Work type: Original Research
Topic: theriogenology and obstetrics

Purpose of the work - To ensure a correct delivery assistance and the birth of a live and viable foal it is necessary to add a simple and inexpensive field test to the clinical observations. The aim of this study is to evaluate the electrolyte (Ca2+, Na+, K+) and the pH changes in pre-foaling mammary secretions.

Materials and used methods - A sample of 3-4ml of mammary secretion was collected daily from 9 mix-breed jennies, after 6pm, at Day -4, -3, -2, -1, 0 before foaling. Ca2+, Na+, K+ concentrations were detected by a BT3500VET (Biotecnica Instruments SpA) biochemistry analyzer. With the testo®230 pHmeter and strip test (range 1-14) pH was determined. The data were analyzed by a mixed model two-way ANOVA test, considering time as fixed factor and jenny as random factor. For sampling time the Least Significant Difference (LSD) test was used (p<0.05). Correlations were determined among parameters.

Outcomes - Ca2+ levels significantly increased (p<0.05) in the last 5D before foaling, especially between D-2 and D-1 (p<0.01). Mean Ca2+ concentration at D-2 was 22 mmol/L (876 ppm). 5/9 jennies reached 1000 ppm at D0. No significant changes in Na+ and K+ levels and their ratio were detected until foaling. No significant decrease of pH was detected by pHmeter. Conversely test strips measure showed a significant decrease between D-4 and -3, D-3 and -2. 6/9 jennies foaled within 48h after reaching a pH 6.5 detection by both methods. Ca2+ levels showed a correlation (-0.8) with both the day of sampling and the test strip pH.

Conclusions - In conclusion, Ca2+ levels reported in our work are in accordance only with the one of Mancuso (1) and are supposed to be a good indicator of fetal maturity in mares and also in the jennies (2) but not a sign of impending delivery. Na+ and K+ levels do not show the inversion cited by Carlucio (2) and the pH values are comparable to the few data available on mare (3,4). Currently a vulvar device is the only option to assist promptly a foaling jenny. The alarm system is expensive but justified by the incidence of dystocia and the economic value of newborn and lactation.
