can be identified as the ecological sensitive area. The author buffered the areas as follow;

<table>
<thead>
<tr>
<th>Attribute/parameter</th>
<th>Buffer zone distance(meter)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Native species</td>
<td>50</td>
</tr>
<tr>
<td>Matured trees</td>
<td>10</td>
</tr>
<tr>
<td>Seen wildlife</td>
<td>10</td>
</tr>
<tr>
<td>Hydrology</td>
<td>15</td>
</tr>
</tbody>
</table>

Table 5 The buffer zone distance for the ecological sensitive area

ESAs in Gunung Keriang are land and water areas containing ecological functions of such significance as to warrant their protection in the best long-term interest of the people. The delineation of this sensitive area can apply the zoning approach to control the visitor movement at the park and the proximity to nature closely monitored.

5.1.3. Site cultural context

5.1.3.1. Land use

From the site land use, the site primarily encompasses with paddy fields plantation after the Gunung Keriang itself. Based on the proposed landuse in Rancangan Tempatan Daerah Alor Setar(RTDAS), Gunung Keriang is intended to become an open space for the recreation area activity.
The beautiful geological landscape scenery in the middle of the paddy field and local settlement also have the significant adjacent land use. It will support the planning of recreation area at Gunung Keriang. The mountain area provided site activities that can divide into the limestone discovery, water edge activity, cultural connection and nature exploration.

Paddy Museum that become adjacent attraction to the user of Gunung Keriang

Weekly pasar of local people

Map 7 Detail site activities

5.1.3.2. Legal
Gunung Keriang itself and its surrounding is a state land which the only boundary that is separating this site. Road and river are the physical boundary that can be seen on site. Gunung Keriang surrounded with Jalan Kampung Gunung Hilir, Jalan Kampung Simpang Tiga, Jalan Kampung Bukit Raja and Kampung Gunung Hulu. This site also located about 10 km north-west of Alor Setar close to the Kedah Paddy Museum.
The nearby river is including Sungai Anak Bukit, Sungai Alor Gunung, Sungai Tanjung Morah, sungai Tanjung Pauh and Sungai Kampung Hutan. The private land in the study area boundary usually full of houses that nearby the crops plantation. The state land ownership can be categorized into developed state land and planned state land. This area gazette as geo-heritage site under state law.

5.1.3.3. Circulation

Vehicular Circulation
The linkages are used only to connect user from adjacent area to the site. The majority of the users are move using their cars and motorcycles.
The vehicular user are not park at the suitable place

- **Traffic Volume**

Due to the recreational area, the pattern of the traffic volume is quite different with other part urban context. This area mostly busy with traffic at the evening for the weekdays and for the weekend, the traffic will busy in the morning and evening. The map 11 below show the pattern of the traffic volume at the weekdays during morning, noon, and evening.

**Pedestrianized Circulation**

The natural area is mostly vibrant with people who walk, jogging and hike. The pedestrian map on Map 10 show the details of the several of existing pedestrianized system that provided.

The entrance of existing mid-extreme hiking trail

The pedestrian way linked to the playground

The hiking trails that combine the artificial rock structure with the natural rocky structure
Future Resilience

5.1.3.4. Edge condition
The assessment of edge condition at Gunung Keriang is based on Visual Management System (VMS) by Forest Practice Boars, Tasmania. The forest areas of Tasmania are of growing importance for their scenic, cultural, biological and wood resource values. These are factors need a very careful evaluation. To address the public’s concern, the visual landscape must be considered a basic “resource”, to be assessed and managed along with other forest resource values.

**Basic Visual Assessment Method**

There are many steps to identify a visual quality of a specific area. For the Gunung Keriang, it is to follow the Visual Resource Management (VRM), by using four criteria:

a. Landform
b. Vegetation
c. Color
d. Land cover

Next step is to categorize the suitable classes (grade) for each criteria into:

1. Low quality
2. Moderate quality, and
3. High quality (or more)

The rating criteria must be clear before the site inventory is conducted. These are the scenic quality valuation and criteria that has been used.

<table>
<thead>
<tr>
<th>SCENIC QUALITY</th>

<td>variety of plants types and species below 3</td>
<td>amount of green space/natural area is less than 20% (significantly more developed area)</td>
</tr>
</tbody>
</table>

Table 7 The table of valuation and criteria for Gunung Keriang.

LEVEL 3- LOW SENSITIVITY
Forest and only busy on weekends in peak season. Walking track of local significance. Recreational areas with only very occasional use and of local significance.

LEVEL 4- VERY LOW SENSITIVITY
Roads with fewer recreational vehicles per day. Seldom-used forest tracks.

Three distance zones, as measured from the viewpoints, are used to stratify the viewing importance of the plotted seen-area

View from west towards east
View from north towards south
View from east towards west
View from south towards north

Visual Impact Assessment Evaluation

Determination of public sensitivity levels are as follow:

LEVEL 1- HIGH SENSITIVITY
Primary transportation systems of state importance. These includes classified tourist roads and routes, and tourist trails. The roads with cultural and scenic significance. Primary and high-use recreational routes. High level of concern for scenic quality and landscape change.

LEVEL 2- MODERATE SENSITIVITY
Recreational, cultural or scenic sites and viewpoints of state significance. Low-use recreational areas. Villages or residential areas with moderate concern for scenery and landscape change.
5.2. Identification of primary user

Table 10 The Landscape Priority Zones- result of the evaluation.

Figure 7 The percentage of user group the the activity-facility need.
Target users obtained from observation evaluation revealed that 25% of user are from the domestic tourist. This make them are the primer user of this site followed by school group, family, spelunker/climber and local resident. After being interviewed on what they need on site, the activity- facility needed are gathered in the table above.

6. Conclusion

Based on the inventory and analysis has been made, it can conclude that the Gunung Keriang must be protected as its valuable element that are unique. If they disappear, our future generations will not able to appreciate them and to understand the past. Thus, efforts are need to be taken to maintain the geological landscape at their original condition. Gunung Keriang area has potential to become a successful geotourism site by flourish the flora and fauna that are needed by community here. Knowledge about geological landscape are lacking among the professionals and they have to undertake in-house training for the enrichment of their knowledge.

Future Resilience

Abstract

The ecological state of rivers is declining worldwide because of regulation and construction of hydro power. On the other hand, there is an interest for removing dams and reviving migratory fish stocks also in constructed rivers. When removal of dams is not possible, nature-like fish passes and reproduction channels enable migration of all species but also reproduction of fish. They provide an option to compensate the loss of river habitats. They can also bring new aesthetic values with flowing water.

The Imatra City Brook in Finland was constructed in 2014 to be a new spawning and reproduction site for a local stock of Brown trout (*Salmo trutta*). Also the importance of the site for tourism was considered. With height difference 25 m and length 1 km, stone material as rapids was used in the entire length of the channel. Logs and stumps were added for protection of fish. The steep sections fish migration was a concern. The water into the brook is lead into two ponds at and the upper reach flows at the site of an old log floating chute. The brook flows in a tunnel under a street with a peer for pedestrians along the brook. An aqueduct over a valley is constructed as a resemblance of log floating. The downstream section is curving to reduce gradient and to increase length and width for optimal fish habitats.

Flow and habitat modeling was used during the design to evaluate flow velocities, depths and suitability for juveniles of different age. The finalization of the construction was done according to the best practices of river restoration. After construction, measurements showed that the gradients and hydraulic features were near to the planned.

Monitoring of benthic macroinvertebrates show that the brook is getting high diversity and that the macroinvertebrates serve well as nourishment for fish. The brook has been adopted by several natural fish species. Brown trout has migrated and spawned in the brook from the first autumn onwards and in two years the densities of trout juveniles became even higher than normally in natural brooks. The brook has fulfilled or exceeded the expectations of the
performance as reproduction channel. Ongoing monitoring will show the development and limits of the juvenile production.

In landscape design of channels with special requirements for fish, knowledge of hydraulics and fisheries needs to be combined with aesthetics. Monitoring of succeeded cases is essential to convince decision makers of the benefits of compensative habitats as an effective way to implement environmental flows. The good results of Imatra City Brook are equal to international similar cases and gives confidence that the experience can be applied at other hydropower sites allover.

**Keywords:** nature-like fish pass; rearing channel; compensation; fish; benthic macroinvertebrates

1. **Need for research**

Rivers with rapids and waterfalls are prominent features in landscape. Their natural values with migratory fish have in many cases been lost or deteriorated by other interests like power generation. In many countries movements for removal of dams are increasing. Political decisions have been made to revive fish stocks despite also use of power generation. Defining environmental flows for the benefit of river ecology in power plant permits is ongoing. In Finland the National fish pass strategy is made to promote decisions for reviving migratory fish.

In constructed rivers where natural reproduction areas have vanished under damming, fish passes are not a sufficient solution reviving fish stocks. Compensation measures and are needed to replace the lost reproduction areas by constructing new ones.

In some countries like Canada there is a long history of reproduction channels for Pacific salmon species [1] and there are applications also for Atlantic salmon [2]. In Germany, Switzerland and Austria new reproduction channels have been constructed according to environmental legislation requiring compensation of lost habitats [3]. The channels serve also as migration routes or they can be connected with separate fish passes. In Finland there is some experience and guidelines of constructed habitats.[4] Their values need still to be proved by research.

2. **Case: Imatra City Brook**

Imatra City was founded at the famous rapid of Imatranksi, once the biggest rapid in Finland. The place is still important for tourism. After construction of a hydro power plant in 1929 the rapid can only be seen during limited water release events in summertime. Imatra City Brook, constructed in 2014, is the first artificial channel in Finland which was planned mainly as a new habitat for fish, Brown trout (*Salmo trutta*) in connection to a hydro power plant (Fig. 1).
The length of the brook is one kilometer and height difference 25 meters. Rapids are prominent in the course of the brook. The upper, rather straight section is constructed on the site of a log floating chute (Fig. 2).

The city wanted to promote natural trout reproduction for touristic fishing at the river Vuoksi and also to design a new water feature in which flowing water can be seen all year round. The power company Fortum was willing to give water into a compensative habitat for the local Brown trout stock, which was in danger in the seepage brooks because of dam reparations. The discharge, 300 litres/sec in summer and 180 litres/sec in winter, is lead into the brook by pipes into two ponds (Fig. 3.).

The brook goes in a tunnel under the street with a peer for pedestrians (Fig. 4) and flows as aqueduct over a valley, resembling the old floating chute (Fig. 5). The downstream part is designed curving as a more gentle sloped habitat section. Because of the need of protection for fish, a lot of wood material is placed in the brook.
2.1 Planning

The leading planner of the project was landscape architecture bureau MA-Arkkitehdit, together with Finnish Environment Institute SYKE and Ecoriver Ltd. Special consideration was set in the planning of the habitat section, which was planned meandering to increase length and to maximize good quality of juvenile habitats (Appendix).

Gradients in the plan of the habitat section were from 0.25% to 5 % with deeper pools between. Cross sections were defined considering low water depth for juveniles but also possibility for bigger fish to migrate up and down. (Fig. 6.)

2D flow modeling was used to evaluate the velocities and depths by different discharges (Fig 7.)

Habitat model was created by adding bottom substrates and preference conditions of Brown trout in the plan. The habitat model showed good condition especially for small juveniles (Fig.8.)
2.2. Evaluation of the channel after construction

The channel was first constructed roughly according to the plan and then finalized, having water in the channel, by experts of river restoration. After construction the channel was scanned and gradients between pools and steep rapids were counted. The gradients were mostly between 0.5 and 1%, which are similar to the plan. (Fig.9)

2.3 Measurements of hydraulics

The hydraulic parameters, flow velocities and water depths were measured in three channel types: juvenile habitats with gradient 0.5%, spawning gravel areas, and steep sections, which could be difficult for fish to swim up [5]. The juvenile habitats (Fig.10) showed velocities 0.05-0.85 cm/sec and depths 0.3-0.4 m. The spawning gravel areas which are mostly situated at places where the velocity begins to accelerate after pools (Fig.11), velocities were 0.5-0.75 cm/sec and depths were 0.1-0.25 m.
The steepest section downstream had gradient 16% and maximum velocities 2 m/sec (Fig 12.)

The measurements verified that the velocities and depths were nearly same as in the flow model and also within the limits of the preference conditions of trout in natural streams. The fastest velocities were higher than normally in fish passes but still under the burst velocities of most fish species. Fish are also able to find smaller velocities in vortexes.

3. Monitoring of vegetation and fauna

First monitoring of fish was possible in May and June 2015, as big amounts of Roach (Rutilus rutilus) and Bleak (Albumus albumus) were seen in the up most pond, showing that the steep section is passable for also weak swimming species. Comprehensive monitoring of fish and benthic macroinvertebrates was conducted in 2016 and 2017, taking samples of different sections of the channel (Fig. 13).

3.1 Vegetation

Especially the downstream section is still without shading and protecting trees. Trees like alder (Alnus glutinosa and A. incana) were noticed to have natural sprouts on the banks. Aquatic vegetation begun to spread from upstream, entering probably with the water through the pipes. Monitoring in 2017 showed 10 submerged aquatic plant species in the ponds upstream. Most of them were typical for lakes, showing an influence of the great lake system of the Vuoksi river basin.

3.2 Benthic macroinvertebrates

Benthic macroinvertebrates consist mostly of larval stages of insects. A significant increase of individual amount in the samples, from 1500 to more than 8000 could be noticed between the two years. Also the amount of species increased from 26 to 40.

The composition of the invertebrates was analyzed by dividing them into functional feeding groups. In 2016 there was a
dominance of predators, which shows availability of other groups and high diversity in the new channel (Fig.14). 2017 the amount of scrapers, which feed on algae, increased significantly. The algae are a result of openness of the new channel. (Fig 15). Gatherers and shredders were still rather few because of the lack of litter from leaves.

3.3. Electrofishing

Electrofishing in 2016 showed that Brown trout had found the brook in autumn 2015, already. There was a high density of first summer (0+) trout juveniles in the channel, average 40 juveniles /100 m². In 2017 there was again about same density of first summer juveniles (Table 1).

Table 1. Results of electrofishing for Brown trout

<table>

</table>

In 2017 there was an exceptionally high density, altogether 150 juveniles/100 m² on site 4 downstream from the tunnel (Fig 4). In average there were 30 second summer (1+) juveniles /100 m². The survival rate, 75 % is much higher than normally in natural streams. This gives the estimation of 2000
smolts (juveniles beginning migration to the river) per hectare, which is much more than in natural rivers. Estimation is normally only 400 smolts per hectare. Additionally, several bigger trout were caught in the electrofishing (Fig 16).

![Fig.16. A trout of half kilogram was caught](image)

3.4. Dietary samples of fish

Dietary samples were taken by flushing from some fish (not harming them). The most common nourishment were larvae of Mayfly (*Baetis*), which were also the most common species of the macroinvertebrates. The fish were in a very good condition, showing that there is enough nourishment for them in the brook.

4. Conclusions and applications

The Imatra City Brook is an example of landscape architecture project where special ecological and hydraulic knowledge were combined in the planning. An interesting new feature in the landscape could be created in an area with touristic importance.

The monitoring of the hydraulics verified the information of flow and habitat modeling, which thus was proved to be useful in evaluating the expected effects of the planning of aquatic habitats in the planning phase.

The monitoring of benthic macroinvertebrates showed a rapid colonization and development of the channel to a diversified new ecosystem and that there is plenty of nourishment for fish. The immediate migration and reproduction of Brown trout and high densities, good condition and survival of juveniles give confidence that constructed reproduction habitats can have great possibilities in reviving migratory fish stocks. Steady and protected circumstances give basis to a high production rate per channel area with a rather limited amount of discharge.

The case shows that in relation to the discharge which is needed for the channel width and habitat area, reproduction channels are an effective way to utilize environmental flows for creating new reproduction habitats. The reproduction is in three years bigger than natural streams. This corresponds to some international similar sites. The good experience can be applied in hydropower plants in different circumstances.

Acknowledgments

The modeling during the planning was conducted by Simo Tammela. Construction of the brook was done by VRJ South Finland and finalizing and later electrofishing by Markus Tapaninen and Pekka Vähänäkki from Southeast Finland ELY -centre. Macroinvertebrate samples in 2016 were taken by Pinja Kasvio from...
Future Resilience

SYKE. The samples in 2017 were taken and all samples were analyzed by Kirsti Leinonen from SYKE. Dietary samples of the fish were taken by Saija Koljonen from SYKE.

Appendix. Plan of the habitat section
Sustainable recovery of the mangrove forest based on productive landscape

Yan Chen, a Fan Zijun, a Zhu Zhipeng a

a Fujian Agriculture and Forestry University, 15 Shangxiadian Rd, Cangshan District, Fuzhou, 350002, China

Abstract

Due to the pressures of urbanization, land exploitation and economic development, we are losing urban habitats at an alarming rate, such as the mangrove forest in the south of Shenzhen City. This paper aims to discuss the problems of disappearing mangroves caused by the aquaculture, and also attempts to propose some feasible methods to balance the habitats preservation with land exploitation. According to mangrove’s characteristics and water environment of the experimental site, it is suggested to transform the aquaculture ponds into productive landscape. In this case, a symbiotic relationship between mangroves and aquatics would be built, and the gradually sustainable recovery of the mangrove forest would be great potential.

Keywords: mangroves; habitat; productive landscape; recovery; water environment

1. Background

Nowadays, most of the mangroves have been relegated to the edge of the city because of the serious urbanization. As one of the most diverse ecosystems in the world, mangroves have a positive effect on the development of the city, such as wind protection and wave protection, the promotion of silting and the beach protection and the bank protection. It is a special ecological system for the transition from land to the sea. However, this ecosystem is being seriously threatened by human beings. [1]

Shenzhen, located on the East Bank of the Pearl River Delta in southern China, is a new and modern city with a certain international influence. The coastal border of Shenzhen has a large number of natural mangroves, but as the population of Shenzhen continues to increase, the urban area is expanding. In order to meet the demand for production, in order to obtain more economic value, the mangroves are cut down, the border of the city and the sea is encroached, and the cultivated fish in the sea are encroached by the sea. Shrimp. Over time, a large number of mangroves at the junction of land and sea gradually evolved into shrimp ponds for production. At the same time, because of the gradual disappearance of the mangroves on the east coast of the Pearl River Delta in recent years, Shenzhen has been repeatedly attacked by typhoons, and the shrimp ponds have also been damaged by the waves, which
have brought bad influence to the local urban construction and economic development.

2. Objectives

Based on this situation, we seek to create a sustainable development mode combining production and ecology based on the concept of protection and economic development.

Through the analysis of the current land use, we found that the area of mangroves and the area of urban land are disproportions, and the area of mangroves and the proportion of the area of the shrimp ponds are disproportions. The development of the urban border is incongruous. If we can make mangrove, shrimp ponds and urban land balanced development and achieve "dynamic balance", we can achieve a sustainable development mode.

3. Medium: mangroves

Mangrove forest is a woody biome of tidal flat wetland, which is composed of evergreen shrubs or trees with mangrove plants as the main body of the tropical and subtropical low energy coastal intertidal zone, which is flooded with periodic tidal water. It is a special ecosystem of land to ocean transition, growing on tidal flat shoal of land and sea. [2]

The mangrove is the main component of the mangrove family, and the mangrove family has 16 genera and 120 species. Some of the mangroves are grown in the inland, a part of the mangrove, and some of the associated elements of the so-called semi mangrove trees near the mangrove community.

Mangrove is the last "ecological barrier" in the transition from land ecosystem to marine ecosystem. It plays an important role in purifying sea water, resisting wind and wave, protecting the coast, improving ecological conditions, maintaining biodiversity and ecological security in coastal areas. As mangroves grow on the sea tide and soaked saline soil for a long time, a unique and unique ecological characteristic is formed. It promotes the formation of the soil through the net debris, resists the impact of the tides, and has a good effect on retaining the bank and resisting the wind and waves. The strong roots of the mangroves, which grow in the seashore, have a strong ability to fix the banks of the beach, and have a strong "energy dissipation" effect on the wind and waves, which are the natural barriers to the tsunami.

3.1. Biological characteristics of mangroves

Because of the special conditions of marine environment, mangrove plants have a series of special ecological and physiological characteristics. In order to prevent the shock of the waves, the trunk of the mangrove plants generally does not grow infinitely, but most of the support roots from the branches and into the mudflats to keep the plant stable. At the same time, a lot of finger shaped aerial roots grow from the roots and come out on the beach floor. They are used to ventilate at low tide or even when the tide is submerged, so they are called breathing roots. [3]

The most wonderful feature of the mangrove is the so-called "viviparous phenomenon". Many of the plants in the mangrove, which have not yet left the mother, have begun to germinate in the fruit and grow into a bar shaped hypocotyl. When
the hypocotyl develops to a certain extent, it breaks away from the mother tree and falls into the silt of the beach. After a few hours, it can grow in the mud and grow into a new plant. The hypocotyl that fails to root in the silt in time can grow on the coast of thousands of miles along the sea for several months.

3.2. Growth environment of mangroves

The distribution of mangrove plants on tidal flats is strictly controlled by the degree of tidal immersion. Mangroves can only be distributed on the beach surface between the average sea level and the average high tide level of the regression tide.\(^4\) The high or low tide immersion will affect the normal growth of the mangrove plants. This is the most suitable area for mangrove growth. We call it intertidal zone. With the development of coastal landform and mangrove itself, mangroves often extend to the outer edge of the coast.

The adaptability of mangrove plants to salt soil is stronger than any terrestrial plant. It is determined that the salt content of the sea water in the outer edge of the mangrove belt is 3.2 - 3.4%, and the salt content of the inner rim is 1.98 - 2.2%. At the outlet of the river, the salt content of the sea water is lower. Mangrove plants are salt loving plants. They are usually not found in riparian banks.

Temperature plays a decisive role in mangrove distribution and community structure and appearance. The mangroves of the equatorial region are up to 30 meters high, and the species are also the most complex, showing the appearance and structure of some terrestrial tropical forest communities and the presence of vines and epiphytes in the forest. With the increase of latitude and temperature, mangrove forest is less than 1 meters. The most suitable for the growth of mangrove sea surface temperature is 21°C - 25°C.

4. Strategies

4.1. Base peri aquaculture system

The base peri aquaculture system is a low investment and low production of self-sufficient and self-sufficient farming system, which can be contracted by farmers. It uses natural seeds and natural bait, which could continue to operate for a long time without damaging the environment. Its specific practice is that surrounded by a slightly higher earth dyke, a pond is constructed, while there would be several artificial dredging connected channels between them. In this simple system, the beach land can be grown for mangroves, and mangrove plants provide a better breeding environment for fish and shrimp. At the same time, waterways can be used to breed fish and shrimp, and the excreta of fish and shrimp can also promote the growth of mangrove plants.

4.2. Suitable environment for growth

Considering that the normal growth of mangroves requires suitable intertidal zone, suitable salinity and temperature, we try to put the pile array out a suitable area for the growth of mangroves. Then, some baskets filled with soil could be used to fasten the pile. During the tide, the silt brought by the sea was deposited in the region. Over time, the silt raised the elevation of the beach surface,
increased the area of the intertidal zone, and also changed the salinity and temperature of the sea water to a certain extent, and provided a more suitable environment for the breeding and growth of the mangrove.

5. Results

In terms of the overall planning strategy, we aim to minimize human intervention. First of all, we should protect the existing areas where mangroves grow well and create suitable conditions for their growth and reproduction in their marginal areas. Then, combined with fishery production, the shrimp pond area with the largest area will be rebuilt based on the base aquaculture system. Finally, landscape elements, transportation system and auxiliary facilities are introduced into the small area to meet the functions of modern fishery production and recreation.

5.1. Layout

According to the urban land use type and the growth cycle of mangrove, we take the shallow coast suitable for the development and growth of the mangrove area as the protection area, the original farmland and the reformed shrimp pond as the production area, the green space and the park near the city are transformed into a recreation area with the mangrove landscape and culture.

The mangrove protection area has minimal manual intervention, minimal facilities design and strict human volume control to guarantee the natural growth of mangrove plants. The main activities here are scientific researchers and professional maintenance workers and help to reproduce mangrove plants with professional technology. Tourists can enjoy the mangrove landscape at a distance, and there are also a few walkways for crossing mangroves and close contact with plants and animals.

In terms of economic benefits, we optimize its environment in the production area and refer to the new mode of fishery production and operation to promote the growth of mangrove and fishery production. The production area as a transition area of the city to mangrove community, coordinate the contradiction between human and nature, and achieve a symbiotic ecological balance.

Recreational areas are mainly distributed on the outer edge of the city, connecting to the urban area, providing an open space for citizens and tourists. In these public spaces, people can not only carry out leisure activities, sports activities and parents and children's activities, but also know some of the science knowledge about mangroves, so that tourists can understand the important role of mangroves and improve the awareness of mangrove protection at the same time. In addition, the recreation area as the city green corridor, to enrich and enhance the city border color and energy.

5.2. Transportation

The external transport links attached to the Shenzhen City traffic system, the traffic is divided into urban ring road, urban expressway and urban primary and secondary roads after the planning and adjusting which provides a convenient transport links between the city boundary and the city.
The internal transportation system within the growing mangroves’ border mainly have the primary and secondary roads in the boundaries to connect the urban transport system, the water marine traffic routes to meet the needs of transportation at sea, the roads in the shrimp ponds for the product requirement and the garden path to service open space areas. The planning takes the sustainable development goals of the municipal boundaries into consideration, trying hard to provide a balanced developed environment for the mangrove forest, shrimp ponds and the urban land.

5.3. Facilities

To meet the development and life needs of the city boundary’s growth, we organize the auxiliary facilities into a system. Based on its function and local conditions, those facilities are arranged properly. In the place of highly used, ancillary services, medical care, inquiry, restrooms, and parking lots are planned to satisfy the tourists’ need as well as the requirement of production. Meanwhile, in those areas, several medical care and services that supply insurance for the travelers are taken into account. Besides, to fully protect the protected area, little facilities are set to control the tourist’s number.

6. Conclusion

The sustainable recovery of mangroves is crucial to the future development of the city and the protection of the global environment, which is widely used in other cities with similar status in the world by using the system of basic peri aquaculture, the insertion of recreation, production and protection of different functions. We hope to realize the dynamic and balanced development of mangroves, shrimp ponds and cities through this sustainable development model, take the growing border of mangroves as the protection Gallery of urban development, use green barrier to protect the city and provide fresh vitality for the city, attract different people and strengthen the economic development of the city.

Impact of Summer Campus Square Marginal Space on Microclimate Environment

CHEN Zhu, a FU Wei-cong, a Huang Ya-bing, a QUE Chen-xi, a* DONG Jian-wen a

aCollege of Landscape Architecture, Fujian Agriculture and Forestry University College, Fuzhou, Fujian 350002, China

Abstract

Abstract: Taking the edge space of three plazas in a campus in Fuzhou, Southeast China as the survey object, selected the typical summer weather (after rain, cloudy and sunny days), monitored the data of wind speed, humidity, temperature, and so on, discussed climate monitoring data and human comfort degrees of time and spatial change characteristics and regularity of degree index in different constituent type edge spaces. The results show that: (1) The temperature and humidity changes at different sites are basically the same in different weather conditions. The comfort index of the human body is uncomfortable on sunny and cloudy days, and the comfort index of the human body after the rain is comfortable; (2) The plant constitutes the main In addition, the edge of the tree shading has the strongest ability to adjust the edge space, and the monitoring ability of the monitoring site with the hard paving and no shading on the underlying surface is the weakest; (3) Different types of edge space have different functions, and the adjacent space has different functions. There is a clear difference in the microclimate environment.

Keywords: campus square; edge space; typical weather; microclimate; human comfort

1. Introduction

Christopher Alexander stated in the book “Architecture Mode Language”: “If the boundary no longer exists, then space will never be full of anger” [1]; American design master William White defined the edge as “a positive margin is a means to enhance the sense of place in a square, and a sense of security is at the edge of the Plaza” [2]. In summary, the edge can not only cut off the space, but also the limitation of the field, which is equivalent to the connection and transition of the two adjacent main bodies.

With the development of urban leisure life in China, people’s demand for outdoor activities is increasing day by day. Squares are the spatial forms of people’s leisure activities in cities, and they also affect people’s physical and mental health [3-7]. College squares are part of the city square and their clients are more clearly focused [5]. At present,
the researches on microclimate mainly focus on green space systems, urban waterfront belts, urban plazas, and urban residential areas [8-15]. There is little research on campus plazas, and about the campus plazas mainly focusing on the interior of the site, while little research about the microclimate environment of the edge space.

The square edge space described in this article refers to the space within the red line of the square land and directly adjacent to the land surrounding the square, that is, the outermost space around the square [16-18]. The research chose different types of edge space of Fujian Agriculture and Forestry University campus square as the research object, seted up its adjacent space as the reference object, and explored the relationship between different typical weather, different time periods, different space and temperature, humidity and wind speed. This study provides data support for the planning and design of urban square marginal spaces and new construction ideas to ensure a comfortable microclimate environment. Research can also expand the relevant aspects of microclimate environmental research, provide guidance for the planning and design of the square and the travel of people in Fuzhou and even the whole country.

2. Test plots and research methods

2.1. Sample selection

The test sample was selected on the campus of the Fujian Agriculture and Forestry University in Fuzhou, Fujian Province (119°23' east longitude and 26°08' north latitude). The campus is located in the west of Fuzhou City and belongs to the maritime subtropical monsoon climate, the winter is short and summer is long. Therefore, the season of this study chose long summer. Three spaces in the campus of Fujian Agriculture and Forestry University were used, which are relatively frequent and representative: the front square of Boxue Building, the front square of Yifu Library, and the Tuohuang Square. Finding the test points of the edge space in accordance with this study, and the control test points were seted outside the center of the square and inside the square. A total of 17 test points were used for the actual measurement of the microclimate data.

The components of the test points mainly include: plants, pavement, cement and so on. The 17 measured sites can be divided into 6 types: lawn-based edge space (S7), arbor and lawn-based marginal space (S2, S4), arbor, shrub and lawn-based edge space (S9, S16), arbor, lawn and pavement-based edge space (S12, S14), pavement-based adjacent spaces (S1, S6, S11, S13, S15), and the cement-based adjacent spaces (S3, S5, S8, S10, S17) [19].

2.2 Test instrument

The test equipment adopted the United States NK5920 Kestrel 4500 portable climate measuring instrument, measuring range was -29.0～70.0 ℃, resolution was 0.1 ℃; Humidity measurement range was 0 % ~ 100.0% RH, resolution was 0.1 %RH; Wind speed measurement range was 0.4 to 4 m/s, resolution was 0.1 m/s.

2.3 Test content and methods

The monitoring date was June 22, June 17 and June 27 (cloud after rain 2d); June 24, June 25 and July 10 (sunny day 3d); July 3, July 4 and July 11 (cloudy 3d) [20-21]. The observation period was 6:00-22:00, observed every 2 hours, and monitored 8 times daily. The NK5920 Kestrel 4500 portable climate measuring instrument was used to measure the points in three sample plots in advance, for a total of 17 points. The actual measured data were temperature, humidity, and wind speed data. Each observation point was set to repeat three times for each measurement. The test height was 1.5 m, which is the height that the human body is most sensitive to temperature and humidity. The final data statistics, processing, and chart production were performed using SPSS19.0 and Excel2013 software.

2.4 Human comfort

Human comfort is based on the principle of mutual exchange of energy
exchange between the human body and the surrounding environment, and it is a meteorological point of view to evaluate a biometeorological index of humans in different climates [22-23]. In this experiment, the “comprehensive comfort index” proposed by Lu Dinghuang [24] was used to evaluate the microclimate comfort of the campus square in Fujian Agriculture and Forestry University. The formula is as follows:

\[ S = 0.6( | T-24 | ) + 0.07( | RH-70 | ) + 0.5( | V-2 | ) \]

In the above formula, \( S \) is the comprehensive climate comfort index, \( T \) is the temperature (°C), \( RH \) is the relative humidity (%), and \( V \) is the wind speed (m/s). The classification criteria for \( S \) and human comfort [25] are shown in the table.

3. Results and analysis

3.1 The daily variation of microclimatic factors under different weather conditions

3.1.1 Diurnal variation of temperature

According to Fig. 2, the microclimatic elements had obvious changes under different typical weather conditions, and the characteristics of the test points under the three typical weather conditions were basically the same. The overall trend was that they first increased and then decreased. The daily maximum temperature appeared around 14:00. In sunny days and cloudy days, the temperature of test points without shade was higher than those with shade; After the rain, the overall temperature difference between the observation sites was relatively cloudy and the weather was relatively small. Because the rain and rain water evaporate, the temperature dropped rapidly, and the humidity in the air was higher than the sunny days and cloudy days after the rain. As a result, the atmospheric diffusion slowed down and the warming effect decreased.

3.1.2 Daily changes in humidity

According to Figure 3, the humidity changes at the three test points were basically the same, the trend of change was opposite to the temperature, showing a “V” change trend of decreasing first and then rising, and the lowest humidity appears around 14:00. In sunny days and cloudy days, the humidity at the test points decreased with the increase of temperature, the
humidity reached the lowest value at the highest temperature, and then gradually weaken, therefore, the overall difference in humidity within the air was small, but weaken, therefore, the overall difference in humidity within the air was small, but

Fig. 4. Diurnal variation of wind speed

According to Fig. 4, in the three types of weather, the wind speed changed most when the site was relatively open or there were no shelters around the test points, while the change of wind speed was relatively gradual at test points where the vegetation is rich

Fig. 5. Diurnal variation of comfort index

The comprehensive human comfort index can directly reflect whether the crowd is comfortable or not, and it is also an evaluation index of the site's microclimate environment. As can be seen in Figure 5, the overall human comfort index at various test points in sunny and cloudy weather showed an inverted “V” pattern, which basically appeared at around 14:00, this time period basically coincides with the time period when the highest temperature and lowest humidity occur; The overall change trend of the weather after the rain also showed a first rise and then a decrease, but the change was more gradual than the sunny and cloudy days. On sunny days, the marginal space formed by arbor and shrubs and grasses reached grade 3 after 12:00, and the uncomfortable feeling appeared, the rest of the test points were reached after 10:00; On cloudy days, the basic trend was consistent with that of sunny days, but except for the marginal space formed by arbor and lawn, the time to reach the level 3 of the edge space composed of arbor, lawn and pavement is also delayed by 2 hours; After the rain, the comfort level of all test points reached the third grade, which was mainly due to the increase of humidity and the decrease of temperature after the rain.

3.2.1 Comparison of microclimate regulation effects in different types of marginal spaces

The marginal space observed in this experiment can be mainly divided into four types: lawn, arbor and lawn, Arbor and shrub and lawn, Arbor and lawn and pavement. According to Tables 2, 3, and 4, it can be seen that the average daily temperature was the lowest in three typical weathers in the marginal space dominated by arbor and lawn, the daily average temperature of marginal space dominated by lawn was the highest among the four types and the largest daily diurnal variation. This was mainly due to the fact that it without shade of trees, low canopy density, and accepts increased solar radiation, resulting in rapid heat dissipation. The ability to regulate temperature is weak; Also in the three weathers, the average daily humidity in the marginal space dominated by arbor and shrub is the highest and the daily amplitude is the smallest. This is due to the higher canopy closure, the plant leaves can adhere to water vapor, and the internal air convection is slow, and the evaporation effect is slow; The maximum daily average wind speed basically appeared in the marginal space that was mainly composed of lawns, and the marginal space of the other three types was relatively low, indicating that the marginal space with large canopy closure can reduce the average wind speed to some extent.

In the marginal space consisting mainly of lawn, arbor and lawn, arbor and lawn and pavement, the middle layer of the plant is more open and transparent, which has a positive effect on the integration of landscapes inside and outside the square; While the marginal space formed by arbor, shrub and lawn is rich in vegetation, and the sights inside and outside the square are not transparent, so the opening is poor and closed, and its ability to regulate the microclimate environment is strong [26]. Lawn, arbor and lawn and pavement are the main elements of the edge space where people can walk through and belong to a relatively open edge space.

3.2.2. Comparison of microclimate regulation effects between marginal and adjacent spaces

As can be seen from Tables 2, 3, and 4, the average daily temperature of the interior space consisting mainly of pavement and the external space composed of cement is the highest among all types of test points. Among them, the marginal space difference between the arbor, shrub and lawn type is the largest, and the difference between the marginal space and the lawn type is the smallest. Because there is no shelter on the site, the solar radiation directly
acts on the underlying surface, and the ability to adjust the temperature is weak. There is a large temperature difference between the edge space where the trees are shaded and the observation point in the square. This is mainly due to the fact that the plant has a certain transpiration, and the arbor crown itself also has the effect of absorbing heat and reflecting. Therefore, the cooling rate is larger, but the temperature variation is smallest throughout the day. The order of cooling rates of various types of observation sites under the three kinds of weather is: Arbor, shrub and lawn > arbor and lawn > arbor, lawn and pavement > lawn > cement; In the three kinds of weather, the humidification rate of the marginal space dominated by arbor and shrubs is the largest, and the external space with the cement composition mainly has the lowest humidification rate. Because the underlying surface belongs to the hard paving, the air convection and exchange capacity are increased. Among them, the difference in humidification rate was greatest at each observation point on the sunny day, and the difference was smallest after the rain, because the increase of water vapor in the air caused the humidification rate of the observation points to decrease. However, the daily changes in humidity at the observation sites have increased relative to sunny and cloudy days. The humidification rate of each observation point was ranked as follows: Arbor, shrub and lawn > arbor and lawn > arbor, lawn and pavement > lawn > cement [27-28]; The smallest change in wind speed is the marginal space formed by arbor and shrub grass. The wind reduction rate is higher than that of other observation points, because the wind speed changes are relatively flat and the wind speed can also be reduced.

The marginal space microclimate environment has certain differences with the interior of the site. Through the comparative analysis of the marginal space of the site and the microclimate elements of the interior and exterior spaces of the site, different types of edge spaces have a certain regulatory effect on the site's microclimate environment, demonstrate that marginal space has a greater impact on the site's microclimate environment.

4. Conclusion and discussion

(1) Marginal space has a moderating effect on the microclimate environment. Through this study, relatively shady monitoring sites with shaded plant monitoring sites have a stronger ability to regulate the microclimate, and the research results are consistent with the previous ones; However, in this study, the main selection of the site marginal space and the adjacent space microclimate and human comfort compared, while the predecessors focused mainly on the site of the microclimate environment research.

(2) Giving people a certain reference value for travel. The different types of edge space in different weather have a significant effect on the microclimate and human comfort. The comprehensive index of human comfort on the edge of the campus square was the lowest after the rain and the highest on the sunny day. The marginal space composed of abundant plant elements plays a relatively obvious role in reducing temperature and increasing humidity, and the human comfort index
Future Resilience is relatively low. The underlying surface is mainly composed of paving or cement and the adjacent space has weak adjustment capacity [29]. The human comfort index is high. The conclusions of this study can provide more comfortable weather, space, and time for the campus and student and recreational activities of foreign tourists.

(3) Guiding Square Planning and Design. The fringe space can also regulate the microclimate environment of the square to some extent, so the planning and design of the fringe space is an important issue to be solved in the site planning and design [30]. This study mainly compares the measured microclimate data, and uses statistical methods to organize and analyze the relevant data. It is found that different types of edge space have great differences in the adjustment of microclimate and human comfort. The results obtained from the research have certain reference value for the construction and transformation of the future city square.

Abstract

This study examines Fujian Agriculture and Forestry University as a possible site of “spongy-” or “eco-” (ecological) campus practice. Located within an urban catchment for a bigger urban “spongy city” green and gray infrastructure area, the site analysis follows the China Spongy City Construction Technological Guideline policy and determines that the query of direct volume of 15\% to 20\% of annual precipitation in total volume of storm and runoff water allowable to drain out of city boundaries and rivers is possible. An estimated total of 80\% to 85\% of a 2.5 recurrence storm and runoff water volume is detained at the site of the campus. Consequently, the study proposes a schematic plan to adapt potential hazards due to a series of predictable extreme weather events. It proposes progressive design rainfall intensity with unexpected precipitation as well. The study preliminarily concludes that the site has no impact on the extraordinarily improbable flooding or combined sewer or overland drainage detain function. Yet it is very likely a lack of communication and an attitude on campus to bring in in-field and off-site water of deteriorating quality. The study boldly innovates a collecting and recycling garbage plan. All students, teachers, and university staff along with surrounding business district owners, shall collect and recycle all kind of paper, plastic, and metal products associated with disposable boxed brunch, lunch, and dinner and wastes in the near future. The study hypothesizes that the programming will lower solid suspensoid pollutants in retention facilities and stop possible in-field and off-site water quantity and...
quality deterioration together. The study organizes these independent variables and tests the hypothesis in respect to two major strategies: first, to launch watershed-based water contamination which includes, but will not be not limited to how to apply site planning and life-quality improvement by this unconstructed collecting and recycling measure; second, to reduce possible imperviousness of the campus site if campus land use is changed. In the end, this study is to place a voluntary participation of recollecting, recycling, and reprocessing campus garbage and particularly taking individual take-out food wastes out of campus site and further making composts and manures for campus and or community’s vegetation use. The study will simultaneously measure the contamination ascending and descending indicators on the in-field site. This bottom to top programming is to observe the said spongy city concept with different or seemingly improving urban and or rural community- residences. The study must count and solve the ecological and nature element which improves polluted and tainted environments associated with worsening runoff and storm water problems.

---

1. **Background: Defining the Problem**

Hand in hand with the swift momentum of industrialization and urbanization these years, China de facto has developed a polluted and tainted environment associated with worsening runoff and storm water problems. [1,2]. A great deal of unexpected precipitation poured into overland drainage system elevates in-field and off-site urban storm and runoff water drainage quantity and quality corrosion. (3). In several regions and cities such as Beijing on July 21, 2012, within 16 consecutive hours, 170 mm of precipitation in total caused a fearsome catastrophic consequence: 79 fatalities, 1.6 million evacuations and 11.6 billion yen in property damage. See the Figure 1 the precipitation of Beijing and its surrounding areas on July 21, 2012. The Figure presents a sample of clear picture between higher dBZ value of representative of basic albedo rate and the much higher rainfall of precipitation around Beijing Metropolitan.

Fig. 1 The precipitation record of Beijing metropolitans and its surrounding areas on July 21, 2012.

From the year 2012, China officially has set into motion an energetic program which applies the “spongy-city” policy to mitigate the situation of storm and runoff flooding. Governments in 2015 specify 17 cities to comply with Spongy City, cities that had a kind of adaptation, reduction, detention, retention, and or absorbance of urban storm and runoff, and infiltrate, treat and improve pollution issue. These cities must meet,
among others measures, low impact development standards.

At the same time, various governments and agencies also fiercely initiate a hypothermic “beautiful village”, or, “beautiful rural community” enhancement or movement. The movement defines a “beautiful countryside” with an appropriate or a beautiful “human settlement living environment” for all of people; this is a from-top-to-bottom approach, a policy generated series of aggregative agenda for so-called “beautifying” metropolitan surroundings and or rural communities. Yet, they are ironically evaluated as an uncompleted solution at best if not total failure at worst.

Many agencies have recognized that expensive cost and low effectiveness of investment is inevitable. Even worse, it is the case that the programs spoil or worsen rural county’s eco- or nature factors. The land use of a campus, of course, whether it is established for a higher education level such as universities or colleges or for a junior or senior elementary one level at urban or rural areas, is eventually an excellent spongy city experimental component of the city and rural area.

2. Programming and Analysis of Eco- and Nature Campus

In view of a straight question and answer or rational approach, the flooding overland drainage associated with in-field and off-site storm and runoff water quantity and quality deterioration problem appears to be too complicated to understand. It is unlikely that a thorough or “right” solution has ever existed since there are so many existing questions and unknowns. Nevertheless, this study looks at issues of contamination and inundated land-use coverage concerns, and exposes the reality of their possible failure at the study site.

Preliminary test results make the said water quality and quantity questions sound coherent and linear when in fact the recital of results is only conventional. See figure 2, 3, and 4. for the site, Fujian Agriculture and Forestry University at Fuzhou.
The Figures of 2 and 3 present the study site, Fujian Agriculture and Forestry University, at Fuzhou, China. The campus is located between Oolong River and Min Jiang River as shown. Figure 4 presents the Campus Guanyin Lake waterfront which is heavily polluted by small business strip area. There are garbage dump sites located along the water-front near the retention facility of wet pond, that is, the Campus Guanyin Lake. The dark hatch areas represent a varied garbage tanks. Inside of the lake at Figure number 4, present the test checkpoints for the pond’s temperature, pollutants and fluctuation levels. The preliminary test results, see the Figure 5, 6, 7.

Figure 5, 6, 7, and 8 present the existing garbage collection and or pollution situation.

Fig. 5 The garbage tanks at campus.

Fig. 6 Garbage Creating: night market stalls and pedlar booths surrounded campus.

Fig. 7 Garbage creating: Night market and street peddlers.

Fig. 8 Garbage picking and collections.

The study in the beginning is anticipated working with communities and
other universities nationwide to compare the possible outcomes of launching recycling of plastic and food-waste for eliminating condemnation, particularly for solid waste in the retention facility on seasonal basis. Later, during and after the last summer, this study preliminarily concluded that the site of FAFU campus and the impact of extraordinarily improbable flooding of overland flow and drainage are not effected or were not to bring about in-field and off-site water quantity and quality deterioration.

The study then moved to emphasize that garbage concern such as paper, plastic, and metal products associated with brunch, lunch, and dinner wastes directly bring about solid suspensoid pollutants.

Furthermore, a tentative explanation in the form of an observation is that a number of places across campus are developing into polluted and tainted environments. See the Figure 5, 6, 7, and 8 of photos taken at the corner and at Campus restaurants, transportation hubs, and pedestrian gateways. The hypothesis is that if promotion of re-progressing of “county beautification and amenity enhancement” can lead to a neater, cleaner and more beautified setting than before. The study site would then have greatly reduced pollutants flowing into the retention facilities.

The study assumes that any current successes, if there are any, are not final, and any failure is not fatal either. It is the courage to continue that counts. The study is to try a new approach that a neighborhood community resolution, by, from, and of Olmsted’s “communitiveness” shall apply successfully. The application of a sense of shared community and dedicated service, shall count. [4]This urban or rural urbanism of China shall particularly fit into the community and students, teachers and staff. So do the University and educational administration staff.

3. Preliminary Research and Details

This study is thus to place a voluntary program of recollecting, recycling, and reprocessing campus garbage and particularly for individual take-out food wastes of brunch, lunch, and dinner for making composts and manures for campus and community vegetation use. The study will measure in parallel campus contamination ascending and descending indicators. This will be a bottom to the top programming and observation. And the administration is to elevate a spongy city concept of improving urban and rural community-residence beautifulness to solve the eco- or nature elements. A polluted and tainted environment associated with worsening runoff and storm water is to be solved by an un-constructed approach.

In the end, that is not an approach through a so-called “constructed”, “engineering structures”, or “mechanism” approach but through a non-constructed measure, policy and approach. The campus or county 3R project is at least to imitate a sustainable function and is to abandon a kind of baroque European or informal romanticism of China common recently.

The schematic design of approach is preliminarily to divide the campus into ten (10) voluntary participation parcels. Each parcel-zoning is therefore based on the maximum of a sixty- (60-) student recollecting, recycling, and reprocessing (3R) garbage every day. In addition, 3R for
the individual food waste is focused on students and teachers’ during lunch and after dinner time within campus food court surroundings, and student-shopping strip areas. See figures 7, 8, 9. The process of making composts and manures for campus and community use is pending. So does the collecting and storage procedure. The samples showing campus contamination ascending and descending indication will then be designated and located. See the preliminary total C, Total NO₃ and Total P results of the location shown at Figure 4.

4. Developed Study and Discussion

The study is to judge storm and runoff water quantity and quality by cultivating campus users’ campus-universes attitude, similar to or equivalent to the promotion of Olmsted’s “communitiveness” idea [4] since 1857 by promptly initiating recycling programs. It is at all ethics viewpoint with urban storm and runoff water management. Studying and living in the university, the groups of student, teacher and staff are assured to be persistent and continuously applying spongy city concept for flexibility yet indiscriminately apply into unconstructed approach and save his or her environments together. This is in reality to assume that existing approaches can normally be evolved rest upon a single premise: the individual is a member of a community of interdependent. People instincts prompt individual including students, teachers and staff, to compete for his or her place in the community; that is, in this study, studying or educating the place in the campus, his or her esthetics prompt he or she to cooperate perhaps in order that there be a place to compete for.

The universes campus’ esthetics simply enlarges the boundaries of the university field with the community surrounding to include not only physical or natural factor of soil, water, plant, and collectively, the campus land, pond, garbage, food and food waste as well. Unless the assumption extends students, teachers and staff’s morality in this way, the study is not not validated and to risk dooming and missing the point of people to live in an unhealthy or unappealing biotic community.

The study assumes that we students, teachers and staff are all quite willing to or recognize obligations to protect the university campus and the community resource such as transportation roads and specified college- schools. Yet there is assumed the schools are far less responsible when they come to protecting ecological systems in which “other people” and all creatures live. The environment will not be kept in good repair unless our ethical sensibilities changes. The problems this study is in reality to face or to solve is the extension of social conscience, the awareness of a moral or ethical aspect to one’s conduct together with the urge to prefect right over wrong from people to the land of the university campus[5]. Therefore, the study will further test whether the students, teachers and staff are taking responsible for cleaning, collecting and recycling “their” own garbage, food and food waste; The test of ideal eco- or natural storm and runoff water quantity and quality which could be sustained.

Finally, the discussion for eco- or nature campus is to get to the bottom through solving its surrounding storm and runoff water quantity and quality. It is necessary to
organize the independent variables such as “communityiveness” or “campus-ness” sense and or attitude, with dependable variables such as collecting garbage and or recycling food and food wastes, and to test the hypotheses in respect to the following storm management strategies: first, to launch watershed-based water management which includes, but is not limited to, how to apply site planning and quality improvement by an unconstructed policy or measure, and second, how to apply to reduce possible imperviousness of the campus if needed [6].

The former, the university or any scale of educational campus, is the appropriate object of site, yet it may not have always adequately addressed downstream flooding or water quality and non-point sources of pollution as well; The later, the campus’ retention or detention basins or facilities basically are established or located at most campus constructions on a site-by-site basis. The basins are in fact actually increasing flooding potential based on the possible simultaneous timing of peak discharges.

In addition, there are increased maintenance requirements and associated high costs of individual social interaction and site management revisions; As a result, many campus retention or detention basins systems are not properly maintained or worsen effectiveness. Thus, based on ecological adaption, mitigation, and reduction of campus environment, the students, teachers, and staff in campus shall take care of their eating, drinking, and save energy cooking at home and adjust to less expansive and energy-consuming taking out habits. It is that the spongy or eco-campus practice is the case at Fujian Agriculture and Forestry University at Fuzhou.

This study emphasizes that an eco- or nature environment of university campus is applicable, and the study of relationship between ecological system and human welfare is not solely reliant on structure constructed approach but on un-constructed policy or on programming as one as applied in this preliminary hypothesis of study. The proposed results are to significantly be expected [7]. In-field and in-person participation in improving the ecological campus shall not be a strict constraint but an opportunity for the society. Students, teachers and staff themselves, shall be able to pay more attention to “communitiveness” participation associated with performing in rewarded effectiveness [4]; That is, a sense of shared community and dedicated services among students, teachers, staffer and community residents, and it is a present, a gift reward to an alternate from a concept of solely unconstructed methodology into an improving campus reconstruction and or construction as well.

Development Considerations For Edge Protection: A Case Study Of The Central Catchment Nature Reserve (CCNR)

Chang, Pearlyn*

*Department of Architecture, National University of Singapore, Singapore

Abstract

Land-use changes adjacent to urban forests highly affect the edge conditions of the forest and either introduce more disturbances or improve the ecological connectivity of the forest patch. These are key issues faced by forests in the compact city-state of Singapore, especially the largest of the nature reserves of Singapore, the Central Catchment Nature Reserve (CCNR) in the heart of the state. Apart from the adjacent Bukit Timah Nature Reserve (BTNR), it contains the only remnants of the native primary vegetation from pre-development Singapore.

Rapid urban development since the 1980s fragmentized the CCNR through infrastructure and urban development across and around it. The presence of habitat destruction and biodiversity loss caused by land-use changes within and around the CCNR despite conservation laws in Singapore expresses a dichotomy. To gain an understanding of the situation, the spatial changes of and around the central catchment and consequential fragmentation effects are studied in detail. The study is divided into three parts according to magnitude of scale:
1. An examination of the current and future land-uses adjacent to the CCNR (Fig 1),
2. The assessment of surrounding green patches and
3. The study of edge conditions,
executed through a collection of government master plans, field observations, reports, news articles, blogs and literature to provide a holistic understanding of the site and its future interventions. Speculation of the effects and proposed mitigating measures are generated through a combination of site observations and reference to case studies.

This paper seeks to fill the knowledge gap of the threats faced by the urban forests due to encroaching development, in particular, fragmentation and edge effect, addressing the Central Catchment and surrounding areas as a region of study. Applying ecological models and design principles to the case, it presents development considerations and design potentials for habitat conservation, connectivity and edge protection of green spaces to mitigate edge effects to ensure the long-term existence of the nature reserves.

Keywords: Fragmentation; Edge Effect; Land-use changes, Systematic Conservation Planning
1. Introduction

1.1 Development and Landscape changes inducing fragmentation in Singapore

Developmental pressures of a densely populated, land-scarce city-state of 719.2km$^2$ supporting a population of 5.6 million [1] has led to the inevitable extermination of the natural vegetation that once enveloped the island. Urban development in Singapore is largely executed through the tabular rasa (a clean slate) method - the clearance of the previous land-use to make way for the new development. Primary rainforest cover was depleted to less than 0.5%, or 192 hectares, scattered within the Central Catchment Nature Reserve (CCNR), Bukit Timah Nature Reserve (BTN) and Singapore Botanic Gardens [2]. Secondary forests, deemed to have less ecological value, were usually designated as developable land. Large patches like the Tengah forest, Tagore and plots in expanding estates of Punggol and Pasir Ris are gradually being cleared for development. The resulting loss in ecosystem services and biodiversity cannot be substituted by the insertion of artificial manicured parks.

Although Singapore has established legal protection for the protection and conservation of nature reserves (Table 1), these policies are often loosely enacted [3], insufficient to overcome the threats caused by urbanization [4]. One apparent shortcoming is that there are still no laws mandating Environmental Impact Assessments (EIA) for development projects that affect the environment [5][6][7], which was an aspect emphasized by the Rio Declaration, in the Convention of Biological Diversity [5].

1.2 Central Catchment Nature Reserve

The CCNR is the largest of the four nature reserves designated in Singapore today, occupying over 2000 hectares of forest cover [9]. It comprises predominantly mature secondary forest, interspersed with some primary forest patches [2]. These plots are home to more than 1000 flowering plant species, 100 ferns, 222 species of birds, 44 mammals, 100 reptiles and amphibians, and 34 native species of freshwater fish [10], constituting one of the most biodiverse areas in the world. The CCNR is also a protected water catchment containing the four main reservoirs of Singapore: MacRitchie, Upper Pierce, Lower Pierce and Seletar, providing a raw source of water supply for Singapore.

---

\*In 2001, Sungei Buloh Nature Park and Labrador Park were converted to nature reserves (MEWR, 2002).
1.3 Fragmentation of the CCNR

The CCNR comprises of a total of 24 fragments, disjointed by the presence of reservoirs, utility pipelines, roads, military amenities and security fences [9]. The maps (Fig 2, 3) show the areas of hard and soft fragmentation zones, according to the adjacent land-use.

Once patches of wooded, agricultural and low-rise residential areas, they are now high-density residential, industrial and manicured golf courses [11]. The effect of transport infrastructure; particularly the Bukit Timah Expressway (BKE), Pan-Island Expressway, Lornie Road and Mandai Road, fragments this precious forest resource. Most mammals that make the attempt to cross result in roadkill. The fragmentation limits species distribution, preventing the spread of primary biodiversity across the fragments [9] and also leads to an increase in perimeter ratio, higher exposure to the invasion by urban and exotic species, and increase of human access and activity that can disrupt the natural habitat [4]. The boundaries of the CCNR have transformed substantially since independence.

These were mitigated by an ecological corridor, Eco-link@BKE, in 2013 to restore ecological balance between the CCNR and BTNKR [12]. NParks has also increased the size of the reserves and the recreational buffer area near the reserves from 63 hectares in 2009 to almost 300 hectares in 2019 [13].

1.3.1 Insufficient edge consideration in surrounding Land-use planning and development

As the CCNR is not an isolated patch but part of a diverse matrix system of habitats, any changes in land-use, eg. removing a patch for urban development, could present adjacency effects - the effect of the adjoining area on the patch habitat [14] that threatens the biodiversity in CCNR. Some major threats today include the controversial alignment of the Cross Island Line and the continued expansion of Mandai Nature Hub. The Nature Society Singapore (NSS) and conservationists have fought hard to minimize damage to the reserve, through evaluating the EIA [15]. Public outcry had also successfully lobbied for more transparency and accountability in the planning of infrastructure. Yet, the final outcomes and impact remain a mystery.

The land-use near the perimeter is also critical in influencing species movement and degree of edge effects- the differences in environmental conditions of the outer portion of a patch compared to the interior of the patch [16]. Apart from buffer green areas protecting some of the edges of the CCNR, there are dense residential estates are located within 1km proximity from it. Surrounding green spaces, with the exception of BTNKR and nature parks, are highly manicured with limited ecological function. Adjacent biodiversity-rich forests like the Lentor forest [14] are slated for future development [17]. Such interventions pose a challenge in protecting the nature reserve in the long run.
Majority of the edges created around the CCNR are artificial—determined by administrative boundaries planned by URA. Residential developments, major expressways, transport infrastructure and utility lines adjacent to the it become a critical zone for nature-human interaction [15], potentially contributing to loss in biodiversity and reduction in ecosystem services.

1.3.2 Fragmentation: Long-term Edge effect on CCNR

One of the largest threats to biodiversity is the isolation of forests due to land-use changes [18]. The extent of edge effects depends on the fragment size, shape and the nature of the edge [19]. Smaller fragments of the forest experience a higher proportion of edge effect [13] due to a higher edge-to-interior ratio. Observing from Fig 2, much of the northern and southern parts of the CCNR comprise of relatively small fragments. Most of the edges of the CCNR are hard and straight-edged, as per in most urban areas [13][20]. This includes expressways, roads, utilities, residential areas, open spaces, waterbodies, golf courses and nature park trails.

This paper seeks to address the lack of understanding on the fragmentation and edge situations in the urban context, with focus on the largest nature reserve, CCNR. This paper will highlight the effects of urban development in adjacent and surrounding areas to identify potential threats to be mitigated, and opportunities of enhancement to ensure the long-term existence of the nature reserves.

2. Research Methodology

2.1. Study Boundary and Scope

The region of study is the Central Catchment Nature Reserve (2114 hectares) and the surrounding areas within 1km buffer of the defined perimeter, which includes adjacent Bukit Timah Nature Reserve and forests adjacent to it (Fig 1).

2.2. Assessment & Analysis (Land-use, Green space, Edge)

A mixture of both quantitative and qualitative aspects is used in the collection of data. A repository of news articles, online commentaries, discussion papers and governmental reports were used as reference alongside the fieldwork done on site. Spatial analysis were recorded and analyzed in ARCGIS and referenced with Google Earth satellite imagery and Openstreetmaps. The spatial changes, particularly fragmentation, are generated using FRAGSTATS 4.0. The metrics are selected to highlight the loss in green space, patch disconnectivity and isolation to identify areas of around the boundary of CCNR that may face edge disconnectivity.
3. Land-use and Development around the CCNR

3.1. Ongoing and future Land-use changes (MP2014)

Fig 4 illustrates the distribution and percentage of various land-use within the study boundary, comparing the situation today (2017) and as proposed in the URA 2014 Master Plan. Table 2 reveals that residential, followed by military, open spaces and golf courses are the predominant land-uses, together constituting half of the total area of land-use studied. The areas north of the CCNR and scattered plots within and around the CCNR (Mandai, Nee Soon, Sembawang) are restricted for military training and a large plot of 222.2ha for the Military Industrial Complex located west of Upper Pierce Reservoir. There are 9 golf courses scattered around the CCNR. Open spaces are currently unoccupied forested areas that can be found at Mandai and Upper Bukit Timah near the old Turf club.

According to the URA Master Plan 2014, which guides Singapore’s development in the next 10-15 years, there are a few designated sites to undergo land-use conversions, which are highlighted in Fig 8. Table 2 and 3 shows the changes in area by the type of land-use, through which we can determine that the largest conversion in land-use is from open spaces to residential areas.

* Fields adjusted according to projected park provision in the new residential estates.
While green areas are maintained above half of the total area around the edge, a decrease in green area from 67.4% to 59.1% is observed (Table 2, 3). Correspondingly, built-up areas increase from 32.6% to 40.9%. These additional 278ha are a mixture of business, civic, institutional, mixed residential developments, transport and utility infrastructure.

Fig 5 and Table 4 illustrate the specific areas of land-use conversions that will face development. As a result of these land-use changes, landscape modifications of patch loss, degradation, and fragmentation are observed. These have varying degree of implications on biodiversity and ecological processes, with habitat loss as the most severe, followed by degradation then fragmentation [13].

<td></td>
</tr>
</tbody>
</table>

This 75ha nature park area serves as a buffer for the CCNR, providing an alternative natural recreational venue to relieve visitorship to the CCNR. It is forested and rich in biodiversity. Amenities and boardwalks are being built to support its recreational function. This is one of the sites considered as interim greens, maintained for as long as possible but will be removed if development is required.

Subject to detail planning

3.2. Threats and potential effects

An analysis of the landscape changes (Table 5) as a result of the land-use plans is conducted through Fragstats 4.0, comparing the patch dynamics between the two scenarios, as shown in Fig 6.

The results collectively illustrate signs of fragmentation, including the decrease in number of patches, increased level of isolation, and a decrease in connectivity. The ENN-MN showed an increase in value, which demonstrates a larger average distance between the patches, and the drop in PROX_MN demonstrates higher isolation of patches (Table 5). The loss and increased isolation of green patches will hamper the ability of surrounding areas to serve as a buffer to the CCNR.

4. Distribution of Green spaces around the CCNR

4.1. Physical attributes of Green spaces

An inventory of green spaces was used to create the chart (Fig 7) comparing the relative area of surrounding green patches to their relative proximity from CCNR. Most of the green spaces larger than 100ha are located within 50m of the nature reserve, including the military areas, Military Complex, Sembawang Air base, golf courses and the 163ha Bukit Timah Nature Reserve. Sites larger than 40ha are scattered within 100m of the CCNR, with the exception of Turf City and a military site at Mandai West, and a reserve site near BTN. The green spaces that are planned for development are circled (eg. Windsor Nature Park, Turf City, Future Mandai parks etc.).

According to the Theory of Island Biogeography-postulating that larger green patches support a greater variety of habitats and species, and the closer the patch “islands” to the CCNR “mainland”, the higher the species richness, Fig 7 and Table 6 provides a general ranking of the value of the patches in terms of supporting biodiversity. The loss of patches larger and of closer proximity to CCNR are suggested to pose the highest ecological threat to CCNR, and the severity of impact depends on whether it is habitat loss, degradation or fragmentation that is induced. Table 6 summarizes the severity of ecological impact on CCNR by the physical attributes of the green patch and consequence with the
planned land-use change (according to URA 2014 Master Plan). This however, does not consider the urban matrix\(^3\), which could also support urban biodiversity. The two main areas, which have the largest impact, are the conversion of Windsor Nature Park and the area of Turf City.

</table>

The managed green spaces in the surrounding urban context are studied to be artificial re-insertions after an urban development is complete. Early park developments were described as ‘mostly unplanned and cosmetic’ [21][22]. These spaces are mostly mono-functional, have highly manicured vegetation or high-maintenance turf grass. While designs of parks today are aiming to be more multi-functional, most of the existing spaces are designed for human recreation and aesthetic appreciation. They include existing parks like Springleaf Nature Park, open spaces including school fields and golf courses.

5. Edge Treatment and Protection

5.1. Adjacent Edge conditions

The edges found in the CCNR are classified according to the adjacent land-use, the degree of hardness/softness of the edge according to edge principles in Landscape Ecology Principles in Landscape Architecture and Land-use Planning\(^4\) [15]. This follows studies that illustrate that species composition and richness varies mainly by edge type rather than length of edge [13]. ‘Hard-edged boundaries’ bring greater ecological impact than ‘more natural, transitional edges’ [23][24]. Seven edge types, determined preliminarily by the degree of hardness to softness (Table 7) were identified spatially in Fig 8 and their proportional composition recorded in Table 8. A summary of their attributes and

---

\(^3\) Includes roadside greenery, trees planted within the urban development, green roofs, potted plants and small pocket green areas

\(^4\) Some of the principles that define the degree of ecological function are adopted and interpreted to evaluate the harshness of the edges. These include: (1) Structural diversity of edge (2) Density of edge (3) Abruptness of edge (4) Degree of curvilinearity of edge [15] (5) The presence of human disturbance and activities (Collinge, 1990 & Chatterjea 2012) [17][18].
The predominant edge interface is water, constituting more than 50% of the entire boundary of the CCNR. This is followed by the interface with nature areas, including nature parks and unmanaged secondary forests (military training grounds or reserve sites). Residential areas occupy a substantial percentage in this study; built-up areas together form almost 1/5 (20%) of the edges.
5.2. Edge effects

As Murcia (1995) guides, forest edges experience altered microclimatic conditions including: increased sun exposure, higher wind velocities, increase in soil temperatures, overall temperature, and decrease in humidity [17][23][25][26]. These abiotic effects subsequently leads to a change in species composition and behaviors, causing tree failures, presence of edge-tolerant species like generalist predators, exotic, invasive species, weeds [13] etc. The presence of human activities, domestic animals, landscaping or growing of crops along the edges also poses significant disturbance to the forest [10][17]. Roads and construction sites bring air, water and noise pollution to the nature reserve that affects the nutrient availability and fauna behavior [23]. Table 9 speculates the edge effects faced by each of the seven types of edges of CCNR through field observations and references to case studies. The edge effects can extend up to 50m into the forest interior, or more depending on the type of effect [23].

Comparing the edge effects of the types, as well as their length, areas highly threatened by edge issues are marked out in boxes in Fig 8. Highways including the BKE, PIE, SLE, and primary roads Mandai Road, Lornie Road poses a significant threat to the CCNR fragments. The high volume of traffic in these roads necessitates the presence of vegetated buffers, which are missing in many of these situations. In addition, the interface with private residential areas has to be treated, as these zones induce human-wildlife interactions that should be strengthened in selected areas and prohibited in others.

6. Discussion

6.1. Systematic Conservation Planning and Development recommendations

Chapters 3 and 4 have surfaced the need to harness multiple tools to read the systems of the landscape (ie. the relationship of patches). Quantitative tools and analytical tools like Geographic Information Systems (GIS) should be employed in the process to study the priority areas for protection, ranking sites by species richness, presence of endangered species, to qualities like ‘irreplaceability’ [27][28].

Additionally, the landscape configuration should be read as a system of green spaces where each patch is unique, contributing to the mosaic system [15]. The protection of one patch, like the CCNR, should be based on identifying and understanding the critical habitat linkages within a reserve network.
This can be carried out through Systematic conservation planning\textsuperscript{5} \cite{26,29} which includes working with different layers of species prioritization, different scales and incorporating selective approaches at specific stages of the development process. Factors like biodiversity values need to be considered even in the planting scale \cite{26,30}. Edge vulnerability can be addressed through the use of vegetation modelling tools to generate detailed planting designs to ensure habitat creation and edge protection at the implementation scale \cite{31}. This way, conservation principles are met and applied throughout the entire process of land-use planning.

6.1.1. Recommendations for Conservation and Selective Development (Fig 17):

1. To conserve green spaces critical to CCNR
   Areas that are found to have a critical ecological function to the CCNR should be prohibited from development, or be designated as buffer parks to complete the ring of buffer parks around the CCNR. Winsor Nature Park, for instance, should be kept designated as a permanent nature park to relieve visitorship of the CCNR as well as provide buffering function. Likewise, Upper Turf City area should also maintain its forested quality to protect the smaller fragments along the south boundary.

2. To develop selectively and sensitively
   Areas that are less of a threat to the habitat configuration are suggested for controlled development. This refers to conducting habitat analysis on the plots of forests to identify areas that should be preferentially preserved, which can later serve as the park provision of the development. This was also suggested by the NSS in the development proposal of Senoko \cite{3}. This could be carried out in lower Turf City area, Mandai and parts of Bukit Timah and Tagore. Existing trees should also be conserved as far as possible.

3. To intensify built-up areas
   As for areas that pose comparatively little threat to the habitat network (ie. distant, small plots or patches), those currently cleared in preparation for groundwork and existing built-up areas could be intensified in terms of plot ratio and density. In particular, the loosely scattered private housing estates are in the areas of Bukit Timah and Upper Thomson, marketed as being ‘close to nature’, are found to have high impact on CCNR. The intensification of the land-use in these areas can prevent development from further encroaching the nature reserve.

6.1.2. Strengthening laws protecting Nature Reserves, Mandating EIA

In order for the continued existence of the CCNR, there needs to be consensus amongst the government agencies involved in planning to put biodiversity conservation as one of the goals for sustainability. There should not be loopholes for agencies to work their way through and cause disturbance to the natural environment. For instance, should the laws protecting CCNR be strengthened, there will not be the situation

\textsuperscript{5} Refers to a ‘suite of methods used determine, implement, and manage’ areas that contain ‘desired conservation targets with the minimum expenditure of resources’. \cite{26}
of LTA executing ground testing works in CCNR. Some educated members of the public questioned their legal rights and whether ministers had the power to approve these acts, or amend these laws. In addition, the state should adopt a policy of mandatory environment impact assessment (EIA).

6.2. Retrofitting current Green spaces

The studies done on managed green spaces show that they are dedicated primarily for recreation [32]. In order to maximize the ecological function of these green spaces as a supporting matrix, Table 9 proposes strategies that promote creation of habitat; supports landscape connectivity and provide an ecological context [33].

Table 9: Recommendations for retrofitting managed green spaces

</tbody>
</table>

Existing efforts have been ongoing in Singapore to enhance the habitat functions of parks. The butterfly habitat enhancement and naturalization of the canal in Bishan Park created habitats for various flora and fauna. Blue Hills Country Club in Kansas City is an exemplar of a multifunctional golf course. By providing nest boxes, native flowering shrubs and wildlife refuge areas, it provided a habitat for many birds and insects [34].

6.3. Measures/ Recommendations to ameliorate Edge effects

Microclimatic alterations are found to be the key cause of edge effects, which can be tackled though modifying vegetation configuration [30]. Forman (2014) suggests enhancing the vegetation structure and treatment of the edge to reduce the edge-to-interior ratio. Such measures protect the interior species as well as promote or discourage fauna movement to manage human-wildlife interactions [30]. Table 10 shows the recommendations for retrofitting edges.

6.3.1. Improving on-going/ Future Development proposals

Recognizing that there are developments taking place adjacent to the nature reserve in future, the following recommendations are proposed to minimize effects of edge creation.

1. Edges with higher structural density support a larger variety of edge species [15][35]. Supplementary planting of a mixture of canopy, understory and undergrowth layers helps to reduce exposure to harsh microclimate conditions by increasing vegetation density and
structure. This is especially crucial for boundaries with hardscape infrastructure like the Mandai Depot where noise and high radiant temperatures can be screened out through mixed plantings.

2. Convoluted/Curvilinear boundary vs Straight boundary: Curvilinear boundaries facilitate fauna movement across the edge while straight boundaries facilitates parallel movement [13][15]. The edge pattern can be designed according to the desirability of fauna entering the matrix.

3. Increasing softness of edge can have ecological benefits like preventing soil erosion and enhancing edge species richness. The planting palette should prioritize native forest species to support the continuation of interior habitats [24][32].

For instance, the upcoming Mandai attractions could include vegetated buffers or vegetated façades of the buildings to soften the edges and prevent microclimatic exposure. Softer edges should be used where wildlife is encouraged to permeate while landscaped barriers should be used to prevent human access into the protected areas. Vegetation models and simulation can help designers plan the edge treatment and protect species-specific habitats in CCNR. While adjacent developments maintain a 50m buffer along the CCNR boundary, the effectiveness of this buffer should be studied without delay for the long-term sustainability of the CCNR fragments.

7. Conclusion

While being designated as a “nature reserve” gives the CCNR some level of protection, its existence within in an urban context creates a complex situation of threats that undermine its long-term sustenance. Apart from improving the understanding of the edge condition of the CCNR, this paper hopes to bring to light the vulnerabilities faced by the nature reserves to urban development. Practical considerations and recommendations are provided to guide future planning and development strategies, working across scales from examining landscape patterns to edge planting. The fate of the CCNR, as well as that of our unique local fauna populations- the endangered Banded leaf monkeys, Pangolins, Leopard cat and Seraya tree (etc.) lies in our hands, for we do have the means to advocate its protection.

Acknowledgments

This paper would not be possible if not for the generous help and support by the following people: First, for her dedication, patience and guidance, to my dissertation supervisor, Ms Hwang Yun Hye, for helping me sort out the structure and logic of this paper. Secondly, to supporting tutors Dr Tan Puay Yok and Ms Jessica Cook, who gave valuable advice. Thirdly, to my family, for supporting me emotionally and assisting me in my fieldwork. Fourthly, to Dr. Shawn Lum and Angela Chan who introduced me to the wonders of the Central Catchment Nature Reserve, that inspired me to work on this topic. Lastly, to Jonathan Christian Chin, for his help beyond this paper.

Humidity decrease  
Higher wind velocity  
Biotic  
Soil erosion  
Change in vegetation structure (presence of shrub and herbaceous)  
Change in vegetation composition (presence of invasives, exotics) | The structural diversity of the edge vegetation can be enhanced (Dramstad et al., 1996) to mitigate the microclimatic effects. However, instead of introducing exotic species for aesthetics, native edge-tolerant forest vegetation can be planted (Lindemayer et al., 2006) to support the continuation of interior species to its edge. |
| Open Ground | Abiotic  
Light penetration  
Temperature increase  
Humidity decrease  
Higher wind velocity  
Biotic  
Loss in biodiversity  
Change in vegetation structure (presence of shrub and herbaceous)  
Change in vegetation composition (presence of invasives, exotics) | The boundary along a path, plaza or shrub area can be made more convoluted (e.g., using curvilinear edge patterns) (Dramstad et al., 1996) to serve as an extension of the forest. Fauna can use these green spaces as a connecting matrix to move between green patches (Lindemayer et al., 2006), and also can encourage human interactions (Perl, 2016) with wildlife. |
Creating a resilient and biophilic cityscape in a concrete jungle through highways landscape in Hong Kong

Kathy T.K. Ng, Jason C.H. Wong

Abstract

The identity and image of a city are always associated with the landscape along the carriageway; and the greenery of the roadside landscape is also one of the key elements of green infrastructure and an indicator of a resilient and biophilic city. Hong Kong is one of most densely populated city in the world. The challenge and need of creating a resilient and biophilic Hong Kong is both pressing and important. Due to the scope and the high volume of pedestrian and vehicular traffic (about 12.6 million average daily passenger trips by public transport with a population of over 7 million), and the large number of trees i.e. over 0.6 million being maintained by Highways Department in Hong Kong, its landscape initiatives and proactive urban forestry management contribute directly to creating a safe, healthy and resilient city.

Highways Department aims at providing an efficient transport network and enhancing the quality of living. The department has been progressively moving towards the direction in enhancing the resilience as illustrated by our Acacia slopes enhancement programme, proactive vegetation management, green finger linkage enhancement by strengthening green corridors along road network, and providing more enjoyable environment to the public in streets, promenades and other highway structures; which in parallel promotes the contact of the community with nature.

To illustrate the above, we will share our experience in enhancing the biodiversity and safety of the Acacia slopes. Over the past decades, the Hong Kong Government has carried out large-scale afforestation on slopes to prevent soil erosion. Fast growing exotic pioneer species such as Acacia confusa, have been extensively planted. In recent years, Acacia confusa, which has low ecological value, has reached its senescent stage and the poor health and structure has been posing risk to the public. Hence, an enhancement scheme was formulated to replace the senescent Acacia gradually along the roads by a palette of native and naturalised plant species to improve the biodiversity and resilience in the long run. To further connect nature with the
community, various measures were implemented on upcycling wood logs generated from the scheme to bring benefits to the community, for example, through using logs for educational use, art work and other uses.

To further enhance the resilience of our green network, we are applying various innovative measures to proactively manage highways’ vegetation including the extensive use of technology for monitoring the health and structure of the trees and develop management plans and cycles. To strengthen green corridors along road network, green finger linkage enhancement is used to connect the highways landscape in urban area with countryside or country parks through robust planting to enhance wildlife niches and the green network.

To provide more enjoyable environment to the public in streets, promenades and other highway structures; landscape initiatives are being implemented to create pleasant public spaces to promote social interaction and contact with nature.

Keywords: Biodiversity, green finger enhancement, highway landscape, proactive urban forestry management, streetscape

1. Introduction

The identity and image of a city are often associated with the landscape along its carriageway. The pollarded Horse Chestnut trees (Aesculus hippocastanum) along Champs-Elysees in Paris or the golden Gingko trees (Ginkgo biloba) in autumn in Beijing or Seoul are some of the exemplary cases. The greenery of the roadside landscape is also one of the key components of the urban green network and an indicator of a biophilic and resilient city; as illustrated by the integration of road network with the sustainable stormwater management system in a growing number of cities.

Hong Kong is one of most compact cities in the world. The challenge in creating a biophilic and resilient environment for the public is both pressing and challenging for the government of Hong Kong. The Highways Department is responsible for the planning, design, construction and maintenance of public road systems and implementation of new highway and railway infrastructure projects in Hong Kong. The department plays an increasingly significant role in creating a safe, healthy and resilient cityscape.

2. Background

Hong Kong is a highly compact city with over seven million people in only 1110 km² of land [1]. It is one of the most densely populated cities in the world with an average of over 6,690 persons/km², and district such as Kwun Tong has a density as high as 57,300 persons/km² [2]. For comparison, the population density of London was around 5,600 persons/km² and that of Berlin was 4100 persons/km² [3][4].

Apart from maintaining over 2,100 kilometres of roads, Highways Department currently manages the largest number of trees in the urban areas, amounting to 0.6 million as of 2017. Due to the high volume of pedestrian and vehicular traffic (about 12.6 million average daily passenger trips by public transport [5]), the department’s work on landscape and vegetation management contributes directly to enhancing public safety and building a biophilic and resilient environment.
Highways Department aims at providing an efficient transport network. In parallel, through the network, we strive to enhance the quality of living environment. As such, the department has been progressively moving towards the direction in building a biophilic and resilient environment as illustrated by our proactive urban forestry management and landscape design work. Some recent initiatives include the rejuvenation programme of senescent Acacia slopes, fostering innovation and leveraging research and technologies on tree asset management, green-finger linkage enhancement, and thematic approach in enhancing our streetscape and walkability.

3. Proactive urban forestry management

3.1. Rejuvenation programme of senescent Acacia slopes along highways in Hong Kong

Over the past half century, Hong Kong has undergone rapid economic development. Due to the hilly terrain of the territory, large scale site formation was required. As a result, many man made slopes had been formed on which large-scale afforestation were carried out to prevent soil erosion. *Acacia confusa* (*Acacia*) being a tree species that can grow rapidly on dry and poor soil and was therefore chosen as the one of the key pioneer species for extensive planting on slopes along roadsides in Hong Kong for achieving slope greening [6].

With an average life span of approximately 50 to 60 years, the majority of the *Acacia* trees planted in Hong Kong over the past decades have gradually reached their senescent stage. They have become more susceptible to drought, compaction and secondary pathogens when injury occurs [7]. Furthermore, the *Acacia* in Hong Kong have been very densely planted. As a result, the stem taper of these trees in close stands has not been well developed. This impacts the ability of the trees to be self-supporting [8]. They are also even-aged which tend to grow uniformly tall and generally have little diameter growth with small live crowns. These trees with high height-to-diameter ratios and poor stem tapers are more susceptible to wind thrown [9]. The situation is aggravated by the fact the *Acacia* on slopes tend to be slanting seriously in particular for those at the lower part of slopes (figure 1). In many situations they are arching directly over pavements and carriageways. The deteriorating health problems and declining structural stability have been posing a significant threat to public safety (figure 2).

![Fig.1. Acacia with severely leaning is commonly found on slopes in Hong Kong](image-url)
The maintenance record showed that the number of Acacia with poor health and structure in need of removal by Highways Department alone has been increasing steadily each year since 2010 (figure 3). According to the reports on tree failure cases from the local authority in November 2012, Acacia-related cases constituted 35% of the reported total [10].

Moreover, Acacia, being an exotic tree species to Hong Kong, has a lower ecological value than most native species. It releases detrimental biochemical (allelopathy) to understorey plants [11][12], and the densely planted clumps hinders the natural propagation and growth of other plants due to the reduction of light, moisture, nutrients and space available (figure 4). Also, it disrupts the ecology of natural ecosystems by displacing native plants and the animal species that depend upon them [13].
In order to reduce the risk and safeguard the public and promote the long-term sustainability of highways landscape, a six-stage landscape improvement and habitat restoration programme known as ‘Rejuvenation programme of senescent Acacia slopes’ (Programme), has been developed and led by a team of landscape architects in Highways Department and will continue to evolve and develop in the coming decade. This territory-wide Programme is the first of its kind in Hong Kong, in form of its scale and comprehensiveness. The objectives are:

- to create a biophilic and resilient cityscape;
- to better safeguard public safety; and
- to promote the long-term sustainability of highways landscape via biodiversity enhancement.

Stage 1 – Planning and consultations
Extensive consultation is essential. We obtained expert views from academia, local and overseas tree experts, the Tree Management Office and the Expert Panel of Tree Management of the local authority. Highways Department has been communicating with the local residents through the District Councils.

Stage 2 – Work prioritisation
We have been carrying out systematic surveys with a scoring system to assess the current tree health, structure and habitat conditions, and setting the order of work priority. In determining the schedule for gradually phasing out the senescent Acacia trees, a basket of factors (figure 6), such as target rating, failure potential, size of Acacia, site conditions and site sensitivity are duly considered with reference to the international guidelines on tree risk assessment [14].
Stage 3 – Public engagement
While we have managed to gain support from the academia and the tree experts on the Programme, it is equally important for the community to understand and support it. We have been providing information of the Programme through website information, video clips, radio interviews and leaflets to the general public. In addition, we promote more interactive publicity activities such as educational talks (figure 7), wood sculpture exhibition and live demonstration (figure 8), and engagement with local District Council members. We are planning for wood upcycling workshops and hands-on activities where community can experience “grow–learn–play” for promoting public awareness on the benefits of the Programme and further connect nature with the community.

Stage 4 – Implementation
Prior to the replacement on site, we will strike a balance between public safety and social impacts, an optimum replacement arrangement will be carefully developed for each chosen site, with due consideration given to biophilic design, traffic impact, visual impact and site sensitivity (figure 9).
Fig. 9. Biodiversity enhancement

We follow the principle of "the Right Plant at the Right Place" in plant selection. Factors such as design theme, biodiversity, landscape character, environmental factors (i.e. soil conditions, microclimate, traffic, spatial factors, plant characteristics, etc.) are taken into account in determining the appropriate species, for replanting. A palette of native and naturalised plant species is selected to improve the biodiversity and to establish a self-sustaining urban forest with multiple strata and higher ecological value [15][16]. Furthermore, we also strike a balance in providing different host plants and nectar plants for butterflies and selecting plant species with fruits and seeds for the wildlife (figure 10) in order to promote self-succession in the restored habitat via natural dispersion.

Fig. 10. Ecological network

Native species to Hong Kong, such as Wild Pear (*Pyrus calleryana*), Hong Kong Gordonia (*Gordonia axillaris*), Pop-gun Seed (*Bridelia tomentosa*), Holly (*Ilex* species), Machilus species, Buch-like Reevesia (*Reevesia thyrsoides*), Hong Kong Hawthorn (*Rhaphiolepis indica*), Rose Myrtle (*Rhodomyrtus tomentosa*), etc., are extensively used together with some naturalised species, such as Camel's Foot Tree (*Bauhinia variegata*), Camellia species, Azalea (*Rhododendron* species), Golden Dewdrops (*Duranta repens*), Chinese Privet (*Ligustrum sinense*), Pagoda Flower (*Clerodendrum japonicum*) etc., so as to establish an urban forest of higher ecological and aesthetic value, and to promote local district character with seasonal effects (figure 11), and to attract the community to enjoy the outdoor space.
Fig.11. A palette of native and naturalised plant species is selected to improve the biodiversity.

A four-year pilot study was carried out in Pui Man Street in Wong Tai Sin, Hong Kong since 2012 prior to the full launch of the Programme (figures 12a & 12b).

Fig.12a. Before restoration in 2012: Monoculture of *Acacia*

Fig.12b. After restoration in 2015: Lush vegetation with multiple strata of high ecological value

The results of the biodiversity index, performance and survival rate of native plants were compiled. Wildlife such as birds and insects were attracted as seed dispersers in the process that had greatly enhanced the richness of biodiversity. A sharp increase in native species from 5 to 20 and naturalised species from 9 to 16 were recorded in the study site from 2012 to 2016 (figures 13a & 13b).

On reviewing the above completed work in the initial phase, it is concluded that the objectives have been successfully accomplished. The landscape with diversified flora and fauna are seen in the restored habitats (figure 14) and at the same time the tree risk level has been substantially reduced.

Fig. 14. Diversified flora and fauna are seen in the restored habitats.
Stage 5 – Upcycling of Acacia logs
We manage the life cycle of the Programme namely from inception and implementation to the post planting work. In line with the government policy of waste reduction, we target to make meaningful use of the materials generated from the replacement work instead of adding burden to the landfill sites. We upcycle the Acacia logs generated from the Programme to bring benefits to the community. For example, through using logs for educational use, art work and other uses (figures 15a & 15b). We continue to explore more means to reuse or upcycle the logs.

Stage 6 – Monitoring, evaluation and improvement
Continuous improvement of the Programme requires feedback, monitoring and evaluation. We are collaborating with the academia to track the biodiversity and quantify the performance of different composition of species and methodology. Based on the findings, we aim to further refine the overall plan for its further advancement.

3.2. Green-finger Linkage Enhancement

In a less tangible dimension, the green space network contributes to the physical and psychological health and well-being of individuals. It is believed that biophilic cities in which design of the cities includes natural elements and green space network as a crucial element can build resilience and benefit the well-being and health of the population. Numerous international research studies confirmed the positive contribution of green spaces to mental health in relieving stress [17][18], giving relief and providing recreational spaces and opportunities
There is growing recognition among international communities that mental health is one of the most neglected and pressing development issues [21]. In an increasingly compact Hong Kong, the green space network plays an indispensable role in enhancing both physical and mental health of our population. Both the quantity and quality of green spaces are essential in providing the necessary venues for developing and enriching social cohesion and interaction which are fundamentals to a quality living environment. Providing green spaces close to living spaces and making them accessible also helps provide restorative environments. As such, there is a strong case to promote communal green spaces in the neighbourhood at multiple levels and scales, and to facilitate recreational and leisure functions.

Highways Department is launching the green-finger linkage enhancement scheme to link green spaces by making use of the greenery under its management and reinforcing the landscape character of roadside planting. For example, the autumn colour of Chinese Sweet Gum (*Liquidambar formosana*) in Tai Lam Country Park (figure 16) has become very popular, and the green-finger linkage enhancement in this area will strengthen the landscape character of the place by planting the same native species along the roads leading to the country park.

In Tsuen Wan and Route Twisk area where the spring blossom of Camel's Foot Tree (*Bauhinia variegata*) gives a sense of place (figure 17), the green-finger in the area will link up the fragmented locations under the theme of the spring bloom. These green-fingers in various districts will also become effective eco-corridors along carriageways as native and naturalised species will be planted. These green-fingers connect the originally fragmented patches of greenery and therefore nurture a biophilic environment that is conducive to the sustainability of natural habitats.
3.3. Fostering innovation and leveraging research and technologies on tree asset management

Trees growing in urban and surrounding areas are subject to considerable environmental stress. It is therefore essential to properly maintain them and upkeep their health and structure and avoid potential hazard to life and property. These trees are important components in the urban forestry and the sustainable urban ecology. Tree management in Hong Kong faces the challenges of the lack of space for tree growth in the urban area and in addition there are typhoons and torrential rain in summer that may cause damage or collapse of trees. Moreover, Highways Department is managing trees on slopes and along expressways where inspection and maintenance work alongside busy traffic is not easy. On-site inspection of the tree though provides in-depth assessment of tree conditions is labour extensive and the result is dependent on the expertise of the personnel. For the management of large number of trees, it would be beneficial to make use of technology and innovation to complement the on-site inspection work.

For the effective management of trees over the whole territory, Highways Department aims at developing a tree asset management system to plan and prioritise work. An updated GIS-based tree database and management system for analysing data to effectively plan for tree management work is therefore necessary. The location of trees, distribution of species and dimensions, and complaint hot spots are useful information in planning work flow and prioritising operations, and devising a rapid response management plan.

We are keen to explore fit-for-purpose technologies for application in tree asset management. Apart from making use of data captured by Mobile Mapping System (MMS), the latest collaboration with research institutions include making use of remote sensing techniques to monitor tree health over time as the early warning of anomalies detected can complement on-site tree inspections to better identify trees with deteriorating health conditions or under stress (figure 18).

![Fig.18. An application of remote sensing technology with the use of Infra-red image in vegetation management (source: Lands Department)](image)

Other current research topics include the use of remote sensing data in capturing tree locations and dimensions. This would be useful for managing trees in locations with difficulty in access.

The GIS based spatial information facilitates planning and maintenance work, management decisions and long-term
preservation of trees. By fostering innovation and leveraging research and technologies, we aim to enhance and manage the valuable green assets more efficiently.

4. Pedestrian-friendly design along highway landscape

Promoting walkability in the urban environment should form an integral part of the green space planning framework, and is a key element for sustainable cities. A comprehensive development of a pedestrian-friendly walkway system can help reduce the reliance on road-based transport, which in turn alleviates the demands put on the transport system and lessens the impact on the environment. It can reduce the number of short motorised trips and the conflict between pedestrians and vehicles. This will increase mobility, enhance road safety and improve local air quality.

It is desirable to promote walkability and applying a pedestrian-oriented approach in streetscape design that encourages community interaction and street life to replace that of ‘car-based’ approach (figure 19).

Fig.19. Enhancing the streetscape of our community through greening, design and selection of paving patterns and street furniture commensurate with the environment

It was under such background that Highways Department has been launching some streetscape improvement schemes that promote walkability and build the identity of a place (figure 20). A recent example is the thematic design to highway structures under the theme of ‘Appreciate. Life. Colours’, which aimed to bring interest to the walking experience. Inspired by elements found in the nature and our daily lives, the design re-created delightful scenes such as walking the dog in the woods, watching wild birds with the family in the country, and the first time being in an aquarium as a child, in the style of simple silhouettes. All these happy scenes in the memories serve to slow down the pace and brighten up the mood of the passers-by (figures 21).

These improvement works have given new energy and rejuvenated the otherwise underused spaces (figure 22).
5. Conclusion

In a compact city such as Hong Kong, the green assets along highways should be leveraged to enhance livability. Through the above proactive urban forestry management strategy and landscape initiatives on pedestrian-friendly environment, Highways Department has demonstrated the recent progress and initial steps in creating a resilient and biophilic cityscape in a concrete jungle for the benefits of the community and the environment.

Acknowledgments

We have to express our sincere gratitude to the visionary guidance and enormous support of the senior management of the Highways Department without which the proactive initiatives in creating a resilient and biophilic cityscape would not be successfully launched. We also express our gratitude to Lands Department for the permission of our use of the aerial photo (figure 18) and to Parry Ling, wood sculpture demonstrator, from Hong Kong Baptist University for the support of our public engagement events.

Abstract

Indonesia is the fourth most populous country in the world and city population by 2017 reached 54.8\% and is expected to increase every year. Population growth and development in urban areas are rapidly followed by an increase in demand for land. This condition will encourage the conversion of land, especially the conversion of agricultural land to non-agricultural land. Urban development requires a solution so that the agricultural sector can be integrated into other sectors in the design of the development. AGROSUPERBLOQK concept is the idea to be a solution in overcoming the problems of urban areas. This concept is an integration between integrated urban farming and superblock city concept. The techniques used in the implementation of Agrosuperblock can be done in cooperation with related parties especially among professionals, businessmen, community and government. In addition, the delivery of Agrosuperblock related information is very important. Information provided on the benefits derived from the Agrosuperblock concept, particularly in terms of creating urban areas as as comfortable residence and mixed use center in urban areas through sustainable development by promoting ecological and environmental sustainability with the integration of multifunctional and agricultural sectors. In addition, urban development currently focuses on the concept of 'green' strongly supports the implementation of Agrosuperblock. As a key stakeholder and regulator, the government is also responsible for ensuring the concept of Agrosuperblock can benefit all parties without emphasizing only certain aspects or parties. If the concept idea of Agrosuperblock is applied consistently, it will create an independent city through sustainable development by promoting ecological and environmental sustainability and land and energy efficiency.
Keywords: Agrosuperblock, agriculture; efficient; mixed use center; multifunctional; urban area

1. Introduction
The major urban areas in Indonesia have a problem in the formulation of policy and strategy urban development. One of them is the population density and carrying capacity of the urban area. The Statistics Indonesia (2014) showed that the population density level increased in 2010 is 124 people/km$^2$ to 132 people/km$^2$ in 2014. The growing population and development in urban areas quickly followed by an increasing in demand for land, this will encourage the conversion of agriculture land to non-agriculture land. The alteration agriculture land in urban areas can lead to problem in the economic, social, cultural, and environmental sectors. This condition has worsened with the government policy to development-oriented in urban area. Data from The Ministry of Agriculture (2014) mentioned that the decrease of agriculture land area by 25% at year 2012-2013. Development of city need a solution for integrated multifunctional sector in development planning.

Government efforts in the development or urban areas are written in Law of The Republic of Indonesia Number 26 of 2007 concerning Spatial Planning and Government Regulation Number 34 of 2009 concerning Guidelines of Urban Area’s Management. In accordance with these laws, urban areas are the main non-agricultural activities with the function of the area as urban settlements, centralization and distribution of government services, social services, and economic activities. Urban development planning is based on condition, potential, characteristic, and relatedness with surrounding area. This regulation doesn’t support the sustainability of the agricultural sector in the urban areas. This condition is exacerbated by the policy of designing new urban areas from rural areas. The problem cause land conversion function of agricultural land. The conversion of agricultural land in urban areas needs to be avoided because the existence of agricultural land will always exist and when converted agricultural phenomenon will penetrate the forest which resulted in other polemics. Therefore, urban farming needs to be implemented to be more effective and efficient.

Urban Farming becomes a solution for the agricultural sector in urban area. The benefits of urban farming are to improve environment quality, social cohesiveness, cultural, economy community, value aesthetic urban area and food security (Arifin, 2016). However, it is necessary to develop urban farming with integrated management to make it more efficient in economic, technology, and energy. Beside it, urban development also focus on integration various sectors in a complex areas. Kamil (2008) said that the source of city’s problems is due to the inability of the city system to control the growth and change of the city. Human civilization, lifestyle, and physical aspect of the city are so rapidly changing, while the controlling of the city’s system get slowly, so the big cities in Indonesia are experiencing this problem. The problem can be solved through the concept of superblock city. Superblock is an area in urban contexts are designed in integrated development, high enough
density in land use mixed-use concept. This area is a multifunctional complex (commercial area, office, residential, and entertainment) into one unity. The disadvantage of this concept has not yet include urban farming, actually agriculture sector become an important part of sustainable urban development particularly in food security that gaining the independence mixed-use center.

Agrosuperblock is solution in overcoming urban area problem. This concept is an integration urban farming and integrated city or mixed-use development. The objective of this study is planning and designing the development of urban areas through sustainability development by increase ecological and enviromental with integration of multifunctional sectors. It’s expected to become a reference or model for the government in implementing urban development with the concept of Agrosuperblock.

2. Methods
2.1 Study design

We employed the case study, literature review, and qualitative method from the development of urban areas in Cibinong Raya, Bogor Regency. Cibinong Raya, Bogor Regency is one of the centers of urban areas in Indonesia that included Jabodetabek (Jakarta, Bogor, Depok, Tangerang, and Bekasi). The city located in 40 km south of Jakarta, the capital of Indonesia. Based on Regional Spatial Planning Policy (2016), role and function of Bogor regency consist of the settlement's population of Jabodetabek, provision of agricultural land to support the availability of food supplies, and conservation protection area in the middle and upstream region.

2.2 Case selection

Cibinong Raya is the capital city of Bogor Regency. Cibinong Raya is the urbanized area in Bogor Regency that connected to Jakarta by railway (2 stations), arterial road and highway road with three entrance. The growth of Cibinong Raya is mostly caused by the orientation of public services in this area as a capital city, high accessibility to core city; and availability and high quality of land. The rapid growth of Cibinong Raya is indicating by high growth in population: 1.3 million inhabitants with growth rate by 3.99%, rapid development of built-up area, 38.77% of built up area with growth rate by 3.46%, and rapid development of infrastructure (Regional Spatial Planning Policy of Bogor Regency, 2016).

The study is focused on Cibinong Situ Front City (situ means lake in local language) as a pilot project of the Agrosuperblock. Cibinong Situ Front City is one of the most potential resources to develop. The goverment has announced that Cibinong Situ Front City will be a new icon and promotion spot for Cibinong Raya and tried to focus on developing two main lake Situ Cikaret and Situ Kabantenan (Kompas, 2016). Figure 1 show the existing of Situ

![Figure 1 Cibinong Situ Front City: A.Situ Cikaret; B. Situ Kabantenan](image-url)
Cikaret and Situ Kabantenan.

2.3 Analysis

Analysis of the Agrosuperblock’s concept consists of agricultural context and superblock context. Agricultural context describes the application of urban farming, permaculture, and green city to support the Agrosuperblock’s concept in Cibinong Situ Front City. The analysis of urban farming and permaculture will be conducted through a literate study to search the suitable application and calculate the estimation of food needs and production for the Agrosuperblock’s concept. While, green city’s analysis is based on eight indicators, there are green planning and design, green open space, green building, green waste, green transportation, green water, green energy, and green community. Superblock context is focused on developing Cibinong Situ Front City as superblock area. The analysis for this context is begin with identifying the overall area in Cibinong Situ Front City by site analysis.

2.5 Concept

The concept of this study refers to the Agrosuperblock’s concept that integrated multifunctional area (superblock) and agricultural area. After the Agrosuperblock’s concept created, we established the zoning concept and function.

2.6 Site planning

Site planning is built from all concept and result of the analysis. The output of this step is the siteplan of the Agrosuperblock’s concept in Cibinong Raya, Bogor Regency.

3. Results

Cibinong Situ Front City consist of Situ Cikaret and Situ Kabantenan. Both are part of Ciliwung river stream. Situ Cikaret has 29.5 Ha areas while Situ Kabantenan has 4.5 ha areas. Based on the government policy, the planning of this site is connecting Situ Cikaret and Situ Kabantenan (Figure 2). The planning aims to revitalization area of Cibinong Situ Front City, integration green and blue open spaces, and increase waterbody for water management. The study of Puspita (2017) showed that Situ Cikaret has a good landscape condition and Situ Kabantenan has passably condition to development.

![Figure 2 The connecting of Situ Cikaret and Situ Kabantenan](image)

3.1 Analysis

Permaculture and urban farming combined to support the Agrosuperblock concept. Permaculture is linked agricultural productivity based on socio-economic, and ecological has a big chance to be applied (Nabilah, 2017). To implemented permaculture and urban farming concept, it’s important to know the estimation of food needs. Food needs are analyzed by some assumptions based on Priandono (2006), there are:

1. the population around Cibinong Situ Front City is 3,500 peoples (15% of total population);
2. calory need per days is 2,500 kkal;
3. the one day meal menu of population same as the 2006 data; and
4. the conversion of the food menu into agricultural commodities is the same as the 2006 data.

The food needs which is analyzed consist of vegetable and animal food. The commodity that is the priority of vegetable food needs is rice, soybeans, sweet corn,
papaya, kale, chili, spinach, beans, tomatoes, potatoes, carrots, cabbage, leaves onion, celery. Animal food is needed milk, chicken, eggs, and fish (Priandono 2006). The result showed that the estimation of food need is 6,386.5 kg/day and the food production area need 1,188,361 m² (Table 1).

The analysis of green city is based on 8 indicator’s evaluation. Green city is a concept of health city considering ecological aspect. The results of the study from Desdyanza (2014) showed that Bogor has had a city development plan towards sustainable city, but the implementations still haven’t been maximized. As a reference, Table 2 showed the result of evaluation Green City in Bogor City.

Table 2 knew that implementation of green open spaces’s indicator has the maximum percentage in amount of 50%. While green building’s indicator has the minimum percentage in amount of 0%. The result showed that implementation of Green City in Bogor has still not maximally done.

3.1 Concept

The concept of this study refers to the Agrosuperblock’s concept. Agrosuperblock is an integration permaculture, urban farming, green city and mixed-use development (superblock). The integration aims improve land and energy efficiency, reduce the conversion of natural land and forests, promote the diversity of activities in an integrated manner and synergies, efficiency of movement, reduce congestion, improve urban spatial, supply the food needs, the improvement of the quality of environment, and the avoidance of community gaps and small blocks so that the creation of sustainable self-sustainable cities with land and energy efficiency. Agrosuperblock is illustrated in Figure 3.

In practice, permaculture is integration between agricultural, livestock, fisheries, and human in the symbiotic system of products (Morrow, 1993). Permaculture is implemented in landed farm that consists of a fish pond, livestock, and paddy field. Permaculture as production system concept in the site aims to sustainability uses.

Implementation of urban farming in Agrosuperblock implemented through Vertical Farm Centre. The design of Vertical Farm Centre places agricultural land specifically vegetables and fruits as a component of the superblock building. This component is based on a vertical farming system that is divided into greenhouse and intensive agriculture with integration with fish pond, and livestock.

Green city concept in Agrosuperblock implemented based on the criteria of green city, there are:
1. Green planning and design implemented through mixed use development in superblock.
2. Green open spaces is supported by implementation of permaculture and urban farm. Beside it, blue open spaces available as lake or Situ that has function water supply and water catchment in around Cibinong Situ Front City.
3. Green building implemented through environmentally friendly building structures and decrease uses of air conditioner.
4. Green waste and green water is combined through water management of blue water, grey water, black water, and green water. Implementation of 3R (Reduce, Reuse, and Recycle) is supported by waste processed technology that environmental friendly.
5. Green transportation is developed through increase pedestrian way, bicycle way, and public transportation.

6. Green energy is implemented through solar panel to harvesting solar energy. It’s so potential cause the site located in tropical climate that has high solar radiation.

7. Green community is developed by collaboration between stakeholders. Development of Agrosuperblock is developed by the main concept of superblock according Wibisono (2010) said that the concept of superblock can develop and respond positively by the community if in superblock design has five the main concept of the planning process until it becomes a ready product marketed, among others identity/branding, mix of uses, massing framework, efficient vehicular circulation, and multilayers pedestrian linkage.

3.2 Site planning

Agrosuperblock is implemented in Cibinong Situ Front City consist of Situ Cikaret and Situ Kabantenan. The design of this study area considered the potential area which is planning as superblock development. Agrosuperblock in Cibinong Situ Front City is applied consider:

1. Identity/branding of Cibinong Front City
   a. Green and blue open spaces: Situ Cikaret and Situ Kabantenan

b. Buffer zone of city center
c. Water catchment in upstream area
d. Center of government activity

2. Mixed of use
   1. Government office zone
   2. Park and open space
   3. Commercial and shopping zone
   4. Residential zone
   5. Urban farm zone

3. Massing framework
   a. Adaptive from characteristic and function of building
   b. Consider focal point and landscape view around the site
   c. Consider of wind and sun direction
   d. Make the building facing towards Situ Cikaret and Situ Kabantenan.

4. Efficient vehicular circulation
   a. Pedestrian way
   b. Bicycle track
   c. Vehicle way

5. Multilayer pedestrian linkage is applied by presenting a comfortable pedestrian, accessible to various buildings, safe, and close to nature.

Figure 4 showed site plan of Cibinong Situ Front City based on Agrosuperblock. The design effort to supply land area required for permaculture and urban farming. The availability of land for permaculture and urban farming can be seen in table 3. The total land can supply 19% of the urban farming requirement.

3.3 Program development

Development of Agrosuperblock in Cibinong Situ Front City requires collaborative role of various element such as academic, professional, business, government, and communities. This collaboration named Pentahelix collaboration. Each element has its own function and capability that affect the implementation of Agrosuperblock. The collaboration will great with the support of communities as a main goal and who benefit from the implementation. For example, government can consider tax, an academic can consider about research and innovation for Agrosuperblock, professional can be consider availability of the implementation, and business sector can be an investor. For
more detail the schematic can be seen in Figure 5.

The other strategy is concerning about Agrosuperblock scheme. The integration between permaculture, urban farming, green city, and superblock is connected to each other. The scheme is illustrated input-output of the process and benefit from each cycle. All the program have functions that support environmental sustainability. For example, permaculture produces food, but others product like compost and biogas recycle can use for other needs. The schematic diagram shows in Figure 6.

**Conclusion**

The study in one of the new approach concerning agricultural and urban problems. Agrosuperblock is an integration between permaculture, urban farming, green city and mixed-use development (superblock). The study is focused to Cibinong Situ Front City (Situ Cikaret and Situ Kabantenan) as a pilot project and case study of the Agrosuperblock. The result of food need’s analysis showed that the estimation of food need is 6,386 kg/day and the food production area needs 1,188,361 m$^2$. The design of Agrosuperblock effort supply 19% or 341,522 m$^2$ of land area required for permaculture and urban farming in superblock area. If the concept of Agrosuperblock is applied consistently, it will create an independent city through sustainable development by promoting ecological, environmental sustainability, land and energy efficiency.
Acknowledgement

We give thankful to lecturer, staff, and student of Landscape Architecture Department, Faculty of Agriculture, Bogor Agricultural University to support so we can implement it to paper.

Abstract

Urban green space (UGS) can help to moderate particulate matter air pollution through the impact of landscape design parameters. The current work investigates the particulate matter modification potential of urban block (1 km) in Wuhan, China and the effects of its landscape parameters by field measured data. Bivariate relationship is evaluated between the particulate matter concentration and landscape parameters. Strong positive correlation is found between the percentage of vegetation and PM$_{10}$, PM$_{2.5}$ concentration, and strong negative correlation is found between the percentage of hardened ground and PM$_{10}$ concentration. Meanwhile, weak negative relationship between the percentage of building and PM$_{2.5}$ can be observed. The impacts of water body on particulate matter modification are found to be uncertain to some extent. Stepwise multivariate regression analyses show that the most significant influential factor on the moderation of particulate matter is the vegetation, 10% increase of the area of vegetation will decrease about 9.1% and 10.2% in PM$_{10}$ and PM$_{2.5}$ concentrations, while the hardened ground and building exhibit negative effects. The outcome of the current work can provide evidential bases and available knowledge for the landscape architects to improve the urban air quality by means of urban green space.

Keywords: urban green space; landscape design parameters; PM$_{10}$; PM$_{2.5}$
1. Introduction

Rapid urbanization has changed urban underlying surface and had a significant impact on the urban climate, such as the serious particulate matter air pollution. In recent years, PM\textsubscript{10} and PM\textsubscript{2.5} became the main pollutants, which refer to particulate matter in air that is less than 10 μm and 2.5 μm in aerodynamic diameter respectively. This kind of air pollution became the focus all over the world and the experts and scholars from various fields are trying to find solutions.

Urban green space (UGS) can help to moderate particulate matter air pollution through the impact of landscape design parameters. Those landscape parameters include vegetation, water body, hardened ground (walking path and plaza) and building. The vegetation components of the UGS like lawn and trees can reduce particulate matter concentration\cite{1}. The water body such as lakes can also reduce particulate matter by increasing air humidity\cite{2}. However, highly constructed cities experience higher concentrations of PM\textsubscript{10}, which are composed of buildings\cite{3}. Nonetheless, these has not been taken into account in current urban planning or landscape design guide. With the continuous reduction and fragmentation of UGS in modern cities, it is important to further reveal and emphasize the positive effects of UGS, such as the particulate matter modification potential, and put forth a series of measures aimed at minimizing particulate matter.

Previous works focused on the effect of limited numbers of selected landscape parameters on particulate matter modification effect, but no available information on the comprehensive contributions of various parameters in an UGS can be found so far.

The current work investigates the particulate matter modification potential of urban block (1 km) in Wuhan, China, and the effects of its landscape parameters by field measured data. The main aim of this work is to reveal the influence factor of landscape parameters on particulate matter air pollution and influence degree. The outcome of the current work can provide evidential bases and available knowledge for the landscape architects to improve the urban air quality by means of urban green space.

2. Methods

2.1. Study area

Wuhan (113°41′-115°05′E, 29°58′-31°22′N), 8494.41 square kilometers in area, is the largest city in central China. It is located at the intersection of the Yangtze and Han Rivers, and is divided by the two rivers into Wuchang, Hankou and Hanyang. In recent years, Wuhan’s urban population and yearly construction area have been gradually increasing, which resulted in serious particulate matter air pollution. According to
the 2016 global air pollution database published by the world health organization, Wuhan was the 12th worst particulate matter air pollution in 210 cities in China. Thereby, it becomes a target site of many studies relevant to urban particulate matter air pollution\cite{4-5}.

The interest domains of the current study, 14 air quality monitoring stations, are relatively evenly spread around the main city of Wuhan, including 8 national automatic monitoring stations, 4 urban national automatic monitoring stations and 2 self monitoring stations set by research group. 2.2. Particulate matter measurement

Based on the 14 air quality monitoring station in main city of Wuhan, PM$_{10}$ and PM$_{2.5}$ sample data of 4 months from June to September 2016 was averaged respectively. These data was selected on the sunny and breezy condition when UGS play a better ecological benefits. The data of national and urban automatic monitoring stations originated from Wuhan Environmental Protection Bureau (http://hbj.wuhan.gov.cn/?COLLCC=1182685071&), where we can get daily data of PM$_{10}$ and PM$_{2.5}$ concentration. The data of self monitoring stations was measured by LD-5S laser dust meter and hourly data can be obtained.

2.3. Landscape parameters

Four type landscape parameters including vegetation, water body, hardened ground, and building were obtained by remote sense image (GF2, September 1, 2016) and field survey. Based on the object-oriented classification techniques, ENVI (The Environment for Visualizing Images) can achieve the automatic recognition and extraction of vegetation target from high-resolution remotely sensed imagery. NDVI was used to distinguish vegetation, and NDWI was used to distinguish water body. Hardened ground and building were obtained by artificial depiction. Moreover, combined with artificial visual interpretation, the results of extraction were optimized. The output results are shown in Table 2.

2.4. Statistical analyses

Bivariate relationship is evaluated between the particulate matter concentration and landscape parameters including vegetation (VE), water body (WB), hardened ground (HG) and building (BU). The analysis results show the different effects of various landscape parameters in the block. Moreover, stepwise multivariate regression analysis is conducted to assess the contribution of those landscape parameters to particulate matter quantitatively, according to a predictive equation (Eq.1):

\[ Y = a_0 + a_1 \text{VE} + a_2 \text{WB} + a_3 \text{HG} + a_4 \text{BU} \]  

(1)

Where Y stands for the values of PM$_{10}$, PM$_{2.5}$ concentration; VE, WB, HG and BU are the percentages of each landscape parameter as previously described; $a_0$ is the constant; $a_1$-$a_4$ are the coefficients for each variable. The statistical analysis are carried out using SPSS 19.0 software.

3. Results

3.1. The distribution of PM$_{10}$ and PM$_{2.5}$ in different blocks

In the form of high density city, the concentrations of PM$_{10}$ and PM$_{2.5}$ in different blocks are significant difference, and the trends for PM$_{10}$ and PM$_{2.5}$ concentration are similar (Fig. 2). On the whole, the highest concentration of PM$_{10}$ and PM$_{2.5}$ is East lake High-tech area, and the lowest is Design Institute, Huazhong and Nansi Huazhong, which is significantly lower than other sites. Apart from these sites, the concentration of PM$_{10}$ varies from 60 μg/m$^3$ to 70 μg/m$^3$, and the concentration of PM$_{2.5}$ varies from 50 μg/m$^3$ to 60 μg/m$^3$.

3.2. Relationship between landscape parameters and particulate matter

There was a certain relationship between different landscape parameters and concentrations of PM$_{10}$ and PM$_{2.5}$ (Tab. 3). Strong negative correlation is found between the percentage of vegetation and PM$_{10}$, PM$_{2.5}$ concentration, and strong positive correlation is found between the percentage of hardened ground and PM$_{10}$ concentration, but hardened ground seems to have weak positive relationship with PM$_{2.5}$. Meanwhile, weak positive relationship between the percentage of building and PM$_{2.5}$ can be observed. The impacts of water body on particulate matter modification are found to be uncertain to some extent.

According to the correlation between these landscape parameters and PM$_{10}$, PM$_{2.5}$, some regularities can be obtained. First of all, the more the vegetation is, the lower the PM$_{10}$ and PM$_{2.5}$ concentrations there are.
Secondly, the more the hardened ground is, the higher the PM$_{10}$ and PM$_{2.5}$ concentrations there are. However, water body and building in urban blocks has little effect on PM$_{10}$ and PM$_{2.5}$.

3.3. The kind of landscape parameters that significantly influence on PM$_{10}$ and PM$_{2.5}$

Stepwise multiple regression analysis of those aforementioned landscape parameters on PM10 and PM2.5 concentrations were conducted to evaluate the contributions of those parameters on the air quality modification effect. Results is displayed in Table 4. The correlation coefficient (R$^2$) serves to describe the proportion that can be explained by the variables (difference landscape parameters) of the regression model. The coefficient (B, Beta) of each variable allows assessing the variation and contributions extent of the target parameters (i.e. PM$_{10}$ and PM$_{2.5}$ values in the current case) upon the corresponding variable$^{[6]}$. The results show that only vegetation is included in the regression model of PM$_{10}$ and PM$_{2.5}$. According to the stepwise multiple regression, the relationship between particulate matter and these landscape parameters can be expressed by $Y_{PM10}=82.821-65.353VE$ (P=0.001), and $Y_{PM2.5}=69.433-56.520VE$ (P=0.000). 60.1% of the variation in PM$_{10}$ concentrations can be explained by vegetation, and 90.7% of the variation in PM$_{2.5}$ concentrations can be explained by vegetation, since the R$^2$ value is 0.601 and 0.907, respectively. Although water body, hardened ground, and building are not included in the regression model, the impact of them on PM$_{10}$ and PM$_{2.5}$ can also be obtained through the coefficient (Beta).

The most significant influential factor on the moderation of particulate matter is the vegetation (P<0.01). Relatively speaking, the contribution of vegetation percentage to PM$_{10}$ and PM$_{2.5}$ concentration is 67.8% and 71.8%, respectively. The values of B coefficient of the vegetation is -65.35 and -56.52 respectively, which can be revealed that 10% increase of the area of vegetation will decrease about 9.1% and 10.2% in PM$_{10}$ and PM$_{2.5}$ concentration, relative to the Wuhan average PM$_{10}$ and PM$_{2.5}$ concentration. Hardened ground is the second significant influential factor, which contributes 17.3% and 11.3% to PM$_{10}$ and PM$_{2.5}$ concentration. The increase of hardened ground will also increase PM$_{10}$ and PM$_{2.5}$ concentration. The impact of water body and building on the PM$_{10}$ and PM$_{2.5}$ concentration is relatively weak.

The current work shows that vegetation plays positive effects on particulate matter air pollution. There are two aspects of the impact mechanism. On the one hand, vegetation can decrease particulate matter air pollution through its deposition. The secretion of vegetation leaves can adhere particulate matter in air, and the roughness of vegetation leaves and the length of the leaves villi are the main influential factor of adhesion effect[7]. What’s more, in the space constructed by vegetation, the changes in the air flow drive the particles to disperse, which increase the opportunity for the particulate matter to contact the vegetation[8]. The adhesion effect can be repeatedly realized during rain. On the other hand, the transpiration of vegetation can create a relatively humid and low temperature environment, which is beneficial to the settlement of particulate matter in the atmosphere[9]. Through these comprehensive effects, the effect of the vegetation to reduce the atmospheric particles is particularly significant.

4.2. The impact of hardened ground on PM$_{10}$ and PM$_{2.5}$

In the 14 blocks, the main hardened ground is composed of different degrees of urban road, which is the main source of particulate matter. Therefore, the larger the area of the road, the higher the concentration of particulate matter. This also reveals that the main pollutant is from car exhaust, and it is also consistent with the traditional cognition and results from many other studies[10]. Apart from that, road is often

4. Discussion

4.1. The impact of vegetation on PM$_{10}$ and PM$_{2.5}$
regarded as gray space in urban area. Compared with urban green space, this kind of space only influence the disperse of particulate matter, but can not decrease the particulate matter concentration through deposition like vegetation. In the actual planning and design, in order to ensure that the road can be opened normally and the concentration of particles can be effectively reduced, the reasonable road area rate should be determined.

4.3. The impact of other landscape parameters on PM$_{10}$ and PM$_{2.5}$

The water body and building are considered to have almost no effect on particulate matter. But some studies show that highly constructed cities experience higher concentrations of PM$_{10}$\[3\]. It shows the variation of particulate matter in different scales. The reason may be related to the difference of the study area and the resolution of the data. Water body plays an important role in reduction of particulate matter through wet deposition$^{[2]}$. In current work, due to the research object are the urban blocks, there are no water bodies in many blocks. Besides, these water bodies are greatly different among the type and scale. Therefore the water body has almost no impact on particulate matter.

5. Conclusion and outlook

5.1. Conclusion

The current work investigates the effects of urban green space on thermal comfort in views of the common urban blocks and the individual landscape design parameters. The effect of landscape design parameters on particulate matter air pollution is found though high resolution remote sense image and 14 air quality monitors. Vegetation and hardened ground are the two main influential factors, which contribute 60.1% and 90.7% to PM$_{10}$ and PM$_{2.5}$ respectively. 10% increase of the area of vegetation will decrease about 9.1% and 10.2% in PM$_{10}$ and PM$_{2.5}$ concentrations. However, hardened ground has negative impact on PM$_{10}$ and PM$_{2.5}$. Building and water body are found to be uncertain to some extent.

Based on the results of the current work, for improving the urban air quality, it is suggested for the landscape designers, policy makers and city managers that:

1) Increase the area of vegetation. Among the green coverage rate and green space rate, the increase of green coverage rate is easier to implement relatively. Designers can protect the huge trees, and construct the tree-dimensional greening including vertical greening, green roofs.

2) Decrease the area of hardened ground. The results yielded from the present work show a negative correlation of the percentage of hardened ground with particulate matter. Designers can use lawn or other kinds of vegetation to replace
hardened ground to the largest acceptable extent. Besides, reduce the road area without affecting normal traffic is also a practical approach.

5.2. Outlook

The current work only focus on the percentage of these landscape parameters, and the further research will take their spatial form into account. Moreover, other influential factor such as temperature, relative humidity, wind speed should also be taken into considered.

Abstract

The increase in impermeable areas of land due to urbanization causes problems such as overflow and inundation during rainfall. Green roof reduces the speed of rainfall on the roofs. As a way of assisting in stormwater management to protect against urban flooding, it is necessary to develop green roof design elements, which contribute not only to the delay of stormwater runoff but vegetation growth, which benefits the ecological system. The purpose of this study is to develop the design elements for green roofs by evaluating both the stormwater runoff delay function and the plant growth function.

According to Korean landscape design standards (2013), green roof design elements include a green roof module, soil, and plants for stormwater management. First, using system dynamics modeling, a simulation is made of the effects of stormwater runoff delay on a building where a green roof module is installed. With evapotranspiration and infiltration as parameters, a stock-flow diagram is drawn to depict the stormwater runoff delay effect. Using the main parameters of the amount of evapotranspiration and infiltration, a stock-flow diagram is created showing the stormwater runoff effect. The temporal range of the model is 23 hours.

Second, the content of the bottom ash that has a delaying effect on stormwater runoff is evaluated. This can also provide a plant growth function. For this study, green roof modules were installed in a greenhouse, and the differences in the growth of \textit{Vitex rotundifolia} Linne fil., \textit{Pennisetum alopecuroides} (L.) Sprengel, and \textit{Sedum takesimense} Nakai in conventional soils (with a bottom ash content of 15\% bottom ash and 30\%) were analyzed. The plants were randomly arranged, and the greenhouse was monitored from 8 weeks in 2017. The statistical analysis of plant growth (leaf length, leaf width, height, plant height, chlorophyll content) was carried out using SPSS Ver. 23.0 at 5\% significance level.

The result of this study: First, comparing the cumulative rainfall and stormwater runoff using the green roof module, it can be seen that the rainfall occurs constantly at a slower rate than the existing rainfall after the end of the rainfall event. It was shown that the delay effect was about 16 hours. Second, in an analysis of effects of soil material on the differences in plant growth, a difference in length growth was observed, but there was no difference in chlorophyll content, leaf length, and leaf width. Therefore, 15\% bottom ash for all three plant types was the design element for both stormwater runoff delay and plant growth.
This study suggested green roof design elements to prevent flooding. Through the use of developed design elements, green roof is significant in that it is considered a social-ecological system in terms of flood prevention and plant growth. This study has limitations in that it does not provide logical modeling for the case in which the stormwater runoff delay effect for soil and plant materials is applied to the module. However, the study can contribute to the working design of a green roof as a practical way to improve urban resilience in the future.

### 1. Introduction

An increase in impermeable areas of land due to urbanization causes a decrease in the space where rainwater can penetrate the ground. This leads to a decrease in the peak runoff time and an overloading of the overflow path. In other words, the increase of impermeable land areas causes disturbances such as flooding in urban areas. The 259.5 millimeters of rainfall that hit Seoul in 2010 was the largest amount in 102 years [1]. The biggest cause of flooding was load due to the increase of the urban pavement, which is impermeable by rainwater. To solve this problem, local governments such as Seoul City are expanding the application of small-scale green infrastructure aimed at infiltrating urban areas. In the landscaping field, the LID facility is naturally constructed to induce penetration of the ground by rainwater. One example is the green roof. A green roof can cope with flooding by reducing the speed at which rainwater falls on the roof.

According to Korea Landscape Design Standards [2], the design elements of green roofs are categorized as facilities (modules), soil, and vegetation. In order to design a successful photovoltaic recording system, it is necessary to confirm how much delay there can be in the green roof recording module. The delay effect of a storm drain can be verified by a simulation model. Logical modeling can be performed using computer software such as STELLA, VENSIM, and Powersim to evaluate the main phenomenon of the system over time [3]. Modeling is expected to simplify complex systems related to storm drainage in urban areas and to quantify the effects of planned sites by identifying the impact variables. In addition, soil technology should be presented to ensure that drainage and growth conditions are good. In connection with this, a vegetation soil for rain gardens (Application No. 10-1674126) has been developed. This soil can delay the storm drainage time in artificial ground, such as in a green roof system [4]. Vegetation soil for rain gardens is a soil developed to improve permeability by controlling the mixing ratio of inorganic materials (bottom ash, vermiculite), which increases the porosity of the soil to the organic material (coco feet) of the soil. It is necessary to develop green roof design elements which include not only the stormwater runoff delay function in the social system but the vegetation growth in the ecological system. Most of the developed soils have been proven effective in improving permeability but have not been validated with regard to their use in growing plants.

According to Korea Landscape Design Standards [2], the organic matter content standard of general soil is classified as good (more than 5%), normal (3 ~ 5%) and low (less than 3%). However, this criterion is not the standard for artificial soil, and there is no proper standard for organic matter content of...
lightweight artificial soil such as green roof. The research on plant growth in artificial soil for rain gardens according to the organic compounding ratio is insufficient as compared with the study on proper water and salt [5]. Therefore, the purpose of this study is to develop the design elements for green roof by evaluating the stormwater runoff delay function and plant growth function. The results of this study can be applied to project implementation, which can improve urban regeneration from flood.

2. Methods

2.1. Stormwater runoff delay formulation

The indoor model was constructed to analyze the delay effect of stormwater runoff. The objective of the indoor model is to establish a basic model for evaluating the stormwater runoff delay performance of the storm drain module with the exception of environmental factors, such as monthly average temperature, wind speed, relative humidity, atmospheric pressure, and latitude. Stock-flow diagram of indoor models and values are show in Fig. 1 and Tab. 1.

2.3.2. Plant materials

The plant material was selected in four stages. First, 58 kinds of plants were selected through literature review. Second, 18 plants selected more than 2 times in the literature were selected and their growth characteristics were investigated. Third, seven kinds of plants applicable to use in green roof systems were selected according to OECD guideline 227. Then expert opinion was collated, and finally *Vitex rotundifolia* Linne fil., *Pennisetum alopecuroides* (L.) Sprengel and *Sedum takesimense* Nakai were selected.

The selected plants were planted on the module and directly irrigated through water irrigation, and they were observed through continuous monitoring once or twice a week. The temperature and humidity were adjusted to be equal to room temperature during the experiment. During the experimental period, the plant growth was measured with regard to plant height, leaf length, leaf width, and chlorophyll content. Leaf length and leaf width were measured by selecting 10 standard leaves in each experimental group, and the chlorophyll content was determined as an average value of 5 repeated measurements with portable chlorophyllometer (SPAD). Statistical analysis of each measurement data was performed by using the ANOVA test at 5% significance level using SPSS Ver.23.0.

3. Results

3.1. Stormwater runoff delay effect of LID module

In this study, the model was analyzed under the conditions of two rainfall events with 10-minute rainfall change from 00:00 on July 11, 2010 to 10:30 on July 12, 2010. The flow rate is set to 1 (mm / 10 min.) If the amount of storage in the module is 0, the flow rate is set to 0 if the storage amount is in the module. If the amount of rainwater stored in the module exceeds 100 mm. Finally, when there is no storm drain module, rainfall accumulated as rainfall, and 170 mm of rainfall was leaked for about 8 hours from 10:00 am to 17:50 pm, when rain first came down. The overflow occurred twice, at 13:20 and 17:50, and the efflux delay was 16 hours longer than the control.

3.2. Relationship between soil mixture ratio and plant growth

3.2.1. Difference in *Vitex rotundifolia* Linne fil plant growth according to soil mixture ratio

A one-way ANOVA was used to investigate the differences in *Vitex rotundifolia* Linne fil according to soil mixture ratio (Tab. 4).

Tab. 4. Result for difference in *Vitex rotundifolia* Linne fil plant length according to soil mixture ratio
It revealed significant preferences for plant height ($F=7.996, p=0.001$). A Tukey post-hoc comparison was used to determine whether or not there were any differences between specific groups. Differences were found between the bottom ash 0%, 15%, and 30%; however, there was no difference between soils containing 15% and 30% of bottom ash. Soil mixture ratio had no significant influence on leaf length ($F=1.654, p=0.204$). Also soil mixture ratio had no significant influence on leaf width ($F=1.541, p=0.226$). Finally, soil mixture ratio had no significant influence on chlorophyll content ($F=1.223, p=0.305$).

### 3.2.2. Difference in **Pennisetum alopecuroides** (L.) Sprengel plant growth according to soil mixture ratio

A one-way ANOVA was used to investigate the differences in *Pennisetum alopecuroides* (L.) Sprengel according to soil mixture ratio (Tab. 5).

Tab. 5. Result for difference in *Pennisetum alopecuroides* (L.) Sprengel leaf length according to soil mixture ratio

<td>18.09</td>
<td>3.939</td>
<td>c</td>
<td>3.677</td>
<td>.034</td>
</tr>
</tbody>
</table>

*p<.05

The ANOVA revealed significant preferences for plant height ($F=3.677, p=0.034$). A Tukey post-hoc comparison was used to determine whether there were any differences between specific groups. Differences were found between the bottom ash 0%, 15%, and 30%. Soil mixture ratio had no significant influence on leaf length ($F=0.501, p=0.209$). Also soil mixture ratio had no significant influence on leaf width ($F=0.227, p=0.798$). Finally, soil mixture ratio had no significant influence on chlorophyll content ($F=2.562, p=0.089$).

In case of three plants, there was difference in plant height growth, but there was no difference in leaf length, leaf width, and chlorophyll content. The length of the plant can affect the green roof landscape. It can be interpreted that the remaining growth...
is due to the green roof system because there is no difference between the control soil and the treatment soils. In particular, soil with 15% bottom ash was the most similar to the control group.

4. Discussion

As a result of the study, it was confirmed that the green roof module is effective in delaying storm drainage. The difference of length growth was also observed to be in accordance with the proportion of bottom ash as a result of the analysis of plant growth difference according to soil composition ratio. The bottom sole which added the bottom ash which can delay the storm drainage was finally selected as the improvement material for soil with excellent length growth (bottom ash added 15%). When the proposed soil modifier was applied to the rooftop greening, natural pressure was not generated and an excellent permeation rate could be provided. Soil modifiers containing 15% of bottom ash were also effective in promoting biodiversity.

This study can improve environmental ecology by selecting soil with an excellent plant growth rate. Also, it was possible to establish a design standard suitable for light green roof technology. Finally, there are two social implications. First, flood prevention and local water circulation recovery are possible through the effect of storm drainage delay. Second, to provide a space where people can relax and enjoy themselves, a beautiful soil improvement material can be developed to form a landscape.

However, there is a limitation to this study, in that the monitoring result and the simulation result cannot be converged on the bottom part. In further studies, the effects of plant growth should be included in the simulation model to verify more quantitative effects.

Re-branding Landscapes of Forgotten Resorts.

Case of the Healing Resort Kemerī in Latvia

Daiga Zigmunde\textsuperscript{ab}, Natalija Nitavska\textsuperscript{ab}

\textsuperscript{a}Latvia University of Life Sciences and Technologies, Department of Landscape Architecture and Planning, Riga Street 22, Jelgava, Latvia

\section*{Abstract}

The health resorts have been important landscape identity elements and economy drivers in European cities since the beginning of their development. The sea coastal area in Latvia is rich in sulphur springs that have been used for health procedures since 19th century. Kemerī resort in Jurmala City is known as unique place that got its name from the foresters house Kemeres where the first health procedures were performed by using sulphur spring mud. In the 1836 Kemerī was declared as a resort and became known in whole Russian Empire and later also in Soviet Union. There were significant landscape changes occurred after Latvia regaining independence in 1990, when ownership of the land changed from the state to the private. Affected by disagreements between the new owners, lack of private and state investments, decrease of visitors from former Soviet Republics, insufficient capacity for competing with European resorts, the resorts in Latvia often became abandoned and forgotten. Historically valuable buildings and parks of the resorts were degraded, number of inhabitants and visitors decrease. Today the regional government found opportunities for re-development of Kemerī resort by searching for the new identity and re-branding of the place. Re-branding has been used to enhance attractiveness of the place and increase economic benefits. Therefore the aim of the study is to identify historic heritage values suitable for the re-branding of the place and to analyse potential development of the resort Kemerī. Assessment part of the article is based on historic heritage study by comparison of historic and today photography, field surveys to identify historic heritage values of the place and their influence on possible development scenarios. Historic heritage values were identified according to the Historicity and authenticity; Aesthetic quality and integrity; Social meaning. Other part of the article is addressed to the re-branding of the place that includes involvement of identified historic heritage values into the new identity to enhance functionality, recognisability and attractiveness of the resort Kemerī.

\textit{Keywords}: forgotten places; health resorts; landscape revitalization
1. Introduction

Due to the impact of political and natural processes cities can become abandoned [1]. As the result population is decreasing, places are becoming forgotten and degraded. Most of cases it is caused by different political events – change of political power and regime, land reforms, wars; or natural factors – natural disasters, forest fires, flooding etc. [2]. Revitalization of forgotten and degraded places is a great challenge for local governments [3]. The article reflects revitalization project of the former health resort Kemeri in Jurmala City, Latvia by using re-branding principles.

1.1. Re-branding places

The common definition found in the different resources states that a brand is something that distinguishes one product from another in eyes of the customer [4]. This could be name, style, symbol, quality of product, process etc. [5] and involves some degree of expectations and imaginations. Place, city or town branding is a complex of activities – planning, producing, governing and promoting specific and unique objects, products, activities in order to compete with other places in attracting of tourists, investments, new residents, national and global events etc. [6].

The re-branding is more related to the territories that have lost their identity and attractiveness due to some specific reasons. Therefore the main aim of the re-branding of places is to shape a new identity and to promote economic potential of the area [4]. There are different types of re-branding according to the scale of the place (national, city, town, village, and place) or some specific values of the area (agriculture, nature, healing potential etc.) [6].

1.2. Forgotten health resorts in Latvia and the need for re-branding

Mud and hydrotherapeutic resorts in Latvia have more than hundred-year history. Till the 90s of the 20th century most of them were oriented to the tourists from the Soviet Union. There were operated 9 resorts, more than 30 sanatoriums and spa institutions in the coastal city Jurmala. After Latvia regained independence in 1990 the business of health resorts decrease. Today we can found only 4 actively functioning specialized sanatoriums in Jurmala. Reasons of the decline mostly connected with political factors [2]. Those are change of ownership from the state in Soviet period to private, political decisions about non-investment of EU funds into re-branding and redevelopment of Latvian heath resorts, low competitiveness with European resorts due to the poor comfort level that required major repairs of buildings and infrastructure [7].

The aim of the particular study is to identify nature, culture and social values suitable for the place re-branding and to analyse potential development of the resort Kemeri in correlation with the main principles of re-branding.
2. Materials and methods

2.1. The research area

The study observes former health resort Kemeri in Latvia. Kemeri resort is a part of Jurmala city located in the sea coastal area of the Gulf of Riga (Appendix 1). Total area is 13.8 km2, inhabitants - 1962. Kemeri resort has important mineral water and therapeutic mud resources that were economic drivers for the resort since the end of the 19th century [7].

Since 1836 Kemeri was well known as the healing resort in whole Russian Empire and later in Soviet Union. Number of visitors reached 21 000 in 1965, when there were 8 sanatoriums and 29 operating sulphur springs [10].

After Latvia left USSR in 1990 Kemeri resort met the same problems as all resorts in Latvia, and soon it became forgotten and started to get degraded [2]. Today Kemeri resort is facing new challenges to become one of the brands of Latvia again.

Kemeri resort has several statuses. It is a monument of the state importance of city building. Park of Kemeri resort and several historic buildings and elements located in the park are monuments of the state importance of architecture [10].

2.2. Methodology

The re-branding of Kemeri resort is based on enhancement of economic potential of the place by promoting its visibility in local and national market, attracting tourists, investors and potential inhabitants. The methodology of the re-branding of Kemeri resort included:

1. Identification of nature, culture and social values of the place existed in the past and today by comparison of historic photography and maps with today’s situation in Kemeri resort [1][11][12]. The aim of this activity is to evaluate potential impact of detected values on the development of the place and possibility to use them into re-branding of Kemeri resort. Values were evaluated according to the attributes [8][9]:

1.1. historicity / authenticity represents connection between the past and today. Those are all elements that are representing important nature processes (example, still existing oak forest, swamp, sulphur springs) or human activities (buildings, network of streets, artificial water elements, terrain, greenery etc.) and still can be found in the area.

1.2. integrity and aesthetic quality represents harmony of historic elements especially from different historic periods. Activity includes evaluation of composition, scale, proportions etc. of materials, greenery system / design, architectural elements, landscape spatial structure remained from different periods. Activity helps to find out best solutions for the development of place and to detect which elements should be highlighted and used for re-branding of the place.

1.3. social importance shows to what extent the place symbolizes events, elements, activities and traditions important for local / national community. Social importance is evaluated in the context of similar places of local, regional or national importance. What was more different and unique in development of particular place and how to make it more visible? The most difficult part of this activity is to choose which of historic periods will be base for
the new face of the place. Will those be elements most remained for one of the historic periods or some specific and unique separate elements?

2. Use of identified nature, culture and social values in additional with new functions for development of new image, identity of the place, re-branding of Kemeri resort.

Each of identified values are evaluated according the main principles of re-branding – to promote place as tourist destinations, attractive place for investors and potential inhabitants. How detected values are important in re-branding process? And how they could be used to make the re-branding more effective?

3. Results and discussion

3.1. Key elements for re-branding Kemeri resort

Key elements for re-branding Kemeri resort are grounded in the origin of the resort. The research on historic information showed that the key elements of the origin and development of the resort were in Latvia unique sulphur springs, as well as natural environment and elements – forests with oak-trees (*Quercus robur*), linden (*Tilia cordata*), elm trees (*Ulmus glabra; Ulmus laevis*), and ash trees (*Fraxinus excelsior*), small rivers, lakes and swamps. First healing activities with the use of mud and mineral water from sulphur springs were dated to the beginning of the 19th century. At that time patients also used local forests for walks and other activities. Based on the long history of use of nature resources in Kemeri area they are highlined as identity and brand elements of the place also in the revitalization and re-branding project of Kemeri resort.

3.2. Old streets and directions – the base for the main axes of the resort landscape

Till the end of the 20th century Kemeri resort has grown from a few buildings into a town with good infrastructure and connectivity with the largest cities of Latvia. Old streets became important landscape elements as they represented history of development of Kemeri, marked main directions and determined the compositional structure of the landscape. It is possible to find remains of the town structure also in nowadays (Appendix 2). One of the important axis in the past and also today is Tukuma Street. It was the main linkage to the rail way that connected Kemeri to the Riga (capital of Latvia) and even Russia. Also today Tukuma Street is one of the central compositional axes in Kemeri resort complex. Robezu (in English - Border) Street represents old border area between Courland Governorate and Livland Governorate (1795-1918). We can find Director`s Street in the Kemeri park area. In the 19th century it directed visitors of the resort to the main building and divided central park of the resort into wild and “cultivated” parts. Alley Street is reflecting long history of planting alleys in Kemeri resort.

The main old axes and directions are kept as linkages with the history and roots of the place also in the revitalization project of Kemeri resort.

3.3. Historic buildings with new functions

Kemeri town got its status as a resort in 1836, but development peak of the town was the beginning of 20th century. At that
time there were different type and size bath buildings, post office, Catholic, Lutheran and Orthodox churches for visitors of different confessions, more than 200 summer cottages, 12 pensions and hotels [10].

After World War I most of buildings and park were destroyed, but very soon the resort again was one of the most demanded in the Latvia. At that time Kemeri has own power and water supply, sewerage system. Also, today one of the landmarks of the resort is 45 meters high water tower. In the past water tower had two reservoirs for drinking and sulphur water, and sightseeing platform on the top [10] (Fig. 1.).

There are several architectural elements that are promoting attractiveness of Kemeri resort. Those are pavilions, small bridges, benches, sculptures etc. (Fig. 3). One of the most famous architectural elements of the Kemeri park is monument (1896) in shape of the tree dedicated for the first directors and developers of Kemeri resort (Fig. 4.).

In the revitalization project of Kemeri resort main important buildings are planned to use as visual landmarks of the place. Functions of building will be supplemented or change to new according to the arrival of new technologies and needs of visitors.

Other land mark of Kemeri resort is Kemeri hotel’s white building that was built in 1936 and provided different activities throughout the year (Fig. 2.). When number of visitors from former Soviet Republics decreased, most of buildings for sulphur spring mud therapies were not used anymore and become degraded [10].

In the revitalization project the water tower will not be used as water reservoirs anymore, but provide tourists information

Fig. 1. Bath buildings and water tower on Tukuma Street, 1936 [11]

Fig. 2. White building of the Kemeri hotel, 1936 [10][12] and 2017

Fig. 3. Love Island with rotunda pavilion, 193- [10] and 2017.

Fig. 4. Love oak tree (not exists)[10] and monument for the first developers and directors of the resort Kemeri, 2017
centre, exhibition place and a view platform. Kemeri hotel besides hotel functions will serve new ones – place for conferences and seminars, spa and sports area etc.

3.3. Green spaces with high biodiversity symbolizing environmental quality for good health

Positive effects on patients from forests of Kemeri resort are described by several authors. Forests of Kemeri resort were formed as landscape parks by supplementing them with a large number of introduced species of trees, shrubs and perennial plants. Diversity of plant material was initiated and provided by first gardener of Kemeri resort, owner of the Riga nursery - K.H. Vagners (1785.-1846.) [10]. Diversity of plant species is kept also in the revitalization project of Kemeri resort for better connection with existing nature of this place.

Other important elements are alleys and hedgerows. In analyses of historic literature and photos it was found that almost all streets and pedestrian trails are enclosed with alleys and hedgerows of different species of trees, shrubs and perennial plants (Fig. 5.). Today old alleys and hedgerows are in low quality because of poor maintenance during last 25 years.

Historic materials show that since the beginning of 20th century there were two types of green spaces in Kemeri resort – urban forest with pedestrian trails and wild vegetation; and “cultivated park” with a large number of introduced plants. Trends of that period were thuja trees (Thuja) and white robinia trees (Robinia pseudoacacia) that can still be found in the park areas of Kemeri resort. Diversity and colourfulness of the Kemeri park’s greenery as positive and unforgettable elements are highlined in many evidences of that time [10].

New tendencies in the design and composition of the Kemeri park arrived together with Kemeri hotel built in 1936. According to the architectural style of the building the composition of the plantings is developed in the style of classicism with symmetrical design of ornamental parterre in front of the hotel and bath buildings. Plantings of the style of classicism could be read only from historic photography. Today in the park and near buildings we can find plantings designed in 1960. They have typical for that time attributes – large and irregular areas with perennials, ground covered by concrete plates, decorative retaining walls from stone (Fig. 6.).

Last 25 years Kemeri resort was left without any significant interruption to its development. It is affected the green spaces of Kemeri resort both ways.

It is positively that we can find old, beautiful trees and great biodiversity, but there are also many problematic places – broken and unsafe infrastructure elements, overgrown plantings, tree seedlings have grown as big trees and overshadow park area.
The revitalization project of the park of Kemeri resort is based on compromise between design of the classicism that is more appropriate for the architectural style of the Kemeri hotel, and existing diversity of plants that can be found in the park area nowadays.

3.4. Landscape for active participation

Kemeri resort since its foundations had not only healing function, but also provided different activities for patients after their therapies. First of all those were activities in the nature – walks in the forests, sunbathing, sport activities etc.

Since the end of the 19th century there were developed indoor and outdoor spaces also for entertainment activities, music, dancing, reading, gaming, restaurant and library [10].

After World War I the café was located on the Love Island with access to the water channels. At that time channels of small river Versupite were suitable for boating. The set of water sluice gates was built for this purpose. Today this system is not working anymore (Appendix 3).

In 30th of the 19th century international chess competitions were organizing to promote Kemeri resort. In historic materials we can found that social activities were important elements of the identity and recognisability of Kemeri resort (Fig. 7.).

3.5. Revitalization and re-branding project of Kemeri resort and its park

Due to specific conditions of Kemeri resort that are connected with different historic landscape layers found in the area, the re-branding and revitalization project of Kemeri resort divides the area into four parts – ornamental parterre’s part in front of the Kemeri hotel building, active part, forest park part and forest wild part (Fig. 11.). Each of the parts has its own specific attributes, as well as requirements for
planning, protection and management.

The Active part of Kemeri resort park is more opened visually and functionally, but still has clear composition and spatial structure that corresponds to the historic period of its development. Alleys, hedgerows, flowering and colourful plantings are used to establish connection with the historic values of the place (Fig. 10). There are new functions added to this place – exhibition and entertainment squares, recreation places, children playground.

The Ornamental parterre is made as one unit with the Kemeri hotel and is planned as one of the landmarks of the resort. Design of the green space is based on the symmetry and includes plantings with formed hedgerows and flowering plants, as well as architectural elements – benches, sculptures etc. Flowering plants are reflecting white colour of the building of the Kemeri hotel. As compromise there are left existing old trees that were not in the original plan (1936), but now can be found in the area and influence new design of the ornamental parterre (Fig. 9.).

The Forest park is “cultivated” part of the forest with open spaces, groups of trees, cultural heritage objects and elements – Love Island with rotunda pavilion, Orthodox church, bridges, monument for the first directors and developers of the resort.

Fig. 8. Kemeri resort and park areas, where 1. - ornamental parterre, 2. – Active area, 3. – Forest park, 4. – Forest “wild” area, 2017 [13]

Fig. 9. Ornamental parterre with the symmetrical structure and a large number of perennial plants, 2017 [13]

Fig. 10. Active part with central composition axis with the water tower and alleys, 2017 [13]

Fig. 11. New design of Love Island with rotunda, 2017 [13]
The main function of the Forest park part is to connect the Active part and Forest “wild” part of the park.

The Forest park keeps the historic structure of the landscape and nature values – diversity of local plant species, river Versupite with natural banks, old trees and groups of trees, specific habitats for bats and insects (Fig. 11.)

The Forest “wild” part is spatially closed forest area with separate open spaces, pedestrian trails and architectural elements. This part will be kept as natural biotope for highlighting nature values of Kemeri resort.

4. Conclusions

The landscape of Kemeri resort is changed several times influenced by the political processes, ideology and trends of the historic periods. However the mental image of the place was always determined by presence of sulphur springs and their use for medical therapies, but the visual and spatial image of Kemeri resort - by nature values (a large number and diversity of plant species, where next to the native species were introduced new ones, used large number of perennial plants, alleys and formed hedgerows) and cultural heritage of the place. Therefore nature and heritage values are defined as one of the key and brand elements for new identity of the place.

Other key elements for the branding of Kemeri resort are old streets and historic directions that can be used as connection between the past and today, and base for composition and spatial structure of Kemeri resort landscape.

The most problematic issue was how to make unity between the landscape elements of different historic periods and styles. Each of the time periods has left its mental message. Therefore new image of the place is developed as a compromise between the elements of different historic periods. The composition and landscape structure is developed in the style of classicism taken from the development time of the Kemeri hotel, but principles of plantings are used from the Soviet era where large number and diversity of plant species was used.

The social activities also are key elements for the re-branding of the place. We can find them already from the origins of Kemeri resort. Social activities will provide extra interest from possible visitors to experience the place not only for medical therapies but also for living and working.

LWCircus Shared Operative Program, Landscape Design Methods based on Social Practices for an Inclusive and Resilient Urban Future

PhD. Annacaterina Piras
LWCircus-ONLUS, Via De Pandolfini 12, Firenze 50122, Italy

Abstract

The shared collective urban practices, such as opportunity on the production of symbolic space through ephemeral expressions, both in landscape and urban contexts, dominate within the research’s areas that deal with project of the city. Wanting to push further along the boundaries of the disciplines directly interested on the future of our contemporary cultural landscapes, inside urban and rural contexts, during 2016 born LWCircus International Program. Focused on experimental methods and strategies of design based largely on social and cultural practices on the field, LWC aims to enhance sensitive areas inside cultural heritages and redesign contemporary urban landscapes under environmental, social and economic transition. The first two editions of the Shared-Operative Workshops called LWCircus-ArnoLabs, have been held in Florence, from 21st till 30th of September 2017 and from 23rd May till 3rd June 2018, creating ephemeral installations, as light urban furniture, staging points, temporary shelters, realized on site by the revisitation and assembling of recycled natural material transported by the changing Arno River’s moods. A temporary international, multi cultural and multidisciplinary creative community has tested fruitfully on the field shared practices by using multimedia languages, artistic approaches and performative-spontaneous attitudes in the specific urban context, with the direct involvement of local actors and public institutions responsible for the River's management and safeguard, looking for a RESILIENT and INCLUSIVE urban future, in terms of responsible cultural valorization and sustainable development for the local community and the diverse minorities directly involved in each step of the operative shared process. The Shared Process among Arno river banks gave life to a series of ephemeral installations and performances realized by recycling of natural elements collected on site coming from the natural Resource and the skills and attitudes of the participants to the Activity. A group of young refugees, temporary hosted in the Florentine context, invited to join the international creative group, worked profusely highly animated to design and realize the series of installations, sharing wishing and hopes with the rest of international participants and the locals, becoming temporary part of the local community and starting a process of social inclusion that gave life to successive opportunity for further inclusion on the local realities. The locals sharing the process in conceiving and realizing the works, started in look at the others in different way, transmuting the concept of others in the feeling of us, by the sharing of the entire process. Work reported would love to give a contribute inside the evolving of the traditional figure of the landscape architect to a sort of “landscape facilitator” as well as to the Landscape Architecture Discipline, underling the operative shared method as fundamental and intrinsic part of the design process in itself.

Resilient Inclusive Urban Future; Operative Landscape Design Method; Social Practices
1. Introduction

Nowadays, where we are even more called to manage complexity, made by crossing confused fluxes of people, goods, informations and energies that provokes irreversible changes affecting our planet, the landscape itself becomes the unintentional protagonist suffering the imminence of the events.

Thanks to these events, that contribute to the depletion of the resources and to the increasing soils's impoverishment, the landscape could be considered a privileged point of view from where to study all the consequences that those changes provokes in terms of transformation and proliferations of opportunities, as well as a value for the landscape itself, for the people and for the resultant new cultural landscapes, be they new energy or emergency landscapes, composed by their new temporary communities.

Among the swirling whirl of these flows and changes, I think that an interesting and in some how "salvific" attitude, as a regained point o reference, would be to try to rediscover the sense of the places, even inside the immanence of the temporariness. This will permit to read trough different layers that contribute composing the sophisticated mosaic that makes the place itself, deeply understanding its genius loci to valorize and manage the new cultural landscape in its complexity. Doing this, it will be fundamental to understand the deep sense of the quite abused word sustainability, to learn how to manage the landscapes together with either locals or temporary inhabitants.

To achieve the results in this process of understanding the dynamics, relationships, customs and traditions that deeply link the locals or the temporary inhabitants to their landscapes, it will be fundamental in the field of our discipline to undertake, as much as possible, an operative, spontaneous, multicultural and multi disciplinary, ephemeral approach, all as precious and useful attitudes able to solve the problems linked to the complexity of our new contemporary transitional landscapes.

So, it will be strategically important to test the boundaries of the Discipline, trying to find as much as possible an interaction with the other correlated topics as art, design, architecture, as well as anthropology, sociology together with science, biology, geology, among the others, but it will be important also to take in consideration the politics, international cooperation and environmental and human resources management studies, that could help in shaping a new declination inside our traditional practice.

In this way, it could be possible to stimulate and activate a new perspective that approach the traditional practitioner toward a figure of a landscape's facilitator, transforming the landscape architect in a sort of translator, acting as mediator between all referents interested in the landscape, be they local people, temporary communities, local Administrations, as Civil Protection, Forest Rangers or even Military Forces.
At this time, I think that we need to look for a different method, as well as a different way of making school of landscape architecture. To satisfy another kind of request, that needs to test on site the management of the contemporary cultural landscape's complexity, conscious that nowadays there are different exigencies in reading, analyzing and redesigning the places. It will be necessary a new way of teaching how to manage and solve the problems linked to the new under-transition realities.

Then, it will be necessary to test in the field the exigency to involve different disciplines at the same time and to introduce a shared approach, involving group of experts with completely different attitudes on the landscape design, intending the operative method as an intrinsic necessity of a deep link between the theory and the practice inside our Discipline. It will be necessary to feel the urgency in solving the problem on site when it appears and when it happens, finding the best solutions as soon as possible, being able to act with an high speed proportional correlated to the dynamics and the different fluxes mentioned before.

Inside the process to define a new methodology, it will be definitely crucial the participation of the locals together with the experts, because if participation is the main strategy to achieve the best result, *a fortiori*, the sharing will be fundamental inside the particular social-economical conditions that feature the contemporary landscapes.

So, sharing the project together with all the actors interested to the investigated places or landscapes and assigning roles and competences to let feel the project their own responsibility, until this will make feel them affection for the gained results, it could be a fruitful way in discovering an effective and virtuous new method.

Making others feel like a fundamental part of achieving the result, could be a successful strategy that could help to achieve great results in a very short time, as possible solutions for temporary or transitional situations, such as those that can generally be observed, inside of our altered and mutable contemporary landscapes, especially if addressed to urban contexts.

On the heels of the shared collective urban practices, such as opportunity on the production of symbolic space through ephemeral expressions, both in landscape and urban contexts, dominate within the research’s areas that deal with project of the city and wanting to push further along the boundaries of the disciplines directly interested on the future of our contemporary cultural landscapes, inside urban and rural contexts, during the year 2016 has been created the *LWCircus International Program*.

1. Objectives

Just as it is not possible to talk about the city without thinking of the people who compose it, in the same way it is not possible to talk about the resilience of the urban landscape, without going through social inclusion. Nowadays our cultural landscapes are not only the stratification of that sophisticated socio-ecological mosaic
that has overlapped over time, but are the result of a vortex of flows of people, goods and services that cross it, leaving a multitude of signs, open, more than ever, to multiple interpretations.

Within the disciplinary framework, we are witnessing a flourishing and proliferation of participatory urban practices, which contribute to the urgent and spasmodic search for answers regarding the community construction of places of meaning, a fundamental characteristic of the city's project. Thinking of a sort of renaissance within the urban landscape, the research at the base of the **LWCircus International Program**, with the devices of the ArnoLabs **Shared Creative Workshops** in particular, focuses on experimentation through artistic and multimedia languages, which through the medium of art in the landscape, can give back meaning to places and reconstruct those ways of living and enhancing the landscape, typical of the times when communities actively contributed to the construction of their cities.

To this direction is addressed the research within the **LWCircus Project**, deliberately based on a necessarily participatory formula, which sees through close cooperation, local communities with their minorities, to work in urban landscapes in prestigious environments, to share and build places of exchange and interaction, towards social inclusion, giving rise to ephemeral installations between art and landscape, towards what we can define *Urban Land Art*. In all this, the protagonists are the places and people who interact with it in various ways, local communities, minorities of various typologies, including political refugees and asylum seekers, administrators appointed to their management, who are solicited by a multidisciplinary and **International Creative Community**, through the use of artistic and multimedia languages, to revisit the historical memory of the places concerned, towards a plausible future increasingly resilient and inclusive.

## 2. Methods

Focused on experimental methods and strategies of design based largely on social and cultural practices on the field, **LWCircus Program** aims to enhance sensitive areas inside cultural heritages and redesign contemporary urban landscapes under environmental, social and economic transition.

**LWCircus Program** looks for alternative tools and devices to activate sustainable development and responsible action through operative shared workshops, through the direct involvement of local communities, minorities and well known international practitioners. The workshops stimulate the interdisciplinary exchange of knowledge, information, attitudes, skills and real-world know-how through artistic expression and multiple forms of media.

**LWCircus Program**’s outcomes aim to an integration, a cultural and economic development for local inhabitants and minorities involved.

The first two editions of the **Shared-Operative Workshops** called **LWCircus-ArnoLabs**, have been held in Florence, from 21st till 30th of September 2017 and from
23rd May till 3rd June 2018, creating ephemeral installations, as light urban furniture, staging points, temporary shelters, realized on site by the revisitation and assembling of recycled natural material transported by the changing Arno River’s moods.

During both the Florentine editions, a temporary international, multi cultural and multidisciplinary creative community fruitfully tested on the field shared practices by using multimedia languages, artistic approaches and performative-spontaneous attitudes in the specific urban context, with the direct involvement of local actors and public institutions responsible for the River's management and safeguard, looking for a RESILIENT and INCLUSIVE urban future, in terms of responsible cultural valorization and sustainable development for the local community and the diverse minorities directly involved in each step of the operative shared process.

3. Results

The Shared Process among Arno river banks gave life to a series of ephemeral installations and performances realized by recycling of natural elements collected on site coming from the natural Resource, and the skills and attitudes of the participants to the Activity.

For both the editions, groups of selected young refugees, coming form Niger, Senegal, Mali (ArnoLab017), Burkina Faso, Ghana, Gambia and Bangladesh (ArnoLab018), survived crossing of Mediterranean, coming from Libya and temporary hosted in the Florentine context, were invited to join the rest of international creative group (coming from Mexico, China, USA, Australia, Lebanon and Syria, Colombia, Venezuela UK, Holland, France, and Italy). They worked profusely highly animated in designing and realizing the series of installations, sharing wishing and hopes with the rest of international participants and the locals, becoming temporary part of the local community and starting a process of social inclusion that gave life to successive opportunity for further inclusion on the local realities.

The locals sharing the process in conceiving and realizing the works, started in look at the others in different way, transmuting the concept of others in the feeling of us, by the sharing of the entire process.

The focus of the experimentation within the LWCircus Program is to link the actors, for various reasons, deputies to managing the landscape component of contemporary urban contexts, through shared creative workshops, such as the ArnoLabs in Florence or the MayaLabs in Merida, Yucatan, intense experiences where the different fields of belonging of the protagonists are disparate and the multidisciplinary and multicultural component is fundamental, for the empirical experimentation on the field and the subsequent phase of observation and evaluation of the results: as possibility of production of symbolic space through occasions of ephemeral expressions, which contribute to generate space of knowledge and relationship, fundamental characteristics of the city's project.
4. Conclusions

Work reported would love to give a contribute inside the evolving of the traditional figure of the landscape architect to a sort of “landscape facilitator” as well as to the Landscape Architecture Discipline, underling the operative shared method as fundamental and intrinsic part of the design process in itself. Making feel the others as a fundamental part to achieve the result, it resulted a successful strategy that helped in permitting to achieve great results in really short time.

Wanting to go further, the work, by implying the sharing of the project together with all the actors interested to the investigated places or landscapes, by assigning roles and competences to let feel the project their own responsibility, until this will make feel to them affection for the gained results, contributes in illustrating a fruitful example in defining an effective and virtuous new method, that can help in approaching solutions for the under transition and mutable contemporary cultural landscapes, emergency landscapes, composed by their new temporary communities.

Redefining An Abandoned Old Aqueduct System
As Green Infrastructure

Akihiko Ono\textsuperscript{a}, Yerin Kim\textsuperscript{b}

\textsuperscript{a}Nagoya City University, 2-1-10, Kitachikusa, Chikusa, Nagoya-city, Aichi, 464-0083, Japan

Abstract

Through our research, we realize the abandoned old aqueduct system, Tamagawa aqueduct in Tokyo, has potential to play a role as green infrastructure to prevent flooding in the river, Tamagawa. Tamagawa aqueduct was used for drinking water in Edo and Tokyo city from 1653 until 1965. The water of Tamagawa aqueduct came from Tamagawa river. The aqueduct had 33 branches to offer drinking and irrigation water to center and suburb of Edo. Main stream of the aqueduct is now preserved as the national historical heritage. However, drinking water system changed to piping from open ditch so that most parts of the aqueduct lost its function. After the history of the aqueduct ended, the aqueduct ditches which treated sewage water flows through are still preserved but with not good maintenance. Actually it is not completely clear who control the aqueduct. On the other hand, recently Tama river have risks to flow over the center of Tokyo because of unexpected heavy rain. So we point out to potential to reuse the aqueduct as bypass of Tama river. The aqueduct system has not only ditches but also many garden ponds which has potential to reserve water. This proposal is important for not only flooding but also purificating dirty water in Edo castle moats as isolated water as the aqueduct connect to Edo castle from old days. This aqueduct is already lost traditional functions but still useful for future resilience in the city.

Keyword: Civil Engineering Heritage; Tamagawa aqueduct; Green infrastructure

1. Introduction

This research aims to redefine the abandoned historical water network as green infrastructure of the dense complicated city. It focuses on Tamagawa aqueduct network in Tokyo, Japan. Tamagawa aqueduct was used for drinking water in Edo and Tokyo city from 1653 until 1965. The water of Tamagawa aqueduct comes from Tama river. The aqueduct had 33 branches to offer drinking and irrigation water to center and suburb of Edo. As drinking water system changed to piping from open ditch, most parts of the aqueduct lost its function. After the history of the aqueduct ended, the aqueduct ditches which treated sewage water flows through are still preserved but with not good maintenance. At this moment, eight branches (Tamura, Kumakawa, Haijima, Shibasaki Nobidome, Sunagawa, Shinb ori, Senkawa) remain. Main stream of the aqueduct is now preserved as the national historical heritage. However, few fragments of branches are preserved by
municipalities. Actually it is not completely clear who control some sections of the aqueducts.

On the other hand, Tamagawa aqueduct network is payed attention because rare green corridors in complicated city, Tokyo. Some researcher suggest potential to purify the outer canal of Edo castle[1]. It is right now to need to redefine Tamagawa aqueduct network as green infrastructure with background Tama river increase risks to flow over the center of Tokyo because of unexpected heavy rain. So we point out to potential to reuse the aqueduct as bypass of Tama river. The aqueduct system has not only ditches but also many garden ponds which has potential to reserve water.

In history of Tokyo, actually, “Tokyo green plan in 1939” defined Tamagawa aqueduct network as green corridor as parts of green infrastructure[2]. Tamagawa aqueduct network has potential to connect inner city to outer city of Tokyo. However, this plan was never implemented.

Most of previous research focuses on historical process of main stream and few researcher points out Tamagawa aqueduct as network. K.Kosaka point out whole network’s detailed history and K. Watabe draw sections of some branched to show us spatial composition of canals[3] [4]. However, these researches do not describe connection between canals and surroundings in terms of spatial composition.

2. Objectives

Through the observation mentioned above, this research aims to reveal spatial connection between green spaces and canals to try to recognize Tamagawa aqueduct

Fig. 1 Tamagawa aqueduct network
network in terms of function as green infrastructure. This research focuses on function of water network.

3. Methods

To clarify the relationship between green spaces and canals in Tamagawa aqueduct network, we take the following steps.

3.1 Surveyed site

Eight branches in Tamagawa aqueduct network are chosen for the research on the basis of existing in open ditches: Tamura, Kumakawa, Haijima, Shibasaki Nobidome, Sunagawa, Shinbori, Senkawa. Main stream is not surveyed because it is prohibited to enter and there is no park and no garden.

3.2 Surveyed green space

In this research, garden is defined as green spaces in private area. Gardens with flow of canals are selected by observation in field survey and map survey. On the other hand, park is defined by municipality information. It includes also green road in the law. Park alongside flow of a canal are selected by observation in field survey and map survey.

3.3 Field survey

The overview of these green spaces are found out from maps by the government. However, it is not clear enough for observation of detailed connection to green spaces and ponds. Some private area need permission to enter for surveys.

3.4 literature research and Interview

Literature research and interview to owners and municipality are also necessary to understand how to construct green spaces alongside a canal. Especially, we try to clarify the reason to construct ponds and history, process.

4. Connection between green spaces and the canals

Through observations, 73 parks (public green) and 16 gardens (private green) are placed alongside canals. In only 15 spots (17%), water of canal are used to water reservoirs. In other spots, canals are ignored with fences and shrubs as spatial composition of green spaces [Table.1]. In these cases, mostly canals flow at the edge of the spaces, so that people rarely notice a canal flows there. 64% green spaces have fence between sites and a canal to prevent people from entering water to gain risk to drown [Table.1].

Now private green spaces alongside canals are less than public green spaces, however, some documents describe some gardens existed before. At this moment, it is not clear how many gardens existed where water of a canal is used because any documents describe no detail of garden. Most of cases, demolishing a branch of canal is trigger to demolish gardens.

In terms of branches, Shinbori branches, which has also many branches, has 53% green spaces alongside the canals, especially Ogawa branch (Shinbori branch’s branch) (28%) [Table.1].

5. Ponds and urban structure

Through observations, 6 ponds exist in gardens and other 9 ponds exist in parks[Table.1]. Ponds in gardens are separated from canals and water are taken from a canal at nearest points of garden and finally return to a canal as bypass. Ishikawa garden and Tamura garden were constructed to their guest to their family’s Sake factory in Meiji era. Old photos and drawing of Ishikawa garden and Tamura garden and Heirinji temple garden remains. However, history of other 3 gardens is not clear.

On the other hands, ponds in parks have following 2 types; 1) separated from a canal 2) enlarged ditches with direct connect[Table.1]. These ponds are used for biotope or touchable spaces with stairs to a a canal. Ajisai park and Ogawa ryokuchi park have gates to control water intake.

Analyzing relationship between these ponds and branches, branches which have ponds in gardens do not exist park with ponds, except for Tamura branch. This reason can be related to urban structure and size of lots. Tamura, Kumakawa, Haijima, Nobidome, Shibasaki, Senkawa branch flows in area of non-land readjustment. These area’s lot are different size by topographical reason, so that some landowners have large enough to construct garden ponds. On the other hand, Shinbori, Sunagawa branch flows in center of area of land readjustment. These area’s lot are generally narrow width to main street and a canal and long depth. It is too small to construct gardens however, it is suitable for municipality to buy land alongside canal to construct parks.

6. Planning for canals and surroundings

Through interview to municipalities, only Kodaira city has practical planning to canals in Kodaira city; Shinbori and Sunagawa. Most powerful trigger is “Kodaira city canal plan” in 1995. This plan is based on survey in 1992. The survey clarified following problems; 1) drought 2) disconnection 3) less attractive 4) water quality. Based on this results, this plan represent practical plan with many drawings at the specific sites with evaluation. Finally six proposal have completed in 18 proposal included in the plan.

7. Conclusion

Through analyzing the relationship between green spaces and canals, this research clarifies that there is different connection between green spaces and canals related to urban structure and municipality planning. More detail is the following:

1. Most of green spaces on canals are no connection to canals with fences
2. Ponds in garden with canal water are only observed in area of non-land readjustment
3. Practical planning and studies by a municipality is a trigger to make new connection between a park and canals.

The previous studies on this canal network focus on historical surveys and water quality. On the other hands, this research reveals potential sites to reserve water in the network as new definition of an abandoned aqueduct system. The aqueduct has already lost original functions, but it is
still useful for future resilience in the city. However, at this moment, as every canal just flow straightly to fields and there are few water reservoirs in the canal network to reduce risk of flooding of Tama river, it is still important to construct water reservoirs to renovate exiting parks on canals.

These results clearly indicate the necessity of concerning whole planning of network of Tamagawa aqueduct canal system to think future of Tokyo, based on researches of historical background. As S.Terai suggests in their research, if the network extends to outer canals of Edo castle, it helps to purify water quality of outer canal of Edo[1]. Increasing ponds connected to the network, it can help to preserve rare animals and plants in Tama river as S.Ito suggests in their research in Biwa lake aqueduct[5]. These research insists that it is important to approach from not only disaster reduction but also ecological viewpoints to develop planning of Tamagawa aqueduct network.

Han river masterplan: three resilient landscape strategies

Steven Petit*, Carolien Decq

Design Office OMGEVING, Uitbreidingstraat 390, 2600 Antwerp-Berchem, Belgium

Abstract

Three general resilient landscape strategies have been integrated into the design of a masterplan for the Han river, which runs through the Da Nang city centre over a length of seven kilometres. At this scale, a rehabilitation of the natural riverbanks will be combined with a diverse program within the public space, connected by an extensive recreational network of pedestrian paths. Using these paths on the riverbank, the deck paths over the water and the water-taxi stops, you can reach floating river nature, a floating market, a city park, an urban sport park etc. The integration of four public buildings adds to the public nature of the river as a whole: from north to south over the whole length of the river, a new opera building, a waterhub building, a redesigned market hall and a concert hall will be built. The combination of a landscape and architectural design makes for a high quality and diverse riverfront. Increasing the (semi-) public program alongside the river, creates support and involvement with the public to appreciate the investment in an ecological upgrade of the river delta. The masterplan will be the solid base to manage the rapid development of the city up to 2030.

To implement and to realize the three resilient landscape strategies the following keystones are important: set up a logical phasing with a range of short, medium and long term initiatives and identify funding resources for operational costs.

- Phasing: The flexibility of the vision and the planned initiatives increases as the scale and the implementation period increases. At the same time, new insights on the different scale levels can influence and interact with the other scale and implementation levels. This flexibility and interaction is important for community supported plans and projects. Design Office OMGEVING also selected a specific, strategic site to develop a catalytic project that is implementable within the short term and can kick-start long-term change.

- Funding resources: Design Office OMGEVING suggest some primary types of potential funding sources: enterprise revenues; local government funding; republic government funding; public-private and private funding. Each source comes with a series of challenges and opportunities.

steven.petit@omgeving.be
1. Representative challenges for growing Da Nang and its Han river

Like in many South East Asian cities, Da Nang is growing fast. Vietnam’s urbanization rate up to 2009 was about 30%. Several research organizations expect a rise from 35% up to 45% towards 2020. Also Da Nang’s population growth was swift in the last decades. In 1999, the city counted about 687,000 inhabitants and in 2010 this was already 926,018. Until 2009, the population of Da Nang grew at an annual average rate of 5.2% [1]. Based on this fact, the population will rise to 1.56 million by 2030. Along with the fast urbanization, the city of Da Nang faces major challenges in terms of climate change, mobility and land use. These challenges are representative for many emerging countries in this region and their cities.

In response of these challenges, Design Office OMGEVING and its partners developed the resilient Han river masterplan in 2016. The masterplan was awarded the joint first prize in the prestigious international design competition for Han Riverfront Da Nang City. The jury decided to select two laureates out of seven accepted applicants. Although the masterplan contains valuable resilient strategies for the future, till now the implementation is proving difficult to achieve.

1.1. Climate challenges

Floods, increasing precipitation, extreme weather conditions, erosion and waste water are climate related problems the city of Da Nang faces, causing a need for a future oriented strategy with long-term solutions for these increasing threats.

Floods

A combination of the challenges described below (increasing precipitation, extreme weather, sea level rise, increase of impervious surfaces etc.) is the cause of the growing problem of flooding. The aftermath of floods or flood surges is significant, with damage to public space, private homes and the natural environment. After the typhoon Ketsana in September 2009, a flood surge demonstrated the importance of coastal protection.

Precipitation

Patterns of precipitation and storm events are likely to change. Projections of the IPCC (Intergovernmental Panel on Climate Change) show that future precipitation and storm changes will vary by season and region. Some regions may have less precipitation and others more. However, the amount of rainfall and winds associated with tropical storms is likely to increase in most regions. This will be particularly distinct in tropical and high-latitude regions such as Vietnam [2].

Impervious surfaces (parking lots, roads, building, compact soil) do not allow rain to infiltrate into the ground. As a consequence, growing cities generate more and more runoff. This additional rapid flowing runoff can erode watercourses (streams and rivers), encourage weed invasion and alter natural flow as well as flooding when the storm water collection is overwhelmed by the additional flow.
Sea level rise

Warming temperatures contribute to sea level rise by expanding ocean water and melting ice caps. In 2014 the USGCRP National Climate Assessment projected that by the year 2100, the average sea level will rise up to 1.2 m since the date of the 2014 assessment [3].

Regional and local factors will influence future sea level rise for specific coastlines. Inflowing sea water will cause salinization of groundwater and the natural sweet water supply with drastic effects for the ecosystem.

Erosion

Coastal erosion is expected to increase given the fact that Vietnam is one of the countries which are severely affected by climate change and sea level rise. Coastal erosion is breaking dykes, causing floods and saltwater intrusion. Stormy weather and typhoons, regularly smash into the white beaches of Da Nang’s east coast, causing damage to the coastline and touristic infrastructure.

Wastewater

Combined systems in areas with many impervious surfaces cause flushes during extreme rain events and this heavily polluted water will enter connected storm drains and eventually the river. This highly concentrated pollution results in severe deterioration of the water quality in rivers and streams.

In most areas not all houses are connected to a sewage system and consequently pollute the environment. Secondly, the sewage of the connected houses does often not even lead to wastewater treatment plants, because there are none or few plants in the area which are often not up to date. Sewage water will infiltrate into the groundwater aquifers and put a risk on groundwater extraction for drinking water or other applications.

1.2. Mobility challenges

Da Nang’s traffic is currently functioning well. However, more and more residents are replacing their motorbikes by cars, using about four times more street space, which will lead to traffic congestion in the very near future (4% of car-users in 2016 will increase to 9% by 2025) [4]. The need for parking spaces will increase, the air quality in the city will deteriorate with increasing health problems as a result and the city’s positive image will suffer. Da Nang’s public transport system is not yet functioning at full capacity to be an attractive alternative for cars or motorbikes.

1.3. Land use challenges

The map for Da Nang’s land use shows the situation around 2003. The land between the river delta was still mostly used for agriculture, rice fields to be exact, intertwined with scattered rural residential areas. Current aerial images show that the rice fields east of the 1A national highway have all but disappeared and have been replaced by urban areas and a dense road grid. West of the highway the urbanization appears to have been less drastic although
most of the forests and some of the rice fields have made way for residential areas as well.

The urban area of Da Nang city itself has not increased since it is strictly bound between coastlines and mountains explaining at length the fast urbanization in the river delta area. Of course, there is a lot of variation within the term ‘urban land use’, it does not necessarily implement hard surfaces. Da Nang city is known to be very green and to be the most pleasant metropolitan city in Vietnam.

2. Three resilient landscape strategies and tools for implementation

2.1. Three resilient landscape strategies

The proposed approach to tackle the challenges Da Nang and its Han river are facing, is a combination of three separate strategies, defining the focus for the masterplan 2050. These strategies are called the ‘green corridor strategy’, ‘green connection strategy’ and ‘green program strategy’. All design concepts for the masterplan can be assigned to one of these three strategies. The ‘green corridor strategy’ focuses on providing answers for the climate challenges by reintroducing and detaining greenery in the river delta area as well as in the city centre, in particular alongside the river, and by presenting water related improvements. The ‘green connections strategy’ proposes ideas for an interlaced system of sustainable modes of transportation. The ‘green program strategy’ aims to ensure the quality and strategic clustering or dispersion of Da Nang’s architecture typologies, range of activities and touristic highlights.

The masterplan combines all strategic elements from the ‘green corridor’, ‘green connections’ and ‘green program’ into one combined strategy. The plan highlights the activities with a link to the river, strengthens the sustainable transportation connections towards and alongside the riverfront and also reinstates the green continuity. The multimodal transportation hubs and green connections will transform Da Nang into a well-functioning, pleasant and appreciated metropolitan city.

Successful adaptation to the climate challenges, eco-friendly city development and the emphasis on green space will make Da Nang the number one exemplary city of Vietnam and will attract foreign tourists since eco-tourism is gaining importance and popularity worldwide.

Green corridor strategy

The fast urbanization of the city requires the determined protection and development of a robust and resilient ecological river network, the ‘green corridor’. This network is the green basic principle for the masterplan. Its central themes include the green network city, the qualitative development of green riverbanks, beaches, coastlines and parks, the preservation of natural values and biodiversity and the protection of the landscape itself, responding to climate-change challenges in urban spaces and rain and waste water management. The key elements of this strategy are:
Future Resilience

- Continuous green network: recovering the ecological function of the river delta with a network of green riverbanks, green coastlines, green roads and green parks.
- Protected and maximized river delta: reducing the risk of erosion and flooding in the flood prone south river delta by protecting and maximizing the riverbed for water storage.
- Permeable street network: reducing the risk of erosion and flooding in the flood prone north urban neighbourhoods by maximizing water infiltration and water storage in the city centre.
- Two safety thresholds: protecting the north city centre and manage water retention in the south river delta.
- Clean water network: Stopping the flow of sewage water, keeping the river clean and pollution-free by adding a new sewage line on the north urban riverbanks and a natural water treatment system in the south.
- Flood surge protection for the coastlines: protecting the coastlines from high waves associated with tropical storms.

Green connections strategy

The ‘green connections strategy’ devises a comprehensive, well laid-out public transport system in which a water-taxi network, a bike and pedestrian network and, on the long term, a tramline network complements the existing bus network in Da Nang. These connections are the basis in terms of mobility for the masterplan. The service level of the public transport network will be sufficient during the daytime as well as at night. The overall reachability of urban neighbourhoods, workplaces and other services by public transport will be enhanced. This will require substantial investments in new traffic routes and better designed interchange stations: the multimodal hubs. The key elements of this strategy are:

- Continuous recreational walking and cycling network: developing two river routes connecting the south river delta with the north city centre and offering bike rental at strategic locations.
- Waterborne public transport system: integrating services for water-trams and water-taxis, linking them with other modes of public transport (buses, bicycles) to optimize movement by public transport, creating qualitative infrastructure for cruise boats and tourist boats.
- New (motor)bike bridge and new pedestrian bridge: connecting the waterhub, the biggest multimodal hub with a cruise terminal, port and new urban neighbourhoods on the left riverbank, recovering and enforcing the historical axis of the city centre with a slow connection to the urban area on the right riverbank.
- New coastal and city centre tramline: developing a tramline, connecting the north coastline, the city river and the east coastline.
- Bridges as multimodal hubs: developing the base of existing and new bridges as multimodal hubs, aiming to provide fast and efficient transfers as well as comfortable and convenient facilities.
- Cooling river: using the cooler river water as a cooling system for the city.
Green program strategy

Sufficient construction of private housing and commercial facilities in tune with the population growth results in significant new building volumes and increasing claims on the open space. To protect and preserve Da Nang’s green areas for future generations, it’s irresponsible to only expand horizontally on the outskirts of the current built environment. A new way of perceiving the city’s innovative capacity needs to be introduced. The emphasis of the city’s investments will lie in restructuring and supplementing the existing urban areas. The key elements of this strategy are:

- District level mixed use urban centres: developing the district level urban centres with a high density, distinctive architecture and a mixed program
- Different areas for urban development, each with their own character and identity: developing urban areas with functions and building typologies which are related to their context: coastline area, mountain area, river delta area and city river area
- Network of river related public buildings: integrating a network of river related buildings to guarantee the public character of the riverfront and to support a memorable riverfront identity
- Waterhub: developing a waterhub as the multimodal gate to the city river and as a city icon
- Airport park: developing the green area next to the airport as a central park on the scale of the city
Fig. 1. Three resilient strategies: green corridor – green connections – green program
2.2. Tools for implementation

In addition to the three ambitious resilient landscape strategies, the Han river masterplan 2050 also provided tools for implementation: a logical phasing strategy with a range of short, medium and long term initiatives and the identification of funding resources for operational costs.

A logical phasing strategy

The Han river masterplan 2050 sets out the vision and goals for the riverfront on three scales, with a range of short, medium and long-term initiatives.

- **Short-term, 2016 to 2020.** Short-term projects establish critical first elements for the overall riverfront transformation. These projects reflect key investments anticipated to produce important short-term results and/or set a strong foundation for the longer-term project elements.

- **Mid-term, 2020 to 2030.** Mid-Term projects reflect the results of a public and private sector cooperation to achieve large waterfront redevelopment projects like the opera building.

- **Long-term, 2030 to 2050.** Ambitious, long range efforts, which are important, but often still flexible/adaptable to remain responsive to changing market conditions, community needs and other factors.

The long-term initiatives for 2050 apply to the whole river delta. The medium-term initiatives for 2030 affect the urban river and the short-term initiatives for 2020 are part of the strategic area. The flexibility of the vision and the planned initiatives increases as the scale and the implementation period increase. At the same time, new insights on the different scale levels can influence and interact with the other scale and implementation levels. This flexibility and interaction is important for community supported plans and projects. Other keystones for the implementation strategy are communication and public involvement.

Potential funding resources

The vitality of the strategic area and in general the whole urban Han riverfront will depend on identifying funding resources for the operational costs. We suggest some primary types of potential funding sources: enterprise revenues; local government funding; republic government funding; public-private and private funding. Outlined here are examples of some of these potential sources. Each source comes with a series of challenges and opportunities. The strategic area is a collection of unique river related projects. Comprehensive discussions with city representatives will be a critical first step in assessing which funding strategies might be appropriate for these and other riverfront developments.

- **Enterprise Revenues**
  - Concession Fees: the urban river and especially the Waterhub with a cruise terminal and other commercial facilities will include concessions and rent which can be allocated towards Waterhub operational costs. The shop concessions within the Waterhub as well as the restaurant will pay a basic rent and could pay an extra percentage from net cash flows above an agreed-upon threshold. Ferry and / or water taxi operators will pay landing fees and
city-owned underground parking in the proximity of mobility hubs will generate more profit.

- Special Events Fees: The urban river already hosts numerous large-scale public celebrations and special private events, for example the annual fireworks event. These draw significant crowds and media attention from throughout the city and the region. And yet, as a matter of policy, the city has not captured the value of hosting these events on its riverfront and surroundings. Instead, event organizers receive permits for events with little, if any, monetary consideration paid to the city. Waterfront parks, public promenades and other municipally owned venues throughout the city, should identify ways to monetize the value of their riverfront venue to support ongoing public programming and operations.

- Local Government Funding: Directed by the City Council, City Staff may be able to identify additional sources, reserved for public projects.

- Republic Funding: The riverfront of Da Nang and especially the Waterhub can be accessed from boarding points for ferry transport along the East Sea coastline. This could open up opportunities for republic funding support for the Waterhub-project.

- The Han river Fund, public-private Funding through impact fees: An important way to obtain impact fees are one-time fees collected from developers with projects within a specified radius from a public infrastructure investment, like the urban riverfront of Da Nang.

Impact fees are typically utilized to fund road, sewer or open space renovations, water related projects etc. There must be a rational nexus between the private development and the need for infrastructural improvements. Furthermore, the developer’s fair contribution to the public-private fund must be defined.

2.3. Unclear perspectives towards implementation

Even with all the tools for the implementation prepared in 2016, the implementation of the master plan has yet to be kick-started by the government. For future projects and implementation of climate resiliency strategies, it is important to find out what is causing the holdup. The scale and complexity of this study area are too large to determine one clear answer to why the project seems to have stranded. Building on previous experiences with master plans, the following possible reasons come to mind:

- Da Nang is growing at such a high pace that the city council is overtaken by events. The government may lack experience in coordinating complex planning processes. An experience expert from the project team could assist the government and act as a hinge between design team, government and private stakeholders.

- Immediately after the completion of the masterplan elections led to a new city council. The masterplan may not be a priority or may not be supported by the new city policy.
The spatial but also financial tools for implementation might have been too general and should have been more detailed and tangible.

There is a need for a project director as a link between the government and the design team.

The masterplan had a strong focus on the public space. The relationship between property developments along the river and the added value for developments in the public domain should have been highlighted.

Awarding a joint first prize made the already complex assignment even more difficult to work out since there is no clear definition how the cooperation between the two winning teams should proceed.

3. Towards a resilient policy and management

Like many South East Asian cities, Da Nang and its river needs a spatial answer for the challenges related to the rapid urbanization due to population growth, climate challenges concerning the Han river such as floods, precipitation, extreme weather, erosion, wastewater etc., mobility challenges with increasing car use, traffic congestion, air pollution etc. and land use challenges with the gradual intake of open space, the increase of hard surfaces etc.

The Han river masterplan of 2016 tried to formulate an answer to these challenges with three general resilient landscape strategies integrated into the design of a masterplan for the Han river.

To implement and realize these resilient strategies the following suggestions were provided: set up a logical phasing with a range of short, medium and long term initiatives and identify funding resources for operational costs.

But even with these suggestions, the masterplan of 2016 has not been activated. It shows that the government needs more than just a masterplan. The implementation of large scale masterplans demands a specific expertise to support the local Vietnamese authorities. A middleman project manager could help steer the project in the right direction and could bring the design team and the government closer together so that resilient strategies and masterplans can gain ground in local policies and can turn the tide in favour of sustainable urban development. In that sense resiliency is also necessary in terms of policy and management.

Re-use of Contaminated Soil in the Dense Cityscape

Catherine Combe

Architect, Plan b architectes urbanistes paysage, 45 rue de Sèze Lyon 69006, France

Abstract

As city planning in Europe aims towards densification and sustainability, empty or buildable plots are becoming hard to find. Ancient and unused industrial plots, old landfills, abandoned tracks, now part of the inner city, are now often seen as a new opportunity to densify the city and the problematic of contaminated ground is becoming a new concern. We are dealing, at the same time with the necessity to build a more sustainable environment, mixing new housing and buildings with green public spaces, preserving biodiversity, enabling “green commuting”, cycling, walking, playing in a safe environment. Re-use of contaminated soil tends to reshape the way we plan and design, public and common spaces in these neighbourhoods. Full phytoremediation directly on site in often not an option as the pollution happens to be ancient and often deeper underground. In France, Law implies, as we plan new buildings, parks or public squares, to analyse ground and classify the way polluted soil in going to be stocked reused or decontaminated: (ISDND / ISDI /ISDI+ / ISDD)
- Dangerous versus non-dangerous
- Inerte (inactive) versus non-inerte (active)

Pollutant such as Heavy metals, Hydrocarbons, PCB, etc.. are analysed and located. Main guideline are as follow and depends on the classification and density of each pollutant present in the ground :
- If dangerous and above legal limits : removed and treated in a specialized facility
- If not dangerous and above sanitary legal limits: kept on site and confined as to not endanger the people living there and as to not spread pollutants.

Keeping contaminated soil on side generates new ways to rethink how we design open spaces, and the way people are going to use it. These guidelines, when applied to small scale projects can impact the whole concept of the new design. As we encounter this problematic in some of our current project, we wish to present two case studies
- Place des Carmes (public square), Clermont Ferrand, France (20 000m² / 215 sqft)
- Quartier Ambroise Paré : Construction of a social Housing complex, underground carpark and upgrade of the small residential park, Lyon France. (13 000m² / 139sqft)
Place des Carmes:
- Located contaminated ground: Hydrocarbons, copper,
- Impacts on playground
- Impacts on storm water infiltration

The impact is rather small, and the choice has been to « block » the pollutants under a concrete pavement. Stormwater infiltration will be limited and a fair amount of natural ground will be brought on site.

Quartier Ambroise Paré:
- Deeply contaminated ground (dates end of WW2): Hydrocarbons, copper, arsenic, antimony and PCB
- Impacts deep underground: excavated ground from the underground car park (5 300m3)
- Impacts on storm water infiltration
- Impacts on the surface: heavy metals contamination

The choice has been to re-use soil as much as possible:
- Under a newly built concrete pathway on high ground allowing a direct level access to existing hallways.
- Under planted earth banks with thickets and grove thus creating a new landscape.

1. Introduction

For a few decades now, densification of cities has been a relevant and recurrent thematic of European urban planning. As the trends towards suburban urbanisation and urban sprawl lead to low density and consumption of agricultural land, urban planners aim to tackle this issue by promoting a more compact city and implement mechanism to densify the city centre itself as well as its vicinity.

A few figures of population density in middle size cities in the 3 past decades in France illustrates this trend:

Fig 1: Population Density evolution in France - source INSEE
The dense city centre tends to gain population and the surrounding cities of the urban area seem to follow this specific trend.

Fig 2: World Population [1]

2. Contaminated Soil and Density in European cities.

Promoting densification versus sprawling cities is also a tool to protect agricultural land as well as to promote better and more efficient public transportation and reduce car use. It is part of a global scheme towards sustainability.

At the same time, as we are dealing with a compact city, we also need to create a more sustainable environment for its inhabitants, mixing new housing with ancient building refurbishment, creating new public spaces, green networks preserving biodiversity in the city itself, enabling green commuting, cycling, walking, playing and living in a safe environment.

But, we must confront the problematic of the lack of vacant plots, making this densification of the urban fabric more difficult.

Reuse of abandoned industrial plots has been a common response to this lack of urban space to develop since the early 80’s and its steady closing and relocation of industries and smaller scale business from the city core to the suburban areas. When developing the city on such contaminated soils we must tackle the problematic of planning, planting and building on polluted ground.

These urban projects are well documented and there are well established procedures, but as this kind of re utilisation of vacant plots are more and more common, the way of planning and conceptualizing have been influenced by those procedures. The two following well known projects showcase ways of dealing with contaminated soils and infrastructure such as

- Ecological restoration of water banks.
- Phyto remediation.
- Restoring natural process.
- Sealing contaminated soil and excavated materials.
- Cut and fill balance and displacement of polluted soil.
- …

These operations, show us the influence of a contaminated context on planning and conceptualisation of an landscape project.

2.1. Westergasfabriek

[Imagery of Westergasfabriek: A reclaimed industrial site transformed into a public park.]
The park is located on a partially dismantled industrial facility. The site was heavily contaminated, and, as not to spread "contaminants", the contaminated soil could not be taken off site:

- A cut and fill balance had to be calculated.
- New soil has been brought on site and polluted soil displaced.
- An Undulating ground has been created as to re stock the surplus soil.
- A woodland has been newly planted with new salix babylonica.
- The remaining basement of the old gasholder has been filled with the worst pollution and caped and has become a waterlily pond.

2.2. Landschaft park

Duisbourg Nord

Situated in the Ruhr district, the park takes place amongst a wider network of several projects with the aim of transforming an old industrial district. There, patterns and fragment of industrial vestiges found on site are reinterpreted as to form a new landscape.

Trees have been planted and a square build in the midst of the old structures, the open waste channel has been transformed in a clear water canal.

Most contaminated places have been demolished and evacuated. Enclosed garden have been build, their high walls now enclose old pollutants in sealed containers or excavated materials.

In a dense cityscape these techniques are hardly possible to implement as empty space lack tremendously. Phyto remediation of soil by a long-term cultivation, while being an appropriate technique in a park, is here not a viable option.

Phyto stabilisation on the other hand, might be an effective procedure to keep pollutants underground and reduce toxicity in the aerial parts of the plants. For instance, it has been noted that Festuca Rubra can be quite effective in a copper accumulated context, as well as Acer Pseudoplatanus (Zn) and Robinia Pseudoacacia (Cd + Pb) in other contaminated soils.

Other methods available tend to reshape the way we plan and design open spaces as we are dealing with re-use of soil and treat contaminated land.

In France, part of the ALUR Law (2014) takes into account contaminated soils. Its aims are as follow

- To prevent future pollution
- To treat existing contaminated sites
- To keep trace and memorize soil and contaminated sites.

On every new urban development, or new project, whether it concerns a public space or a new building, ground assessment must be organized.

Soil analysis lead to classify contaminated soil into 4 classes ranging from mostly harmless to the worst case scenario that needs to be evacuated and treated in a specialised facility.
These 4 classes are from less dangerous to worse: ISDI / ISDI+ (inert - inactive)/ ISDND (non-dangerous) / ISDD (dangerous).

Pollutants such as heavy metals, hydrocarbons, PCB are analysed, and located on site. Main guidelines are as follow and depend on the classification above, as well as density and quantity of each pollutant present underground:

- If dangerous and above legal limits: soil must be removed and treated in a specialized facility
- If non Dangerous, non-active but above legal sanitary limits: soil can be kept on site, marked and protected, as not to endanger people living near and as not to spread pollutants.

As seen in the Gasfabriek Park project, contaminated soil can be displaced and/or kept on site. New, clean soil must then be brought on site to replace the existing displaced soil. As for the contaminated soil if kept on site, it must be blocked under any hard materials such as concrete, as well as, if planted, a certain thickness of new top soil.

These guidelines imply to work with shapes, to deform the site, to create an “undulating terrain” dyke walls, banks and shoulder that shape the landscape and the cityscape no longer seen as a levelled and simple site.

Keeping contaminated soil on site as well as to try a certain form of phyto-stabilisation generates new and different ways to think and design open public spaces such as parks, places and common grounds. These guidelines when applied to a smaller scale project in a dense cityscape can impact a whole concept or design.

3. Case studies

As we encounter in our daily practice such problematic we would like to share two case studies.

3.1. Place des Carmes Déchaux Clermont Ferrand, France

Clermont-Ferrand is a middle size city in central France bordered by an ancient volcanic mountain chain, with a population of 142 000 inhabitants. It is the headquarters of global tyre company, Michelin. The Place des Carmes is an urban 20 000 m² / 215 sq feet square situated north of the train station, in front of “Campus Michelin”, the Research and development Michelin Facility. It is noticeable in the urban fabric since the early 20ᵗʰ century and has never been part of an industrial facility. In the 80’s the square has been divided in two parts to allow the construction of a elevated road bridge used by car and the tramway line.

![Fig 5 : Google earth image of the square](image)

Nowadays the square presents a fragmented space that the remodelling project aim to reinvent and reconnect. The two slip roads will be demolished and three new monumental staircases will be build,
allowing pedestrians to climb on a newly accessible bridge and reach from there the tramway station. Old trees, Platanus x Hispanica and Pinus Sylvestris will be protected, and a fair number of new species will be planted.

Pollutants found on site in 2017 originates from car traffic pollution as well as general urban pollution.

The impact is here rather small, but other environmental and archaeological constraints must be taken into account:
- Presence on antic vestiges and relics as well as medieval relics.
- Floodable zone of the river Tiretaine.

As the project location is an urban site, long term phytoremediation can’t be implemented and choice has been made to keep the contaminated soil on site and to block hydrocarbons as well as heavy metals. Storm water infiltration is going to be heavily controlled and most of the storm water will be discharged to the municipal sewer.

Almost 50 trees will be planted, including new species such as Alnus Cordata, Amelanchier Lamarckii, Carpinus Betulus, and Pines. Tree pits will be created and filled with new top soil, brought on site.

Here, in this special case, the problematic implied by soil contamination was easily solved.

3.2. Ambroise Paré Laënnec – Lyon France

This 60 years old residential building complex is located in the eastern part of Lyon “8th arrondissement”. This area began its development in the very beginning of the 20th century when the Grange Blanche Hospital (now Hôpital Edouard Herriot) was completed (1910-1933). Nowadays the IARC (International Agency for Research on Cancer) and one of the main science and medicine university can also be found in the vicinity.

In the 30’s and 40’s, small scale industries began their development on the ancient agricultural lands, and small suburban houses surrounding the newly established hospital, as well as some higher
constructions began to be build on each side of the main roads.

In the 50’s, and as part of the post WW2 massive reconstruction plan, bigger scale social housing as well as rental units were built in the area, as industries began to be relocated in the city suburbs.

Those rental units and social housing complexes were build around large green common spaces, which now tend to be redeveloped and densified as part of the city growth.

As regulation and newly implemented laws lead to ground assessment, these ancient and often forgotten industrialized plot are rediscovered and contaminated soil resurface.

• The creation of a two levels underground car park (100 vehicles) that can host cars of the new building inhabitants as well as the older buildings.
• The development of 1.3 Ha common spaces on the new-found surface freed of the old aerial car parks.

As per French law guidelines, ground assessment was done in 2 phases (2016 an additional testing in 2017) and the ancient landfill linked to the small factories network was rediscovered.

Most found pollutants are mostly common in such context, but number and density of heavy metals was such that the site was deemed unfit to allow ground excavation without treatment.

The Ambroise Paré / Laënnec housing complex was built from 1950 until 1964, partly on ancient vegetables patches and partly on a forgotten WW2 landfill. It’s on this specific location that a 3 parts project was decided to be developed in 2015.

The whole plot restructuration was to allow:
• The construction of a 37 units social housing building.

The whole plot restructuration was to allow:

</tbody>
</table>

High levels of arsenic and antimony have been found in the 2017 ground assessment,
as soil was tested between ground level to 7.00 m deep.
No ground water was found as the water high level seem to be far below the contaminated soil.
The specific danger resides then in pollutants vaporization and dissemination, thus impacting health and safety of the people living in the polluted plot.

As construction work is about to begin, precise guidelines have been established such as:

- **Removal and treatment** in a special facility of polluted soil with high density of arsenic and antimony.

- **Kept on site** non-dangerous contaminated soil (stocked and protected while construction is underway) and located as follow:
  - Under concrete path and sidewalk (this specific contaminated soil being not fit to resist a road charge)
  - Under 50cm of clean top soil plus geotextile fabric, marker tape being placed above the kept on site contaminated soil.
  - No fruit trees should be planted, and vegetables parch should be cultivated off ground.
  - Trees should be planted in specific 12m3 tree pits, protected by geotextile fabric.
  - New pipes and sewer, as well as water supply network should be placed in a clean brought on site ground.
  - Strom water infiltration is possible as long as contaminated soil in replaced in specific zones where infiltration is located.
  - As there is a strong soil acidity, concrete infrastructure must be protected, and / or special concrete formula must be used.

This guidelines led to a totally renewed and reshaped design of the housing complex common spaces:

- To allow kept on site contaminated soil led to a global raise of ground level from 30cm to 150cm at the highest.
- As to stock more contaminated soil, three different landscaped shoulders were created.
- As to keep pollutants underground, and to allow some long term Phyto stabilization, as well as to reduce the urban summer heat, more than 80 trees, hedgerows and wooded hedges are to be planted.
- Contaminated soil is also going to be kept and blocked under concrete pavement and confined between walls as new levelled access to the existing buildings are to be created, thus replacing the old stairs and implementing universal design.
- An undulating landscape will help noise reduction and sound reverberation in the common spaces.
• These gradation in different ground levels will allow some of the building units and their private gardens to gain some privacy and protection.

4. Conclusion

Implementing these guidelines as well as allowing some long term Phyto stabilization, led to a chance to improve a pre-existing design and include general conceptualization process ideas dealing with universal design and a sustainable urbanism.

These constraints were taken as a real chance to rethink the whole plots organization and its landscape.

New Waterfront for the Ecological City: Redesign of Namhang-dong Pier, Busan Korea

Wongyu Noh, a Yumi Lee, a *

*Graduate School of Environmental Studies, Seoul National University, 1 Gwanak-ro Gwanak-gu, Seoul 08826, South Korea

Abstract

Busan Port is Korea's first trade port which opened in 1876. Namhang-dong pier has a facility where fishing vessels can berth, and equipment and catches related to landing, sale, and transportation of fishes can be processed and stored. However, facilities for processing and storage and repair facilities located in the Namhang-dong pier were closed due to the bankruptcy of the Hanjin Shipping Corporation and the downturn in the shipping business. Thus, the city became a deserted city, and there were many neglected buildings and idle spaces. And although it is a coastal area, its waterfront cannot be utilized because of its role as a port. And the green area ratio of the Namhang-dong area is low (no parks and street trees). The idle space in the industrial facilities was 2.2% of the total area of Namhang-dong. And we analyzed about Coastal breakwater, section, and possible to waterfront ecological design. The coastal and breakwater areas were surveyed to determine the areas where biodiversity is likely to increase, the space that can be accessed by humans, and the spaces inhabited by living creatures. And currently, the rate of greening in Namhang-dong is 1%. We propose an ecosystem diffusion strategy through first diffusion of biodiversity in sea and breakwaters, second diffusion to coast (waterfront), and third diffusion to idle space in Namhang-dong. And through the direct experience of people, we will revitalize the Namhang-dong pier to strengthen its resilience. With much interest and volunteer programs, it will increase its resilience. Due to the existing green area of 6,930 m², the green area of 14,443 m² through the diffusion of idle space, and the waterfront green area of 10,521 m², Namhang-dong will secure 5% of the green area of 31,894 m² of the total area of 662,634 m². And because of the design of the sea and breakwaters to increase biodiversity, the increase in ecological rate is infinite. If all these ecological re-designs are completed, there will be a numerical 5% real ecological space, and invisible ecological values will be too large to be quantified. And the most important component in reviving a dying city is attracting users. The goal is to provide rich ecological space and resting space and bring economic value through ecological activities that can be practiced. Because of its geographical accessibility, Namhang-dong has a resilience to revive quickly if you create a bright city through ecological redesign. Through this design, people will be able to manage the biodiversity without forgetting the history of Busan Port and Namhang-dong, and as a result, it will create a great economic benefit.

Keywords: ecological resilience, port, pier, waterfront, eco-system, Biodiversity, idleness space;
1. Introduction

1.1 Study background

Busan Port is Korea’s first trade port which opened in 1876. Busan Port is classified as North Port and South Port. Namhang-dong pier has a facility where fishing vessels can berth, and equipment and catches related to landing, sale, and transportation of fishes can be processed and stored. Connecting the north pier and south pier in Busan Port is the Namhang-dong pier, and it is also important in terms of location. However, facilities for processing and storage, repair facilities in the pier of Namhang-dong closed due to the bankruptcy of Hanjin Shipping Corporation in February 2017 and the downturn in the shipping business. [Thus, the city became a stopped city, and there were many neglected buildings and idleness spaces. And although it is a coastal area, it can not utilize the waterfront due to its role as a port, but now it can utilize a waterfront that is not used for the downturn of the shipping business. And the green area ratio of the Namhangdong area is low (no parks and street trees).] So it is urgently necessary to transform the city into a green city before it completely dies out.

1.2 Purpose of research

The physical strength of the Namhang-dong pier starts at a site that has been shut down as a dock and has not been used. From the sea and the breakwater to the coast (waterfront) and the idle space in Namhang-dong, ecological redesign leads to the diffusion of ecology. In order to induce contact between nature and human beings, we provide ecology by the coast from the north to the south of Namhang-dong. In addition, since economic value can be provided through nature, the economic development of Namhang-dong is gradually achieved through ecological design methods.

2. Present analysis Introduction

2.1 Present condition of idleness space

The idle space in the industrial facilities was 2.2% of the total area of Nambang-dong (total area of Nambang-dong 662634 m², idle space 14443 m²). In order to present the concept of idle industrial facilities, it is first necessary to examine the concept of idle
Future Resilience

space. (Urban regeneration method utilizing idle industrial facilities —Focused on culturally regenerated spaces, (Cho, 2011). It refers to an existing space that is unused, space that is utilized but unsuitable, and wasted space that created by the loss of function due to social change (Baek, 2003).

As the industrial structure changed, the facilities that can process and store the buildings and the fishing facilities for landing, sale, and transport ceased to function and only the forms remained. In order for these spaces in the port city to energize the city while improving the quality of life of people, nature must breathe together. Among the contents that the space should be equipped to operate vigorously with the sustainable vitality (The necessary strategies and planning factors for making cultural space), it is necessary to strengthen the cultural identity of the city center (Securing the place-specificity and enhancing the symbolism in the city) and to preserve and utilize the historical and cultural elements in the port (Use of historical symbolism of preserved resources, reuse of old buildings, preservation of historical cityscape and street landscape, preservation of traditional buildings, cultural properties (Son 2005). At present, the shipping facility is closed by more than 30%, so the alleys are not cleaned or managed, and there are brownfields left after the buildings have been demolished. And there were many short-term accommodation facilities that were not open. And people did not live in aging low-rise housing. So, we selected unused space that is not utilized, polluted land due to coastal garbage, uneven gravel sand, and large spaces gathering scrap iron and garbage.

2.2 Characteristic of Namhang-dong pier

We analyzed Coastal breakwater, coastal species, and possibility of waterfront ecological design. Marine species were found in the coastal area, most of which were seaweed.

However, as we entered the breakwater zone, some shellfish were found.

The coastal and breakwater areas were surveyed to determine the areas where biodiversity is likely to increase, the space that can be accessed by humans, and the spaces inhabited by living creatures.
2.3 Green area ratio of Namhang-dong

Currently, the rate of greening in Namhang-dong is 1% (the total area of Namhang-dong 662634 m², green area 6930 m²). Nambang-dong is mostly composed of ship repair facilities, short-term accommodation facilities and old low-rise houses. So it is quite unpleasant when you walk down the street.

3. Method

3.1. Ecological Diffusion Strategy

We propose an ecosystem diffusion strategy through first, diffusion of biodiversity in sea and breakwaters, second, diffusion to coast (waterfront), and third, diffusion to idle space in Namhang-dong.

3.1.1 Sea and breakwater - supplement of ecological elements (ecosystem functioning as a habitat for various fauna and flora)

Case of Coral Raise, Ebru Özer
A. Transplanting into the sea after coral form raise
When field-grown coral specimens reach appropriate size and age, they are transplanted into the ocean. Coral plays an important role as natural barriers to help protect coastal cities from the effects of storm. Corals also account for about 25% of the world's marine life. (Nova Southeastern University Oceanographic Center: Phase Landscape – Hollywood, FL - Methodology for Landscape Performance Benefits, Ebru Özer, 2014).

B. Creature inhabitation in breakwater
The composition and surface roughness of building materials at microscale (<1 cm) have a significant impact on the structure and function of colony communities (Coombes et al., 2011; Green et al., 2012). Small breaks (<10 cm) of holes and rock pools in small- and medium-sized (1-10 m) breakwaters provide important havens for many species (Bracewell et al. 2012). The artificial surface of most breakwaters lacks the micro-habitat that can be found on the coast of natural rock (Firth et al., 2013a, b). Therefore, many species using this microhabitat will decrease (Chapman, 2003). Furthermore, if the material used to make the structure is different from the natural habitat, the sedimentation and survival of the species can be varied and reduced (Davis et al., 2002).

When resident species are more suited to living on gentle slopes, they may not survive on a vertical surface, especially where the waves are severe. Therefore, the steep intertidal zone can reduce the quality of the habitat in addition to the available area, thus the structure of the relevant community is different (Glasby, 2000; Vaselli et al., 2008). So far, little research has been done on the importance of biological habitats in artificial and natural environments. Slabs with low tide height and greater surface complexity have been found to support higher biodiversity (Borsje et al., 2011). This approach relies on the general logic that the habitat becomes richer as the complexity of the habitat increases. Changes in the artificial environment can be implemented for conservation or species diversity. For example, adding a pit to a breakwater increases the limpet patella candei (shellfish) as the complexity of the microbial habitat increases (Martins et al., 2010). In the case of The Creation of Artificial Pits on Plymouth, England, Investigated the species richness of No pit and pit (14mm, 22mm) by piercing 14mm and 22mm in 100 * 100cm width on breakwater. The many pit of waterbreak was higher in species richness and there was no difference in width between 14 mm and 22 mm (Between a rock and a hard place: Environmental and engineering considerations when designing coastal defence structures, L.B. Firth et al. 2013).
In the case of Manipulation of the rock sizes in gabion baskets: Wales and the Netherlands, Progressed experience through (1) small rocks (6-10 cm); (2) large rocks (>18 cm); and (3) rock mixtures of different sizes (between 6 and 18 cm). We hypothesized that gabions containing multi-size mixtures would have a higher abundance than gabions containing only small stones or large stones. As a result, the species richness of the rock mixture was high. (Between a rock and a hard place: Environmental and engineering considerations when designing coastal defence structures, L.B. Firth et al. 2013)

ECOncrete®Antifers (EA) undergoing deployment by a technical dive team. (Blue is the new green – Ecological enhancement of concrete based)

We investigated the effect of concrete composition and complexity on the biological performance of external structures named Antifers. Increased surface complexity and ecologically reinforced concrete, ECOncrete®Antifers-EA, were compared to standard Portland cement-based devices (StandardAntifers-SA) (Blue is the new green – Ecological enhancement of concrete based coastal and marine infrastructure, Sella Ido et al. 2015).

A 30 × 30 cm² quadrate used to monitor the fauna and flora on the ECOncrete®Antifers – left, and on the Standard Antifers – right.

In the EA breakwater, various species (Barnacles, Bivalves, Bryozoans, Coralline algae, Gastropods, Oysters, Sabellidae, Serpulidae, Sponges, Tunicates Colonial. Tunicates Solitary) were inhabited and in the SA breakwater, Turf algae accounted for 80%. (Blue is the new green – Ecological enhancement of concrete based coastal and marine infrastructure, Sella Ido et al. 2015).
Typical live cover of the ECOncrete® Antifers (EA), exhibiting diverse benthic assemblage composed of oysters, sponges, tunicates, Sabellidae, Serpullidae, bryozoans, coralline algae and more.

3.1.2 Ecological Diffusion Strate Waterfront ecological design

Busan is a temperate climate and plant trees called ‘southern species’. They are planted in the order of the halibut plants and the plants resistant to salting, spreading from the area facing the shore. Salty plants in the southern area plant Elymus dahuricus, Cynodon dactylon, Setaria viridis var. pachystachys, Carex boottiana, Cyperus rotundus L., Boehmeria pannosa Nakai & Satake, Aster hispidus, Tetragonia tetragonoides, Sagina maxima, Dianthus japonicus, Melandryum oldhamianum, Corydalis heterocarpa, Raphanus sativus, Arabis stelleri var. japonica, Sedum oryzifolium Makino, Rosa wichuraiana, Eurya emarginata (Thunb.) Makino, Oenothera laciniata Hill, Angelica japonica, Peucedanum japonicum, Lysimachia mauritiana, Hedyotis biflora var. parvifolia, Aster spathulifolius, Farfugium japonicum, Wedelia prostrata, Crepidiastrum lanceolatum.

Arbor plants resistant to saltiness in the southern area plant Camellia japonica, Pinus thunbergii Parl, Pinus parviflora, Prunus sargentii Rehder, Styrax japonica, Koelreuteria paniculata, Salix babylonica, Acacia catechu, Chionanthus retusa, Tamarix chinensis, Celtis sinensis Persoon. Shrub plants are Rhododendron yedoense, Euonymus alatus, Ficus carica, Abelia mosanensis, Rosa rugosa, Vitex rotundifolia, Poncirus trifoliata, Ficus erecta, Callicarpa dichotoma. Herbaceous flowers are Aster koraiensis Nakai, Aster spathulifolius, Typha orientalis, Zoysia sinica Hance, Phragmites communis, Campsis grandiflora, Yucca.

3.1.3 Design of Idle Space in Namhong-dong

The unused space that is not utilized, are turned into a southern species planting and resting space, and the atmosphere of the downtown is changed brightly. In order to solve the situation, we had to go through the polluted land which caused walking discomfort, and garbage through which we had to go through and uneven gravel sand in order to go to the coastal area. We made it into a small coastal park after washing the soil. And a large area of coastal scrap irons and garbage is transformed into a space where coral farms, skin scuba and snorkeling can be operated.
3.2 Ecology-Human Connection

Through the direct experience of people, we will revitalize the pier of Namhang-dong to strengthen the resilience of Namhang-dong pier. With much interest and volunteer programs, it will increase its resilience. It can be reborn as a new coastal city through experience of coral aquaculture and biological experience (skin scuba and snorkeling) in breakwater. In the case of Okinawa, a project was carried out to raise the gradually disappearing coral and send it back to the sea. This makes it possible for people to participate in the restoration of coral and to enjoy the scuba diving experience.

Coral raise and tourism in Okinawa of Japan

4. Result

4.1 Masterplan

Fig. 4. masterplan

4.2 Section

Present condition
4.3 Change in the green area ratio

Due to the existing green area of 6,930 m², the green area of 14,443 m² through the diffusion of idle space, and the waterfront green area of 10,521 m², Namhang-dong will secure 5% of the green area of 31,894 m² of the total area of 662,634 m². And because of the design of sea and breakwaters to increase biodiversity, the increase in ecological rate is infinite.

5. Conclusion

Now Namhang-dong pier has stopped, but it will led to the diffusion of ecology through ecological redesign, starting from sea and breakwater to coastal (waterfront) and idle space to revitalize Busan Port, which has a long history. Although only seaweeds exist in the present coastal area, ECOcrete®Antifers (EA) breakwater promotes biodiversity and ties coastal waters between the sea and land to link ecosystems through the use of marine plants. If all these ecological re-designs are completed, there will be a numerical 5% real ecological space, and invisible ecological values will be too large to be quantified. And the most important component in reviving a dying city is attracting users. The goal is to provide rich ecological space and resting space, and bring economic value through ecological activities that can be practiced. Because of its geographical accessibility, Namhang-dong has a resilience to revive quickly if you create a bright city through ecological redesign. Through this design, people will be able to manage the biodiversity without forgetting the history of Busan Port and Namhang-dong, and as a result, it will create a great economic benefit.

Abstract

Massive and rapid urbanization caused considerable land use changes, biodiversity loss, and habitat fragmentation. To understand the potential impacts to urban ecosystem services, give the suggestions on how to solve the conflict between environmental protection and the economic development, and explore several opportunities on policy-making for the future, we developed a spatially explicit land use change projection for a rapidly urbanized urban region in Seoul 2030. For 7 districts developed since the 1970s in Seoul city, we quantified the interaction of future development on biodiversity maintenance. The Land Use Land Cover (LULC) maps of 1972 and 2015 were employed to predict the LULC scenario for 2030 using Multi-layer Perceptron (MLP-ANN) and Markov Chain Analysis (MCA) method. Then we quantified habitat quality (HQ) as a proxy for biodiversity in 1972, 2015, and projected 2030 using Integrated Valuation of Ecosystem Services and Trade-offs (InVEST) model. The results show the area with high HQ-value and low HQ-value decreased by 35.15% and 27.42%. In Contrast, the area of medium HQ-value increased by 20.93%, while the area of non-habitat increased about 6 times from 1972 to 2015, dramatically. The MLP-MCA-based prediction for 2030 showed that fragmentation of forest habitats would be increased slightly which causes the decrease of the area with high HQ-value. We hope that the results will contribute to an understanding of the potential of future landscape changes based on the ESs concept in green-infrastructure and land-use planning, and conclude with providing some challenges for future research.

Keywords: land-use projection; urban biodiversity, ecosystem services, Seoul 2030

1. Introduction

Massive and rapid urbanization caused considerable land use changes, biodiversity loss, and habitat fragmentation [1]. This situation makes urban planners and policymakers needing to move beyond a mere management of urban landscape to translate and uptake the concepts of ecosystems functions, resilience, and sustainability into the governance policies.

Ecosystem services (ESs) is defined as the manners in which ecosystems benefit humans. Since Costanza et al (1997)
evaluated the ESs valuation at a global level in a paper published in Nature [2], the term of ESs gained broader attention. From 2001 to 2005, the United Nations finished its Millennium Ecosystem Assessment (MA), a four-year, 1300-scientist study for policymakers [3]. This assessment defined the functions of ESs as four aspects (provisioning, regulating, cultural, and supporting) which were broadly accepted and applied by public and professionals. Between 2007 and 2010, United Nations Environment Program undertook a program called the Economics of Ecosystems and Biodiversity (TEEB), which brought ESs to a broader audience through the mass media [3]. Later, Intergovernmental Science-policy Platform on Biodiversity and Ecosystem Services (IPBES) was created in 2012 further enhanced the ability of the evaluation, management, policy application, and international cooperation on ESs.

ESs are still prone to frequent rapid degradation and depletion by multiple natural and anthropogenic disturbances [4, 5]. The Land use and land cover (LULC) changes have been defined as the most important anthropogenic disturbance to the environment at the local level that can greatly alter the provision of ESs [6]. The LULC projection is a useful tool to understand the potential impacts to urban ESs, which give the suggestions on how to solve the conflict between environmental protection and the economic development and explore several opportunities on policy-making for the future.

This study aims to detect the response of ESs to a LULC projection, using biodiversity as a case study. We developed a spatially explicit land use change projection for a rapidly urbanized urban region in Seoul. For 7 districts developed since the 1970s, we quantified the interaction of future development on biodiversity maintenance. We try to answer these two questions: 1) how did the habitat quality change during the rapidly urbanized period of 1972 to 2015? 2) what will the trend be in habitat quality according to land-use projection in 2030?

2. Methods

2.1. Research Site

South Korea is one of the most urbanized countries in the world, with an urbanization rate of almost 90%. One of the major challenges experienced by Korea was the reduction in biodiversity due to the expansion of population and the loss and fragmentation of natural habitat caused by the rapid industrialization. In Seoul, the capital of South Korea, forest areas cover 24.5% of the city area, and parks cover
2.0%. This study investigated a newly expanding and developing urban area since the 1970s in the southern part of Seoul. A region of approximate 20430 ha in size, including Gangdong-gu District, Songpa-gu District, Gangnam-gu District, Seocho-gu District, Gwanak-gu District, Geumcheon-gu District, and Dongjak-gu District (Fig. 1).

2.2. Data collecting

A time series of LULC maps were derived from historical aerial photos with 5 meters resolution. The map of 1972 was digitalized from historical maps and the map of 2015 was provided by Seoul Metropolitan Government (Appendix 1); we then standardized and transformed the significant LULC types in the different maps into a common classification using ArcGIS 10.2.2. Finally, 12 re-classified LULC types were created.

2.3. Research methods

This study developed a spatially explicit land use change projection for a rapidly urbanized urban region in Seoul. We quantified the interaction of future development on biodiversity maintenance. The LULC maps of 1972 and 2015 were employed to predict the LULC for 2030 using Multi-layer Perceptron (MLP-ANN) and Markov Chain Analysis (MCA) method, firstly. Then, habitat quality (HQ) was quantified as a proxy for biodiversity using InVEST model.

2.3.1. LULC projection

The LULC change analysis, simulation, and future LULC change prediction were carried out using Land Change Modeler (LCM) for ecological sustainability which is an integrated software environment available in IDRISI. Clark laboratory and International Conservation cooperated for many years and designed the IDRISI LCM mainly includes MLP-ANN, MCA, Cellular Automaton, and Soft and Hard Prediction Model.

The modeling of potential change was used LULC maps of 1972 and 2015 to simulate the year 2030 (see Appendix 1). Firstly, a transition map was generated for all LULC classes to produce the empirical likelihood of change statistic [7, 8]. Then, six major transitions were considered that was supposed to be possible factors driving LULC change in the study area. The variables used to derive this included nature factors and spatial distance factors, regarding (1) slope, (2) terrain height (DEM), and (3) soil classification as natural factors; (4) the distance from green space edge, (5) the distance from roads, (6) the distance from water bodies (river and wetlands), (7) the distance from the green belt, (8) the distance from urban infrastructure, and (8) the distance from urban core of Seoul city as spatial distance factors.

2.3.2. Assessing habitat quality (HQ) and hotspots through InVEST tool

We apply InVEST model produced by Clark Labs to evaluate HQ as a proxy for biodiversity [5, 9]. The modeling process of
HQ module is based on the hypothesis that areas with higher HQ support higher richness of native species, and that decreases in HQ lead to a decline in species persistence [10]. This study has assumed that the changes in ESs are caused mainly by changes in land usage [11]. The input parameters including the suitability of land use type for providing habitat for biodiversity, the different anthropogenic threats likely impairing HQ [10, 11, 12, 13], and the sensitivity of each land use type to each threat was referenced from previous studies (Table 1) (see InVEST user’s guide for further details on this method) [5].

### 3. Results and Discussion

#### 3.1. How did the habitat quality change during the rapidly urbanized period of 1972 to 2015?

The HQ model result shows the pixel values range from 0.1 (lower quality) to 1 (higher quality) for urban habitat (Appendix 2A). The map result represents the previous and future conditions based on LULC 1972, 2015, and 2030 data. The good quality habitat was mostly in mountain landscape, followed by secondary forest/remnant forest and plantations in public parks. The hotspots of biodiversity are concentrated in Gwanak-gu and Seocho-gu District both in 1972 and 2015. Most of the hotspots of habitat quality decreased in Gangnam-gu, Songpa-gu and Gangdong-gu District where multiple land-use types are present (Appendix 2B). The reason for this landscape change is related to many various development projects with little consideration on the natural environment in Seoul [14].

We scored the HQ value into four groups: between 0.85 and 1.0 (high), between 0.55 and 0.85 (medium), between 0.01 and 0.55 (low), and 0 (non-habitat) (Fig. 2). During the rapidly urbanized process (1972 to 2015), the area of high HQ-value and low HQ-value decreased by 35.15% and 27.42%. In contrast, the area of medium HQ-value increased by 20.93%, while the area of non-habitat increased about 6 times dramatically from 1972 to 2015.

#### 3.2. What will the trend be in habitat quality according to land-use projection in 2030?

![Habitat quality projection](image)
Habitat for the HQ we modeled showed overall declines under land-use change projection. Till 2030, biodiversity of hotspots shows a decrease in mountain-foot area. The fragmentation of forest habitats mainly causes the decline of the area with high HQ-value (Fig. 2). The area of medium and low HQ-value increase a bit, correspondingly.

3.3. The implication for future projection in ecosystem services of Seoul

The conservation of biodiversity is the main biodiversity strategy in Korea. National research organizations specializing in biodiversity and its conservation have been continuously stabled to enhance the research capacity and conservation of biological resources [15].

The 2030 Seoul Plan is the Seoul Metropolitan Government’s priority plan for the direction and change to be pursued by the city until 2030 [16]. One of Seoul 2030 plan’s goals is to preserve the ecological environments and scenery that are unique to the city, particularly, protecting and restoring the four inner mountains, located within the boundaries of the old capital, and the four outer mountains, which are outside the boundaries of the old capital. The MLP-MCA-based prediction for 2030 showed that fragmentation of forest habitats would be increased slightly. Therefore, the conservation of forest area and careful design of green spaces should be paid attention to in the future policy-making to biodiversity conservation. In addition, effective projects of green infrastructure should be built to link fragmented habitat continuously on the ground and build a habitat network, such as well-created green rooftops that can support animals and plants extensive and play an important role in conserving urban diversity.

4. Conclusion

This study explored the response of habitat quality to land use change projection in a highly urbanized area, using Seoul as a case study. Our findings indicate that the huge decline of biodiversity happened in a rapidly urbanized period (1972-2015), and this negative situation will be continued according to the MLP-MCA-based prediction for the year of 2030. These findings support a reference to implement the plan of Seoul 2030. The conservation of urban forest remnants and construction of newly formed green spaces should be viewed as essential components in future ecological planning and integrated into biodiversity conservation schemes. We hope that this study will contribute to an understanding of the potential of future landscape changes based on the ESs concept in policy-making, and conclude with providing some challenges for future research.

The San Leandro Creek Urban Greenway in Oakland, CA
Resilient Infrastructure for Retrofitting the Future Biophilic City

Abstract

This paper presents the efforts of an ongoing community-based “biophilic” infrastructure project that demonstrates future resilience by reclaiming a fragmented and compromised urban creek corridor within East Oakland (San Francisco Bay Area), CA. The San Leandro Creek Greenway project took shape through the shared vision, engagement and leadership of an applied urban greening studio program at Merritt College working directly with neighborhood residents in the explicit effort to restore community livability by bringing nature back into the fabric of the built environment. This section of Oakland, under-resourced and disadvantaged, is a culturally rich mixture of Latino and African American residents. Due to historic neglect and the hubris of high-modernism, it is also a community ensnared in concrete, asphalt and all manner of pollution that not only is crippling to habitat biodiversity but leaves this bay-side community extremely vulnerable to sea-level rise and storm-surge inundation. Addressing these cumulative conditions is a sustainability and climate resiliency effort but most importantly for the residents, it is a health and environmental justice issue.

When it comes to green infrastructure investment and initiatives, neighborhoods like these are below the city’s radar. This project highlights though how landscape architects and students successfully collaborated with community leaders to strategize a “bottom-up” design-build approach to transform the neighborhood culverted-watershed into a greenway that can weave together people and place as part of a living environment. The authors convey how this unique intensive local planning approach not only garnered implementation funding to establish needed non-motorized transit and recreation but also provides residents with new contact to the existent wildlife corridor, spaces for urban agriculture, and infrastructure for floodplain protection and climate adaptation. In a larger sense, this paper illustrates how neighborhood-based urban greening, as a landscape strategy oriented
Future Resilience

around the often hidden natural assets of place, can lead the inspirational citywide strategic visioning for a city that is retrofitted for transformative resilience. This is the future “biophilic city” that is rooted in equitable everyday livability.

Key words: community engagement; urban challenges; greenway; retrofitting; creek rehabilitation

1. Introduction

“Trees don't grow to the sky” – the old saying goes. By now, more and more people realize that there is no such thing as limitless growth in a limited system. This is especially true for the world’s cities and metropolises. Currently, more than half of our global population is concentrated in cities or in urban areas, and this number is exponentially rising. Today’s societies must find a way to make cities, our largest human artifacts, livable and sustainable.

2. Nature and the future biophilic city

Sustainability and urban “greening” approaches, including specific focuses on climate adaptation and resiliency, have been increasingly emerging as critical city development strategies over the last decade. However, these strategies do not necessarily imply how such development relates to nature, people’s connection to nature and natural processes. In fact, many sustainable development and infrastructure projects may be applied without any direct engagement or integration with local site “nature” or the ecological health of a site. This marginalization of the conditions of “first nature” in the realm of sustainability planning may be starting to change.

Cities such as Singapore as a celebrated example, are now beginning to showcase urban redevelopment that reflects a deeper ecological understanding and “biophilic” sensitivity with an explicit intent to make greening more than just aesthetic additions - a move to imagine a 21st C “city in a garden” as a transformation from the 20th C “Garden City” ideals. Many environmental urban planners, led by the seminal work of Timothy Beatley, are emphasizing the overlap between such biophilic approaches and climate adaptation, sustainability and resiliency planning. Others are emphasizing the need to be able to interact act with nature and natural processes as a fundamental part of our human existence.

However, the critical question remains whether new urban eco-greening approaches are putting connection to nature at the core of city planning in just a figurative sense (read new eco-downtown as the latest complement of “smart growth”) or in a literal sense of transforming cities and citywide planning as a whole? Do such developments increase the City’s climate adaptation or resiliency or overall sustainability? Are such developments equitable and accessible to integrating people to nature or do they mostly stand as commercialized spectacle? Optimistically, large center-piece urban development projects start the re-imagination of “future biophilic cities” in a strategic way that is compatible with growth. Even if this is true, such eco-greening as urban redevelopment needs to be balanced, perhaps even led, by approaches that provide opportunities for natural process to be woven into the everyday fabric and infrastructure of our urban environment for a deep citywide transformation that is sustainable, resilient and livable.
Consider how thoroughly our current built environments are quite the opposite of the biophilic approach to nature succeeding in suppressing the visible natural processes while our cities remain more unsustainable and vulnerable to climate change even as we claim progress with green architectural gems. Our high-modern infrastructure is built on the logics of domination, suppression and overcoming nature and natural processes – are characterized by urban patterns of fragmentation and social isolation. Despite such logic, our urban landscapes still are place-based and must work together with nature in a dynamic balance. Our cities of grey infrastructure are unsustainable, vulnerable to climate change events like sea level rise, urban heat island effect, storm surges and even cascading social upheavals.

Often, we do not sense the precarious status of this balance until there is an event that overwhelms our systems as we have seen with storm-surge flooding, urban-wild-land interface fires, mudslides and so forth. The current infrastructure, instead of enabling adaptation to stress and shocks, is actually very fragile and dependent on large capital intensive super structures and mobilization of resources on a global-scale to maintain itself. Meanwhile, the urban ecologies of concrete and asphalt landscapes have been unceremoniously denuded of diverse native habitats and place features to be replaced by invasive colonizing monocultures.

Can we retrofit our existent urban infrastructure to integrate biophilic ideas to become more balanced with natural processes and more resilient – an infrastructure that is about transformative adaptation as opposed to ad hoc reforms? What would such infrastructure look like? What features, and characteristics would it have? How would it affect the ordinary life of urban residents? How can such infrastructure help support local diversity, equity, and organic cultural emergences? To achieve biophilic city planning that reflects the natural processes, makes such processes visible and accessible in different scales; integrates the nature of place with the built environment in a sustainable manner, creates points of shared intimacies of people with the rhythms of place requires the cooperation of landscape architects, city planners, civil engineers, architects, ecologists, biologists, sociologists, but most importantly, involvement of the people living in a place. Such approaches means nothing less than putting standard planning, even in its focus on green development, on its head.

3. Focusing on watersheds and topography – the intersection of people and place

When it comes to natural landscape forms, nothing shapes the topography – the topos – more than water. Water also sustains life of all forms and is the conduit for ecological richness and interaction. Human ecologies are no different. Since the ancient ages, water is the place where we come together and celebrate our conviviality.

After a century of hydraulic engineers’ flood control management, most urban creeks and rivers have been channelized, while wetlands and marshes have been filled in and regraded for development. In the
current form of the built environment, site water is often relegated to hidden infrastructure – conduits, culverts and pipes. Springs are obliterated, rivers dammed, flood-plain graded while the new constructed landscapes are dotted with closed-loop water fountains that help attract consumers to glitzy malls and pavilions. This outcome denies residents access to connect with actual site water forms and ecosystems that these features support. [6]

The cost of altering the existent hydro-scape is an increased risk of flooding, habitat destruction, and the removal of a key natural asset that many do not even know we are missing. The city with truncated marshland and concretized rivers is far more vulnerable to climate events like hurricanes as we saw vividly with Katrina in New Orleans. The lessons are clear. The topography, exemplified by water and how we interact with it, cannot be the after-thought after all the buildings and freeways and parking lots are laid – it cannot be what is wedged into to the left-over spaces. These spaces must come first, be valued and protected and supported – be built around. They are the fundamental assets of the place and can be connected with the hidden assets of our communities as well.

With this approach, our aim as biophilic landscape planners is to envision and seed topographical-oriented infrastructure that builds inter-connected conduits weaving together people and place in the city. These living conduits exist already – our urban watersheds. For example, as highlighted in this paper, we focus on designing infrastructure interventions as “greenways” that connect the communities in which people live to the city as a whole. While the term greenway has its roots in the rather staid if not genteel naturalized landscape expression exemplified by Olmsteadian parkways, in our current treatment, they have to be more than just a walking path, a creekside trail and a palette of trees – they are where nature, culture and everyday life can be woven together. [5] They are the emergent structure of the resilient and biophilic city.

This greenway emergence must directly involve the community and the living aspects of a place if it is to resist the unintended consequence of re-colonizing space and the tentacles of a probing capital-growth machine that thrives on the extractive logic of commodifying nature and displacing that which it cannot digest. As a principle, a biophilic and resilient city must involve at all levels protecting the health of its diverse populations and habitats. It is a sad reality that too often the creative rawness of our most poor and disadvantaged communities...
are seen as a threat to the social order of the city – to only be policed and managed. Really, such in-situ creativity and the people as creative agents are like the ecological “indicator” and keystone species upon which the health of the macro-community is reflected and predicated. With all of this in mind, our team of landscape architects, planners, teachers and students started working to help establish a watershed-based greenway project in Deep East Oakland along the San Leandro Creek – a corner that the city government has essentially bypassed. The residents though began their own neighborhood greening campaign starting in 2007. One of the first projects identified was creating access to the fenced-off creek at the end of 105th Avenue.

4. The San Leandro Creek as a case study

“Greening without Gentrification” reads the flyer. Our team joined by students from Merritt community college meets with a group of residents on this bright fall morning for a series of community conversations and an informal “charrette” to gain a better understanding of what the San Leandro Creek means to those who live next to it and what their visions entail. We show creek maps, photos of the creek and with note boards, talk about how the creek and the neighborhood could work together. Conversations ensue retelling how this creek has been fenced off, how it attracts trash dumping and other negative activities. But there are more positive stories: of remembered times fishing down at the creek, exploring and riding bikes as kids, of picking wild watercress and other useful Creekside vegetation. The hum of the nearby freeway straddling the creek interrupts the conversation as the streets rattle with the passing of each diesel truck overhead. On this day we are working with a new group of largely Latino neighbors of Sobrante Park and Columbia Gardens inviting them to be part of shaping the design of the greenway. Merritt College has been taking students down to this creek for the last eight-years to help start the visioning and planning process of how this forgotten creek can become a

Fig. 3. The San Leandro Creek flows across East Oakland as the only remaining entirely day-lighted watershed in the city.

Fig. 4; 5. Opening new routes: East Oakland “scraper bike” crew riding along creek towards a shoreline park (right) less than one-mile from where they live though most never visit as it is cut-off by freeways and railroad tracks.
jewel reinvigorating a neighborhood seeking healthy planning solutions to counter the alienation of the everyday struggle in this corner of East Oakland – “one way in and one way out.”

Our classes have been working with small neighborhood groups and community gathering with a direct intention that what emerges from this creek project must reflect, involve, and benefit the residents who live here and not further exacerbate conditions that might make their neighborhood more vulnerable to unwanted cultural or ecological dissolution.

We talk about existing assets: there are several schools nearby, a church and a new plant nursery. We talk about the existing London Plane (*Platanus × acerifolia*), the few Redwoods (*Sequoia sp.*), Acacias and the Prickly-Pears (*Opuntia sp.*). We talk about how and where the kids bike, the formal and informal paths people use to cut across the neighborhood, and the community enthusiasm for clean-ups and greening projects. We also talk about the deficits, such as the lack of safe, attractive and useable parks. On this day, there is a great reluctance when the idea of potentially establishing access to a new park on the creek greenway emerges. “This will attract the drug-dealers… it will create an area for criminals to run.”

Residents point out that the existent small Columbia Gardens Park has been thoroughly stripped of its swings and just sits as a desolate patch of unkempt grass and a broken sign. Ironically, the general idea of a creek path is heartily accepted – as long as it is not directly immediate to their backyard – a strange twist to the well-known planning NIMBYism typically reserved for richer...
folks fighting against unwanted land-uses. Surprisingly, the idea of improving the current park as a gateway to the creek was supported and soon various ideas were spurred of what this could contain.

As we talked, we were all frustrated by the fact we were locked out of the very creek area we were discussing, only able to gesture to it behind a Flood Control fence. Suddenly, one of the neighborhood residents who lived next to the service entrance to the creek remembered that a County worker had entrusted him with a spare key and decided to try it. It worked and with the group of skeptical residents we excitedly walked back to a tree-lined world where the neighborhood cul-de-sac disappeared, and we stared into the pulsing life of this creek confluence area where it conjoined with another culverted tributary. The place that only moments earlier was resoundingly dismissed as any kind of park looked different in person. The fall leaves littered the ground in a beautiful red and orange carpet, egrets skipped low over the water, and the shimmering rise of the creek water in this inter-tidal zone reflected a long band of impressive murals framed by the gentle sway of the trees. There was silence and hushed talking. There was a new energy awakened by the nature of the creek. Suddenly, it all made sense about what the intentions of the greenway were. Here was a creek that these long-time residents have never actually been able to get to and only had negative views. This was a hidden asset and they were now ready to help shape it.

Over the next few months, our team took the accumulated community input compiled over the eight-years and packaged a grant funding application to initiate a one-mile design-build phase to what this greenway linking the neighborhood to the Bay could become – a watershed corridor of “organic” place-making, community reflection and inspiration and not the default standardized “off the shelf” style of development that radiates value-engineering and business-as-usual or more focused on bringing in “outsiders” without providing for the “insiders” first. To construct, the project calls for prioritizing resident job-training, education and workforce development in the design refinement and building of the project as well as tree plant establishment for three-to-five -years post construction and on-going resident stewardship. The project also calls to establish places for job opportunities and places for neighborhood businesses.

5. Conclusion

In October 2017, the State of California awarded $4.1M from greenhouse gas reduction funds to start building this project. The greenway project stood out in its unique level of participatory design and the deep ground work that modeled what co-benefit
urban greening, climate mitigation, and adaptation strategies could look like. On a more intimate scale it is about improving health, increasing resilience, and fostering connections to re-awaken the senses to natural processes, to think about where the water comes from, to think about the steelhead trout spawning in the creek, to feel the totality of earth, wind, water and fire.

As an urban design feature, the greenway it enables people to adventure out to the Bay marshlands, to feel the coolness on a hot day, or the shelter of the tree canopy as a respite from city noises. This project will succeed when neighbors create a connected zone between their gardens, backyard fences and the creek, when kids ride and walk to school, parents go on group exercise walks, the neighborhood boxers come down and do a training regimen, families hold picnics, older couples stroll hand-in-hand, cyclists and joggers pass through with a smile (Appendix 1-4).

At a larger level, the life and soul of the San Leandro Creek’s rehabilitation is addressing the current issue of our age: the already-felt climate change and sea level rise impacts and shows how such watershed corridors can operate as a buffer protecting ground areas from critical flooding. This project thus sets the stage for the type of needed “biophilic” investment that can retrofit the city structure for climate resilience and sustainability while improving the health of local residents. While city planners can easily talk about the need for such investments, actually manifesting such projects where they are needed most have not only not been done successfully, they have been not prioritized – losing out favor to big commercial-oriented development projects.

Reconnecting our landscape to the nature of place through under-valued watershed corridors has clear benefits on multiple scales however the push has to come from those people, planners and landscape designers operating closest to the water.

We started this green infrastructure/urban greening project on the San Leandro Creek to re-stitch a broken and fragmented landscape and hopefully to plant a seed for a larger restructuring of the city.

There are eight other of these significant creek corridors in Oakland that connect to the San Francisco Bay. To achieve a transformative adaptation, further watercourse rehabilitation promises to be a good strategic goal and should be carried out along this principle pioneered by the conversion of the San Leandro Creek.

Like water breaking through rock or concrete, this infrastructure will find its path and in doing so, set the stage for a more resilient and biophilic city not just for the future but for the quality of life we are for building now.

Abstract

Since climate change has made floods and droughts more drastic, our city often faces the condition where flooding and water shortage are easy to take place. Urbanization has fundamentally changed the characteristics of water, which are gravity flow and cycle process, and has overlooked the comprehensive consideration of the impacts of water management on ecological improvement, comfortable environment, scenic beauty, and disaster prevention and control. Therefore, integration of water management and landscape have become important issues.

Observing the water emitted by the city environment, rainwater and grey water, which were considered wastewater, can be regarded a type of resource. Sustainable water cycle strategy is to consider the space, water, and natural resources for the integration of the urban environment. Developing a sustainable landscape environment through the integration of water management measures with creativity and the urban areas are combined with the development of ecologically balanced water environment in order to ameliorate urban heat island effects and the crisis of water shortage.

This study mainly used the methods of literature research and content analysis to collect theories to serve as the basis of its argument and combined analyses of international cases. The aim was to reduce the reliance on tap water input, transform the construction of impermeable infrastructures, increase infiltration and provide evaporation, optimize urban water cycle, improve the quality of the water flowing back to the environment.

Through the research and development of the strategies for sustainable urban water cycle, it was hoped that the study could promote urban water resources to have multiple uses for people and for the environment, and that it would serve as the reference for practicing sustainable engineering and developing ecological cities.

Keywords: Water cycle, water management, sustainable landscape

1. Preface

Due to the impact of climate change, the uneven distribution of topographic features, rainfall timing and rainfall areas in Taiwan Island have led to the increasing frequency of disasters such as: torrential flows, landslides, urban floods, and shortage of water supply during dry seasons. Moreover, City planners using the traditional urban development model has always neglected the function of water cycle, changes the characteristics of rainfall runoff, and infiltration that has reduced the natural detention capacity and as a result, it has caused the deterioration of water control in urban areas.

2. Issue of current urban water cycle under climate change

The climate warming rate in Taiwan is twice as fast as the global average, and the main hazard arising from climate change is hydro-meteorological disaster, due to such warming affects the delicate balance between water cycle, rainfall, evaporation and all processes in it, which in turn causes the change of the intensity and type of rainfall and the spatial distribution. The phenomenon of excessive dryness and torrential rains possibly caused by increased evaporation along with the additional environmental factors of landscape change due to urban development, have all contributed to the deterioration of urban water resources (Figure 1) which leads to the following issues:

Fig. 1. The changed phenomenon of water cycle caused by climate change Source: https://www.epa.gov/climate-impacts/climate-impacts-water-resources
2.1 Water supply affected by uneven rainfall

The warming phenomenon in Taiwan mainly appears in the increasingly uneven rainfall during the dry and rainy season periods. The increased intensity and frequency of extreme rainfall during the rainy season has elevated the risk of flood, while the incapability of keeping water by reservoir system due to restriction of safety management and the lack of rainfall during the dry season have affected the detention of surface water and the groundwater recharge. In return, it has downgrade the supply of water resources.

2.2 Increased probability of high temperature leads to worse problem of water use

Temperatures in urban areas of Taiwan are still significantly higher than those in non-urban areas. Among them, the heat island effect is playing an important role in fuelling the flames. When the temperature rises, people and animals and plants need more water to maintain the health and growth of themselves. When the demand of water increases, gradually, the use of water dispatch becomes more and more intense. As a result, it will face the crisis of water resources shortage.

2.3 Impact on infrastructure carrying capacity

The extreme rainfall caused by climate change often leads to serious urban flooding. The floods are always for beyond the designed drainage system.

For example Typhoon Soudelor, August 2015 brought in a heavy rain of 253mm in 3 hours, that severely damaged the urban flood-water facilities (Figures 2, 3), while the engineering means to improve the frequency of flood protection in urban drainage system design may not be able to accommodate the extreme rainfall under climate change in terms of economic efficiency and time consuming. [1]
2.4 End treatment concept leads to rainwater is treated as waste water  

From the perspective of the construction of urban water resources facilities, the intricate network of pipelines constructed that carries water to urban premises, in which the used water will be transferred to a sewage treatment plant and then discharged to the ocean via a series of underground sewage pipelines. In the meantime, the relatively clean rainwater under the current concept of centralized end treatment often leads to the lack of water infiltration and interception to earth soil. In addition, due to the promotion of the collection and transportation of pollutants, rainwater is treated as waste water to hydrate the lands under natural water cycle and as a result, it destroy the capacity of ecosystem to recover or compensate. We must re-think the functions and benefits of water cycle in order to let it balance and restore the ecological environment!

3. Case study

3.1 Case of Sidwell Friends School

Sidwell Friends Middle School was completed in September 2006 and was awarded a LEED Platinum rating in March 2007, (Figures4,5) The innovative stormwater management systems included both an on-site constructed wetland treats wastewater and green roof and outside bio-retention that reduces stormwater runoff and improves the quality of infiltrated runoff. After first flowing through a treatment tank to remove solids, the wastewater is treated using biological processes. These constructed wetlands treat wastewater to the same standards as the municipal system but due to health codes, the water can be reused only in commodes. Models show that the building uses 93% less District water by treating our sewage in the wetland and reusing the water, as well as through water-efficient landscaping.

The planting design was inspired by this ecological context. Peripheral areas were converted from lawns to “micro-restoration areas” intended to showcase native ecosystems such as oak-beech woodlands and wet meadows. More than 80 kinds of plants in wetland garden. So Aquatic plants, water, sun, soil, microorganisms, sand, and air filter and clean the water.

9. Woodland screen at neighborhood edge;  

Fig. 4. The configuration map of Sidwell Friends School, Washington, USA Source: http://pruned.blogspot.tw/2009/06/wetland-machine-of-sidwell.html
Also using plant species that are drought resistant and able to thrive naturally in the area eliminates the need to irrigate, saving water and energy. Planting native species and non-invasive adaptive plant varieties preserves local biodiversity.

The goals of the master plan were to integrate educational opportunities into the campus landscape. The aesthetic proposition was to feature a traditional academic quadrangle while turning its focus outward to the natural world and its systems. Integrated water management solutions into the landscape, inextricably linking the building to its site. The wetland becomes a “working landscape”; in their dirty, smelly, real-world engagement with the landscape, using biological processes to clean water while providing students with a vivid example of how such systems work in nature. This “working landscape, wherein natural processes are co-opted into a cybernetic amalgam of landscape, architecture, geology, biology and institutional pedagogy.

3.2 Case of Dockside Green Community, Victoria, Canada

Located in Victoria, British Columbia, Canada (Vancouver Island) and covered with seven hectares, the Dockside Green community is the world's first platinum-certified community (Figure 6). In addition, it was rated as one of the ten sustainable and green building demonstration programs by the American Institute of Architects (AIA). The first phase of the project was completed in July 2008 with an overall construction project including residential buildings, commercial buildings, sewage treatment plant, and thermal energy plant. Dockside Green's rainwater management is designed to mimic the natural hydrological cycle, in which the rainwater is filtered through roof greening and grass ditches, and it adopts visible open water and small waterfall designs to replace the grey rainwater pipe design. Through the processes of rainwater gardens and native plants,
Future Resilience

rainwater is stored in underground water storage tanks or flows into central artificial rivers to facilitate it to be integrated into the water recycling system. All collected rainwater can be reused for irrigation and toilet flushing, and its rainwater management measure adopts infiltration and treatment design of ecological greening. This not only reduces impervious paving surfacing, slashes storm runoff, restores the ecological functions of the site, creates a diversity waters features landscape, and enriches green planting. It will provide the community a vibrant landscape serve and eases the urban heat island effect as well.

The artificial rivers in the center of the community is the core belt for development, which serves as a barrier between the public and private spaces, providing places for children to play and for environmental education, it will also serve as habitat for local wildlives, ducks, crayfish, Ardea herodias and otters, etc. This model has increased the value of the “water front area” residential units. More important, as the sewage treatment plant is located at the center of the site and the outdoor terrace has been designed as a public recreational space. It can jointly serve as an environmental education demonstration site for on-site treatment and resource recycling.

4. Suggestions for the sustainable water cycle and landscape development strategy in the city

When a city has changed its water cycle for city development, it should re-face the
falling raindrops and change the thinking about the urban system only on the implement of discharging rain and sewage. The paper put forward suggestions as follows:

4.1 Continuing the natural water cycle model to return to the function of the ecosystem

Strategies of the urban environment in response to the warming phenomena is to maintain more water in the environment and allow the city to integrate into the natural circulation of water: the processes of flow, infiltration, filtration, sedimentation, and purification, the opening of closed rain drainage pipelines and impervious pavements in order to strengthen rainwater storage and infiltration facilities for reducing surface runoff and drainage pipeline load. At the same time, the concept of centralized sewage treatment in the past should be changed, and local water use and source treatment methods should simulate the natural water cycle model in water transport, recovery, and utilization of the city in order to reduce runoff and increase permeability so that to increase the evaporation amount of the metropolitan environment, reduce surface temperature and increase the comfort of the city.

4.2 Developing a sustainable landscape environment through the integration of rainwater and Wastewater management measures with creativity

The current urban rainwater sewerage project should consider the cooperation of urban landscape and greening as well as integrate the ecological landscape facilities of the purifying function into the rainwater and Wastewater purification design, so that the organic substances and nutrients of phosphorus and nutrients in the city’s sewage can be circulated on the spot to nourish urban planting greening in order to create a green eco-city landscape. It is suggested that the landscape engineering method shall be based on ecology and natural life and select appropriate construction materials and measures to reduce the ration of cementation and hard paving, so as to gradually transform into a sustainable urban landscape environment system that integrates with the ecology, and thereby facilitate the urban construction technology engineering method to return to the original value of nature. Among them, the water cycle is also an important process of ecological diversity and climate regulation, which will enable the restoration and reconstruction of the environment landscape and improve the water management mode from the remote input and output.

4.3 Creating regional water texture and imagery

Through the construction and pavement of land preparation and road facilities, the landscape is often altered in the course of such transformation, and the original hydrological context is erased as well, leading to multi-faceted environmental issues and the change of landscape. However, “water” is an important design element for activating the urban environment. Although the water space of
point distribution can achieve local environmental improvement, if the water network can be implemented through water management measures, the ecological environment not only can become more rich and stable, the water governance can also be integrated into urban planning strategies so that to create a landscape ecosystem and form an urban open space system. In this way, not only can the urban environmental comfort be improved, but the transformation of urban construction can also be promoted, and the rich ecological benefits of the natural environment can thereby be returned to the city.

5. Conclusion

Sustainable water cycle strategy is to consider the open space, water, ecosystem and natural resources for urban environment. Through the integration of landscapes, architecture, soil geology, environmental protection, ecology, and education, it regulates and simplifies the management of the dirty and smelly metabolic wastes in urban water systems into urban water cycles and reverses the traditional practice through on-site processing methods as a perpetual and recyclable resource for the environmental landscape. Our management of the water environment should be based on regional circulation to reduce the pattern of reliance on external input, and to integrate landscapes and natural elements through continuous regeneration cycles in order to maintain the ecosystem and enhance the environmental quality.

Flood Resilience through Learning from Experiences – A Case Study of a Frequently Flooded Village

Kuang Da**

*School of Architecture, The Chinese University of Hong Kong, AIT Building, Shatin, NT, Hong Kong

Abstract

Despite resilience increasingly comes to be an important goal for many cities, both the definition and implementation of this concept remain vague. Although recent flood resilience literature generally emphasizes that cities as complex social-ecological systems should adapt to flood, current flood risk management still highly relies on hard measures and people’s risk perception remains low for an extended period. To improve people’s capacity of flood adaptation, this paper constructs an argument that, in flood-prone cities, urban and landscape design should accommodate with flood and make space available for citizens to experience and learn from it. This research is based on a case study of the Xinnongcun village, which is a frequently flooded village and located in the west of Wuhan city China. To explore what kind of knowledge can residents learned from past flood experience, I propose data collection through semi-structured interviews with local households and observation in site. Findings illustrate that people with more experiences of flood will hold more tacit knowledge of adaptation. In addition, with continuously observing flood level changing, fear of flood event will be diminished, which also reduce the losses during emergencies. Learning from the village, this paper suggests that urban and landscape need to be designed with resilience thinking, including designing for multifunctional space and promoting people’s interaction with floods, through which the flood adaptive capacity of citizens can be improved.

Keywords: Learning; flood resilience; tacit knowledge; transformation
1. Introduction

Globally, climate changes have caused impacts on natural and human systems [1]. Floods are the most frequent hazards among all natural disasters, resulting in widespread devastation, economic damages, and loss of human lives [2]. Due to urbanization, population density in flood-prone coastal zones and megacities is expected to continue growing [3]. This future megatrend emphasises the need for better flood-risk mitigation approaches. However, it is believed that traditional flood control infrastructures are unreliable to protect cities, especially after the case of Hurricane Katrina [4]. Thus, a new approach to design and plan for flood-resilient cities is increasingly important.

As resilience increasingly becomes a buzzword, extensive studies propose that resilience could be achieved through a professional design and urban planning practice. Some researchers consider green infrastructure as an effective approach to achieve flood resilience. For example, Lennon, et al. [5] outlined green infrastructures as a means for achieving urban resilience to flooding by providing a design response focused on the receptors of flooding and the pathways by which floodwaters reach these receptors. Ahern developed a ‘safe-to-fail’ framework [6-7] and stated that use of green infrastructures can be a strategy to improve urban resilience capacity. Other scholars focus on flood resilience through architecture design. For example, the United Kingdom published a flood resilient-construction guideline which laid out design strategies for new building construction [8]. The New York Department of City Planning released a guidance [9] for flood-resilient architecture. In general, the current discussion of flood resilience design mostly focuses on expert knowledge. Local knowledge, regarded as the source of social-ecological resilience [10] was ignored in design practice, however. Furthermore, there are very limited works on how to operate flood resilience at a street or neighbourhood scale.

Learning is an important pathway to provide adaptive capacity that enhances and builds resilience [11]. In this regard, this research argues that learning from flood experiences is essential for improving flood resilience. Based on Argote and Miron-Spektor [12] organizational learning study, this paper refers to learning from floods (LFF) as the accumulation of flood adaptation knowledge that occurs during or after an organisation experiences flood events.

In the rest of this paper, a brief review of resilience with learning will be presented. Second, the background of the Xinnongcun village, where the fieldwork has been done, will be introduced. Third, this paper discusses the results of the fieldwork transforming a village from suffering from floods to tolerating floods. After that, the advice for urban street design for flood resilience will be suggested, followed by a discussion of learning from experiences and a general conclusion.

2. Resilience and learning

The recent discussion of resilience always goes back to Holling’s research [13] in 1973 which challenged the classic equilibrium
paradigm in ecological research. Because ecosystems and social systems were considered to be interrelated, resilience later was brought into a larger context and discussed with social-ecological systems [14-17]. Social-ecological resilience emphasizes the ability to adapt to disturbances and to transform once the current state can no longer exist. It addresses disturbances as opportunities to learn from experiences [18]. Based on Holling’s ecological resilience study, flood resilience was defined as ‘the capacity of the city to tolerate flooding and to reorganize should physical damage and socioeconomic disruption occur, so as to prevent deaths and injuries and maintain current socioeconomic identity’. [19]

To enhance resilience, recent research found it is important to identify the ‘source of resilience’ [20]. In this regard, learning and knowledge are increasing linked with resilience as knowledge represents an important determinant of adaptive capacity [21-22]. Adaptive capacity is the main factor in a system that influences resilience [18]. To improve the adaptive capacity of the system, it is important to improve the learning cycle through which humans directly experience and receive ecological feedback from their actions [23]. Gunderson stated that successful management for resilience should contain a learning-based approach that allows for the accumulation and periodic testing of knowledge [24]. Nykvist and von Heland proved that accumulated experience held by the community play as an important source for general and specified resilience [25].

3. Background of Xinnongcun Village

3.1. Uncertain flood risks

Xinnongcun is a small agricultural village located in the middle of Dujiatai Flood Diversion Area (FDA) (Fig. 1). FDA refer to rural areas or polders which could be used to store and transfer floodwaters in emergencies so as to lower the river water stage and protect nearby cities. The Dujiatai FDA is situated in the west of Wuhan and was constructed in 1955. There are about 180,000 people and 29 townships inside the Dujiatai FDA. The FDA aims to divert floods from the Han River to the Yangtze River so as to control the water level in Wuhan and protect the city. Up to now, the Dujiatai FDA has been used 21 times and most of the time, the flood diversion causes severe economic losses and injuries. For example, in 1984, the Dujiatai flood diversion resulted in 56,700 hectares of farmland ruined and 8,000 people relocated inside the area. In 2011, the flood diversion destroyed about 5,000 hectares of farmland and resulted in 1,700 people with no annual income [26]. Villages inside the Dujiatai FDA suffer from the uncertainties of flood diversion.
3.2. Research method

Two fieldtrips to Xinnongcun were taken in June 2017 and February 2018. This research adopted the focus group interview as the data collection method. Ten group interviews were organized in the front yard of 10 houses. Residents who lived in the village for more than 30 years were encouraged to participate. Both homeowners and neighbourhoods joined in the discussion. Each interview lasted 30–60 minutes with questions focusing on participants’ perception of the flood, living experience in the drought season, and living experience during the flood. Field observation also was conducted to record their living environments.

4. Findings

Until 2017, the village consisted of 100 households with about 400 people. Most people that lived there migrated from the west Xiliuhe town in the 1970s to escape hunger. Before moving into this area, people had no experience of floods. This research found, however, that after having experienced flooding more than 10 times during last 50 years, locals’ perception of flooding, the street form and lifestyle have changed to adapt to the uncertain flooding.

4.1. Perception of flooding

People living in Xinnongcun village now hold a high awareness of flood. The villagers call flood ‘Wushui’, which means ‘inundation’. Local villagers evaluate the risk of the flood according to whether the flood inundates their agriculture land and houses. They believe flooding between June and July to be the most serious as this is close to the harvest season but flooding after September (after the harvest) is relatively acceptable as it will not cause too many losses. The interviewees also said that the fear of flood has been reduced because of many experiences with flooding. They understand that floods are inevitable, and they must live with it.

4.2. Street transformation

Besides changes in the awareness of flooding, to mitigate hazards, the street form has been transformed to be more floodable. This paper summarizes the three stages for street transformation (Fig. 2). In the past, when people initially migrated to this area without any experience of floods, houses
were built at ground level. A typical house could have a thatched roof, front yard, and backyard. For most households at that time, there was no preparedness for floods. As a result, houses directly exposed to floods suffered huge losses. In 1983, the severe flood produced waves and collapsed almost all the buildings in the village.

In the second stage, a typical house is characterized by an elevation base, backside pond, and front trees. The flood in 1983 was a turning point for the village transferring to this second stage. After the flood ruined houses in the village, local people reconstructed buildings at the same site. Considering the past flood level, however, houses were elevated with soil excavated from the backside of each house. The excavation area later became a family pond that some used to raise poultry and grow lotus. At the front, trees were planted on a soft soil base to avoid erosion. Most interviewees believed the reconstruction effectively helped them avoid being inundated. Until the last field trip in February 2017, some poor households in the north of the village remained at this stage while other better-off households (most households in the south) shifted to stage 3 with a structurally stronger house and foundation.

The third stage is the current street form, which is also the most interesting one. As shown in Fig. 3 and 4, there are four main elements. The first element is the living quarters which are situated 2–3 meters above the main road. The difference between the second and third stage is that, for some houses that remain subject to inundation, the owners further improved the building structure to make it more floodable with two tips. Firstly, to reduce loss, the
households self-organized two extra spaces for safe storage during the flood (Fig. 5 and 6). Homeowners used to keep water-sensitive products such as fish feed, fish drugs, and clothes inside. Secondly, in the past, the wall of the house was made of clay soil, which is very fragile to flood. After clay walls were destroyed by flooding, homeowners rebuilt houses with stronger concrete (Fig. 7).

The second element of the street is the front yard, the most active part of people’s daily life (Fig. 8). The width of the yard ranges from 3 to 5 meters. The yard offers different functions supplement to the houses. First is breeding. Most front yards used the clay soil excavated from their agriculture land as a foundation. These clay yards not only provide space for livestock but also is used to raise little insects and seeds which could be served as food for chickens and other poultry. Second, it acts as a communication place. Walking in to the village, the researcher found that people like to sit in the front of their yard smoking, talking, or just watching. Local residents say that the front yard is popular for family talks, neighbourhood meetings, and children playing. Third, the front yard serves as a traffic network. This function appears when floods submerge the lower muddy road. Although front yards in the village are mostly connected, in the drought season this place is quite private, and people used to travel on the lower muddy road on motorcycles. When the muddy road is inundated, however, the connected front yards are transformed into a public space that everyone can walk and cross (Fig. 9).

The lower level of the street includes elements of the muddy road and a storeroom (Fig. 2). The muddy road is the main road of

![Fig. 7. Reconstruction house with concrete rather than clay.](image)

![Fig. 8. The connected front yards in Xinnongcun village.](image)

![Fig. 9. Spatial pattern of the Xinnongcun village. The front yards of each house was connected together to act as traffic network during flooding.](image)
the village that connects to the nearby town. As there is no public transportation service in the village, each family used to have a motorcycle. The school also is far from the village, and a school bus picks up students every day. Moreover, the muddy road is also a very important ‘economic network’ because local farmers need to use this road to sell and transfer their fish and crops. Finally, the last element of the street is the storeroom. People use this room to keep their fish feed, motorbike, boats, and other tools. The storeroom not only exists near the muddy road, some families locate it in their backyard.

4.3. Living style transformation

The transformation of the street form also associates with changes in residents’ lifestyles. Before 2000, local people relied on agriculture and mainly grew crops, corn, soybeans, and cotton. Because of the uncertain flood diversion and water logging in the farmland, however, local people felt the pain of living on unreliable farmland cultivation. Although their agriculture land was not inundated every year, once a flood occurred, all the farm products would be destroyed. Therefore, after the flood diversion in 2005 which inundated the village’s entire agriculture area and resulted in no harvest, local people started thinking about alternative ways to use their land and make money. About 80% of the local households reached a consensus to ‘renovate’ their agriculture land into fish ponds. Compared with growing crops, fish farming is more ‘flexible’ as collecting fish is much easier and faster than traditional agriculture land cultivation during flooding. One interviewee said,

‘如果是养鱼的话，在洪水来之前我们至少还会抢收到一些。如果是种庄稼的话，那就淹了什么都没有了。’

‘Anyway, we will collect some fish before the flood level rising and submerge the fish ponds. However, if we grow in agriculture land, everything will be washed away and we will have no harvest during that year.’

5. Learning from the case

Communities never control conditions that affect them, but they hold the ability to change many of the conditions that can increase their resilience [21]. Learning from this case, the community’s ability to tolerate floods can be increased by understanding the flood regime and modifying the living environment. In cities, increasing flood risks, coupled with climate change, already has given some urban design concepts opportunities to take flood-risk management into account, such as a water sensitive urban design, low-impact urban design, sponge city, etc. This paper summarizes two principles learned from this case. Firstly, the urban street needs to be designed as multifunctional. Secondly, the urban street needs to keep connectivity during floods.

5.1. Multifunctional

The urban street is a place where people live and work. It is complex, and its functions are highly mixed. Multifunctional use is efficient and economically can be fulfilled by combining functions, stacking,
or time-shifting [6]. Stacking refers to operating different functions in the same space independently or in a complementary manner. Time-shifting refers to using the same spatial location but at different times. In Xinnongcun village, front yards were self-organized by local villagers to adapt to both drought and flooding. People in the village applied both stacking and time-shifting strategies to use the place and concern about floods as a part of its street life.

The practice of multifunctional design in urban areas always is associated with green infrastructures, which often are a hybrid of artificial ecosystems and built infrastructures. Many authors [27-29] emphasise the importance of considering nature in the design process; this can bring benefits of the ecosystem service into human practice. As urban streets keep functioning during flooding, modern cities can include ecosystem service within the street design. For example, Portland’s ‘Green Street’ programme integrates storm water infiltration, pedestrian, automobile transportation, and parking in the street design.

5.2. Connectivity

Ensuring streets connected with the city is essential during floods. Learning from the village, there are two key points that could support the street connectivity – aboveground pedestrian walkways and alternative transportation. Aboveground pedestrian walkways refer to the village’s upper-level private front yards which become pedestrian paths during flooding. To practice this principle in urban street design, it possibly could be a temporary pedestrian walkway, such as the temporal bridge constructed in the Nanyuan residential area in Wuhan city that supports residents’ daily movement during flooding.

Alternative transportation also aims to keep mobility. It is dangerous to drive a car during flooding as drivers may get injured when cars hit pools, stall, and get stuck. In this case, people used to drive motorbikes during drought season but transfer to traveling by boat during flooding. Although developing alternative transportation for flooding is difficult to achieve in compact cities because of density, safety problems, and many other issues, this is valuable to help the city to tolerate and transfer to live with floods. For example, in Chennai, India, a local taxi operator Ola tried to provide boat services for residents. Although this service was offered only to rescue people in the waterlogged areas and take them to safer places, it potentially could be developed to be a daily service during a flood.

6. Flood resilience through Learning from experiences

So far, the case reveals that a flood-resilient street needs to be multifunctional and keep connectivity during flooding. Both principles are built on the fundamentals of learning from flood experiences. Learning from experiences helps people to understand the flood regime, such as the inundation area, flood level, flood speed, and duration of floods. This later contributes to the selection of functions such as stacking of front yards, the height of house elevation, and a potential area for aboveground pedestrian construction. Although the development of a mathematic model allows the calculation of
relevant data, simulations cannot capture the complexity of the real situation. Furthermore, people’s reaction during flooding also cannot be simulated.

Learning is essential in responding to uncertainty [15]. Flood resilience requires either the ‘ability to tolerate flood’ or the ‘ability to reorganize’ when physical damage and socioeconomic disruption occur [19]. In this case, although floods still result in disturbance to the village, the ability to tolerate floods has been improved greatly compared with the 1970s when people had just moved into the area. The three stages of street transformation reveal how learning from past experiences has improved the village’s capacity to tolerate floods (such as the self-organized street form, interior design, and lifestyle changes). The knowledge the people learned from experiences and applied to improve the capacity for tolerance is tacit knowledge [30]. In this study village, tacit knowledge was developed from long-term living with floods. This is opposite the cases in modern cities where people always lack experience with floods. Flood control not only reduces flooding but also prevents people from learning from experiences. Thus, to enable communities to learn from flood experiences requires a paradigm shift from flood control to flood adaptation [19, 31]. Without learning from experiences, it is unlikely that communities can test their capacity to tolerate floods and develop the knowledge for flood resilience improvement.

7. Conclusion

In this paper, I discuss a case study of a street formation in a frequently flooded village. The four elements (storeroom, muddy road, front yard, and house) work together to sustain the normal life under the uncertain flood risks. The village reflects a different way of street formation – learning from the floods and then developing a response and practice. The street pattern of the village is more likely to be shaped by floods rather than professional human design. Learning from this case, this paper develops two principles which may contribute to designing flood-resilient urban streets – multifunctional use and maintenance of connectivity. Multifunctional use refers to integrating the function of accommodating floods into the urban street design. Maintaining connectivity aims to keep the flood area connected with other parts of the city to reduce the impact of the flood. This study argues that to improve flood resilience, communities need to learn from experiences and develop tacit knowledge.

Moreover, based on the case study, I found that to adapt to flooding, only designing a floodable streetscape is not enough. People's lifestyles and awareness also need to change and adapt to the flood process. For example, the village shifted from a farmland-based economy to a fish pond-based economy. Almost all the people who live in the village can swim and drive boats. More research needs to be conducted to determine how people in the cities can work and live during floods.

The outcomes of this paper represent the basis for the next stage of my research, which aims to understand how people can learn from past experience of flooding. In the next stage, more fieldwork will be planned, and the final goal is to provide flood...
resilience guidance for urban planning and design.

Acknowledgments

The author is grateful to the villagers in Xinnongcun village for their time in participating the interview. I also thank Liao Kuei-Hsien for her generous support and guidance on resilience research, Hendrik Tieben for his advice on the case study. The constant encouragement by Zhou Wei is gratefully acknowledged.

Abstract

Urban Green infrastructure (GI) refers to the network of different types of green spaces that enables delivery multiple ecosystem services, not only in regulating stormwater but also in providing the diverse urban habitats. The development of green infrastructure has been advocated as an effective way of alleviating the threaten loss in biodiversity by providing the physical basis for ecological networks and maintaining the integrity of habitat systems. Birds play an important role in urban biodiversity conservation, while the urban environmental variation of habitats has an impact on the avian diversity and abundance in many ways. However, it has not been clear how to maintain the biodiversity of urban birds and what kind of GI structures and characteristics that are relatively important for improving avian diversity and abundance. We selected 17 representative GI spaces in Chengdu, including urban parks, rainwater gardens, green corridors etc., using avian diversity and abundance as proxies for evaluating the functionality of three types of GI structure (corridor, node and net). Besides, we analysed the relationship between GI characteristics, adjacent landscape, human disturbance and urban avian species abundance using Canonical Correlation Analysis (CCA). Our results showed that avian species abundance varied greatly in different GI structure types. GI of nets and corridors were higher in bird abundance, while GI of nodes were highest in avian diversity. Avian abundance was most significantly associated with vegetation cover at the adjacent landscape level, and was not significantly correlated with human disturbance according to our research. Different avian species showed greatly different preference in GI characteristics and human disturbance. Species, e.g. \textit{Pycnonotus sinensis} and \textit{Aegithalos concinnus} were inclined to the urbanized environment, while species like \textit{Turdus merula} were sensitive to human disturbance. Based on our research, we proposed the following suggestions on GI designing and planning for landscape architects: (1) GI spaces should consider the connectivity of GI network, taking advantage of GI nodes and corridors that provide crucial stopover sites for birds to move among urban greenspaces; (2) GI spaces should have the largest possible area and contain a complex vegetative cover to improve the resilience of GI system and reduce the risk of bird loss; (3) The way that GI network designed and planned influences the magnitude of
their impacts on urban ecosystem biodiversity. Priority habitat conservation areas should be fully considered in GI network when designing and planning the urban GI spaces.

**Keywords:** Green infrastructure; urban biodiversity; resilience; avian species, habitats

1. **Introduction**

There are many views on the definition of Green Infrastructure (GI). Benedict and McMahon’s define GI as “an interconnected network of natural areas and other open spaces that conserves natural ecosystem values and functions, sustains clean air and water, and provides a wide array of benefits to people and wildlife”, which has been widely adopted \[1\]. GI provides multiple ecosystem service not only for improving human well-being by supplying of water, regulating stormwater, mitigating the diffuse pollutions, and providing the recreation opportunities for psychological and cognitive benefits, but also for protecting the wildlife habitats by providing the physical basis for ecological networks and maintaining the integrity of habitat systems \[3-4\]. There is an increasingly common focus that establishing green infrastructure is a gateway for improving urban biodiversity to build more sustainable and resilient environment \[5\].

Urban biodiversity conservation and maintaining wildlife habitats has become a significantly increasing concern on landscape planners, researchers and city managers. It has not been clear that how to maintain the biodiversity for urban birds and what kind of structures and characteristics of GI that is relatively important for determining avian diversity and abundance. In our study, we used avian abundance and diversity as the proxies for evaluating the functionality of three different GI structure types (corridor, node and net), and the relationship between the GI characteristics, human disturbance and urban avian species abundance in Chengdu. The aims of this study were 1) to explore the relationship between avian abundance and diversity and the GI structure, characteristics; 2) to determine what are important variables of GI landscape variables and human disturbance influenced on individual species; 3) to provide scientific-based suggestions and design guidance of GI planning for landscape architectures and planners to improve the urban bird biodiversity.
2. Methods

2.1. Study area and Sampling

Chengdu is the capital of Sichuan province where located in in the southwest of China. It is a metropolitan city with more than million 16,000, 000 permanent populations, covering an approximate area of 14600 km². In last decade, it was the one of highest rapid development of the urbanization cities in the world that has achieved the urbanization rate of 70.6% in the year of 2017. Chengdu has a diversity of the urban ecosystem. It has a high diversity of wildlife recorded more than 466 avian species 600 the terrestrial wildlife species and 3990 flora species. According to the landscape structure of GI in Chengdu, we selected 17 GI sites which represents three types of GI landscape structure: (1) 6 corridor (e.g. greenway, green/blue corridors); (2) 5 node (e.g rain gardens, bioswales) ; (3) 6 net (e.g residential greenspaces, parks) (Fig.1).

Bird surveys conducted in all sampling sites from July 2013 to February 2014 once a month, and it counted twice a month in the summer (July,2013 and August, 2013) and winter month (December, 2013 and January, 2014). For GI space of node and net, we recorded bird number and species in 500 meters’ radius point counting for five minutes. For strip corridor, six transect line were laid out in 500 meters, and bird counted along the strip corridor sampling site within this 500 meters’ area in ten minutes.

Human disturbed surveys conducted after the bird survey in all sampling site. The number of pedestrians and the number of vehicles was recorded the in the intersection of the sampling sites (20-m radius circular plot) within 60 seconds. Every time we conducted three times for comparative purposes. Noise levels were measured in the same intersection of the sampling sites (within the circle of 20 meters’ radius). We used a sound level meter to record the noise levels by A-weighted decibels (dBA) every 10s for 1min, repeating three times for comparative purposes. The Noise levels required to conduct in the morning time from 8am to 10am in good weather condition.

We measured landscape characterization for each GI spaces at two spatial scales, site level and the adjacent landscape level. At the site level, we measured landscape characterization by 1) Area(A); 2) Perimeter(P); 3) tree species abundance (B); 4) total tree species richness(S); 5) the average tree diameter(DBH). The landscape structure of each site considered at adjacent landscape level (sites with 100-m width.
buffers). We calculated 1) the percentage of tree cover area (Gt); 2) the percentage of shrub cover (Gs); 3) the percentage of herbaceous plant (Gr) in a 100-m width buffer at each sampling site.

2.3 Data analysis

We calculated the species abundance at each GI space surveyed, and sum the number of all bird species in each month. To assess the diversity of bird, we used the Shannon-Weiner index, Simpson index and Pielou index. After ANOVA and Tukey post hoc tests, we applied Linear multiple regression to analyze the relationship between bird abundance and the explanatory variables of landscape characteristics and human disturbance [10]. Then, we examined relationships between both bird communities and landscape characteristics, human disturbance by Canonical correspondence analysis (CCA) [11]. Each CCA included between individual species and 17 greenspaces. Species data included the total number of bird individuals (all surveys together) for each species observed at each GI space.

3. Results

3.1. Urban Bird surveys

We recorded 46 individual species, and the 10 species were registered common species contributing to 91.2% of the total bird abundance (Table 1). Individual species records were categorized into four trophic groups. The species of insectivores accounted for 50% of the all registered common species, granivores accounted for 30% the all registered common species, nectarivore and omnivores accounted for 10% that of all, respectively (Table 1).

Table 1 Resident bird species recorded in three GI landscape structure categories (corridor, node, net) in southeastern of Chengdu City. Trophic group: (G) granivore; (I) insectivore; (O) omnivore; (F) frugivore.

The average avian abundance varied over the months in three GI structures (Fig. 2). Corridor, node and net showed different trend in avian abundance. The average of avian abundance in the corridors and net was the highest in January, N= 126.3 and N=113.7 respectively. The trend of avian abundance in the node shows opposite trend, and it reached highest in August (N= 62). In general, avian abundance was higher in corridors and nets, and lower in nodes (Fig.2).

Fig.2 The average avian abundance in different GI spaces structure
The total avian species abundance of nets and corridors were higher than node by 1482 and 1342, respectively, while the Shannon-Weiner index of nodes was highest 0.74 (Table 2). We found there was a significant difference of Shannon-Weiner index in different landscape structures (P < 0.05). The GI landscape structures of Simpson index and Pielou index didn't show significant differences.

### 3.2. Influence of landscape variables on avifauna

We found a significant and positive relationship between the species abundance and the percentage of tree cover at the adjacent landscape level (P < 0.05) (Table 3). While, the landscape characteristics at the site level, there is no significant relationship between species richness and GI landscape characteristics (P > 0.05). As well as human disturbance, there is no significant relationship between species abundance and visitors flow, vehicle flow rate and noise (P > 0.05).

As for the site level, we did not obtain a significant relationship between species and GI characteristics (P > 0.005). The first axes explained 27.0% of the variance in bird species, and the first two axes explained 80.6% of the variation in the species-human factors relation habitat relationship (Table 5). In general, species like *Pycnonotus sinensis* (*P.sin*), and *Passer montanus* (*P.mon*) were richer in larger greenspaces with bigger and more trees (Fig. 4). Some species were richer in open areas like *Eophona migratoria* (*E.mig*), *Lanius schach* (*L.sch*) and *Acridotheres cristatellus* (*A.cri*). At the adjacent landscape level, we obtained a significant and positive model between the species richness and the percentage of tree cover (P < 0.05). The first three axes explained 29.0% of the variance in bird species, and first third axes 100% of the variance species-environment relation (Table 6). *Eophona migratoria* (*E.mig*) were favored by more shrub area, while species like *Lanius schach* (*L.sch*) and *Garrulax sannio* (*G.san*) were more abundant in larger greenspaces that had more trees (Fig. 5).

**4. Discussion and conclusions**

Our results provided evidence that different GI landscape structures of southern Chengdu City affected the avian species abundance and diversity. Nets had the largest avian abundance among these three GI spaces, which had a complex habitat structure and been away from human disturb. Corridors of GI had higher species abundance playing an important role for avian movements. The same result was found in Clevenger *et al* [12] research that the corridors of green/blue spaces acted as the crucial stepping stones sites connecting the buildings and urban landscape. Miller *et al* [8] also found the linear green strip corridors had a higher probability of attracting some specific species, i.e edge species. Another reason was that these green and blue belts also had been used as an alternative habitat for foraging and nesting [6]. It was worth noting that though the nodes had the lowest avian species abundance, those GI spaces were valuable to hold avian species diversity. In our result, we found the Shannon-Weiner index of nodes was highest. Nodes combine the advantages of good connection and complex habitat structures. In general, nodes were the vital connectivity between landscapes that some species could temporarily take advantage of these stopover sites to fly from man-made area to other green habitats. And the nodes had higher habitat heterogeneity and more complex vegetation structures (e.g, trees, lawns and shrubs, etc.) providing different habitats structure for both granivores and insectivores [13].

Bird species abundance recorded in southern of Chengdu City showed there was no significant relationship between species abundance and visitors flow, vehicle flow rate and noise. Gómez-Aíza and Zuria research also found that the intermediate levels of human disturbance might reach the peak of bird species richness, rather than at zero or very low urbanization [14]. Some urban resident adapted to the urbanized environment, while some species are
vulnerable to human disturbance. We also found that *Pycnonotus sinensis* and *Aegithalos concinnus* tolerant to noise and human visit, while species like *Turdus merula*, *Garrulax sannio* and *Eophona migratoria* was sensitive to human disturbance. One of the obvious phenomenon for the urban bird was that the adaptability to urbanization varied from different species. some residents (e.g., doves and sparrows) are inclined to urbanization, they even take advantage of food resource by human feeding or waste [14]. However, we found the most species have less resilience to urbanization which tends to less urbanized areas with a greater percentage of vegetative cover, e.g. urban park and natural wildland. These species still had a variety of negative impacts on noise levels and traffic of vehicles and visitors, and the higher level of noise nearing their habitats leads to the lower bird abundance (Table 3). Different GI space played important role in maintaining bird species richness. To ensure the plenty of GI space with high-quality bird habitats and biological integrity, it was important to support a diverse bird community.

Many research demonstrated that GI landscape characteristics, e.g. the patch size, habitat heterogeneity, vegetation complexity, these variations of GI space directly affect the bird species richness, which influences the quality of habitat for urban biodiversity. In my research, compared with site level, the adjacent landscape-level of GI landscape characteristics had a more significant influence on bird species richness. Carbò-Ramírez and Zuria[7] had the similar result in the Mexican city. At the adjacent landscape-level, considering the factor of vegetation complexity, the different percentage of vegetation has direct influence to habitat quality. Also, it was, to some extent, decided the species distribution due to the different habitat preference of avian. Granivores and other bird species which nest on the ground area inclined to natural shrublands or grasslands. Some birds (e.g., *Lanius schach* and *Garrulax sannio*) preferred the habitats with a greater percentage of vegetative cover. At the site level landscape-level, we found the area and tree species richness were the most important explanatory variables. Heezik et al. [15] study also found the size of the park to be the most important indicator of species richness, and the similar result found the in New Zealand. Tree species richness not only reflected the conopy density, more importantly, but also it affected the avian food resource and nesting site which could substantially affect the nature of bird assemblages [16-18]. Therefore, maintaining a certain scale GI space and increasing the diversity of trees could help increase the diversity of birds at the site scale. As for the adjacent landscape-level, it was needed to consider keeping a diversity of vegetation cover to satisfy the different habitat requirements for different species.

As a landscape architect and urban planner, we should fully consider how to allocate and design GI space to maintain urban biodiversity and increase flexibility in urban context [19-20]. Our research encouraged systems thinking of GI spaces to fulfil the ecological function of node and corridor, improve the integrity of GI space
network, and thus contribute to improving the overall resilience of the city [21-23]. Though we considered the GI structure, characteristics and human disturbance affecting on avian abundance, the study has the limitations of studying features of GI space, e.g. water cover which could be explored in the further research. Based on our research, we proposed the following suggestions on GI designing and planning for landscape architects: (1) GI space should consider the connectivity of GI network, taking advantage of GI nodes and corridors that provides crucial stopover sites for birds to movement among urban greenspaces; (2) GI spaces should have the largest possible area and contain a complex vegetative cover to movement among urban greenspaces for birds in an urban gradient in a New Zealand city.

Resilient Village: Conceptual Planning for Post-disaster Reconstruction of Wenquan Village in China

Songyao Huai, Song Liu

Department of Landscape Architecture, College of Architecture and Urban Planning, Tongji University, Shanghai, 200092, China

Abstract

The concept of “Resilience” provides a new way of thinking for disaster management and post-disaster reconstruction. Chinese ancient villages are facing threats of various natural and man-made disasters due to their fragile ecological environments. How to improve the resilience of the villages to cope with the disaster and rebuild resilient villages after the disaster has been an important issue for landscape planning. Wenquan Village is a traditional minority village with a long history. However, most of traditional residences were destroyed by a sudden fire on February 20, 2016, which led to hundreds of residents were homeless. It is urgent and necessary to carry out the post-disaster reconstruction planning. We choose the “Resilient Village” as the concept of post disaster reconstruction to build a self-growth and self-sustaining village system from four aspects: planning and layout, ecological environment, architecture design and institutional management. Firstly, planning and layout: Arrange the combination of linear layouts along with contour lines and group layouts to keep enough fire distance. Secondly, ecological environment: Integrate rivers, public space and green space to construct fire isolated belts to form a green infrastructure of disaster prevention and mitigation. Thirdly, architecture design: Design five types of indoor layout according to the wishes of the villagers, and properly arrange the relationship between living space, eating space and sleeping space to satisfy the needs of people. Fourthly, institutional management: Establish village information center and create village information network to realize information sharing when disaster happens. Moreover, strengthen publicity and education of fire prevention and organize fire disaster trainings to enhance villagers’ self-help capacity. In response to natural and social disasters such as fire, the village can self-adjust and self-adapt to achieve normal operation of the living environment, public safety and social order with above four points, which forms a three-dimensional ecology - production - living resilient village system and provides a reference for the building of disaster prevention village.

Keywords: Resilient village, Disaster management, Disaster prevention and mitigation
1. Introduction

Rural communities are generally considered to be more vulnerable to the adversity than their urban counterparts. The frequent occurrences of natural and man-made disasters have brought great challenges to environment security in some villages. Especially in some Chinese remote mountainous areas, being constrained by many factors such as severe geographical environment, underdeveloped economic level, weak infrastructure construction and insufficient public services, they lack the capacity to effectively resist the internal and external disturbances and tend to suffer from devastating consequences when disasters strike. Rural vulnerability to disasters has gradually become a bottleneck that restricts rural survival and sustainable development.

The traditional concept of disaster prevention and mitigation can no longer meet the requirements of future rural development. Village is a complex social ecosystem that integrates agricultural production, ecological protection and residential living. The concept of resilience provides a new idea to rural disasters response from the perspectives of holism and dynamics\[1\]. Resilient villages not only focus on reducing the impact of disasters, but also emphasize their adaptability and recoverability to disasters\[2\]. Landscape design and planning play a critical role in a rural ecosystem to adapt external shocks and minimize interference with organized structures and functions.

The concept of resilience has become a global concern in the face of environment disturbances and emergency management. There has been an increased attention to the issues of building city resilience towards various disasters, however, little research pays attention to rural areas. At present, the concept of resilient city is mainly applied in natural hazards and climate change mitigation\[3-5\], urban and regional economic resilience\[6-8\], urban infrastructure resilience\[9-11\], urban terror attack resilience\[12\]. The research content mainly focuses on the urban resilience evolution mechanism\[13, 14\], urban resilience assessment\[15, 16\] and urban resilience planning practice\[17-19\]. Current research concentrate on economic recession in terms of globalization process, industrialization of agricultural systems, extreme weather and sociodemographic changes\[20-22\]. In China, there was an upsurge in research of disaster and hazard risk management in rural areas after the 2008 Sichuan earthquake. Various attempts have been made to support post-disaster reconstruction from the perspective of resilience with economic and social reconstruction and environmental protection\[23, 24\]. The construction of a resilient village has become a new research trend for future rural disaster management and post-disaster reconstruction planning.

The paper explores post-disaster reconstruction planning strategies from the perspective of rural resilience, utilizing empirical research conducted in a Chinese traditional minority village after a severe fire. With a brief review of studies on resilience, we reported the research methods, including the description of the study area, and builds a “Stability—Adaptability—Recoverability” theoretical framework of resilient village based on literature review and related planning practice. Then, we put forward specific resilient strategies from physical environment (planning and layout, ecological environment and architecture design) and social system (institutional management). Finally, we conclude that the rural resilience relies on the interaction of physical environment and social system.
Implication of this study on improving the existing rural resilience efforts is also discussed.

2. Resilient village

2.1. The concept of resilience

The word "resilience" originated from the Latin word "Resilio" and its meaning was "revert to its original state". In 1973, the concept of resilience was first introduced in ecological system by Canadian ecologist Crawford Stanley Holling\(^\text{[25]}\). Then, its conceptual development experienced three stages from engineering resilience, ecological resilience to socio—ecological resilience\(^\text{[26]}\). Resilience theory provides an effective theoretical framework for linking physical and socioeconomic environments. In the field of landscape planning, as a new research paradigm for sustainable development, resilience theory has been widely applied in various human settlements environments to deal with different disasters and risks\(^\text{[27-29]}\).

2.2. The implication and theoretical framework of resilient village

Researchers who have studied the response of resilient systems to disasters summarized eight essential resilience features: redundant, diverse, efficient, autonomous, strong, interdependent, adaptable and collaborative\(^\text{[30, 31]}\). The paper constructs the “Stability—Adaptability—Recoverability” theoretical framework of resilient village based on literature review and related planning practices.

(1) Stability: A system should consist of diverse and complex components to maintain dynamic stability, which ensures the system is equipped with the self-sustaining capacity to respond the emergency events and severe threats.

(2) Adaptability: A system should realize immediate feedback according to the variation of environment, then have the flexibility of self-adjustment and self-regulation to absorb the outside disturbances.

(3) Recoverability: A system should be made up with multifunctional and multi-level components. They are independent yet interrelated, which provides multiple choices and various strategies when disasters occurred.

3. Methods

3.1. Study area

Wenquan village is a traditional minority village in remote mountainous area in Guizhou Province, Southwest of China, with total area of 54 hectares and total population of 2356. The village is composed of four parts. The northern part is located on the hill, which is the core area of the village because many historic dwellings are mainly distributed here. The western part is a transitional area which connects the Wenquan village with hot spring resort. The southern and eastern part are main areas for residents’ living. As an ancient Miao village, Wenquan village is famous for the traditional folk dwellings and hot springs, which is a popular local tourist attraction. Wooden stilted building is the traditional Miao building constructed on the steep land in high density distribution (Figure1, Figure 2).

February 20th in 2016, A severe fire broke out in Wenquan Village, which hit the northern part of the village with a total population of 120, burning down 97 ancient houses and 4 hectares of residential area (Table 1). It is of great practical significance
and urgency to build resilient village to recover from the fire and resist and adapt the future disasters.

3.2. Data collection

The paper conducts qualitative research with field survey and unstructured interview. Firstly, Unmanned Aerial Vehicle was used to obtain a high-resolution aerial image for master plan analysis. Secondly, three original and typical residential dwelling plans were concluded by architectural site survey (Figure 3). Thirdly, an unstructured interview with villagers was developed to collect data and suggestions for post-disaster reconstruction.

Based on the results of field survey and unstructured interview, we analyze and summarize the current situation and problems of Wenquan village:

1. Buildings with high density and disordered arrangement. Most of the houses are equipped with private pigsty and outdoor toilets, which results in the limited spaces between the buildings being filled. There is a lack of enough fire isolation space between the buildings and disorderly architectural arrangement which make the fire easily spread and uncontrollable.
2. Insufficient fire-fighting facilities. The fire-fighting reservoirs are poorly managed and many of them have already dried up and abandoned. Limited number and uneven distribution make it impossible to provide fire-fighting support for every part of the village in time when a fire occurs.
3. Serious shortage of public space. The green and public space in the village are seriously scarce, which are scattered without systemic layout. Furthermore, villagers have single daily activities and little communication due to inadequate high-quality outdoor recreation space.
4. Disordered layout of traffic situation. There are many twist and narrow roads that make the traffic in the village inefficient. The capacity of emergency evacuation is deficient in responding the sudden risks and threats because of the chaotic traffic organization.
5. Bad electricity usage habits. With lower level of education, villagers lack good habits of electricity and fire safety knowledge. The vulnerability in individual consciousness and social network may be prone to be struck by severe disasters.

4. Results

Original site reconstruction of Wenquan village was conducted both in physical environment (planning and layout, ecological environment and architecture design) and social system (institutional management) to strengthen the stability, adaptability and recoverability of rural areas in dealing with risks, disasters and emergencies.

4.1. Planning and layout

4.1.1 Master plan

Reasonable plan layout can narrow the affected scope and control the spread speed of disasters, which is an effective way to achieve disaster prevention and resilience construction. On the basis of original spatial fabric and original site topography, linear
layout and group layout are applied in new construction arrangement as fire prevention zone unit. In single unit design, traditional dense and compact architectural style is preserved to maintain historic identities. While between the units, adequate fire separation and green belts are considered to restrain the spread of the fire disaster from one unit to another, which can reduce fire loss greatly. In addition, public space is collocated in the interior of group layout to facilitate the daily communication of residents and provide them with disaster evacuation area (Figure 4).

### 4.1.2 Vertical design

Besides the master plan, the proper vertical design is also a key point to mitigate the disaster. The disaster-stricken areas are built around the mountains with complicated topography about 75 meters high. The architectural arrangement formed by the unorderly natural development of the villagers has resulted in overlapped and clustered houses, allowing the fire spreading upward and downward easily. Although the newly-reconstructed houses retained the local dense architectural features, the houses at different elevations were adjusted to be arranged in different layers and the distances between different layers were enlarged properly, which slows down the fire spreading speed from up to down (Figure 5). This kind of design makes it possible for diverse forms of building entrance to fit the elevation differences. Some buildings are placed on the platform from the front to the interior house, others are placed on the edge of the steep terrain from the back or flank to the interior house (Figure 6). The flexible combination of multiple buildings and various terrain not only preserves the traditional style of Miao’s architectures, but also strengthens the building’s resilience and adaptability to fire.

### 4.2 Ecological environment

#### 4.2.1 Water system planning

(1) Rainwater collection system

Rainwater collection system is built on the hillside to collect rainwater and surface runoff to ensure sufficient water supply when emergencies. The system utilizes green planting beds to collect rainwater and surface runoff and store them in underground water reservoirs. They are evenly arranged in every fire protection unit and used as landscape ponds on ordinary days and fire water supply when fire occurs, which can make up for the situation that tap water lacks enough water pressure and water amount at high altitudes. Firewater intake points are set at the foot of the hill and the elevation of the mountains provides the firefighting water pressure. Higher reservoirs can provide adequate pressure for fire suppression (Figure 7).

(2) River network remediation

River network remediation includes connection and purification. The connectivity pattern of the river network affects the ability of water security assurance and water resources allocation. Specific measures include: ① Rivers and ponds are connected to build an integrate river network to achieve rapid provision of water resources. ② Create bio-oxidation ponds to purify the domestic sewage using microbes. The system will improve the ability to resist natural disasters after connection and purification.

#### 4.2.2 Vegetation planning

The planning of fire-resistance tree species can prevent the spread of fire and form a barrier network to control fire. The
fire-resistance features include that the tree body has less oil, higher water content, waxy or leathery leaves, and strong sprouting ability. The main choice is the evergreen broad-leaved fire tree with dense foliage. In fact, there is no absolutely fire-resistant tree species, but compared with other tree species, they can’t be ignited easily and they can recover quickly after a fire. The vegetation coverage of fire-resistance trees should be increased between the group and linear buildings to mitigate the fire spread.

4.3. Architecture design

We redesigned the buildings according to the principles of continuation of style, coordination of old and new, and overall unity. The traditional dwellings of Miao village are generally two floors. The ground floor is used to store production and living materials, keep poultry and livestock, or as a toilet. The second floor is used as a living room, hall, bedroom and kitchen. However, as modern lifestyles fit into people’s living, there are several problems emerging in ancient buildings, such as confusion in streamline organization, spatial interference and inefficient use of space.

Based on the above problems and typical traditional architectural form surveyed at the site, five types of architecture plans were designed and optimized according to the area and proportion of the affected houses and the villagers’ wishes (Table 2, Figure 8).

4.4. Institutional management

It has reached a consensus that despite the ordered physical environment play an irreplaceable role in disaster mitigation, affected communities are becoming increasingly dependent on their local institutional management. Residents’ sense of community are inherent within the community and are constantly developed, reproduced and increased via the daily interaction among the community members and institutions[32]. In the rural resilience system, the construction of institutional management is mainly reflected in two aspects: the improvement of individuals fire prevention awareness and the sharing and interconnection of residents’ fire prevention information. Optimizing the community disaster relief response system and strengthening residents’ self-rescue capability are powerful guarantee for community disaster prevention and reduction. Establish guidelines for villagers to regulate the daily behaviors, especially in the aspect of the use of electricity. Enhance fire prevention education, organize fire prevention training, and cultivate awareness of crisis among residents to improve their disaster response skills. In addition, a villagers’ information center is suggested to set up in the central square. When disasters occur, village information networks will be communicated with each other to ensure the sharing of information. It also provides education facilities, such as libraries and electronic information rooms to enrich the cultural life of the villagers, encouraging the villagers with higher cultural attainment to meet new opportunities for village development.
5. Discussion

The construction of resilient village depends on the interaction and mutual promotion of the physical environment and the social system. The reconstruction of livable physical environment is as important as the recovery and development of social fabric and communal networks. In addition to emphasizing the resistance and recovery capabilities to disasters, the concept of resilience should also mean the transformation and better development capabilities of village. On the basis of protection and utilization of the unique local natural environment and historical culture, after completion of the post-disaster reconstruction plan for Wenquan village, health tourism will be introduced in the long-term planning to achieve connection between disaster-stricken areas and hot spring resort to reach synergetic development. Tourism products related to hot spring and ancient dwellings can be developed to stimulate vitality and provide impetus for the transformation and sustainable development of villages.

6. Conclusion

The study illustrates the implication of resilience, builds a theoretical framework of “Stability—Adaptability—Recoverability” for resilience, and explores the specific strategies for the construction of rural resilience in Wenquan village from four aspects of planning and layout, ecological environment, architecture design and institutional management. The construction of rural resilience should consider the interaction mechanism of physical environment and social system. The study expects to provide a reference of resilience construction for other disaster-affected rural area in China.

Abstract

Lasem is a cultural heritage area that has unique and distinctive Chinese architecture and culture and is still well preserved and known as "Petit Chinois", located in Lasem District, Rembang Regency, Central Java, Indonesia. Lasem is 18.2 km to the East of Rembang city center and is part of the city of Rembang. Lasem is a city that became an important part of the main axis of the northern coastline of the island of Java. Astronomically, Lasem is located on the coordinate line 111° 00'- 111° 30' East Longitude and 6° 30'- 7° 6' South Latitude. Lasem has a rich historical heritage in the form of Chinese architecture buildings, which contained the philosophy and cosmology of Javanese society. Lasem declined in its city after the peak of the glory ended in the 19th century, the city has not experienced a significant development in the procurement of municipal infrastructure. Extreme climate change occurs at the Lasem site and its location is close to the coastal area, causing the temperature to become extreme heat and frequent drought in the area. The purpose of this research is to reduce the impact of extreme climate change and to maximize the infrastructure of the area. The method used a descriptive method. The results of this study for environmental improvements carried out by setting green city arrangements using the Lasem's typical vegetation areas, also proposed hydrological improvements at the Lasem site, in an effort to reduce the impacts of climate change, drought, extreme heat and create resilience of future Lasem sites.

Keyword: Lasem site, infrastructure, impact, climate change, resilience

1. Introduction

Lasem is a cultural heritage area that has unique and distinctive Chinese architecture and culture and is still well preserved and known as "Petit Chinois", located in Lasem District, Rembang Regency, Central Java, Indonesia. Lasem is a city that became an important part of the main axis of the northern coastline of the island of Java. Astronomically, Lasem is located on the coordinate line 111° 00'- 111° 30' East Longitude and 6° 30'- 7° 6' South Latitude. Subdistrict Lasem has an area of 4,504 ha and is divided into 20 villages (Nurhajarini, 2015). The Lasem site is traversed by the North Coast Highway, formerly known as the Grote Postweg or Daendles road that stretches from the West to the East. The boundaries of the following regions: Northside bordering the Java Sea, the east with District of Sluke, south bordered by District Pancur, and next to the west District of Rembang. Lasem geographical conditions affect the history and development of Lasem sites. Lasem Region in the North is a coastal area, the eastern region is mountainous and the center of flat topography. Lasem have a river which in the past has a role as an artery of trade in Lasem. In the river, there is a port that has a function as a point of entry and exit of people and goods. In addition to acting as a trade-lanes, river morphology Lasem also form the city, serves as a transportation hub, so that the development
of settlements along the river such as settlements. At that time, the city center is located in the port area, the center of government/duchy, squares, and markets (Nurhajarini, Purwaningsih, Fibiona, 2015:18-20). But this time, river silting Lasem experience. Anticipated advances in shoreline seaward Lasem occur due to silting at the mouth of the river and the Java Sea (Handinoto, 2015: 52). (Handinoto, 2010) (Lynch, 1960)

In Lasem there are three Chinatowns that have historical value, namely in the area of Chinatown Dasun, Babagan and Karangturi (Aziz, 2014: 115-118). Because of the influence of these three Chinatown, Lasem has a rich historical heritage in the form of Chinese architecture building, which contains the philosophy and cosmology of the Java community. According Handinoto in his book entitled Lingkungan “Pecinan” Dalam Tata Ruang Kota Di Jawa Pada Masa Kolonial, Lasem town's heyday was in the late 19th century. However, after the peak of its glory, Lasem not experiencing significant growth (Handinoto, 1999: 459). Extreme weather occurred in Lasem site and its location close to the beach area, causing the temperature became very hot and frequent droughts in the region. A longer dry season than the wet season causes dryness in the area. North-Central Java region has great potential to experience drought (Sunarto, 2010: 621). Then, with the descriptive method, does the proposed criteria for environmental improvements and physical Lasem sites with Kevin Lynch theoretical approach about the city's image-forming element to overcome the above problems.

2. Forming The Resilience Of The City In The Future

Factors affecting the absence of significant developments in the city Lasem due to lack of urban green system and change the function of the town square Lasem. Moreover, the lack of urban green arrangement resulting in frequent occurrence of drought during extreme climate changes is characterized by a long dry season at least due to groundwater reserves (Sunarto dkk, 2010: 621).

The purpose of this study to maximize Lasem local infrastructure by improving the city's image-forming element in shaping the city resilience and mitigate the effects of climate change by pursuing green layout on the site Lasem.

To establish the resilience of the city in the future, it is necessary to improve the image forming elements of the city. According to Kevin Lynch (1960: 46-47), There are five elements forming an image of the city that way, ledges, districts, nodes, and landmarks. On the street in the city Lasem elements, the need for improvement of the green on the main road through town Lasem, namely the northern coast road formerly known as the road Daendles. On the banks of the element in town Lasem, repairs can be done by planting vegetation in shaping the city limits Lasem, improvement district element can be done by going green in the Chinatown district. Repair nodes in the city Lasem done by planting vegetation on the crossroads contained in Lasem. And last, city landmarks, namely Lasem town square, the need for restoration to restore the image of the city. It is caused by irregularities in the form of land use change
into places selling food which eliminates image Lasem town square plaza.

Table1. Proposed criteria in repair image forming elements Lasem city

### Conclusion

To maintain the future of Lasem’s site in the future, infrastructure optimization needs to be done by way of improvement of the image forming elements Lasem city. Repairs to do green governance in these elements, in addition to improving the city's image Lasem can also contribute in creating environmental improvements and hydrological town which in turn can reduce the impact of climate change is causing extreme heat and drought in Lasem.

THE STUDY KAMPUNG KASEPUHAN CIPTAGELAR A NOMADEN COMMUNITY

N. Dhea Madinah Al Qibthia, Riska Febriani, Arwindrasti Bandjar K,M.Si

Trisakti University, Kyai Tapa street number 1, West Jakarta 1140, Indonesia

Abstract

Cultural rooted from an ancestor their the community Kampung Kasepuhan Ciptagelar located in Bogor, West Java Province, Indonesia is still awake, where the indigenous people often migrating the other names is nomaden, this as ordered from an ancestor customary Kampung Kasepuhan Ciptagelar in trust the almighty. The existence of the displacement the one area to a new areas in accordance wangsit from the almighty to the priests exclusive of an ancestor Kampung Kasepuhan Ciptagelar, where today their Kampung kasepuhan ciptagelar have 160 family head and quite large, often displacement place live in accordance with of environment support in the new place, problem of environment has been increased if Kampung Kasepuhan Ciptagelar will intended located in conservation area.

The purpose of this research identify the factors that existence of the forest in Kampung Kasepuhan Ciptagelar community was meanwhile expected to increase the acquisition of land for the purpose of an indigenous people of will overlap to a forest conservation a Mount Halimun Salak National Park which is located next. For the conservator the existence of zone the nucleus a Mount Halimun Salak National Park will lose biodiversity therefore it needs to be assessed using qualitative descriptive methods to question research “Whether internal and external factors a residential area new ciptagelar indigenous people who always Nomaden?” And “can it be influenced the development of culture and have a negative impact on Mount Halimun Salak National Park ecological service “, Research study is expected to be the base of the management of habitats on biological diversity in the area in which it can be preserved for the future, in preserving landscape character customary Kampung Kasepuhan Ciptagelar, with did not result in the negative impact of for the community and the function of the zones as zone the nucleus of Mount Halimun Salak National Park.

Keywords: Kampung Kasepuhan Ciptagelar, Nomaden, Core Zone, Biological Diversity, Ecological Service, green infrastructure, urban farm.
1. Introduction

Kasepuhan The cultural values that develops and in Indonesia reflected in there are still many findings of their customary or Kampung Kasepuhan/ Culture Village. For example Kampung Kasepuhan Ciptagelar is one kasepuhan inhabited by indigenous people still revere traditions from generation to generation. Kasepuhan Ciptagelar characterized spatial arrangement which balanced in harmony with the nature and create some sort of natural beauty and their environment.

One of them is Kampung Kasepuhan Ciptagelar, located between the coordinates south 06° 47’ 10,4”; EastLongitude 106° 29’ 52” with altitude 1200 m above the sea level. the area of kasepuhan is 202 hectare. The number of community members ciptagelar kasepuhan a number of 160 families (disbudpar province data in 2010).

Residents of kampung customary ciptagelar believed derived from the royal sunda located in pakuan padjajaran bogor districts approximately 648 years ago has done the displacement of one place to another in line with wangsit received and Kasepuhan ciptagelar inhabited by indigenous people still revere tradisinya from generation to generation.

The area that becomes the main area is the protected forest area of Mount Salak in developing manageable forest zones and protected forests by taking into account the conservation of natural habitats. With the application of descriptive cumulative method with reference of regulation and literature. By explaining all the state of existing to answer problems as follows:

1. The influence of displacement their Kasepuhan Ciptagelar affect ecosystem a Mount Halimun Salak National Park region.
2. The local wisdom Kampung Kasepuhan Ciptagelar but can keep the ecosystem stability to Mount Halimun Salak National Park region.
3. Green infrastructure such as what to support the buffer zone of Mount Halimun Salak National Park against the influence of Kampung Ciptagelar Kasepuhan

2. The influence of nomadenism from Kampung Kasepuhan Ciptagelar Community in Mount Halimun Salak National Park Regional

where the indigenous people often migrating the other names is nomaden, this as ordered from an ancestor customary Kampung Kasepuhan Ciptagelar in trust the almighty. The existence of the displacement the one area to a new areas in accordance wangsit from the almighty to the priests exclusive of an ancestor Kampung Kasepuhan Ciptagelar, In fact is pressure to control the population associated with capacity the environment a Mount Halimun Salak National Park are continuing to decrease. In line with tradition displacement done to avoid a decrease in the quality of its environment which then have an impact on disruption of order customs always they protected.

The explanation of Adimihardja.K.,(1992), Kasepuhan growing over shed: Environmental management traditionally in the region Mountain Halimun, West Java (Kasepuhan yang Tumbuh di atas yang
luruh: Pengelolaan lingkungan secara tradisional di kawasan gunung halimun Jawa Barat), Explaining that the reason displacement Kampung Kasepuhan Ciptagelar never described clearly because only based on wangsit received chairman of customs and related to their belief called “uga”. Can be concluded Materialism approach can be used to assess the nature of the nomaden population as an effort to cope with pressures that can threaten the ecosystem within the Mount Halimun Salak National Park Region. When the pressure population increase and to outside influences start disturbed command wangsit to move come for a reason logical that is they did not maybe satisfy the needs of resources and production pattern limited around a national park guarded its ecosystem to balance ecosystem ecology.

3. The Local Wisdom Kampung Kasepuhan Ciptagelar in keep the ecosystem stability Mount Halimun Salak National Park region

The Kampung Kasepuhan Ciptagelar Community is an indigenous people very preserve nature and respect the environment. Another local knowledge Kasepuhan Ciptagelar relating to see how people perceive the role of available resources which includes the forest, land and water.

The management of a Mount Halimun Salak National Park region based on the system of local knowledge zoning kasepuhan ciptagelar divided some zone specifically as the following:

a. **Strict Natural Zone** (Zona Hutan Titipan) Is a zone which should be protected and conserved.

b. **Wilderness Zone** (Zona Hutan Tutupan), Is part of a national park that may be visited on a limited extent, with the regulations wholeness and authenticity fixed guaranteed. So construction permanent not allowed to these zones can protect core zone.

c. **Tourist/Administrative Zone** (Zona Garapan), Is part a zone that can be further developed into zones of the plants producing that become the characteristics of kasepuhan ciptagelar, for example rice which is a symbol of trust to the goddess sri.

And according to Republic Indonesia Constitution Number 5 year 1990 In maintaining natural resource conservation biodiversity and its ecosystem. A national park is conservation areas that have original ecosystem. So that serves keep ekosisitem a Mount Halimun Salak National Park region.

The purpose of study to increase urban farming in the area of a the Mount Halimun Salak National Park region by taking into account restricting factors that could be governance by a resident of kampung kasepuhan ciptagelar, and as one of overcoming the impact of the influence of Kampung Kasepuhan Ciptagelar a Nomaden Community.
Restricting factors as the determination of usage of space in order that the development of its inhabitants do not break the ecosystem a Mount Halimun Salak National Park, with the application of green infrastructure using agroforestry system. According to huxley (1985) agroforestry is a system land management that combines between excess agriculture and forestry. Space common ground (interface) between trees and crops of is the key in the management of agroforestry. System infrastructure green with agroforestry as the division of the development of zona kampung kasepuhan ciptagelar against a Mount Halimun Salak National Park region in the form of the division of the woodlands from which is considered very protected down to the regions can be processed agricultural.

Strategy of agroforestry system as buffer factor in regulating ecological environment of Mount Halimun Salak National Park region, source:

treeyopermacultureedu.wordpress.com
Conclusion
To keep a Mount Halimun Salak National Park ecosystem salak as conservation area and specific zoning designation for the development of space of the development of kampung kasepuhan ciptagelar by means of green infrastructure to optimize the use of the green agroforestry system other than easy to apply just because the forest and agriculture, also as ecological limiting factor in overcome the displacement Kampung Kasepuhan Ciptagelar in Mount Halimun Salak National Park region.

Abstract

With the purpose of biodiversity conservation, ecological network construction has been acknowledged as an effective way to improve environment quality and response to climate changes. On ecological network of city with the purpose of biodiversity conservation are focused on the habitat assessment and spatial planning, few consider operability of planning policy implementation. Wuyishan is in the southeast of China with high population density and Wuyishan National Park is located near it, facing the pressure from urban sprawl, tourism and tea industry. Although National Park has the boundary, the activity area of wildlife may go beyond the boundary. It is necessary to build an ecological network surround the national park for wildlife conservation. Considering the limit of funding and land ownership, this study focused on the community-based ecological network construction. A four-step framework is proposed. Namely, (1) Habitat suitability assessment of target species; (2) GAP analysis of conservation surround the protected area; (3) Identification of potential small nature reserves; (4) Development of community-based management strategy. Neofelis nebulosa is selected as targeted species considering the species representation and sensitivity. The distribution of suitable habitat areas is evaluated with habitat structure theory model by ArcGIS 10.2. From the GAP analysis of wildlife habitat conservation, potential small nature reserves are identified in suitable habitat in north part of Wuyishan City. In the end, from excavation of the traditional ecological protection idea of Fengshui Forest in the village with community participation, community-based management strategy will be developed. The study not only set up a technique framework for ecological network construction for protected areas near the city, but also establish a basic-line condition for future conservation and management.

Keyword: National Park, Urban Protected Area, Ecological Network, Community-based Management, Wuyishan
1. Introduction

Habitat loss and fragmentation have been identified widely as the major threats to biodiversity [1]. Island-like protected areas can no longer prevent the disappearance of species. Some studies indicate that habitat loss and fragmentation adjacent to protected areas can contribute to the local extinction of protected-area fauna [2]–[4]. Especially for urban protected areas, which are in or at the edge of city, are threatened by urban sprawl and intensification of urban development [5]. Ecological network construction around the urban protected areas has been acknowledged as an effective way to improve habitat quality and response to biodiversity conservation under the background of climate changes [6]–[8].

In China, most researches on ecological network of city with the purpose of biodiversity conservation are focused on the habitat assessment and spatial planning [9]–[15], few consider operability of planning policy implementation[16]. It is ideal to protect all the potential wildlife habitat, considering the limit of funding and land ownership. In our study, we proposed a community-based ecological network construction framework for wildlife conservation around the national park, in which to establish community-based small nature reserves is the main strategy.

Wuyishan is in the southeast of China with high population density and Wuyishan National Park is located near it, facing the pressure from urban sprawl, tourism and tea industry. Although National Park has the boundary, the activity area of wildlife may go beyond the park. It is necessary to build an ecological network for wildlife conservation of national park. in Wuyishan. Wuyishan is located in the southern collective forest area, with the protection tradition of Feng-shui forest. Thus, Wuyishan is a typical case for exploring the community-based ecological network construction near the protected area in China. This study focused on the gap analysis of conservation and community — based ecological network construction. A four-step framework is proposed. Namely, (1) Habitat suitability assessment of target species; (2) GAP analysis of conservation around the protected area; (3) Identification of potential small nature reserves; (4) Development of community-based management strategy. The study not only establish a basic-line condition for future conservation and management, but also set up a technique framework for community-based ecological network construction for protected areas near the city.

2. Research Area

The research area is located in the northern section of the Wuyi Mountains in Fujian Province and borders Fujian and Jiangxi provinces. It is located at longitude 117°37'22" to 118°19'44" and north latitude 27°27'31" to 28°04'49". It is 70km long from east to west and 72.5km wide from north to south with a total area of approximately 2798km².

Surrounded by mountains in the east, west and north, Wuyishan City is a hilly area, in which the peaks and valleys are stacked and the central and southern parts of which are flat. The terrain is tilted from the northwest to the southeast, with the highest elevation
of 2158 meters above Huanggang Mountain and the lowest at Xingtian Town, with an elevation of 165 meters and a relative elevation of 1993 meters. Wuyishan is located in a subtropical monsoon humid climate zone with four distinct seasons, abundant sunshine, and abundant rainfall.

Wuyishan National Park preserves the largest, most complete, and most typical of the subtropical primary forest ecosystems in the world with the same latitude. It has a primary subtropical vegetation community and a typical vertical vegetation spectrum.

Wuyishan National Park has an extremely rich species. Most of the other latitudes in the world are deserted or have poor biological species, while Wuyishan Nature Reserve is rich in species and unique components, and is the center of species formation and differentiation in southeastern China [17] and a key area for the biodiversity of the continent southeast of China [18].

Community-based ecological network construction framework concludes four steps. The main methods of each steps are listed as follows.

(1) Habitat suitability assessment of the target species

According to the current research in Wuyishan District, Neofelis nebulosa is the existing large Cat Predators, whose Habitat requirements can basically cover the protection of other species. Neofelis nebulosa belongs to the national first class protected animal and mainly inhabits the subtropical and tropical mountainous regions and the evergreen forests in the hills. The altitude of the distribution can range from low elevations up to 3000m in alpine forests. Thus, Neofelis nebulosa is chosen as the target specie for wildlife conservation in Wuyishan District.

(2) GAP analysis of conservation

The GAP analysis of conservation is to quantitatively evaluate the status of protection and vacancies of Neofelis nebulosa in the surround the national park. The suitable natural habitat of the Neofelis nebulosa was overlapped with the established nature reserves in Wuyishan City to identify suitable

habitats with high conservation value but were easily disturbed by human activities in Wuyishan city.

(3) Identification of potential small nature reserves

The identification of potential small nature reserves is to identify the village collective forest located in the suitable habitats surround the Wuyishan National Park. Through the overlap analysis of conservation GAP space, forest distribution, boundary of villages of Wuyishan City, the potential small nature reserves can be identified.

(4) Development of Community Based management strategy

Community-based management strategy should be developed from excavation of the traditional ecological protection idea of Fengshui Forest in the village with community participation. The boundary and community-based management should be based on current administration boundary and consultation with local communities.

4. Result

4.1. Habitat suitability assessment

The habitat of Neofelis nebulosa is mainly distributed along the main ridge of the Wuyi Mountains. Around the Wuyishan National Park, the habitat suitable for Neofelis nebulosa is located in the high-altitude forest area of Yangzhuang Township in the north of Wuyishan City and Jiangxi Wuyishan National Nature Reserve in the north.

The fragmentation of Neofelis nebulosa suitable habitat is shown in the Fig.4. It shows that main railroad and national-level road that pass through Wuyishan City are the main influencing factors, blocking national park from the eastern part of Wuyishan City.

Fig. 4. Habitat suitability assessment of Neofelis nebulosa

4.2. GAP analysis of conservation

The number of protected areas established in Wuyishan City is small and the level is low. In addition to Wuyishan National Park, Wuyishan City only established Huanglongyan Provincial Nature Reserve and Donghu National Water Conservation Scenic Area. Huanglongyan Provincial Nature Reserve and Wuyishan National Park are the main cover the most of suitable habitat of Neofelis nebulosi. Near one third of suitable habitat is outside the current protected area. As is shown in Fig.5, the conservation GAP is in the west of Huanglongyan Provincial Nature Reserve. The current protected area is not enough to support Neofelis nebulosi.
4.3. Identification of potential small nature reserves

According to the habitat suitability assessment and GAP analysis of conservation, we can found the north part of Wuyishan City is suitable for Neofelis nebulosa while not protected by official protected area. The north part is the main corridor of ecological network around the national park. Through overlap of suitable habitat, forest distribution map, village boundary, it can be identified Da’an Village, Xiji Village, Kenkou Village, Shangcun Village of Yangzhuang Township.

Fig. 5. GAP analysis of conservation of Neofelis nebulosa

Wuyishan City is suitable for Neofelis nebulosa while not protected by official protected area. The north part is the main corridor of ecological network around the national park. Through overlap of suitable habitat, forest distribution map, village boundary, it can be identified Da’an Village, Xiji Village, Kenkou Village, Shangcun Village of Yangzhuang Township.

Fig. 6. Potential small nature reserves for Neofelis nebulosa

Small nature reserve in China is one of the best practice of community-based management [26]. They are the extension and complement for natural protected areas and have been doing indispensable work on protecting fragmentary wildlife habitats and improve management resilience. We suggest the government promote the forest of four villages to be small nature reserves.

4.4. Development of Community-based management strategy

Potential small nature reserves identified are located in the rural areas between Wuyishan City and national park. In the rural areas of Wuyishan district, the traditional customs of the conservation of Fengshui Forest are common. Fengshui forest conservation means that villagers protect the forest to conserve water resources and ensure agricultural production and living.

Almost every natural village in Wuyishan has fengshui forests such as village entrance...
forests, forests along the river, etc. The protection of Fengshui forest has become a custom developed by villagers. Fengshui forest community self-government model is the wisdom of the community to protect forest resources for thousands of years, with village regulations as a guarantee, the villagers participating in mutual supervision. The traditional system of community self-government and the traditional knowledge of resource utilization should be tapped and integrated into the ecological network construction.

Inspired by the community autonomy management model of Fengshui Forest, the study proposes that to study the changes of the traditional system to improve community-based management of small nature reserve. Through the excavation and transmission of local knowledge, it may help to find new green growth points for community development. When the local residents of the community see the link between ecological network protection and livelihood improvement, they may become more respectful for nature and attach importance to ecological protection. The protection awareness of community residents can be mobilized and they can actively participate in the construction and management of ecological network.

5. Discussion

The study sets up a technique framework of 4 steps for ecological network construction for protected areas near the city considering community-based management. Wuyishan is a special case represent the south collective forest area with Fengshui Forest conservation custom. For the urban protected areas in north or west of China, community-based management may consider the local culture and other factors.

In the assessment of habitat suitability part of our study, we found the suitable habitat is not only located in Wuyishan City, but also across the boundary of Fujian province. It reveals the importance of Cross-provincial protection mechanism for large cat mammals.

Neofelis nebulosa was chosen as the target specie in the study according partly by the limitation of time. Lack of the monitoring point data of wildlife, we applied habitat structure theory model to analysis. The spatial analysis can be deeply refined by add other rare and endangered species and monitoring data update.

Although our study has the limitation mentioned above, it establishes a basic-line condition for future conservation and management. In the future, with the improvement of public awareness of biodiversity conservation, community-based ecological network may be the main supplemental for wildlife conservation near the urban protected areas.

Transforming Thermal Roads into Wind Bridges,
A Case Study of Areas along Tokyo 2020 Marathon Route

Hou Shuyu\textsuperscript{a,b}, Liu Shuhong\textsuperscript{a}, Shimoda Ryosuke\textsuperscript{a}

Abstract

With rapid urbanization in recent years, most metropolises are facing an increasing threaten of thermal environment and stagnated wind. Copious artificial structures keep influencing environment and weakening the resilience to climate change of cities, and among these, roads have contributed a lot while they were supposed to act as corridors for wind. Based on the result of recent experiments, the environment effect of green space and wind are closely related.

Present studies on urban wind and temperature condition mainly focus on green corridor systems creation in large scale, materials of road and buildings, relation between wind and city pattern and green belts’ ecological effect. This study mainly focuses on exploring the specific space-related factors’ function for forming and transferring wind in downtown areas and improve the air condition of local circulation. The factors include density and height of buildings, portion and pattern of passageways, and the arrangement of open space, and by calculated by CFD modelling technology. After modelling and simulating calculation, it forms an index system that could be used for specific site to evaluate the possibility to strengthen the wind with limited resources.

Marathon course is passing through or along many significant green open spaces and rivers in Tokyo which temperatures are relatively low. It also links the core of the city where the high-rises are crowded and air rarely flows, so the potential of transforming into a bridge to connect these two kinds of places and bring wind to larger areas of the city. Firstly, based on mapping and analysing city’s temperature data of land surface along the route areas, sort out large areas with lower temperatures to be the origin of wind, mainly are parks and waters. Secondly, modelling the area by CFD analysis system to sort out places where wind stagnated most. Next, build an index system of factors that can influence wind condition and apply it into evaluating the potential of surrounding areas of chosen places by testing the factors to sort out most potential areas of forming and transferring winds. Then, apply the strategies to ameliorate the wind condition according to the previous factors and remodel the surrounded area. Based on the existing urban structure pattern and architecture layout, the microclimate can be improved by modified little factors value. Finally, simulates the effect of the improving proposals in computational fluid dynamical simulation system to testify the result.
This study forms a framework for bringing out the best in existing metropolitan environment to improve the wind and temperature condition, and provides a practical case of improving wind condition in existing urban environment.

Key words: CFD analysis; downtown environment; urban ventilation corridor; small environment; green infrastructure

1. Introduction
Tokyo is a metropolis with high construction density and now facing increasing threaten of thermal environment and stagnated wind. Copious artificial structures keep affecting environment and weakening the resilience to climate change of cities, making the city less and less comfortable for living while global temperature keeps rising. City’s public spaces are important for citizens’ daily life and environment has significant effect on public activities like gathering and sports. In Tokyo, heat island effect and the wind retard are most severe problem in downtown area, but it is also with high density of population and frequently used as various citizen activities including gathering and sports, these activities have relatively high requirements for air and thermal environment. Since the upcoming Olympics in 2020 will have marathon game around Tokyo downtown area and it is an opportunity to improve city environment and infrastructures, this is a juncture of exploring ways to improve the wind and thermal condition by transforming some vital points within the downtown area.

Many scholars have studied on city wind environment optimizing and forming city natural ventilation path. Since 1980s, researches on thermal comfort in outdoor environment increased because of increasing attention for pedestrians in urban canyons, plazas and squares. In specific calculating and modeling field, most researches concentrate on wind ventilation system of large scale [1], some focuses on single factor like geometry, trees[2], traffic or buildings’ arrangement. Olgyay[3] and Oke[4] focused on the interactions between building and microclimate design.

![Fig. 1. Tokyo wind in a windy day](Source: https://air.nullschool.net)

This study mainly focuses on how to stimulate a specific small-scaled city area’s airflow in field of landscape and architecture, trying to find out ways for improving air ventilation condition by as less change from existing condition as possible.

2. Theory and methods
The function mechanism of forming partial wind bridge can refer to city ventilating theories in the fields of city planning, urban design, and ecology. In 1979, Kress R. put forward assessment standards for climatic function of underlying surfaces in city and classified city ventilating system into three parts, compensatory area, effect area, and ventilation path. The core of this theory is also in correspondence with source-sink-flow theory in environmental ecology. When studying wind condition in small scale, this theory is useful to help analyze the potential corridors and choose target areas to transform for improving wind environment.
In block scale and at pedestrian level, local circulation of wind is much more complex and needs sophisticated system to measure the methods of utilizing existing conditions like temperature, air pressure and building arrangement to create more comfortable air condition in specific areas. At the same time, city like Tokyo is not able to have spaces that are wide and open enough to create the city’s wind corridor in large scale, so it is necessary to try to find ways to stimulate wind circulation in smaller areas. Since the Marathon course links most important areas for both sources and sink of wind.

Then the study selects a specific site in Tokyo downtown area and improve method system using the assessment to form wind bridges within the area.

The study mainly focuses on exploring what landscape can do under the existing condition of the city’s structure and building arrangement, figure out a framework for improving wind and temperature condition.

First, choose target areas to lead the wind. Secondly, select surrounded areas that have potential to be wind source. Then measure the spaces between these above-mentioned places to choose, modelling the site and using CFD model to simulate the wind condition and find the key points where wind is blocked and have potential to be improved. Next, Using CFD model to testify each kind of factor by control variable method. We sorted five influencing factors improved. Next, Using CFD model to testify each kind of factor by control variable and using CFD modelling to simulate how these affect wind circulations at stationary exterior wind condition. After testifying different influencing factors, propose modifying methods and apply them in the city model to recalculate the wind condition in same exterior environment.

### 3. Compensation area, effect area and paths

Based on the heat map of Tokyo downtown area and route of Marathon, sort out inferior areas with higher temperature along the route.

The basic lines for choosing potential places for forming the ventilation path in city scale is as followed. Firstly, relatively low temperature areas linked with targeted areas with road. Secondly, with flexible open spaces that could be rearranged and modified between source and sink. The research picks the core area of Tokyo between the Imperial Palace and Tokyo Dome, since the Marathon course in north part of this area is relatively stagnated wind and the Imperial Palace is the biggest cool area downtown, which make it the source of wind. After building the model of the site

Fig. 4. Tokyo downtown wind simulation and key points

4. Wind related single factor effect simulation and index forming

According to current studies in environment field, factors that have influence on the city’s wind condition and could be adjust in renovation scale rather than planning scale are mainly as follows: Density of structures within wind path, the arrangement of specific amount of structures, the rugosity of the building, the section of street including depth-width ratio and Roadside Structure pattern. Then forming an assessment table by simulating and contrasting each factor.

The study supposes to simulate the wind environment under Winair CFD calculating extension under Ecotect system. We set same wind direction and speed in all the single factor simulation to control the variate under same air volume. In order to ensure the degree of accuracy and control the stability of the weather factor, we set the same input and output air temperature, the same wind direction and same 2m pedestrian level’s air condition in these five factors simulation to figure out how is the wind flow out in the urban street scale. In the simulation in this study, the colour ranges from yellow, red, purple to blue means strongest air flow to the breeze air flow.

In the study of getting more air flow run through the roadside buildings towards the target roads, we consider about three influencing factors including density of structures within wind path, the arrangement of specific amount of structures, the rugosity of the arrangement.

4.1 The Density of structures within wind path

We set up a number of same size building (10m×10m×15m) in the simulation. As shown in the fig.5, density of buildings in a
city area not only influence air temperature but also has impact on the airflow.

**Figure 5. The Density of structures within wind path**

It can be noticed that for the simulation examined higher density buildings causes stronger output wind as we set up all the buildings with the same height of 15m and the same layout pattern. That means the road can get more air flow from the higher density roadside buildings. In this case, we should figure out some methods to reform the Marathon course roadside building into high density to enhance the air ventilation condition.

**4.2 The arrangement of specific amount of structures**

This simulation involves a number of same size buildings (10m×10m×15m. As shown in the fig.6, we change the arrangement of specific amount of structures with the same building height of 15m and the same number of the buildings.

**Figure 6. the arrangement of specific amount of structures**

It shows that comparing with regular pattern, the random pattern causes stronger output wind. That means changing the arrangement of specific amount of structures into random pattern can supply more airflow to the target road. In the existing urban planning layout, the random pattern are much more than the regular pattern.

**4.3 The rugosity of the arrangement**

As shown in the fig.7, we change the height of the building model in the simulation with the range of 15m-30m to create 3 kinds of urban underlying surface. One is the flat underlying surface with 20m height buildings, one is regular rugosity underlying surface with 15m and 30m height buildings, another is random rugosity underlying surface with 15-30m height buildings. In this case, with the same arrangement of specific amount of structures, we get different underlying surface by change the height of buildings.

**Figure 7. the rugosity of buildings**

It shows that for the simulation examined random rugosity underlying surface causes strongest output wind while regular rugosity underlying surface causes stronger output wind than the flat underlying surface. That means with the relatively low range of roadside building height, it can create an underlying surface that allow more airflow to the target road. In this case, we should figure out some methods to reform the Marathon course roadside building’s height at less reform into regular rugosity underlying surface to enhance the air ventilation condition.
4.4 Section pattern of streets

The section pattern of the target road also can be the influencing factors in affecting wind circulation along the target road. In this study, we consider about two kind of situations including depth-width ratio and Roadside Structure pattern.

As shown in the fig.8, we set up the same height of the roadside building with 40m, while change the width of the road width with 60m and 30m in order to get different Depth-width ratio of the target road. In this case, with the same arrangement of specific amount of structures, we get different depth-width ratio by changing the road width.

It is clear that when the value of the Depth-width ratio gets smaller, the air flow on the target road gets stronger. That means under suitable conditions, taking some measures to lower the depth-width ratio to some degree could help enforcing the wind along the target roads.

Fig.8. Depth-width ratio of streets

As shown in the fig.9, the purpose is not to change the road width anymore with the same road width 30m while setting up different roadside structure pattern by enhance the buildings forming a valley section model. The height of valley buildings is from 15m to 40m, while the control model is all with 15m height. In this case, the valley model seems supply an airflow tunnel in the simulation to allow the airflow. It clearly shows that the valley model buildings can allow more airflow along the target road than the flat-arranged type of street.

Fig. 9. Roadside structure pattern

That means we should try to figure out how to form the valley patterns in the roadside buildings by enhancing the building structure or adding some infrastructure on the building roofs to enhance the air ventilation condition.

Fig. 10. Continuous structures of different section

Fig 11. Separated structures with trees and shrubs combine

The small size structures on the target road also affect the airflow condition, the structures can be supposed to be green space, some structures, even landscape sketches. We set up different shape of the structures to simulate the airflow by controlling the structures size with around 10mx10mx10m. In this case we set up the model in 3 types, one is continuous structures alone the road (fig.10), one is
separated structures, another one is combine trees and shrubs (fig.11).

As shown in the fig.10 and 11, the structures with bevel shape can form stronger wind than the structures with flat shape. In addition, the continuous structures (fig.10) allow stronger airflow along the target road than the separated structures. And the trees and shrubs combined together (fig.11) also allow stronger wind flow than the separated structures.

That means we should try to figure out some method to build some continuous structures with bevel shape or just plant more trees and shrubs groups to allow more airflow to the target road.

4.5 Index of wind bridge forming

After single factors’ simulation, the single factors can get score according to the superiority for ventilation. When adapting the research to practical renovation in urban design and landscape design, the difficulty of modify should also be considered. The conclusion of this index for picking factor to improving wind condition in small scale is as follows. Strengths and Weakness assessment is based on how the factor help with strengthen local circulation in pedestrian level.

<table>
<thead>
<tr>
<th>Element</th>
<th>Specific</th>

The number in degree column describes degree of difficulty in transformation. One means the modification is in design level, with plants or structures or facilities, by using one method to achieve. Two is also in design level such as plants, structures, facilities, using two or more methods to achieve. Three is in systematic level, which involves amendment in urban design. Four is in planning level and five means hardly to be changed. In this study, however, we simulate only special factors and leave out material elements such as heat absorption coefficient.

5. Adapting methods in selected site

5.1 Existing condition analysis

The site is located at Chiyoda district and north of The Royal Palace. The large green space in Imperial Palace is a low temperature zone that can bring cooler
airflow to the high temperature areas. In this way, the air flows spontaneously to warmer areas of the surrounded area.

The area is about 1000 thousand square meters, and the main road in this area is about 3000 meters long, and the width of the all roads range from 10m to 60m. The height of the building in this area is from 10 meters up to 150 meters. Most of the buildings are business buildings. The road are mainly double vehicular roads with bicycle lane and single vehicular roads with bicycle lane. Some of the roads has lane separator with bushes and trees, but there is few big shade trees on the main roads.

5.2 Specific strategies for improving ventilation

On this route, the roads that run south and north mostly have a relatively good airflow condition, the surface temperature also gets lower than the roads run west and east. So mainly focus on how to lead the wind to the roads with directions not conform to predominant wind direction of the city in summer.

For target areas, we use three main strategies, adding stair-shaped facilities along the road, making wind path in block areas, and changing rugosity of the building by placing small blocks like flower beds above the buildings.

The figure below shows one strategy of adding stair-shaped structure in the street to stimulate the wind, which can also be the place for recreation.

5.3 Ventilate effect simulation

After the modification, the simulation shows where the wind gets stronger under the same input situation clearly.

As showed in enlarged pictures, the stair-shaped facilities strengthen the wind greatly and affect the wind of few miles. By simply opening part of the first floor of blocking building, the wind is strengthened tremendously.
Fig. 15. Contrast of original wind and modified in section

Fig. 16. Contrast of original wind and modified in path

6. Discussion

By studying the possibility of modifying small-scale space elements to stimulate wind, the study testifies the methods in landscape design scale and forms an index for variable factors in space based on CFD modelling. In the application of the methods in specific site, the factors plays an important role in improving the wind condition of the site.

On the other hand, limited by the data source of climate and ventilation environmental science methods, the result of the simulation are limited. Mainly focus on space related factors and simplified the model of variable factors when simulating. The background climate condition in the simulation is not exactly as the actual situation because of lack of data and calculation methods.

Although the study has limitations mentioned above, the index of space related factors gives future urban renovation and landscape design a new perspective of considering the possibility of improving city environment from tiny points and make tremendous difference in downtown area of metropolis.

Upsurge, Misconception, and Prospect: Brownfields Regeneration in Landscape Architecture in China

ZHENG Xiaodi*, FU Quanchuan*

* School of Architecture, Tsinghua University, Beijing 100084, P. R. China

Abstract

The number of brownfields regeneration projects has increased dramatically in recent years in China, and more and more landscape architecture professionals found themselves involved in them. Based on statistics of articles published by the three key professional journals in China in the past 15 years, it can be observed that the number of articles focused on brownfields regeneration increases steadily every year. Among important professional awards given by CHSLA and ASLA, many were awarded to brownfields projects. Through analyzing the ASLA awards for the past 5 years, it can be found that almost half awards-winning projects are brownfields regeneration efforts. However, under such upsurge, we shall be cautious of couple dangerous misconceptions that have appeared in the public realm which either exaggerate or diminish the role of landscape architecture in relationship to site remediation of brownfields projects. During the 2016 International Conference on Brownfields Regeneration and Ecological Restoration held in Beijing, a declaration was passed unanimously by all attendees in which six principles were written out to guide future actions.

Keywords: architecture; brownfields regeneration; journal; professional awards; declaration

In recent years, brownfields regeneration projects have attracted much attention in the field of landscape architecture in China. A number of key academic conferences have set up forums or keynote speeches focusing on the theme of brownfields. Major domestic academic journals have also used brownfields restoration and related issues as topics or themes. With the issuance of the “Action Plan for Soil Pollution Prevention and Control” and the “Polluted Sites Soil Environment Management Measures (Trial)” and other related policy documents, the brownfields regeneration projects in China are rapidly increasing, and more and more landscape architecture professionals are participating in them. However, brownfields is still a relatively new and unfamiliar field and China’s relevant regulations are still unsound. Therefore, some dangerous misconceptions we need to be cautious of have also been exposed in the rapid outbreak of brownfields regeneration practice. Under the current context, what are the prospects for landscape architects in brownfields regeneration process and what should be paid attention to are essential issues that we need to constantly ponder and discuss.

This article is supported by the National Natural Science Foundation of China (No. 51608295). The Chinese version of this article was firstly published in Chinese Landscape Architecture, 2017(5):10-14. All images are provided by the authors.
1. Upsurge: The increasing attention on brownfields regeneration in landscape architecture

1.1. The number of brownfields-related articles published by major domestic professional journals has steadily increased

Based on statistics of articles published by the three key professional journals of landscape architecture, “Chinese Landscape Architecture” ①, “Landscape Architecture” ② and “Architecture Frontiers” ③, it can be observed that in the 15 years from 2001 to 2015, the number of articles focused on brownfields regeneration reached a total of 105, representing an increasing trend year by year (Fig. 1).

There are two issues with brownfields as the theme in “Chinese Landscape Architecture”, namely “Brownfields Restoration” in February 2013 and “Brownfields Regeneration” in April 2015, which were both organized by the first author. Three other issues also focused on similar areas, including “Waste Land Renovation and Reconstruction” in February 2008, “Ecological Restoration” in August 2011, and “Mining Heritage” in July 2012.

Among the above-mentioned brownfields-related articles, 47 were project introduction, accounting for 44.8% of the total approximately. The focus of articles on brownfields regeneration project is mainly landscape design and ecological restoration, in addition to restoration technology, brownfields management, industrial heritage protection and etc.. From the perspective of project location, more than half of the brownfields regeneration projects introduced are located in China, which mainly distributed in Shanghai, Wuhan, Beijing and Shandong. Foreign ones mainly include projects in the United States, Australia, Germany, and UK (Fig. 2). From the perspective of project categories, 22 vacant lands of industrial and infrastructure facilities accounted for nearly half of the total, and 14 mining waste lands (Fig. 3). The projects of high concern include the London 2012 Olympic Park, the Duisburg Nord Landscape Park in the Ruhr, the Gas Works Park in Seattle, Fresh Kills Park in New York, and the South Lake Ecological Park in Tangshan city.

---

① Founded in 1985 and hosted by CHSLA, “Chinese Landscape Architecture” is a "Chinese Core Journal" and "Chinese Core Journal of Science and Technology". It is also a cooperative publication authorized by the International Federation of Landscape Architects (IFLA) in China.

② Organized by the Ministry of Education and hosted by BJFU, “Landscape Architecture” was founded in 1985. It mainly publishes design practice and academic research articles in landscape architecture and related disciplines such as architecture and urban planning.

③ Organized by the Ministry of Education, hosted by Higher Education Press and Peking University, and prepared by the School of Architecture and Landscape Design of Peking University, “Landscape Architecture Frontiers” (bimonthly) was founded in February 2013. It is published bilingually in Chinese and English.
1.2. Brownfields projects have won significant professional awards at home and abroad.

The "Outstanding Landscape Engineering Award" and "Outstanding Landscape Architecture Planning and Design Award" awarded by the Chinese Society of Landscape Architecture (CHSLA for short) from 2010 to 2015, and the "General Design Award" and "Analysis and Planning Award" awarded by the American Society of Landscape Architects (ASLA for short) during the same period of time have been selected for statistical analysis in this research (Table 1).

Brownfields regeneration projects are divided into four categories for statistical purpose: vacant lands of industrial and infrastructure facilities, mining wastelands, landfills, and comprehensive reclamation of river basins. Among which, the projects of comprehensive reclamation of river basins mainly refer to the projects that clearly indicating in the project descriptions that there are illegal waste dumps and other pollution sources in its basins, but the projects are dominated by water pollution control or water system dredging.
1) Professional awards awarded by CHSLA

The “Outstanding Landscape Engineering Award” is set up by CHSLA. The award winners are landscape projects or traditional garden buildings that were built by formal members of CHSLA in China after a management period for one year. About 200 awards are awarded each year. A total of 1,145 Outstanding Landscape Engineering Award were awarded from 2010 to 2015. Among them, brownfields regeneration projects account for 4% to 12% of the total each year. The awards-winning brownfields projects are dominated by comprehensive reclamation of river basins, accounting for 91%. Thus it can be observed that the projects focusing on soil pollution remediation are still very limited (Table 2, Fig. 4, Fig. 5).

Table 2. Number of Brownfields Projects in CHSLA Outstanding Landscape Engineering Awards from 2010 to 2015.

The “Outstanding Landscape Architecture Planning and Design Award” is another important professional award awarded by CHSLA. It has been selected once every two years since 2011, and 285 projects have been awarded in 3 sessions so far, among which the brownfields regeneration projects in the 3 sessions were accounted for 11%, 6.1%, and 10.5% respectively, with an average of 9 awards per session. Among the brownfields regeneration projects that won the Planning and Design Award, the projects of comprehensive reclamation of river basins also accounted for the largest part, reaching 62%, followed by landfills projects (Table 3, Fig. 6 and Fig. 7).

Table 3. Number of Brownfields Projects in CHSLA Outstanding Landscape Architecture Planning and Design Awards from 2010 to 2015.
2) Professional awards awarded by ASLA

Founded in 1899, the American Society of Landscape Architects (ASLA) has more than 100 years of history, representing professionals from 50 states in the United States and 42 countries worldwide. The annual ASLA Professional Award is one of the most influential landscape architecture professional awards in the world, including the General Design Category, Analysis and Planning Category, Residential Design Category, Communications Category, Research Category and Landmark Award. Only the General Design Category and the Analysis and Planning Category were selected for statistical analysis in view of the purpose of this study.

ASLA awarded 61 “General Design Awards” from 2010 to 2015, including 27 brownfields regeneration projects, accounting for 44.3% of the total. The projects of vacant lands of industrial and infrastructure facilities accounted for 70% (Table 4, Fig. 8 and Fig. 9). At the same period of time, ASLA awarded a total of 51 “Analysis and Planning Awards”, among which brownfields projects also accounted for about 33.3%. In this category of award-winning brownfields regeneration projects, the projects of vacant lands of industrial and infrastructure facilities reached up to 70% (Table 5, Fig. 10 and Fig. 11).
It can be seen that in the "General Design Awards" and the "Analysis and Planning Awards" awarded by ASLA, the proportion of brownfields projects is much higher than that of the brownfields projects awarded by CHSLA. Taking the projects of vacant lands of industrial and infrastructure facilities as the main part, it attaches more attention to environmental issues and soil pollution remediation.

2. Misconception: Be cautious!

2.1. Misconception 1: "As long as the trees are planted, the brownfield site is clean and the process can be very quickly."

Due to the special restrictions of brownfield sites, and the advantages of outdoor open space featuring low cost, short cycle and flexibility of programs, there are indeed a large number of brownfields projects that take urban parks as the end use for transformation and regeneration [1]. However, we must avoid a misconception. That is, as long as we plant trees on brownfields and we have green plants, the brownfields will be “greatly turned”, and people can feel relieved to use them. Meanwhile this process can be very short, and the shorter the time is, the more “great” the achievement is.

One extreme example: the explosion in the Tang Gu Development Zone in Tianjin Binhai New District on August 12, 2015 was a tragic accident that caught the attention of the whole world, causing 165 deaths in total. The explosion took place in the area of dangerous cargo warehouses. The magnitudes of two successive explosions were equivalent to 3 tons of TNT and 21 tons of TNT, respectively. However, in less than a month after the explosion occurred, the conceptual plan for transforming the accident site into an ecological park was posted for input from the general public on the internet on September 5. Regardless of whether it is possible to make a landscape design that pays tribute to the deceased and recounts the painful lessons in a month, the pollution distribution and composition investigation of the accident site alone can be very intense or even difficult to accomplish. It is really worrying that in the absence of the pollution information, the opinions of more than 400 citizens were mainly concentrated on the “planning and construction of ancillary facilities, transportation links on both sides of the Haibin Road, and the noise effect of the Haibin Road” [2]. There was neither a questioning about the pollution situation after the explosion of dangerous cargo warehouses, nor a query on how to carry out pollution remediation in the plan.

Charles Waldheim, former chair of the Department of Landscape Architecture at Harvard University in the United States, once pointed out that in the contemporary landscape architecture practice, the landscape system has been used as “a healing balm for wounds made in the industrial age” with its remarkable corrective effect [3]. However, we cannot regard the landscape as a “green patch” that handles brownfields problems in an oversimplified and crude way. Not all the places with "brown scars" can be quickly healed by the "green patch" with "eco-label". The landscape project of brownfields regeneration is much more complex than that of general sites in the early stage of site analysis and investigation. The design process also requires close cooperation with
the remediation process of environmental engineering. The project timeline must follow scientific and objective laws. Landscape architects can and should play a greater role in brownfields regeneration, but meanwhile it is necessary to avoid playing down the complexity and difficulty of transforming the brownfields into parks under the pressure of market development. Whether within the field of landscape architecture, or facing the government officials, developers and the general public, we must be alert to the spread of this misconception.

2.2. Misconception 2: “The original commercial development was changed into an ecological restoration park, and pollutants have not been eliminated.”

It is necessary for us to avoid insufficient understanding of the complexity and difficulty of brownfields regeneration landscape projects. Meanwhile, there is another misconception we need to be wary of, that is, the transformation into landscape end use is not a good solution to polluted sites.

Another example of national concern is also thought-provoking. Changzhou Foreign Language School has been in dispute and turmoil since its relocation to a new site in 2015. More than 400 students had abnormal symptoms such as dermatitis, eczema, bronchitis, abnormal blood parameters and leukopenia. Some students were also diagnosed with malignant diseases such as lymphoma and leukemia. The problem was an empty "toxic land" separated only by one road from the school’s new site. After investigation, the site was once home to three pesticide chemical plants including Changlong Chemicals. It is reported that pollutants mainly composed of organic pollutants such as chlorobenzene and carbon tetrachloride have been detected in the soil and groundwater of the vacant land with an amount far exceeding the general standard.

The following discussion focuses on the analysis of the reasons causing such serious consequences in major public media after the outbreak of the incident. Basically including: First, the new school site is too close to the polluted land, which does not comply with the national regulations; Second, the school used groundwater, violating the regulations of the environmental assessment report; Third, the excavation of soil made the organic matter to evaporate and thus the pollution spread more quickly; Fourth, “the original remediation plan was changed from soil excavation to clay covering, and the original commercial program has also been transformed into an ecological leisure park. For such soil remediation, some experts believe that pollutants have not been eliminated and that it is still an environmental bomb under the ground sooner or later.” [4]

The last reason needs special attention and vigilance. Although the methods and techniques for soil remediation are diverse and polluted soil can be transported out, in fact, they are more encouraged to be treated in-situ or on-site to reduce the risk of secondary pollution. The “Polluted Site Soil Environment Management Measures (Trial)” clearly stated that “management and remediation should, in principle, be carried out on site.” The purpose of site remediation is no longer in the phase of “complete elimination” of pollution. Currently the more commonly used strategy internationally is site remediation based on risk assessment, that means to take the risks to the environment and human body will be controlled within the safety zone as the purpose of pollution control. Due to huge pressure on capital, time cycle and technology, the method of “completely” eliminating site pollution in the early phase led to delays in the cleanup and transformation of many brownfield sites. It is misleading to include the “original commercial program has also been transformed into an ecological leisure park” in the reasons, as if suggesting that ecological
leisure parks have shortcomings in pollution remediation. However, the fact is that no matter what the end use of the final transformation is, as long as appropriate remediation methods are adopted, the pollution remediation of the site can achieve the expected goal.

3. Prospect: Action Plan

The theme of the “Chinese Landscape Architecture” journal in February 2013 was “Brownfields Restoration”. Professor WANG Shaozeng, the late chief editor, wrote in the Editor’s Words: “I suddenly realized that this (‘brownfields restoration’) is the most important contribution our discipline has made since 20th century... After several years, brownfields restoration may be the most important job in the field of landscape architecture.” Professor Waldheim of Harvard University also told the author during his term as the chair that he believes brownfields projects should be chosen as the research subject in landscape design studios at Harvard Graduate School of Design, because we should no longer teach students to build on green lands that need protection. In the face of such a pressing demand for brownfields regeneration effort, what are the cutting-edge academic thinking and successful practices at home and abroad? What aspects should we focus on in future actions?

On September 10 to 11, 2016, the 2016 International Conference on Brownfields Regeneration and Ecological Restoration was held at Tsinghua University with the theme of "Brownfields Regeneration and Healthy Cities". As one of the important academic activities of the 70th anniversary of the School of Architecture at Tsinghua University, the conference was co-organized by the School of Architecture of Tsinghua University, the Technology and Environment Center of Harvard Graduate School of Design, and the Foreign Economic Cooperation Office of the Ministry of Environmental Protection, and was hosted by the Department of Landscape Architecture of the School of Architecture at Tsinghua University. The conference set up five forums, including themes on policies and regulations, win-win cooperation, design and technology, ecological restoration, and international experience and exchanges. 24 invited speakers from the United States, the United Kingdom, Germany, Israel, and China conducted inspiring speech and had lively exchanges and discussions with more than 250 delegates on policy, practice and theoretical issues in the field of brownfields regeneration. The relevant leaders from the Ministry of Environmental Protection, the Ministry of Housing and Urban-Rural Development and other ministries and committees addressed the opening ceremony. In the Brownfields Regeneration Workshop of Beijing Shougang Group held in the same period of time, joint design activities was conducted by nearly 60 students from the United States, Spain and China under the guidance of the teachers of the three countries, and the results were reported at the conference.

It can be said that this conference is another important academic conference in the field of brownfields regeneration, following the two important international conferences held in Harvard Graduate School of Design—the "Manufacturing Site, a landscape conference focusing on site technology in contemporary practice" in 1998 and the "Brownfields Grey Water: Rehabilitation Process and Design Practices” in 2001. It is also the first international conference with multi-discipline and multi-professional participation in China's landscape architecture field that takes brownfields regeneration as the main topic.

At the end of the conference, the Declaration of the 2016 International Conference on Brownfields Regeneration and Ecological Restoration was read out at
the closing ceremony and all participants approved it by acclamation. The Declaration was initiated by Professor Kathryn Moore, the present president of the International Federation of Landscape Architects (IFLA), discussed with Professor Niall Kirkwood of Harvard Graduate School of Design, and wrote by the first author. The Declaration put forward six core actions, hoping to provide guidelines and references for scholars and practitioners in the field of brownfields regeneration:

1) Support a detailed survey of the current brownfield situation in China, including distribution and contamination extent etc., and construct a thorough public database.

2) Involve all related sectors and adopt a multi-disciplinary approach for brownfields regeneration process.

3) Take a long-term view providing enough time for proper remediation process of brownfield sites.

4) Ensure a regional and holistic approach which examines and envisions the future of brownfield sites' redevelopment in the larger context.

5) Raise public awareness on the risk of brownfield sites, as well as opportunities offered during the regeneration process, through educational events and actions, and ensure public participation through the regeneration process.

6) Revisit and facilitate revisions of academic pedagogy and curriculum setup to be in line with and advance required new knowledge associated with brownfields regeneration challenges.

Abstract

Urban decision makers are faced with many complex issues related to balancing urban development and environmental impacts today. Expectations for increased demand for new infrastructure construction are the natural phenomenon (Wouters et al., 2016). The infrastructure that relies on the mono-function with high complexity system results in a chain of failures in interconnected systems, which lead a significant loss for properties of the physical, social and economic (Little, 2003). This is the reason why we who are engaged in the discipline of the landscape architecture pay attention to the new approaches of Green Infrastructure.

Among the various concepts of Green Infrastructure, this study has focused on the values in including the role of urban hydrology within urban water management. Many of the symptoms of climate change are related to water. Recent changes in rainfall patterns and the increase in impervious water due to urbanization have resulted in increased urban floods, decreased groundwater, increased heat island phenomena, and worsened water pollution. In response to these, the terms of “sustainable urban drainage”, “low impact development”, “water sensitive urban design”, “Water Sensitive Cities”, and “Modified rainwater management” have been appeared. Taken together these terms, Wouters et al. (2016) uses the term Blue-Green Infrastructure (BGI) instead of Green Infrastructure.

BGI not only includes rainfall runoff and pollutant abatement technology elements that are applicable to urban areas in a narrow sense, but also encompasses major ecological infrastructure in urban areas, meaning open space conservation and interconnection in the broad sense. In addition, it can provide sustainable multi-dimensionally sustainable various social, economic and environmental benefits of urban areas as well as water cycle recovery in urban areas.

The purpose of this study is to explore the various potentials and possibilities of the "Blue" area in the BGI, particularly the ecological services aspect associated with water by examining the case of Bishan-Ang Mo Kio park and Kallang River project in Singapore. Briefly to sum
up, there are four fundamental ecological processes occurring in these cases, including the water cycle, nutrient cycle, energy cycle and community dynamics.

In this study, we would like to articulate the functions and roles of ecosystem services of urban hydrology within urban water management in BGI. There are many questions to be answered about the ecosystem services integration of BGI into cities. The answer to the most important questions from the designer's point of view is that, beyond the quantitative expansion of the BGI for the restoration of the city's water cycle, there is a need for a systematic approach to provide citizens with an ecological environment and aesthetic satisfaction at the same time.

**Keywords**: Blue-Green Infrastructure; Ecosystem Service, flooding; mitigate the impacts of climate change

---

1. Riverine Ecosystem services in Infrastructural Ecologies

   Cities and their decision-makers today face many complex challenges that are associated with balancing urban development and its impact on the environment. Consequently, the demand for new infrastructure construction is expected to increase commensurately. These infrastructure expansions are aligned with enormous costs (Morrish, 2008).

   Particularly, conventional, monofunctional infrastructure is prone to catastrophic failure cascading failure of interrelated systems, which results in a significant loss for the physical, social and economic properties (Little, 2003).

   Among the various elements that jointly constitute a city’s infrastructure there is one in particular that, perhaps more than all of the others, shapes a city and supports urban activity and human life – that element is water. Water is necessary for human life and a broad variety of economic activities.

   The conventional approach to urban water infrastructure has been to use quantitative models to predict future water demand and then to construct additional infrastructure to meet this demand. That approach prioritizes technology and large physical interventions which attempt to manipulate natural processes to suit the needs of humankind. However, that focus on “grey” infrastructure – due to the massive amounts of concrete and metal typically involved – is progressively showing deficiencies and limitations in meeting the additional stresses to urban water supply and management, induced by rapid urbanization, impervious land cover, and climate change.

   Riverine ecosystems provide important ecosystem services such as clean water, flood protection, habitats, biodiversity and recreational and social amenities to urban residents. However, riverine ecosystems belong to the ones most degraded by humans (Naiman and Monica, 2000). The hydrology of rivers has been altered by the construction of structures, such as dams and weirs, and water diversions for hydropower and other industrial purposes, irrigation and domestic uses (Jackson et al., 2001). These activities profoundly change the processes that drive ecosystem function and structure (Jansson et al., 2000). A central tenet of the meeting was that any riverine ecosystem is embedded in heterogeneous landscapes consisting of several landscape components that each may have an effect on the target ecosystem (Wiens, 2002). A corollary of this notion is that ecosystems to be restored are not only affected by activities in the target area, but also by processes in the surrounding landscape, making connectivity among landscape components a central
concept (Pringle, 2001). Analysis of the process of recovery is another central field in restoration science as it addresses whether or not ecosystems respond to restoration in the expected way and whether or not the project objectives are met.

This paper introduces key messages from the case of Bishan-Ang Mo Kio park and Kallang River project, focusing on river restoration. First off, we will illustrate the Bishan-Ang Mo Kio park and Kallang River as Blue Green Infrastructure based on the principles of infrastructural ecologies (Brown, 2010). Specifically, we would like to articulate the functions and roles of riverine ecosystem services. We also discuss the critical resources needed to sustain the stream ecosystems in the form of the minimal stream flow, or discharge, necessary to maintain stream ecological and hydrologic function, and how that consideration relates to the ecosystem services concept. Although my emphasis is on the hydrological system, we include domains of institutional management of ecosystem services where relevant.

2. Bishan-Ang Mo Kio park and Kallang River as Blue Green Infrastructure

Brown (2010) argues that the next generation of infrastructure cannot resemble the hard, single-function and carbon-intensive structures of yore. Rather, we need more diversified, distributed, and interconnected infrastructural assets that simulate the behavior of natural systems. She suggested the principles for next-generation infrastructure—“infrastructure ecologies” that simulate the behavior of natural systems. Such systems are multipurpose, interconnected, and synergistic; contribute few or no carbon emissions; work with natural processes; improve social contexts, serving local constituencies; and are resilient, adapting to predicted changes from unstable global climate.

Bishan-Ang Mo Kio park and Kallang River project is suitable case for explaining these principles as a new ecological infrastructure. First of all, the systems of Bishan-Ang Mo Kio park and Kallang River are multipurpose, interconnected and synergistic. This project is one of Singapore’s most popular parks in the heartlands of Singapore. As part of a much-needed park upgrade and plans to improve the capacity of the Kallang channel along the edge of the park, works were carried out simultaneously to transform the utilitarian concrete channel into a naturalized river, creating new spaces for the community to enjoy.

Bishan-Ang Mo Kio park and Kallang River project is part of the Active, Beautiful, Clean Waters (ABC Waters) Program, a long-term initiative to transform the country’s water bodies beyond their functions of drainage and water supply, into vibrant, new spaces for community bonding and recreation (Public Utilities Board of Singapore, 2012). Singapore’s ABC Waters Program aims to improve the water quality, physical appearance, recreational value, and biodiversity of Singapore’s waters. While targeting waterways and reservoirs, the ABC Waters Program also addresses the stormwater runoff generated from the urbanized catchment. A landmark project of the program, the Bishan-Ang Mo Kio Park is one of Singapore’s biggest and most popular parks. Construction began in October 2009, and the park was officially opened in March 2012. It showcases the transformation of a 2.7 km concrete channel of the Kallang River into a 3 km naturalized
river integrated with the surrounding green space (Holmes, 2012).

Bishan Park, with more than three million visitors each year, holds a significant role in the heartlands of Singapore (Landezine, 2014). The longest river in Singapore, Kallang River, flows for about ten kilometers through the city center. The 62-hectare park was designed between 2007 and 2010 by Ramboll Studio Dreiseitl (Ramboll Group, 2012). The main aim of the project was to improve the capacity of the concrete canal and to transform the existing park into a functional park, which is fully integrated with nearby neighborhoods, with a water-sensitive urban design approach.

Before the restoration project, Kallang River, like many waterways around the world, was forced into a concrete channel to reduce the impacts of extensive flooding. The existing park around the river, which could receive some migratory birds due to its geographical location, had wide lawn areas which did not function ecologically. The urban park, with randomly located trees, did not have considerable biodiversity value. Also, the population of the district increased dramatically after the district was completely urbanized.

Second, Bishan-Ang Mo Kio park and Kallang River works with natural processes. Bioengineering techniques were applied to re-construct the river channel. Although the use of bioengineering is common in the developed world, it had not been used in Singapore before. The design team experimented with ten different techniques in combination with native plant species on a 60 m stretch of a side drain within the park, before applying bioengineering to the Kallang River (Channerl News Asia, 2012). Seven of these techniques were selected in the naturalization of the channel, including fascines, riprap with cuttings, geotextile-wrapped soil-lifts, brush mattresses with fascines, reed rolls, gabions, and geotextile with plantings. A hydraulic model was developed to simulate the flow dynamics to help the design of the channel. For example, more robust plant species would be used at locations identified by the model to be subject to higher flow velocity for erosion control. The naturalized channel is the highlight of the park with meander bends, varying channel width, rock beds, and vegetated banks that generate diverse flow patterns. Being aesthetically more pleasing, the heterogeneous geomorphology is also an attempt to provide a variety of wildlife habitats (National Parks, 2012). Several sustainable storm water treatment elements are incorporated into the redesign of the park, among which is the cleansing biotope – the first in Singapore. The cleansing biotope is at an upstream location in the park and it helps to supply clean water needed for the park facilities, such as the water playground, to avoid the use of chemicals (Channerl News Asia, 2012).

Third, Bishan-Ang Mo Kio park and Kallang River project improve social contexts and serve local constituencies. The concrete canal at Bishan - Ang Mo Kio Park was once a vital part of the neighborhood's drainage system and allowed water to flow to a meandering river, the concrete was cut into slabs and stacked to form Recycle Hill. This was a deliberate effort to preserve a part of the park's history, and reuse the concrete in a creative way. Perched on the hill is a sculpture - 'An Enclosure for A Swing' uniquely created to represent the fusion of nature and design.

Lastly, Bishan-Ang Mo Kio park and Kallang River project has designed for resilience, to adapt to foreseeable changes brought about by an unstable global climate. The park is essentially a floodplain river that allows for multiple uses – when flow is low,
people can play in the river channel; when flow rises during storms, the entire park functions as a conveyance channel to pass the flow downstream to prevent flooding of the surrounding residential areas. The naturalized channel, along with its floodplain, was designed to safely convey a 1-in-25-year storm (Public Utilities Board of Singapore, 2012). Any new development in the catchment is subjected to a drainage design code that prohibits the generation of additional stormwater runoff—stormwater should be retained onsite and cannot be discharged into the river until after the storm.

3. Ecological process and ecosystem services of the project

There are four fundamental ecological processes occurring in the case of Bishan-Ang Mo Kio park and Kallang River project, including the water cycle, nutrient cycle, energy cycle and community dynamics, which are as follows: (1) Water cycles; that the increased roughness of the natural riverbed with rocks, pools and riffles means the velocity of river has been slowed down, so fewer particles are transported downstream to the Marina Reservoir where they would need to be extracted through filtration. The increased conveyance capacity of the river and decreased velocity means flood protection for the dense urban areas surrounding the park as well. (2) Nutrient cycle; The restoration of the river has created a huge variety of micro-habitats which not only increase biodiversity but the resilience of species within the park, meaning their long term ability to survive is greatly improved. (3) Energy cycle; the cleansing biotope increases the ecological value of the park’s biotic systems, cleansing water naturally through plants and filtration media. (4) Community Dynamics; no wildlife was introduced to the park but the introduction of the naturalized river into the park has seen the park’s biodiversity increase by 30%. 66 species of wildflower, 59 species of birds and 22 species of dragonfly have been identified in Bishan Park; not bad for a city park.

The key constructed ecosystems of this project are naturalized river and variety of micro-habitats and this constructed ecosystem has offered regulating services, provisioning services, cultural services and supporting services. Cleansing biotopes in the park offer an effective water treatment while maintaining a natural and beautiful environment. This helps to maintain the water quality of the ponds without the use of chemicals. They consist of carefully selected plants in a filter medium which helps to cleanse the water by filtering pollutants and absorbing nutrients. Aside from its unique waterways, the park features a lush greenery, pond gardens and river plains help climate regulation. It was envisioned as a leisure destination for residents ranging from children to nature-lovers, containing facilities such as a football field, a floating amphitheater, and a natural pond. Moreover, new bridges, stepping stones in the water and a riverside gallery were built to encourage increased interaction with water. Existing features such as the foot reflexology feature, community garden, dog run, and fitness areas were refurbished (NG Mee Kam, 2012).

The use of soil bioengineering techniques (a combination of vegetation, natural materials and civil engineering techniques) to stabilize the river banks and prevent erosion was a first for Singapore and is a new reference for soil stabilization in the tropics, which have otherwise rarely been used or documented. In 2009, a test bed was constructed, testing about 10 different soil
bioengineering techniques and a wide variety of tropical plant species along a length of 60 meters at one of the side drains in the park. Within the water park, a new water playground was designed to increase the attractiveness and visitor enjoyment. Water for this playground is supplied by cleansed pond water that has been filtered through the cleansing biotope, which has undergone an ultraviolet (UV) treatment to eliminate any harmful biological contaminants without introducing any chemicals into the water (Harris et al., 2013). Restoration of the river has created a huge variety of micro-habitats which not only increase biodiversity but the resilience of species within the park, meaning their long term ability to survive is greatly improved.

4. Potentials for increasing riverine ecosystem services in Blue Green Infrastructure

Ecosystem service provisioning areas and service benefiting areas are not necessarily co-located, so humans may choose to increase service-connecting areas through infrastructure. Given the diversity and complexity of river ecosystems, it is a significant challenge to synthesize the many ecosystem services that river ecosystems provide to develop clear insights to inform better management of rivers. Numerous tradeoffs exist in the management of ecosystem services from rivers, some of which include: navigation vs. water storage; recreation vs. industrial usage; irrigation vs. fish habitat; and cultural services vs. hydropower production. Over-emphasis on any one ecosystem service (e.g., provisioning of hydropower) can cause the reduction or even elimination of other valuable ecosystem services (e.g., provisioning of native fisheries), and hence it is critical to achieve a balanced approach that considers multiple ecosystem services in any management for river ecosystems across different scales. Although questions that face riverine management may extend beyond the application of an ecosystem services approach, this concept can provide a mechanism for broadening the perspective of linking humans to river systems. When I analyze the scale aspect of the project and the historical context into the results and driver elements, they are mostly related to ecosystem services related to water.

5. Conclusion

In this article, we focused on the riverine ecosystem services embedded in blue green infrastructure with the case of the Bishan-Ang Mo Kio park and Kallang River project. This project shows us Brown (2010)’s the principles of a new ecological infrastructure such as ingenious, multi-purpose, carbon-neutral and resilient systems how to systemically work.

Ecosystems in the new ecological infrastructure contribute to human well-being via the provision of goods and services where the benefits are direct, such as in the production of food and raw materials, and indirect as is the case in the regulation of water quality and supply. In order to manage and enhance ecosystem services provision, understanding the underpinning these services as a suite of ecological functions becomes of a dire importance (Banerjee et al., 2013).

As we can see with the Bishan-Ang Mo Kio park and Kallang River project, ecosystem services are provided by riverine ecosystems in the form of provisioning, supporting, regulating and cultural benefits to both ecosystems and the human societies that depend upon them. River ecosystems
vary greatly in scale, from headwater streams to vast river deltas, and the relative importance of various types of ecosystem services changes dramatically with spatial and temporal scales.

The future of river science may require clearer articulation of the complex problems facing specific river systems and the development of novel methods for integrating the suite of ecosystem services into natural resource management paradigms. One promising approach, for example, lies in the concept of environmental flows, which posits minimal flow regimes for the recovery and/or continued maintenance of critical ecosystem services such as supporting healthy conditions for aquatic species in rivers. This approach is most appropriate when the threat of irreversible damage exists for critical services, and parallels the literature on irreversible damage exists for critical systems. It posits minimal flow regimes for the recovery and/or continued maintenance of critical ecosystem services such as supporting healthy conditions for aquatic species in rivers.

As the supply and demand of riverine ecosystem services continue to shift due to changing climatic, demographic and land use conditions, research on riverine ecosystems that examines the dynamic feedbacks in the coupled human and natural systems that produce different services is vitally needed. A useful tool may be a hierarchical approach combining qualitative and quantitative models to address how changing river governance affects the management of riverine ecosystem services and thus the provision of specific ecosystem services across different scales. Equally important is having an understanding of how different stakeholders may perceive these changes and potentially affect policy decisions. Incorporating experiential knowledge provided by stakeholders can improve the long-term management of rivers and their ecosystem services.

c MSc student in Landscape Architecture, Universidade Federal do Rio de Janeiro, Brazil

Abstract

Urban agriculture has been largely acknowledged as a multifunctional topic. Academic studies from different disciplines and countries have been highlighting urban agriculture as one of the strategies to promote landscape justice, food security, social inclusion and community development; to increase biodiversity, reduce environmental conflicts, and bring into life abandoned and neglected urban areas, among other important aspects. It is therefore one of the approaches towards the idea of a resilient city. This flexibility of the conceptual and practical constructions of urban agriculture allows it to be appropriated and discussed by several fields of knowledge, including landscape architecture. Building on studies of urban agriculture in Rio de Janeiro, this paper argues the importance of landscape architecture to enhance multiple values of urban agriculture for social people.

Landscape; architecture; urban; agriculture

1. Introduction

Since the wave of academic literature on urban agriculture at the turn of the 21st century, much has been discussed and written about the various benefits of reintroducing food production in urban areas. Urban agriculture has been acknowledged as “a practice that encompasses a wide range of contexts (...) and many possibilities to consolidate itself as a permanent, flexible and multifunctional activity” (Santandreu & Lovo 2007, p 4). This flexibility of the conceptual and practical constructions of urban agriculture allows it to be appropriated and discussed by several fields of knowledge - such as geography, biology, agronomy, sociology, nutrition, psychology, among many others, including landscape architecture. But is landscape architecture currently bringing significant contributions to urban agriculture practices? Or would it be only a spark compared to the great contribution that could be made by landscape architects to structure urban agricultural areas by
thinking about processes and dynamics, impermanence and, above all, the multifunctionality inherent in the practice of food production within cities? How could landscape architecture contribute to enhance the multifunctional roles of urban agriculture within cities social and environmental dynamics?

This study is part of a broader research that looks at different urban agriculture experiences, addressing how people have fair access to the benefits deriving from their landscapes. The theoretical approach of the study understands landscape as a context always in movement, where discourses and design practices are in constant interaction and transformation. From this perspective, it is clear the need to understand the processes rather than landscape forms only. From a methodological approach the study draws both on field work and literature review. The paper is organized in the following way: initially it brings a discussion on urban agriculture; then the paper addresses a context in which urban agriculture experiences occur with a focus in Rio de Janeiro. The paper concludes arguing for a more active role of landscape architecture in urban agriculture experiences in order to enhance its multifunctional aspects.

2. Urban agriculture in Rio de Janeiro: discourses and design practices

A number of studies highlight the need of a better engagement of landscape architecture with food production practices in cities. This engagement could occur from different perspectives, specially aiming to enhance the multifunctional roles of urban agriculture.

Name (2016), for instance, looking particularly at the Global South and Caribe, argues that landscape architecture should look at the possibilities of native flora in order to enhance access to a larger range of food alternatives for vulnerable communities. He points out that “food sovereignty is the result of a critical and purposeful approach that understands food as human right, so its condition of merchandise is secondary” (Name 2016, p. 4).

This perspective looks particularly at the reduction of environmental conflicts and against the logic of the food industry focused on monocultures, food homogenization and the de-characterization of cultures and ancestral knowledge about food. Kinupp & Lorenzi (2014) contribute to the work of landscape architects through their book on non-conventional food plants, revealing a path for the financial sustainability of urban agricultural spaces, biodiversity maintenance, food security and the permanence and resistance of some non-conventional species. This work is particularly relevant for landscape architecture, for it opens up a new plant vocabulary which is little explored in landscape design. But how these and other researches could be revealed in landscape design?

These findings may help landscape architects to understand that edible plants could easily replace non-edible plants used in landscape design of urban areas in
different scales. It might be possible to think, than, of an urban agricultural practice that goes beyond the species normally used on the standard vegetable garden. Some edible species, for instance, due to their strong aesthetical character, could be used in well-defined urban open spaces typologies, such as sidewalks, squares and parks. In this case, the choice of plant species would be the determining factor that would differentiate a space that produces human food from another that does not produce it.

Although food and food sovereignty have been the focus of urban agriculture studies in a variety of current research - mainly in the global south - urban farming areas also contribute to other services to cities and their inhabitants. Some of these services require a better attention of landscape architects, such as to promote landscape justice; to generate social inclusion and community development; to reconnect citizens and food production; to reduce environmental conflicts; to generate positive urban sociabilities; to bring abandoned and neglected urban areas back to life, and many other important aspects. For these and other services within the urban space, there is a diversity of areas where agricultural activity can be developed in the city, such as vacant lots, terraces, schools, hospitals, prisons, favelas, railroad transmission and abandoned areas are just a few of the examples. This diversity in terms of typologies and spatiality of urban agricultural areas might bring a complexity enhanced by the contradictions of scale and forms of occupation. It brings therefore, new questions concerning uses and functions related to form and design.

As regards the multifunctional landscape concept, De Groot (2005) defends the idea that landscapes are imperative multifunctional and that, nevertheless, people tend to turn them into nonfunctional landscapes. Since urban agriculture is an interdisciplinary activity and involves different functions and services to the city, reducing the various programmatic possibilities inherent to this activity is to contribute to a reduction in the social and environmental gains of the practice. In an increasingly urbanized world, the idea of multifunctional landscapes brings a malleability that can foster new experiences and urban solutions, especially considering the connections between the environmental dimension and the cultural dimension.

For some of these different environmental and cultural contexts in which urban agriculture experiences occur, we bring an example from the city of Rio Janeiro, which emphasize the challenges related to the architectural design of the urban agricultural area.

3. Urban agriculture in Rio de Janeiro: discourses and design practices

Rio de Janeiro holds a number of different urban agriculture experiences – running from those organized by NGOs, by private or local initiatives, and by public authorities. This paper look particularly at a municipal initiative, named “Projeto Hortas Cariocas” (PHC) - Hortas Cariocas Project. This is an institutional programme created by the City's Environment Department, which the main objective is to support initiative of
food production in favelas and state schools. More specifically, the project aims to assist locations in the city where poverty and exclusion rates are more alarming.

The “Hortas Cariocas Project” supports citizen intervention initiatives aimed at the use of underutilized open spaces for food production in the city. In addition to the authorization to use the area, the city provides supplies and grants as financial aid for those who are deeply involved in the work on the vegetable garden. For food reinforcement, part of what is produced is divided between state schools, public day care centers in the surrounding area and families at social risk indicated by residents’ associations. The surplus goes to the local market and the profit is left to the partners, and part of it must be reinvested. In the long term, the project, aims at the emancipation of the vegetable gardens, thus promoting the financial autonomy of those directly involved in the food production. It focuses at the strategy of local socioeconomic development by training the population in vulnerable communities that have areas able of implanting and managing urban and community gardens, reducing rates of irregular occupation of neglected land, raising levels of social inclusion and offering basic human right to a healthy and quality food, free of GMOs”. (O’Reilly 2014, p 35).

Around 30 urban agriculture areas are linked and supported by the PHC, including favelas and state schools. One of these areas in the one located at a favela named Manguinhos. This used to be one of the most insecure favelas in the city. The PHC managed to organize the largest urban agriculture area of the project, a large strip that was left unoccupied because it was located under towers of electric wires.

This urban agricultural space is nowadays one of the most important public spaces in the community. Besides providing cheap and safe vegetables, it is also a meeting place, a working space, a trade space, a leisure area, and, above all, a place at the favela that contributes to rise the self-esteem of its inhabitants. In other words, it plays an important role in the process of urban inclusion of the community.
However, it can be noticed that the layout of the vegetable beddings shows a composition of several large rectangles organized along the strip. Perhaps it shows an inheritance of a typology of the agriculture planting in rural areas, an arrangement of rectangular shapes with circulation axles in between. Our research has shown that this morphology does not have important functions related to agricultural production. However, it does not explore other powerful social functions claimed by the open space where the vegetable beddings are inserted. Our field work has show how heavily the area is used for community meetings. Local people pop up not only to by vegetables, but to meet other people, to take the children to play or for a walk, and many other social activities.

It is noteworthy that Manguinhos community, like most of the Brazilian favelas, lacks public spaces with basic infrastructure for positive urban sociabilities. With its non-flowing layout, Manguinhos vegetable garden loses the opportunity to operate also as a public square, a public park, a public classroom, among many other functions. In other words, in looses the opportunity to expand the socio-environmental gains that urban agriculture can offer.

From this perspective, landscape architecture has a lot to contribute to enhance the capabilities of the urban agriculture areas to fulfil their multiple roles, particularly the social ones.

4. Final comments

Urban agriculture is, of course, one of the paths to create more resilient cities. Landscape architecture, within the other disciplines related to urban agriculture, has an important role to play in enhancing its multifunctional aspects. It is crucial to reconcile the experience of several professionals to the execution of a plan that meets the biophysical and socio-cultural demands of an area.

However, when it comes to agricultural production in the city, improvisation - both related to agricultural technique and standardized spatial distribution - gains a prominent role rather than a more careful landscape design. Such agricultural spaces have particular processes, dynamics and functions, and therefore require a look and a design with specific characteristics.

Faced with a scenario of little involvement between landscape design and urban agricultural, as well as the rigid layout and social program found in these spaces, one can perceive the urgent demand for a
more active role of landscape architecture in urban agriculture experiments. Landscape architecture can lead a path to increase the socio-environmental gains of these areas in order to improve their multifunctional aspects, their spatiality and contribute to the resilience of cities.

Resilient parking lots

Marta Rabazo Martín

Escuela Técnica Superior de Arquitectura, Universidad Politécnica de Madrid, Avda. Juan de Herrera 4, Madrid 28040, Spain

Abstract
Parking lots were born with the standardization of the car in the early twentieth century, intervening decisively in the architecture of the contemporary city and becoming one of the most important components of urban living [1], requiring huge urban surfaces shared by pedestrians. But they are valued largely for their technical character neglecting its landscape potential [2]. However, in the American context, parking lots are probably one of the outdoor public spaces most used in everyday life [3]. They might not be exceptional and even unpleasant but their magnitude and ever increasing presence deserve new hybrid tactics and programs to help their insertion in the urban fabric.
Maybe due to their humble nature as result of left over space [4], parking lots have been forgotten in landscape architecture and public space studies. But parking lots are public spaces in their use by the community and their great impact on land use. The fact that they are very lucrative spaces cannot discriminate them from having a good design or becoming aesthetically attractive spaces that enrich our cities [5]. If traditionally their use was limited to parking cars, in the contemporary city, more and more parking lots are presented to us as hybrids. Several projects in the last decades have shown the possibilities and success of this coexistence in programs [6]: the alternation in uses in Topotek 1’s Kaiak Market or Büro Kieffer Playing-Parking Lot in Berlin’s Flämingstrasse, Parcal Cribier’s elegant and multifunctional Parking Lot surface in Bonnelles, the new city parking in Villajoyosa (Spain), that use de covering of the semi-underground parking in a really interesting way as an absorbent tree surface for the people or the parking lot as part of the gateway experience of the DIA Art Foundation in Beacon (NY) where the lobby of the museum abandon the building to welcome the visitor in the outdoor area.
If we don’t want to revisit its importance as a public urban space, we should at the least consider their importance within an ecological and sustainable framework where the proper use of its materials can help reduce impervious surfaces, fight heat islands, and contribute to the control of water runoff and effective groundwater recharge [7]. Diana Balmori was correct when stating that “A Parking lot seems an unlikely place to begin the design of a new building and landscape” [8] but she managed to make it the main public space of the Botanical Research Institute of Texas and key for the collection and reuse of rain water on the whole site.
These are flexible and multifunctional spaces, even for spontaneous appropriations, spaces that can positively contribute to urban ecology and as relievers of the increasing presence of cars in our cities. The disappearance or the reduction of these parking lots constitutes a way to obtain
new special relations between the city and the complex environments of the public or private buildings and to improve social realm.

Parking lots; Urban spaces; Multifunctional public spaces; Lost space; Urban gaps

1. Introduction. The dichotomy of Parking Lots

Due to the standardization of the car, our cities and streets have been modified and modeled following the necessities of traffic and parking demand. The car has become such a huge part of our civilization that it is hard to find any streets that do not contain them, and parking below our house is mandatory to have a certain quality of life. But while the streets are being adjusted to meet the needs of different local identities, we should question ourselves why have parking lots always looked the same, especially when cars stay parked approximately 90% of their life.

Instead of establishing an approach to the parking lot as a place of opportunity to integrate activities, regulations tend to care more about how to hide these spaces to the city. Roger Trancik defines parking lots as "those undesirable urban areas that are in need of a redesign –antispaces, making no positive contribution to the surrounding or users…on the other hand, they offer tremendous opportunities to the designer for urban redevelopment and creative infill and for rediscovering the many hidden resources in our cities" [9]. Parking lots can be considered urban lost space at the same time they are an essential part of our urban environment.

This dichotomy is also present in how citizens perceive these spaces: they are often seen as "ugly" and “a waste”; we pay little attention and creativity to its design, planning and innovation and as early as 1981, Lewis Munford stated: “The right to have access to every building in the city by private motorcar, in an age when every-one possesses such a vehicle, is actually the right to destroy the city” [10]. At the very same time, artists have been fascinated by parking lots due to their figurativeness character, mainly in photography. It was already in 1967 (printed in 1974) when Ed Ruscha published his book Thirty-four parking lots looking for its graphical standardized character and the bi-dimensionality of these spaces.

Contemporary photographer Alex MacLean’s work is instead pointing out how parking lots are a disruption in the urban fabric creating abandoned concrete islands. Using, as Ruscha did, an aerial view, his photographs cover a wider range of contexts (not always urban) just to show the dramatist of these scissions. Is in this solitude and isolation where these parking spaces anchor to beauty. This sort of fascination can be summarized in Paula Meijerink words: “Can anyone imagine something more beautiful and fascinating
than a brand new, vast and desert parking lot?” [11]

In 1991, renowned landscape architect Peter Walker proclaimed: “the day will come when parking lots routinely win top design honors” [12] but this prediction has not yet materialized. Few parking projects have ever won a prize. There are only a few books that help us with their design as most publications are about standards and regulations. For example, since 1990, only one parking lot design has won an award from the American Society of Landscape Architects (the project "12000 factory workers meet ecology in the parking lot” from Michael Van Valkenburgh Associates) [13]. Designers should not forget that when people are at a place that is looked after, they will also feel looked after and parking lots should become hybrid spaces and not mere asphalt extensions where to storage cars. Their condition as urban gaps should have already been overcome.

2. Three considerations about parking lots

Through the review of some main projects decomposed in their principal achievements, this paper aims to restore some dignity and find a remedy for the ills of traditional parking lot design. “As suggested by Paul Groth, parking lots should be considered gardens in terms of their relationship to nature and to culture. Parking lots probably cannot be transformed into gardens in the traditional sense, but designers can greatly increase their utility by incorporating ecological, aesthetic and social factors” [14]

The review is mandatory to accomplish the research. The projects analyzed are divided into three big categories: the parking lot as part of the gateway experience (or how the way we “arrive to” has always been essential in architecture and landscape architecture), the parking lot as a multifunctional public space (or the necessity of finding new alternative programs to enrich the public experience) and the sustainability of parking lots (or how these kind of spaces can positively contribute to some of major problems in our cities).

2.1. Parking lots are part of the gateway experience.

Nowadays we take for granted the possibility to park, but those parking spaces are not seen as the arrival point to an architecture or landscape project but are seen only as technical areas. We can appreciate the architecture of a museum but there are few instances when we consider the parking lot as part of it. Diana Balmori, founder of Balmori Associates based in NYC, wisely stated that “A Parking lot seems an unlikely place to begin the design of a new building and landscape” [15] but she managed to make it the main public space of the Botanical Research Institute of Texas.

Fig. 3. Parking Lots’ aerial views by Alex MacLean
From the moment you park the car in the area of the Institute, the botanical experience begins: a large sample of plant species that are under investigation, run along the paths leading from the parking lot to the building and a collection of native oaks shade and characterize this space. Where ever possible, porous pavements were used and roads were designed to follow the contour lines. The parking does its job, but the goal was to create a sustainable and pleasant space.

A similar attitude guided the design for the Dia Art Foundation by Robert Irwin and OpenOffice in Beacon, New York, where the whole parking lot was conceived by the authors as the lobby of the museum; a lobby that abandons the building to welcome the visitor in the outdoor area, while reducing the size of the inside lobby to a small room; a lobby where we can admire the time passing by and the changing seasons.

2.2. Parking lots are multifunctional public spaces.

Its spatial characteristics and its (so far) simple morphology as a paved extension aiming to have the maximum space to park cars, make parking lots highly versatile. Because these are governed by clearly defined schedules (working hours for residential and office use, weekdays for business, etc.) an alternative look at their use is almost an immediate parameter to be dealt with. Based on this superposition of uses and users, forms and functions, Büro Kiefer designed a parking lot in Flämingstrasse (Berlin) with a small number of structural elements and a strong graphic character that gave a clear identity to a new residential building.

A more complex morphology was adopted by a parking lot of a residential block design by Sanfeliu/Martorell/Lamich architects in the Verneda’s neighborhood of Barcelona. This courtyard turns into a very dynamic urban plaza through a design based on a series of parallel strips of different paved sections that create a new artificial moving topography. These strips organize...
the project and give character to the different activities on site; they fold, undulate and group themselves to create all of these different areas both horizontally and vertically, visually hiding the cars parked in the perimeter from the central pedestrian alley and creating some small steps.

Kaiak Market from Topotek 1, probably the most published parking lot of the last years, is an example of alternating uses where the main square of Kopenick reinvents the traditional market, rhythmically following the division of parking lot stalls. Its powerful color and huge umbrella indicating the activity in use at each moment, manage to create a public space of huge dynamism and identity.

Vegetation can contribute very actively in reshaping parking lots instead of being a hiding tool. In the Project for Biosphere Platz, Büro Kiefer uses the confrontation between the historical models of open spaces (the tradition of formal gardens) and new uses of the contemporary city (such the use of the car). Just by changing the scale and introducing a vegetated component as a construction element, he creates a sophisticated car park where shrubs are a maze of parking spots imitating the nearby Prussian gardens.

2.3. Parking lots and sustainability

There are a few environmental costs that large asphalt surfaces produce that mainly have related to soil, vegetation and water. Several studies support the importance of using permeable materials in order to reduce water runoff and to allow water to percolate recharging aquifers (an urban environment with 75-100% of impermeable surfaces produces more than 55% runoff) [16]. And not only that, but the heat accumulated in the impermeable materials heats rainwater decreasing oxygen levels. The pollution in the surface of the parking areas such oil and metals are dragged into aquifers, contaminating them.

The necessity to evacuate the rainwater as quickly as possible from large paved surfaces through the drainage system makes that, when the rains are very strong and we pour that huge amount water into a nearby stream, it quickly erodes the stream bed, dragging the vegetation and existing debris of its banks, and leaving a wide rocky water course. An on-site detention system with a progressive evacuation of the water avoids water runoff and promotes a constant influx into aquifers.

Parking areas also highly contribute to the heat island effect that happens in asphalt surfaces that do not consider any vegetation, making these surfaces 20º to 40º warmer than a vegetated one. Asphalt accumulates heat all day and dissipates it during the night.
hours creating constant heat islands that could be reduced by a simple addition of small-planted areas. These areas not only could provide a place of shade, but they could also become a moment of pause in the vastness of asphalt.

The water runoff from parking surfaces, the necessary roadways, and 330,000 square meters of rooftop would have a devastating impact on the surrounding ecosystem composed by fragile water streams in Michael Van Valkenburgh’s project entitled "12000 factory workers meeting ecology in the parking lot". The first action taken by MVVA was establishing water collection as an essential priority for the project. They then considered its treatment and slow release afterwards into the surrounding landscape in order not to create further violent water intake into the adjacent ecosystem.

MVVA integrates ecology elegantly and honestly with enormous paved surfaces, creating a new model of environmentally friendly, low-maintenance landscape. This model can be applied with equal success in urban and suburban areas, and shows how landscape architects can play a crucial role in producing an effective hydrological management system with good design.

The large space required for 358 parking spots presents an important problem from an economical point of view in the Botanical Research Institute of Texas by Balmori Associates. But, if we consider the parking area together with the building roofs as part of an active system of collecting rainwater and a research field, it becomes an ecological operating system; it is no longer a problem to solve, but an element to delight visitors from the moment they park their cars.

Also Agence Ter links the parking lot on Verdon’s Beach (Martigues) to the hydrological and vegetative territorial system. Because it is located where the Verdon Valley meets the Mediterranean at a popular beach site, the area is prone to massive flooding in the rainy season. It was crucial to understand the hydrological functioning of the site, to avoiding flooding, to reorganize the parking area and to propose a system capable of regulating water flows.

Landscape can’t be just a superficial practice to mitigate or embellish these antispaces, but a methodology that allows us
to work with and from the contradictions of contemporary territories, assimilating all technical and engineering components and cityscape’s figures.

3. Conclusions.

Parking lot’s can be “rescued” from the urban imaginary just by adding some conscious effort to their design as we do to almost every other public space. We can consider three basic actions to change the role of the car parks in our cities, giving them an importance that relates to the occupied area and the impact they have on our daily lives, transforming standard spaces in places linked to a network of urban public spaces:

- Reinvent multifunctional programs according to the needs of contemporary cities with alternative uses. We need to abandon the static and already defined traditional open space and look for vibrant programs that can satisfy a large number of users. The spatial characteristic of a parking lot offers a unique opportunity of wide range alternatives. Their standardized character needs to be overcome by their innate ability to generate identity and its potential power to transform a space into a place.

- Ensure the use of porous materials used in constructing parking lots to make them participate in the hydrological and environmental performance of the area. Pervious materials allow water percolation and groundwater recharge, do not accumulate heat and can be easily maintained and kept in good condition as these areas generally depend on public administration.

- Rethink vegetation as part of a large scale system, not as a punctual intervention, giving continuity to green territorial systems that might be somehow crossing the site. Thus, the projects operating as public space can be constituted as networks to enrich intermediate scale projects.

Sometimes simpler actions have great echoes in designing urban environments and this last example proves it. Walking in Berlin we found this anonymous public parking lot; just a pervious paving and a dense tree canopy made the difference. When raining, the parking efficiently drains off the water; the trees provide shadow in summer and filter the view of the parking area from surrounding buildings. The whole site is not a gap in the fabric but another figure in the urban landscape, a sort of a small forest that enrich the urban experience. It is not hard to imagine it as a picnic area under the trees during empty-cars hours.

Abstract

Urbanization and increase of urban population is a common crisis in urban areas around the world. As a result, urban consumption pattern and life style has changed which has caused a rise in intake and waste production. Solid waste accumulation has increased than the past and that has become a major environmental and social problem. The act of National solid waste management strategy is unable to control the problem because of the unbearable waste accumulation rate in and this spontaneously creates the demand for innovative ideas to answer the problem. Rehabilitation of waste sites is indispensable for sustainable city development in the vision of recovery and conservation of neglected urban spaces. The transformation of waste sites in to open public spaces represent a significant enhancement to the quality of life and land use. This transformation need a new planning approach based on ecological restoration, new technology and collaborative design. FreshKills landfill is being rehabilitated successfully by reclaiming dump site in urban area transforming it for the benefit of society and environment. Here in Sri Lanka, Karadiyāna dumpsite will be used to production of electric power by using methane gas in near future. Freshkills project will be analysed to find the fundamental theories and principles behind the dumpsite rehabilitation and according to that local case study will be analysed. The objective of the present work was to analyze the theoretical principles adopted in dump site rehabilitation and guided to build a theoretical frame work for the future rehabilitation of dump sites in Sri Lanka with landscape architectural approach. Study begins with specific approaches and fundamental principles, moving on to detecting patterns and regularities, then critically analyses the literature sources to find out the theoretical principles adopted to dump site rehabilitation. In FreshKills project it was found that the design strategies adopted to minimize the environmental impact forming a pleasing rehabilitation of the natural environment with assure. Reclaimed waste sites can be used for compatible uses in urban context rather than using wetlands or marshes filled with earth and this should be a sustainable solution for land scarcity in Colombo. Lack of technical and deign knowledge, limited financial resources may clog the commencement of such a rehabilitation project in Sri Lanka.

Keywords: Urban Solid waste, landscape architecture, dumpsite rehabilitation, landscape approach, ecological restoration, urban open space.
1. Introduction

Need of the human begins increased with the evolution in parallel with the population growth, urbanization and diverse consumption patterns. Then the rate of resource consumption has been increased. Eventually, High rate of resource consumption will led to rapid waste accumulation because of the leftovers.

“Due to an increase in the standard of living and population levels, a growing economy, rapid urbanization and changes in consumption patterns have greatly accelerated the solid waste generation rate in developing countries” (Troschinetz & Mihelcic, 2009) (Marshall & Farahbakhsh, K., 2013) Urbanization in developing country will caused to enormous quantities of waste generation and significant environmental degradation. Poor planning strategies of responsible government institutes has been chosen sensitive eco systems such as marshes, wetlands for waste disposal as well.

“The available statistics show that the current generation of municipal solid waste in the western province, Sri Lanka is around 3,200 to 3,500 metric tons per day. Waste generation rate increase by 1.2 to 2 percent per day and it is predicted that in 2050 the waste generation in the western province will increase up to 5,800 metric tons per day.” (Wijayapala, 2012)

This is the present condition of waste disposal practice in Sri Lanka.

1.1. Research Problem

When those open dump sites completely filled with waste where it cannot bear anymore. We let those to abandon without any treatment and this caused controversial social and environmental issues.

Recent literature has shown that rehabilitation of landfill plays and important role on critical issues in solid waste management, including biodiversity conservation, global warming mitigation and land reclamation.

Initiate landfill rehabilitation is a must when considering all the issues which are led by the existing open dumping practice.

1.2. Research objectives and Aims

With the role of Landscape Architect,

- To find out underlying theoretical principles, and strategies behind dump yard transformation which determine approaches implemented by other developing countries.
- Identify the issues occurred when doing this dump yard transformation.

1.3. Methodology

The landscape design approaches of rehabilitated waste landscapes and experiences of dump site rehabilitation in local and foreign context had to be studied.

Begins with specific approaches and fundamental principles, moving on to detecting patterns and regularities, then critically analyses the literature sources to find out the theoretical principles adopted to dump site rehabilitation. Formulate tentative
Frame work base that can be explored, and finally end up developing some general conclusions. (See appendix for Table 1).

1.4. Research Outcome

Present study will be guided to build a proper theoretical frame work for dump site rehabilitation in terms of Landscape architecture with other related professions and elaborate the sustainable land use practice in urban context.

2. Urban Society and Solid Waste Management in Sri Lanka

![Graph: Municipal solid waste generation in Colombo, Sri Lanka. Source: NRI Sri Lanka, 2003](image)

Figure 2: Municipal solid waste generation in Colombo, Sri Lanka. Source: NRI Sri Lanka, 2003

Wasting is a necessary part of living, yet if the processes are not well managed, life itself is threatened. Even when waste is prevented, the result can be deadly, but in a different way. What would a world be like where waste was out of control? (Lynch, 1990, p. 3)

Improper waste disposal action has become one of the general cause of environmental degradation in Colombo and its suburbs regions. As a result of that Meethotamulla, Karadiyana, ultimately has become huge dump yards.

![Image: Resource recovery nearby Karadiyāna dump site Source: by Author](image)

Figure 1: Resource recovery nearby Karadiyāna dump site Source: by Author

National strategy for solid waste management was introduced by ministry of forest and environment in 2000 which based on wide range of policies of waste management from gathering to final disposal and after care. Also the approaches such as resource recovery and biological treatment but those are not implemented well in Sri Lanka.

![Image: On going composting process at Karadiyāna dump site Source: by Author](image)

Figure 3: On going composting process at Karadiyāna dump site Source: by Author

Composting percentage of collected waste in Sri Lanka is more than 50%. Lack of public
Future Resilience

awareness is limited the composting facility to residential level while other developed countries are developing it in to profitable mega scale level.

Lack of public awareness is a disadvantage for the solid waste management as well. The famous 3 R’s of waste management; Reduce, Reuse and Recycle is a good notion which provides best chances for the public to participate in waste management.

More than 95% of waste collected in Colombo disposed in open dumpsites located at low lying lands which are used as flood retentions areas.

This is a valuable move in highly urban areas because of the high land value and the land scarcity for recreational open spaces.

“Mira Engler, a landscape architect and researcher, presents contemporary approaches to the treatment of landfills. These approaches oscillate between the romantic perception, which reconstructs the pristine natural landscape of the site, through an approach that hides the site’s past in favour of converting it into a location for intensive recreational activity, to approaches that empower the essence of the site as a ritual field or monument, or as a place for personal investigation and discovery” (Engler(As cited in Tal Alon-Mozes, 2009).

Variations among contemporary waste related design projects elaborate eight approaches:

- Camouflage
- Restoration
- Recycling
- Mitigation
- Sustainable
- Educative
- Celebtrative
- Integrative

Above approaches will explain how to intervene a waste related landscape reclamation design project in a different perspective.

As Patricia Phillips noted, “Even with an enhanced awareness of the environment, consciousness requires new image to see the changed conditions.” (Phillips, 1990).

Recently many landscape architects have begun to look at the landscape not only as a setting in which to intervene, inserting an

Figure 4: Final disposal at Karadiyāna dump site
Source: Karadiyāna waste management facility

2.1. Landscape Approaches on Landfill Reclamation and Design Strategies in Sustainable Landscape Reclamation

Landfill reclamation projects become more dominant with new design strategies which are devised in recent years, focusing on the sustainability, quality and multi-functionality of the space, with attention to environmental and socioeconomic aspects.
indefinite variety of objects, but as a tool through which to design and manipulate complex material. Understanding of temporal and dynamic character of the landscape & design solutions and design process which represent the existing attitude toward and expectation of the site is prominent for success. A place sensitive to different transformations, which records the movements and event that cross it. It is important to recognize and interpret the significance of the landscape and to understand how “landscape ecology and design can invent alternative forms of relationships between people, place, and cosmos so that landscape architectural projects become more about invention and programs rather merely corrective measures of restoration” (Corner, Ecology and landscape as agents of creativity. In ecological design and planning., 1996).

And also punter explains that, “Any attempt to define principles for good design must embody the principles of sustainable development. Building design, landscape design and urban design must be brought together to deliver a more integrated, skilled and effective design process. According to Punter, landscape reclamation design should integrate five fundamental principles” (Punter, 2002).

- Protect and conserve quality landscapes.
- Develop a clear vision and strategy for an area.
- Apply collaborative design principles.
- Allow resources for long-term aftercare of new landscapes.
- Enhance biodiversity, social stability and economic development.

3. Landscape architectural intervention to dumpsite rehabilitation

FreshKills Landfill is located on the western shore of Staten Island in New York City. This spreads across approximately 2,200 acres of landfill. FreshKills is a well-planned site, with various schemes put in to practice in order to protect public health and environmental safety.

The innovative engineering of Fresh kills Park is one of the major features, which allowed the conversion of this place from been a landfill to a human friendly public recreation space.

This project reveals that, what we must manage in this kind of a project. Such as,
Leachate Management System

A toxic liquid mixture discharged from the landfill which known in the field as “leachate”. This could ooze out of the landfill unless it is controlled through special structure.

Landfill Gas Collection System

Landfill gas consists of about 50% methane and the Landfill Gas Collection System (LGCS) is designed in order to collect the gas and course it to an on-site LFG recovery plant. This is used for energy generation, while preventing the gas from escaping the landfill.

Capping System

Capping System at Fresh kills is the key method for reducing the production of leachate, assisting with the capture of landfill gas, and sealing all contaminants in the landfill from the Park above.

Storm Water Management
Rainwater dipping on the top of the last cover must be carefully collected and carried off the mound to safeguard and make sure that it does not destabilize or erode the layers of soil that make up the cover of the mount. Storm water is gathered via a series of storm water swales, channels, and down chutes.

Landfill infrastructure at Freshkills is designed in order meet and surpass the environmental standards set by the New York State Department of Environmental Conservation for landfill closures and it helps to rectify the environmental and health impacts caused by the landfill. The project provide extensive ecological benefits through reclaimed eco-systems that would offer both wildlife habitat and natural open spaces for users.

“The reclaiming of sites might be measured in three ways: first, in terms of the retrieval of memory and the cultural enrichment of place and time; second, in terms of social program and utility, as new uses and activities are developed; and, third, in terms of ecological diversification and succession” (Corner, Recovering Landscape: Essays in Contemporary Landscape Architecture).

Freshkills is an ecological progression of environmental reclamation and renewal on a vast scale and this is the best example for post landfill reclamation project in all-time. Finally produce the fresh spatial conditions through the new landscape and also does not forget to show the consequences of waste.

3.2. Case Study 02 (Local context): Karadiyāna Dump Site – A dump

site is being rehabilitated.

Karadiyāna was initially converted into a dump yard since more than two decades. It is situated at Thumbovila area of Kesbewa and it comprises of 37 acres. Two sites consist of the total area of 9.6 acres with 20m in height.

Site is located in an eco-sensitive area thus discharging waste into the wetland caused environmental and social catastrophes to the immediate surrounding. Such as, Water pollution is a major issue due to leachate from the site, all water resources contaminated and surround environment degraded.

Number of illegal settlements increased around the landfill. The property value of immediate surround of Karadiyāna dump site is less which reasons for the vast population of illegal settlements.

Future proposal of Karadiyāna is to transform the methane gas in to electric power.
Slope stabilization is a must due to heavy rains on monsoon seasons because waste heaps can be collapsed. After established the slopes project management has plans to plant on those slopes to avoid erosion and provide stability (perennial native grasses and rapidly germinating annual grasses are more suitable).

At the base of the dump site leachate ponds were created to collect the leachate. Leachate is treated before discharged into constructed wetlands that contain plants which can absorbed the heavy metals.

Existing wetland eco system is connected with the Weras ganaga and Bolgoda Lake. Wetland eco system serve their service to this urban environment, especially during flood seasons. When the wetlands fill with waste impulsively flood retention area gets reduced. Then lower lands get flooded. Due to waste disposal activity topography has been changed at the area. Hydrological sources and Aquatic eco systems has been contaminated and degraded with by-products of waste, chemicals. At the end total environment has been affected.

4. Analysis

In developed countries they turning this neglected landfill spaces into extraordinary sustainable landscapes to get the optimum benefit of it. In Sri Lanka it is totally different and the lacking point of local context is that there is no systematic frame work to do this transformation.

Two case studies has been selected for the study. One is an ongoing project located on the western shore of Staten Island in New York called Freshkills Park by James corner field operation.
Karadiyāna dump site in Colombo, Sri Lanka has been selected as a local case study.

Literally this waste site affects day to day life of people who surrounded by here. First contaminated site need to be recovered before the development. Then, site has to be protected and conserved. So actions need to be taken with ecological processes such as restoration, succession with the understanding of how nature works.

Design principles should be applied to wrap up the whole project as a unit. (As an example on going waste treatment facilities and park facilities should be integrated with whole design).

Sustainable use of waste sites should be emphasized equally in three parameters which are namely environmental uplift, economic development, and social stability. Fresh Kills project is larger than Karadiyāna project and the severity of waste composition is less in Karadiyāna. Those things can be considered as an advantages for the rehabilitation program and environmental variables should be considered

Camouflage approach

This continues the traditional disguise of waste related site using screening or cloaking techniques to conceal the waste. At fresh kills they have used capping system to cover and seal the waste. Basically a much needed step to take for the safety of people in this kind of reclamation project. The key method for reducing the production of leachate, assisting with the capture of landfill gas, and sealing all contaminants in the landfill from the Park above. (See figure7)

This capping is the base that can gives the new image to see the changed condition of this reclamation project because all the planting materials should be plant on this. All the design elements have to be built on this as well. This is what camouflage approach reveals.

At Karadiyāna they have planned to use soil cover to conceal the waste and there is a possibility to use the above capping method in here as well.

Restoration approach

Elaborates on fixing the temporary land-use disturbances caused due to unorganized disposal of waste. Finally try to bring back the previous condition into site through ecological restoration. The Freshkills project provide extensive ecological benefits through reclaimed wetlands, grasslands, and new woodlands that would offer both wildlife habitat and natural open spaces for park visitors.

In Karadiyāna they have done the slope stabilization to stop the waste heap collapse during rainy seasons and introduced perennial native grasses and annual grasses (rapidly germinated) to avoid slope erosion. At the base of the slopes leachate ponds were created to treat the leachate before it discharged into constructed wetlands and wetlands consists of heavy metal absorbent plants.

Recycling Approach

One of the main intention of Freshkills project is to reuse the landfill site as public amenity and land development. This is the whole idea of two projects which are taken to study. Provide public amenities through the design and reuse and developed the land for
needs. In Freshkills projects this is being happening.

**Mitigation Approach**
Landfill gas extraction, leachate treatment, slope stabilization, capping system were introduced to mitigate the damage, reduce the severity of pollutant and restore the damaged site and turn it into a viable environment. Finally try to weaken the impact.
In both case studies they have used and mention about this scientific solution which must be added to these kind of a projects to protect and conserve the quality of landscapes.

**Sustainable Approach**
Sustainable approach is concerned with the economics, conservation and self-sufficiency of a waste processing site. It engages a range of diverse programs often including elements of renewable waste resource. For example; at Freshkills they have extract the methane gas and synthesis for power generation while recreational functions are going on at the same time. New ecologies has been introduced to the site which was there before to conserve the newly introduced landscapes. They have planted various verities of trees, grasses, shrubs, etc. storm water management system and reclaiming waste water from on-site treatment facilitates to irrigate vegetation and water bodies.
Main idea of the Karadiyāna project is to extract methane gas and transform that into electric power. According to sustainable approach there is a potential to develop this site for recreational purposes as a public park which can generate alternative income source. Ongoing composting process can be developed into profitable level with above activities as well.

**Educative Approach**
Emphasizing public awareness and changing of attitudes of general public towards waste. Existing waste facilities are opened to public tours and special education facilities are built in the site to creatively inviting people to experience the realities of waste. Freshkills Park is a platform for generating knowledge applicable to a broad range of urban environmental issues, at this site and others: reforestation, habitat restoration, wildlife biology, soil productivity, water quality, alternative energy generation, and even attitudes toward park usage. While parts of the park are under construction other areas will remain undeveloped; with 2,200 acres of land there is opportunity for research projects in a variety of disciplines.
Freshkills Park offers classroom resources and field trips that centre around three major topic areas: biodiversity and the environment, history and social studies, and art and design. The landfill-to-park transformation is a poignant backdrop for education.
As same as at Karadiyāna these kind of educational and awareness programs can be implemented with the proposed project and it will be a great opportunity to public participation.

**Celebrative Approach**
This approach promotes and dramatizes waste sites and waste management facilities through works of art, special design features. Combine all the elements to see the final product as a one system. Design of Fresh Kills Park allow people to get close with the
ongoing processes. That is what celebrative approach reveals and that can be added to Karadiyāna project as well.

**Integrative Approach**

This is a multifaceted one, combining elements from the celebrative strategies. It integrates the “principles of ecology with the philosophy of art” – scientific rigor with express metaphors. The integrative strategy elaborates on changing an abused site or waste facility while at the same time amplifying its reality. Creating Visible Connections is integral to this strategy. Karadiyāna site and Fresh Kills site are contextually quite similar but not totally. (See Appendix for Table 02)

5. **Conclusion**

As an issue of early stages of urban planning, changes are not accepted in urban context in most of the developing countries such as Sri Lanka. Rapid urbanization, growth of population and migration of people to the urban areas, industrialization are reasons behind the change of life pattern. In a situation like that consumption pattern naturally changes. A definite area with more people there is a higher rate of resource consumption. At the end it persist a higher amount of left-overs of used resources. Then where to discharge those remains in urban context is a problem. Most probably at next derelict land or eco sensitive environment has to pay the price. This is how most developing countries including Sri Lanka faces the huge amount of waste accumulation in urban areas. Meethotamulla, Karadiyāna, Bloemendhal were the results of it in the city of Colombo.

Poor quality of technical standards of waste collection and final disposal ends up with massive heap of waste. Good appearance is an indication of a place. Those waste heaps have destroyed the beauty of place as well as the quality of environment.

Landfill gases from dump site is contributed to global warming (Landfill rank third in anthropogenic sources). Finally those by-products of wastes obviously causes irreversible health issues. Urban environment and landscape is being degraded in Sri Lanka and throughout developing countries due to questionable waste discharging and final disposal.

Open dump sites are selected without any scientific assessment as a result of less involvement of technical expertise such as urban planners, landscape architects, environmental engineers etc. Rehabilitation of these dump sites need to be an ultimate option to improve the urban environment, social acceptance, quality of life, economic prosperity, resource preservation, worth use of space and finally should support the sustainability.

Landscape architectural involvement to the waste site rehabilitation has brought out some extraordinary urban recreational spaces around the world. FreshKills at New York, United State of America, Nanjido at Seoul, Korea, and Hiriya at Tel Aviv, Israel are some of these which are about how to turn the waste sites into resource and get the maximum benefit out of it.

In city of Colombo most open recreational spaces have been constructed on wetlands or marshes filled with earth. By earth filling on wetlands or marshes in Colombo area floods keeps causing damages during the monsoon seasons. As an alternative, rehabilitated
waste sites can be used to construct open public spaces since there is a land scarcity in Colombo urban areas. The wetlands and marshes in Colombo areas act as flood retention areas and when those were filled with earth other areas get flooded.

Likewise there are more advantages in using rehabilitated waste sites for compatible urban uses. Renewable energy from landfill gas, as a land reclamation, to increase of the urban green cover/vegetation, as significant recreational, cultural and educational amenities etc. Finally it will help in order to vanish the poor visual appearance of the city because city appearance is the mirror of its planning and development.

Above case studies reveals the Landscape architectural involvement (with other related professionals) to reclaim the damaged sites and how can we apply those engineering applications with an artistic manner. Turning those notorious waste heaps into an extraordinary public space will explained that what landscape architects can do? And the importance of landscape architecture on these kind of projects Instead of distancing ourselves from waste, design can bring people closer to waste operations and help foster creative solutions to problems. Landscape design should not be used to wipe out technological guilt. Rather it should be used to move the public to new level of awareness.
### Appendix

**Methodology**

1. **Case study 01**
   - **Analyzing**
   - Extract key findings such as principles, theories, and strategies discussed in this particular case.

2. **Case study 02**
   - **Analyzing**
   - Extract key findings such as principles, theories, and strategies discussed in this particular case.

3. **Case study 03**
   - **Analyzing**
   - Extract key findings such as principles, theories, and strategies discussed in this particular case.

- Analyzing outcomes (A,B,C) of each case study:
  - Make priority list with findings/outcomes
  - Analyze with the existing theories, principles and approaches adopted in dump site rehabilitation (Find from literature survey)
  - At first what are the factors which found in all 3 cases.
  - Then what are the factors which found in 2 cases.
  - Finally, factors which are unique to each case study.
  - Build a theoretical framework to analyse local case
  - Explain with local case study

Acknowledgement

I would like to express my honest gratitude and deep regards to those who helped to the success of this long tough journey to complete my final year research. Thus it is an honor to express my gratitude towards them.

Firstly, I would like to express my profound gratitude to Senior Lecturer Dr. Gāmini Weerasinghe, Head - Department of Architecture for his assistance and guidance throughout the program.

I would gratefully acknowledge Archt. D.P. Chandrasekara - coordinator of the dissertation program, who gave continues guidance and support for the dissertation throughout the program.

Specially, I would like to express my sincere gratitude to Senior Lecturer Archt. Amanda Rajapakse for her guidance as my research supervisor from the beginning to the end. Her valuable guidance and comments given to make a better final product is priceless.

I am also grateful to Prof. Mira Engler, Department of Landscape Architecture, Iowa State University, and Ames, Iowa. I am extremely thankful and indebted to her for sharing expertise, and sincere and valuable guidance.

I take this opportunity to express my profound gratitude to Prof. Shirani Balasooriya for her advices and guidance.

Landscape Architectural Approach to Urban Flood Management with Special Reference to Diyawanna Oya, Colombo, Sri Lanka

Dulani N. Denipitiya\textsuperscript{a}, Susira Udalamaththa\textsuperscript{b}

\textsuperscript{a} Department of Architecture, University of Moratuwa, Moratuwa, Sri Lanka

Abstract

Urban flooding in recent times have become a challenge for the development of cities. In addition to climate change, lack of drainage caused by urbanization contribute greatly to the increasing impact of urban floods. Previous studies conclude that loss of natural flood detention areas has a greater effect on aggravating floods. Hence, it is evident that a shift from gray infrastructure to an approach of blue and green infrastructure is required. A landscape architectural approach focuses on a holistic solution and considers how flood can be part of our natural landscape.

Flooding in Colombo, Sri Lanka, is a significant threat due to the city’s socio-economical importance. Flood management include several landscape developments focused on the Diyawanna water body and surrounding wetlands in the capital city of Sri Jayawardene pura Kotte. This study investigates the effectiveness of these solutions in the management of floods. A literature review was carried out in order to understand broader notions of the problem and to develop the theoretical framework. The attributes focusing on adaptability to flood, landscape character and social responsiveness were identified as the significant factors for an effective landscape architectural solution.

The research carried out through on-site observations and studies, questionnaires and mapping point out that the landscape developments around Diyawanna Oya are socially responsive and the designs are multifunctional. However, the continuous decrease in natural flood detention areas would affect the adaptability of these solutions to large scale floods. Moreover, these landscape developments have the potential to enhance the ecology and the character of the natural environment better. Hence, it was established that these landscape developments are moderately effective in managing the urban flood situation in Diyawanna Oya.

Keywords: Urban Flood; Flood Management; Landscape Architecture; Wetland; Resilient cities; Colombo
1. Introduction

Natural disasters have become significant global challenges in recent times, of which floods are the most frequent. Floods are generally caused by high runoff rates due to intense rainfall [1]. Urban flooding is associated with inadequate urban planning and effects of climate change and urbanization acting on the lack of drainage in urban areas [2]. Urban floods impact the development of cities, considering the higher concentration of population, assets and economic activities that are exposed to floods in the urban environment.

Many studies have identified that the urbanization process of a city changes the natural landscape, increasing imperviousness and promotes the occupation of flood plains, aggravating flood problems [2-6]. Research by Brody et. al (2008) confirm that “the alteration of naturally occurring wetlands is the most important built environment indicator of flood damage” (p. 13).

Colombo, the Capital city situated in the wet zone of Sri Lanka, experiences rain throughout the year. Flooding in Colombo has worsened in recent years primarily due to the city’s inability to absorb water as the natural flood storage capacity has been reduced by inadequate planning and wetland encroachment. The most recent major floods in the year 1992 recorded the highest ever rainfall (493mm) followed by the years 2010 and 2016. As a result of several studies, five wetlands including a “green belt” around the Diyawanna water body were established as flood detention areas in Colombo [8]. The recent developments in the green belt aimed to preserve the flood detention area through sustainable landscape developments, which are considered significant and influential for flood mitigation in Colombo.

A landscape architectural approach combines the environment and society through design with emphasis on aesthetic quality. A city resilient to floods is considered a city living without flood control [9]. Thereby, in order to ensure a holistic solution for urban floods, greater landscape architectural influence is necessary.

Globally, many studies have been done and measures have been taken related to urban flood management. However, in the Sri Lankan context, this concept is still developing. The aim of this study is to establish the importance of implementing such solutions in Colombo as the sustainable method of mitigating floods, by considering the effectiveness of the solutions currently implemented in and around the Diyawanna water body.

![Fig. 1. Framework for research background](image-url)
2. Literature Review

2.1. Need for a Landscape Intervention

Urban flood management does not necessarily mean absolute prevention of floods. According to Wong & Eadie (2000) stormwater management practices have always followed an attitude of “out of sight out of mind”. However, due to urbanization, there is unpredictability of the nature of floods and restrictions in space in future. Jha, et al. (2012) states “Defending against future floods will require more robust approaches to flood management that can cope with larger uncertainty” (p. 30).

Several early researches demonstrated the ability of wetlands to store water [3,7]. The management of natural landscapes such as wetlands for the purpose of mitigating flood impacts provide a solution by itself [10], restricting the need for built methods. However, to achieve both economic growth and environmental protection, sustainable management through landscape needs to be implemented [11]. This includes not only addressing water quantity and flow issues but integrating society and enhancing the character of the area.

2.2. Multifunctional landscapes

Miguez (2007) argues that in densely urbanized environments, an effective option is the introduction of multifunctional landscapes, using existing parks and squares. By facilitating an area to fulfil different functions and objectives, city revitalization and flood control can go hand in hand [4]. In addition, a multipurpose landscape should not only manage the quantity of water but focus on water quality, social responsiveness, recreation, education and aesthetic values [6,12].

2.3. Theory of Urban Resilience

Several scholars have presented their views on urban resilience to flood focusing on the transition from acting against water to living with it [9,13]. Liao (2012) states, “the theory of urban resilience to floods challenges the conventional wisdom that cities cannot live without flood control” (p. 01). It indicates that flood adaptation should replace flood control in order to build urban resilience. According to this study, depending on flood control infrastructure which are “resistant to floods” (p. 06) could have an impact on the overall character of the city, which is an important aspect of the landscape.

2.4. Principles of Urban Flood Management

With the increase in the need for sustainable solutions, several principles for urban flood management have emerged through studies. These principles take into consideration the theories of urban resilience, multifunctionality and the enhancement of the landscape.

- Best Management Practices (BMP) associated with the concept of green infrastructure [4,14]
- East Asian water management principles which focus on waterfront developments helping the city adapt to flood situations while creating visually pleasing and social interactive landscapes [10,15].
  E.g.: Ang Mo Kio Park, Singapore
• Blue-Green cities which explore the concept of designing open spaces integrating water managements and green infrastructure [16,17].

3. Methodology

Principles and concepts for the landscape architectural implications for flood management are identified through a literature survey. Following this, the theoretical framework is developed considering the views of significant scholars on the implementation of effective solutions for flood mitigation. The recent public open space developments carried out around the Diyawanna Oya, Sri Jayawardenepura Kotte in lieu of flood mitigation and landscape development, were identified for further study.

Data was collected through existing literature, mapping, on-site observations and documentation, and interviews with resource personnel. A research questionnaire was given to a random sample of 30 respondents, to obtain data on social responsiveness of the selected landscapes. Both quantitative and qualitative analysis methods are used to analyze the data based on the framework prepared. However, the effectiveness of landscape solutions is discussed qualitatively.

4. Attributes for effective Landscape Architectural solutions

With the review of existing literature and aspects taken from the theories and principles, key factors are identified. Most scholars express the need for similar factors with few stating otherwise (refer Appendix 1). The most significant attributes for landscape architecture and those commonly addressed have been extracted and summarized to form a framework to assess the effectiveness of landscape architectural solutions for flood management (fig. 2).

![Fig. 2. Framework of most significant attributes identified through literature](image)

The attribute of adaptability to floods is analyzed through multifunctional use of space, the integrated landscape elements and variation of the wetland footprint of the region.

Context responsive landscape character and aesthetic quality has not been addresses sufficiently in literature, however, it is selected as an essential factor for landscape architecture. This attribute is analyzed amalgamating the criteria for landscape types identified by Simonic (2003) and the methodology of Landscape Character Assessment developed by Swanwick (2002) as given in Table 1.
Many scholars have also stressed on the need to address society, in order to achieve an integrated solution for urban floods. As stated by Kaplan [2011; as quoted from Kaplan et al., 1998, p. 149], people do not engage when a certain environment “block their understanding, lack opportunities for exploration, fail to foster experiences that are enjoyable and when they feel they are not welcome” (p. 168). Therefore, the final attribute aims to assess the social responsiveness of the landscape solutions for flood management, determining;

- Previous flood experiences and impact
- Frequency of visit and perception of landscapes

5. Diyawanna Oya and the flood mitigating wetlands

While the city of Colombo remained as the commercial capital, the administrative capital of Sri Lanka was shifted to Sri Jayawardeneepura Kotte in the early 1980’s. The Diyawanna Oya is located within this context.

Colombo is historically a large area of wetland and natural landscapes. Due to imbalanced development and mismanagement of water-related landscapes, the wetlands began to deplete and risk of flooding has increased. Diyawanna Oya and the surrounding wetlands are some of the last remaining extensive areas of wetland in Colombo which have the capacity to mitigate floods.

5.1. Landscape character of Diyawanna Oya and surrounding wetland

The Diyawanna Oya is a significant historic reminder of the ancient kingdom of Kotte. The Parliament now stands as the nucleus of the new capital with the Diyawanna Oya surrounding it; including several water bodies which were introduced for beautification and water retention purposes. The city also includes the natural flood detention area of the green belt around the Oya. This natural landscape of the wetlands and the recently declared wildlife
sanctuary within the city are unique landscape characters of a rapidly urbanizing city. Although these wetlands are meant to be temporary storage basins for flood water, according to current land use the area has reduced greatly due to reclamation and encroachment. Hence, for the purpose of conserving the remaining wetlands, the local authorities carried out several landscape developments in the area.

5.2. Area of Study

Figure 4 indicates the public open space developments of the Diyatha Uyana, Beddagana wetland park and Diyawanna Oya linear park which are studied and analyzed based on the theoretical framework, in order to assess their effectiveness for urban flood management.

6. Analysis of attributes

Landscape Architectural solutions for flood management could have subjective outcomes. The identified attributes for an effective landscape architectural solution takes into consideration these variations.

6.1. Adaptability to Floods

Wetland footprint variation

Sri Jayawardenepura Kotte was home to more than a 1000 Ha of wetland before the administrative capital was shifted here. The dredging of the wetlands for the construction of the Parliament complex and surrounding lake resulted in reclamation of about 272 Ha of natural flood retention area. Since then this area has seen a rapid decrease in wetlands [8]. The variation in the wetland footprint and water bodies was calculated using aerial images of the years 1999, 2007 and 2016 within an area of 1860 Ha (refer Appendix 2).
A significant increase is seen in the area of water bodies due to the flood management and development activities that took place after 2010. Few wetlands along with several reclaimed areas have been converted to water bodies. Hence, considering flood retention capacity, there is currently an imbalance between open water and marsh wetlands.

**Multifunctionality and integration of landscape elements**

- **Diyatha Uyana**

  The activities of this open space include a water retention lake, constructed wetlands, jogging track, waterfront seating and lawn, vehicle parking, children’s play space and weekly sales outlets. Most functions incorporate supplementary functions such as inundation space during floods, social gathering and public performance spaces, alternative seating etc.

  Figure 6 shows the three main walkways, designed at different elevations. In the event of a high precipitation, the lower area will get inundated creating a new high-water level. This multifunctional use of open space enables flood to occur without causing great inconvenience in this particular area. The adjacent part of the Diyawanna lake has been dredged to increase the water retention capacity but there are also problems of silting. The retention ponds and constructed wetlands directly contribute to flood management. However, they are regularly maintained thereby, disturbing ecological succession.

- **Beddagana Wetland Park**

  This park focuses on conserving the natural wetland to maintain flood detention capacity. Therefore, the main activities of a jogging path, boardwalk, birdwatching, dry weather playground, nature trail involves the public in effectively conserving the wetland. This ensures that the natural wetland is protected through multifunctionality combining both the hydrological/ecological benefits of wetland and social awareness.

  The landscape has been designed considering historical flood levels and ensuring least impact to the flood retention/detention capacity of the wetland. Use of compacted earth/gravel-paving encourage ground water absorption, while the raised timber walkways, ensures minimum impact on the natural landscape. Similar treatment has also been given to the other built structures. The area as a whole, including the dry weather playground, acts as a detention basin for flood water at source and excess water from the Diyawanna Oya.

- **Diyawanna Oya Linear Park**

  The linear park along the Diyawanna Oya was developed upon the idea of increasing water retention capacity of the lake and a
water front development to provide recreation and health benefits to the community. Most activities and elements incorporated in this development are designed to be multifunctional in events of high precipitation.

The main element in this area is the jogging track. Most part of it including the carpark has been infilled. They are at a lower level than the main road and is a high-water level for the lake in the event of a flood. The paddy fields in the vicinity act as a natural flood detention area. However, due to the significant absence of natural or constructed wetland or any other BMPs it is possible that excess water will continuously flow downstream and not be detained at source. The slopes of the water bodies are turfed discouraging natural slope vegetation required for conserving biodiversity and water quality.

6.2. Context responsive landscape character and aesthetic quality

Sri Jayawardenepura Kotte is a city of cultural significance and unique in terms of its landscape and character, home to a protected wildlife sanctuary within an urban context. Hence, it is important that landscape developments respond to this character. The landscape character of the four significant landscape developments are analyzed in the tables below.

Table. 5. Analysis of the landscape character of Diyawanna Oya Linear Park

6.3. Social Responsiveness and Community Integration

In the sample of 30 respondents, there was an equal distribution of male and female respondents. 93% of the respondents were residents within the study area or in the immediate surrounding. 30% of the respondents were also employed in this area.

<table>
<thead>

</tr>
<tr>
<td>2016</td>
<td>30%</td>
<td>50%</td>
</tr>
</tbody>
</table>

Table. 6. Comparison of flood experience of respondents

Most respondents could not recall particular information of the flood in 1992. It is evident that from the number of
respondents who had experienced floods, many had been inconvenienced by it and the number has risen each year. Further, 57% of the respondents agreed that the occurrences of floods have increased over the years, with only 43% agreeing that the recent development projects reduced the risk of flooding.

Diyatha Uyana is a park with diverse activities that cater to a wider range of users and it is clearly the more popular public space. It is evident that these multifunctional landscapes have been accepted by the community as 87% of the respondents stated that they prefer spending time in public open spaces.

Table. 7. Frequency of visit

![Fig. 8. Reasons for visiting public open spaces](image)

Considering the public perception of these open spaces, most people preferred these spaces and would recommend it to others due to their natural landscape and relaxing environment. Therefore, the landscape character of the space plays a vital role in the social responsiveness of a landscape.

6.4. Discussion

The landscape developments aim to conserve the natural flood retention capacity but were focused on increasing the water retention capacity of the Diyawanna Oya. Constructed wetlands would be a more effective water management system for flood detention rather than open water wetland. Although an effort has been taken, the water retention capacity has not reached a satisfactory level for flood management due to the continuous loss of natural wetland.

All three landscape developments incorporated multifunctionality in the designs. In the Diyatha Uyana and Linear park, there is a concern that the dredging of large areas may not be effective in the case of a 50-year flood situation but is resilient to minor floods. The Beddagana wetland park,
however, effectively integrates the natural hydrological functions of the area to ensure an effective and flood resilient landscape design. Considering the overall adaptability of the analyzed area, it is not completely effective to manage urban floods of large scales.

The character and aesthetic quality of these landscape developments vary. The geometric character of the parliament grounds is justified due to its formality in the context. The Beddagana wetland park has ensured least disturbance to the ecological habitats and flood detention capacity, effectively responding to the aesthetic quality and landscape character. Although there is an integration of the natural landscape in the designs of the Diyatha Uyana and Linear park, the need to address requirements of a public space has negatively influenced the geometric character of the landscape. However, the use of significant natural elements reduces this highly formal landscape effect to a certain extent. Large open spaces can be made more responsive to the natural environment and predicted flood lines (levels), through clustered vegetation, naturalized lake slopes, abstract land forms and effective BMPs in place of hard landscape material.

Considering the social responsiveness of the above developments, people interact with these public open spaces and it addresses public recreation and well-being of the society. Nevertheless, the community as a whole need to be given a clear understanding and awareness on the objectives and outcomes of such developments in order to have a better a sense of ownership of public landscapes. It can be deduced that people feel welcome in these spaces and have the freedom for exploration and interaction with the landscape, hence making them socially responsive.

7. Conclusion and recommendations for future development

A framework developed based on existing literature identified three possible attributes to assess landscape architectural solutions for urban flood management. Based on this, the study of the public open spaces of the Diyawanna Oya and its surrounding identified a significant contribution to sustainable flood management in the local context. The landscapes were found to be socially responsive and effective in establishing multifunctionality through the integration of landscape elements and spaces for flood management. However, with the continuous decline of wetland, the adaptability of these landscapes to large scale floods is affected. The landscape character and aesthetic quality of the spaces conformed to the immediate context to a certain extent, however, it was identified that common aspects such as vegetated slopes and clustered vegetation in all landscaped spaces were required to support the ecology and natural surrounding better. Hence, these landscape developments can be considered to be only moderately effective as a landscape architectural approach for flood management.

In future, it is recommended that left-over spaces from the years of continuous economic and commercial development in Colombo are developed with green
infrastructure to create a network of public and private open spaces for flood management. Further, strict policies for regulation including mandatory landscape regulations for more permeable ground cover and BMP’s in private lands should be implemented. Flood lines could be part of the landscape designs to create different social experiences and unique flood awareness landscapes. Similarly, a holistic solution including the combination of the human influenced land, wetland and water can be further developed as the ‘LAWW’ concept (LAnd, Wetland, Water) illustrated in figure 10, for future landscape design approaches for flood management.

Several aspects relating to the topic have not been discussed. The ecological components of the biodiversity and water quality, and future maintenance are points which would contribute to better understanding and implementation of effective landscape architectural solutions for flood management. With further studies in this field, future developments for sustainable flood management through landscape architecture have the potential to successfully manage any degree of floods, thereby establishing flood resilient cities.

Air pollution influence on Silesian health resorts
Jedlina-Zdrój and Szczawno Zdrój
Maria Helena Skomorowska
Faculty of Architecture, Wrocław University of Science and Technology, Wrocław, Poland

Abstract
Both Jedlina-Zdrój and Szczawno-Zdrój are well-known, traditional health resorts, located in the industrial region of Walbrzych. Their history began in the 16th century, when mineral spring waters were discovered. After quick development in the 19th century and modernisation before II World War, they are no more popular touristic destinations. The limits of air pollution are exceeded, and Polish government and local authorities are acting to prevent the destruction of local cultural heritage. Analysis of threats and possibilities to protect local environment.

Spa Town; Silesia; health; air pollution

1. Introduction
According to the polish law, health resorts are separated areas for using and protecting natural medicinal resources. The status of a spa town is given to the city, that must have:

- local climate with healing qualities,
- unique, natural deposits of spa resources,
- health care institutions providing services in the field of spa treatment by highly qualified medical staff,
- hospital and sanatorium facilities and full technical infrastructure,
- requirements specified in the provisions of the law on environmental protection,
- an appropriate area allowing for the separation of spa protection zones,
- meaning in the scale of region and country.

Requirements for clean air and healing qualities of a local climate were set to provide best possible conditions for patients. According to World Health Organization, clean air is a basis for human health and well-being, so it should be provided not only in spa towns, but in every place, where people live[1]. Further studies are published in which air pollution is identified as the cause of death[2]. At the same time, quality of air in Silesia, is the worst in Europe, and one of the worst on Earth.

2. Development of Jedlina-Zdrój and Szczawno-Zdrój

2.1. Jedlina-Zdrój

Jedlina-Zdrój is a small city, located in Sudety mountains, with the population of 5000. Spa town in picturesque valley, surrounded by forests is famous for its
mineral spring, mentioned in 1694[3]. Chemical additives of water are mainly carbon dioxide and sodium. Patients come to the town, to heal respiratory system diseases, allergies and neuroses[4].

The development of Jedlina-Zdrój as a health resort began in 1723. The owner was Austrian general, Johann Christoph von Seherr-Thoss. He brought the town into cultivation and gave the name of Charlottenbrunn, in honour of his second wife. In 1835 another mineral spring was discovered, called after next town owner’s wife- Theresienquelle[5].

In 1724, as one of the first spa towns, Jedlina-Zdrój had a hall for patients social meetings and entertainment. On the begging of 19th century, existing bath facilities were not enough. In 1823 new bathrooms were built and in 1885 spa bath was opened. As medical season began to last longer in the year, local authorities tried to increase the comfort of patients.

On the beginning of 20th century, Jedlina-Zdrój was connected to the water supply network, with usage of natural water pressure. At this time spa town was visited by 3 000 patients every year, but it was still one of the smallest Silesian health resorts. Before II World War, in Jedlina-Zdrój were such entertainment places as promenade, spa park and walking routes. In 1935 new colonnade was opened [6].

One of the most important factors in developing modern health resort were a rail line and railway station. In most of the spas summer population doubled after building the railway connection [7]. Jedlina-Zdrój was connected by, the full of beautiful views, rail line number 285, with the local capital city - Wroclaw, via Świdnica, in 1904.

During The II World War, Jedlina-Zdrój had an important function for German army. In the first years of war, in the town was a healing center for soldiers and injured civilians. In next years, when the Nazi-German army leadership found out, that Sowie Mountains would be a perfect location for the system of shelters and underground factories, they located a management of this project (project called Riese, build to provide a new shelters and factories in the mountains connected to the General Headquarters buildings in Książ Castle) in the palace building in Jedlina-Zdrój [8].

Despite the great past of the town, in the second half of 20th century, Jedlina-Zdrój had to face problems. Many owners of spa buildings, necessity of a restoration. Paradoxically, water in a spa pool wasn’t clean, and patients wouldn’t take baths. They also complained about poor entertainment offer[9]. Now, the spa offers healing vacations, but is no longer popular touristic destination.

2.2. Szczawno-Zdrój

Szczawno-Zdrój is the biggest Spa Town in Middle Sudetes. It was popular spa town before II World War. The spa character of Szczawno-Zdrój has been known since the Middle Ages. For the first time, the healing properties of waters was examined and confirmed by the court physician of Hochbergs - Caspar Schwenckfeldt in 1597. The chemical composition of waters, their medical application and the results of the analyzes carried out were described in 1777 [10]. Szczawno-Zdrój gained popularity in the first half of the 19th century. Spa developing and a theater and spa park were established in the town. The biggest building
of a town was built in 1910. Great, empire
styled building was a Grand Hotel. It was
state-of-the-art and biggest hotel in Silesia

Heling properties of bicarbonate-sodium-
calcium-magnesium water: "Mieszko",
"Dąbrówka", "Młynarz" and "Marta” are
used in diseases of the musculoskeletal
system, upper and lower respiratory tract,
diseases of the digestive system and urinary
tract treatment [12].

In 1946, the town was incorporated into the
newly created Wrocław voivodship in post-
war Poland. The spa functions to the present
day, constantly improved and its
attractiveness increased, but the city is not as
popular as in 19th and beginning of 20th
century.

2.3. Spa towns today

Szczawno-Zdrój, as a bigger and more
popular in the past, is still more popular than
Jedlina-Zdrój. They never got back their
popularity from the past. Mostly, because of
a development of medicine. Now, humankind
can prevent or cure a lot of illnesses. Health
resorts were created to help patients with
chronic illnesses. They became a popular
touristic destination on the beginning of 20th
century because of entertainment
possibilities and they social meaning.
Szczawno-Zdrój was even visited by
Winston Churchill. After II World War,
health resorts were a destination for workers,
who got holidays here from government.
Today, patients are mainly elderly or
pensioners. The stay is still payed by National
Health Found, but spa buildings, hotels and
treatment processes are managed by
companies.

Both Jedlina-Zdrój and Szczawno-Zdrój
are municipalities with local authorities.
They have a status of a spa town, but
inhabitants of the city work mostly in other
fields. They are close to Wałbrzych
(Szczawno-Zdrój borders with it, Jedlina-
Zdrój is 10 km away), and not far from local
capital city of Wrocław (90 km away).

Jedlina-Zdrój looks like a small village in the
mountains. Szczawno-Zdrój is a bigger scale
health resort, so it still has the spirit of great
spa town, at the same time becoming a
commuter town of Wałbrzych.

3. Air pollution

3.1. Air pollution in Poland

The growing demand for energy causes
that pollutants enter the atmosphere. The
most important of them are: sulfur dioxide,
nitrogen oxides, coal dust, carbon monoxide
and dioxide, tropospheric ozone. The source
of their emission is progressive
industrialization, population growth, energy
industry and transport.

Poland belongs to the infamous top
European Union countries when it comes to
air pollution. The very poor air quality that
the inhabitants of many regions of Poland
breathe, should be seen not only in terms of
environmental degradation, but also as a huge
development neglect of the country.

While over the last decade, using EU
funds, Poland has made tremendous progress
in the field of water management, waste
management has been regulated over recent
years, air protection issues have not been an
area of adequate solutions for the past decade. Polish air protection policy is largely reactive - air pollution emitted by industry and energy has been significantly reduced because the requirements for this sector have been introduced at the level of EU legislation. What is missing, however, is practically any regulation in the field of installations used in households, i.e. fireplaces and boilers for solid fuels or fireplaces. Also in the field of transport, there are no key legal solutions that would allow limiting the use of the most harmful cars. As a result of many years of neglect, Polish air is one of the most polluted in the entire European Union. European and Polish law regarding air quality standards has been broken for over 10 years.

Analysis of the highest annual concentrations and stations with the highest number of days when the permissible daily concentration of PM10 is exceeded indicates, that the majority of stations with the worst results is located in southern Poland. It is highly negative that the reported results far exceed the norm - especially in the case of daily concentrations. With permitted 35 days, when the daily PM10 concentration exceeds 50 µg / m³, many Polish cities and towns achieve a score of over 100 such days. These are often extremely high concentrations, up to 200 µg / m³, and even 300 µg / m³. It is also worth noting that the highest concentrations, both in terms of the annual average and the number of days exceeding the norm for daily concentration, are noticed not only in large cities, but also in smaller towns. This proves that the problem of polluted air is not only a problem of urban agglomerations. This should not come as a surprise, considering that the main source of PM10 emission in the country is home heating installations: coal and wood-fired boilers and fireplaces.

It should be noted that the weight of individual sources of air pollution will vary throughout the year, the situation will look different in the summer, and differently in winter. It will also depend on the location - the share of sources may vary depending on the type of building (multi-family housing, single-family houses), the size of the town or distance from the large communication artery.

In the scale of the country the largest source of air pollution with dust and benzo(a)pyrene, substances, of which extremely high concentrations Poland has the biggest problem, is the so-called low emission. It is emission from low chimneys (up to 40 m high), created as a result of combustion of solid fuels (coal, wood), and often also waste. The main reason for low emissions is heating households with solid fuels and their use in small production or commercial plants.

Combustion processes outside the industry, i.e. mainly low emissions, account for almost half of the emissions of all PM10 particles emitted in Poland in 2014. Road transport led to the emission of 9% PM10 dust (combustion of fuels, abrasion of brakes and road surfaces). Energy production and industry contributed to PM10 emissions to a similar degree as road transport (9% and 8%).

The dominating contribution of low emission in PM10 emission translates into very high concentrations of this pollutant during the heating season. Exceeding the daily norm for PM10 dust outside the heating season is rarely observed, and high concentrations occur only from autumn to spring, that is when a significant part of Poles
heats homes with coal and wood, and often rubbish.

3.2. Air quality improvement programs

While all limits set by EU and WHO are broken, Polish government and local authorities try to improve the air quality by own regulations. In Szczawno-Zdrój in Jedlina-Zdrój, and in Wałbrzych region, local authorities published a report about the air quality an program to improve it. For pollutants such as NO2, SO2, C6H6, Pb, As, Cd, Ni, PM2.5, acceptable levels, target levels and levels long-term ones were not exceeded. However, for PM10, CO, and benzo(a)pyrene, the levels admitted by the margin of tolerance were exceeded.

The main cause of PM10 and benzo(a)pyrene exceeded in winter is low emission, while in the summer emission from various communication sources. High concentration is characteristic of combustion processes in ineffective heating boilers. Benzo(a)pyrene is a dangerous, toxic and carcinogenic substance that has a negative effect on reproduction, cause hereditary genetic defects and impair fertility.

The analysis of air pollution showed that in the Wałbrzych region, in order to reduce emissions and immissions, activities aimed at improving the purity of the atmosphere are indicated. In relation with the tightening of environmental protection regulations, and in the interests of the residents, these actions should be taken by implementing the following goals:

- Systematic improvement of air quality in the Wałbrzych region communes
- to develop or update a plan for supplying heat, electricity and gas fuels and its successive implementation,
- for the development and implementation of a strategy for reducing the concentration of PM10 fine particles and ozone ground level in the air,
- to increase the awareness of the local community regarding the needs and possibilities of protectionair, including energy savings and the use of renewable energy sources.

- Support and promotion of ecological energy sources
  - replacement of conventionally fired furnaces with coal for gas heating or other friendly ones environment, energy carriers in both public and private housing (implementation of the low emission reduction program),
  - for an increase in the use of renewable energy sources,
  - for supporting and promoting the use of energy-saving materials in construction by residents,
  - for continuing thermo-modernization work in the communes of the Wałbrzych region,
  - for intensification of activities related to road modernization.
4. Air pollution effects on health resorts

Breathing contaminated air causes adverse health effects. Studies indicate that dust in the air can increase the risk of morbidity and mortality from lung and cardiovascular diseases, as well as increase the risk of cancer. Airborne contaminants primarily affect the respiratory system. The most harmful are small particulate pollutants, which due to their small size reach the smallest bronchioles and alveoli. Along the way, they cause irritating and inflammatory effects, which in turn facilitate the so-called allergy, i.e. allergies to vegetal and animal allergens occurring in our environment. In addition, people already suffering from bronchial asthma who, as a result of exposure to air pollution, experience an exacerbation of their disease, must take higher doses of medication and in some cases even be hospitalized. Inflammatory processes in the airways tend to recur, as a result people living in areas where air pollution is present in high concentrations may be more likely to have an upper respiratory tract infection.

As a result of long-term exposure for many years, chronic inflammation of the airways can lead to the development of chronic obstructive pulmonary disease. This is a very serious disease that leads to disability in the long run and the need to use a respirator. Inhalation of fine particles constituting air pollution originating in most of the living-communal sector, may cause inflammatory reaction in the lungs, which is associated with the release of specific mediators changing the conditions of blood clotting, thus contributing to ischemic disorders.

Irritating effects have not only dust, but also gaseous pollutants, such as sulfur dioxide and nitrogen oxides. The smallest particles of dust are able to pass through the walls of the alveoli and go first to the pulmonary vessels, then to the whole circulatory system. As a result of not fully known mechanisms, they promote atherosclerosis. The consequences are extremely serious. As a result of atherosclerotic changes such cardiovascular diseases like hypertension, ischemic heart disease, disorders in the flow of blood through the brain arise. There may be heart attacks and strokes that often end in death.

Changes in the respiratory system in the form of lung cancer or cardiovascular disease have a negative impact on the length of our lives. Estimates made by the World Health Organization indicate that as a result of air pollution from the municipal-housing sector (i.e. the so-called low emission) about 48 thousand deaths in Poland is premature. Estimated this means shortening the life of every citizen by an average of 10 months.

Air pollution particularly adversely affects children's health from the embryonic period. They probably impair the blood flow through the placenta, resulting in the fetus developing more slowly. The result of this is the observation that in areas with high air pollution more children are born with low birth weight. They are not premature babies, only children too small in relation to the duration of pregnancy. In extreme cases, like premature babies, they require intensive therapy. Such children then have a tendency to quickly gain weight and, paradoxically, often have problems with overweight or even are obese. Pre-school children living in polluted areas are more likely to have upper respiratory tract infections than older children or middle-aged adults. Pediatricians,
who know this problem, when they do not see improvement in their sufferers of chronic airway inflammations of small children, often recommend a longer stay at the seaside or in the mountains.

Another group very sensitive are people of an older age. On days when we observe high concentrations of air pollutants, especially connected with adverse weather phenomena such as high humidity, fog, lack of wind, older people experience exacerbations of respiratory and circulatory system diseases, requiring medical assistance, often even staying in a hospital. [13]

At the same time, the acid rain affects stone structures in two ways: they dissolve and cause changes on the surface. Buildings and monuments made of limestone or marble are particularly exposed. They consist mainly of calcite (calcium carbonate, CaCO₃), which is easily dissolved in weak sulfuric or nitric acid. On the surfaces of buildings or monuments one can observe cavities and damage, sometimes all architectural or sculptural details. On stone blocks or slabs one can observe surface or point only damage, depending on the material's resistance. Although in recent years the occurrence of acid rain has been significantly reduced in many regions, many buildings still have visible signs of their effects. This is because the acid rain permanently changed the structure and properties of the stone surfaces. Even metal parts corrode under the influence of acid rain. This applies to components made of carbon steel, nickel, zinc and copper. Damage is also visible on paint layers, some plastic, leather and textile parts. Stainless steel and aluminum are more resistant. Renovating monuments and monuments is very expensive. Economic losses can be calculated and estimated, while aesthetic losses related to the destruction of treasures of world culture cannot be estimated.

5. Summary. The future of Silesian health resorts

Health resorts are no longer safe for patients, they might cause negative effects on their health. Touristic movement will decrease, buildings will be destroyed by polluted environment. It is the negative scenario, but in the worst situation the status of spa town can be reclaimed, as towns will no longer have their healing climate values. Touristic region will lose its source of income. The cultural landscape of this place, originated in 16th century, will not survive.

It is important to protect local heritage. To help health resorts, all must operate together. Government should assist local authorities, and inhabitants must cooperate and get the knowledge about threats of air pollution, not only to the environment, but also for their homes, touristic movement in their city and, most importantly, for their health. It refers to the whole country, but especially to the health resorts.
