The 50 most-cited articles on clear aligner treatment: A bibliometric and visualized analysis

Alessandro Bruni,^a Francesca Giulia Serra,^a Vittorio Gallo,^b Andrea Deregibus,^b and Tommaso Castroflorio^b
Turin, Italy

Introduction: Research on clear aligner treatment (CAT) has increased in recent years. In this study, we aimed to perform a bibliometric and visualized analysis to identify and critically assess the 50 most highly cited articles on CAT. **Methods:** Web of Science was selected as a data source and consulted until March 2020 to identify all articles potentially relevant to the analysis. All the eligible articles were collected until 50 manuscripts were listed. Article-based parameters, journal-based parameters, and author-based parameters were registered to perform the bibliometric analysis. Keywords were automatically harvested from the selected articles to implement the visualized analysis. **Results:** The search identified a total of 378 articles; the total number of citations of the selected articles varied from 15 to 112. The average number of citations per year varied from 1.15 to 13.83. The predominant study design was clinical (31.7%). Over the 15 journals in which the most cited articles were published, the *American Journal of Orthodontics and Dentofacial Orthopedics* published the majority of those included in the list (14) and also received the greatest number of citations (671). A total of 195 authors contributed to the 50 most cited articles; a significant portion of them (26) were unaffiliated with academic institutions. A total of 184 keywords were gathered from the article list. **Conclusions:** The number of citations on CAT is expected to grow steadily in parallel with the rising number of research projects. The present work identifies the most influential articles on CAT and their characteristics, placing emphasis on the journals, the authors, and the topics addressed. (Am J Orthod Dentofacial Orthop 2021; ■:e1-e20)

Clear aligner treatment (CAT) has a long-standing history in orthodontics,¹ but the recent advancements in applied biomechanics and the achievements in biomaterials design and engineering have led to its adoption as a suitable technique in dealing with several clinical conditions.

Despite the advantages in patient comfort and acceptability,² oral hygiene maintenance^{3,4} and esthetics,⁵ the efficiency of clear aligners is still under

debate, and a broad consensus on their clinical performance has not been reached in academia.⁶⁻⁹

As a result, a significant surge in research activities has been observed over recent years, in line with the growing number of publications on CAT.

To evaluate and track the research output in a specific field, we employed several analytical instruments with the final aim of determining the historical trend of a topic and speculating on the direction in which the research is proceeding. Bibliometric analysis is a means by which any measurable information pertaining to published scientific articles can be retrieved, collected, and analyzed. Citations are the primary measure used to quantify the impact—and often the quality—of a publication in a specific area; citations also reveal a connection between authors, groups of researchers, topics of study, or countries.¹⁰ The establishment of a citation ranking list identifies published works that can potentially influence trends in clinical practice and future research.¹¹ In addition, the use of visualized analyses to map bibliometric networks, often referred to as *science mapping*, can provide an intuitive yet comprehensive overview of a large dataset.¹²

When submitting a manuscript, it is important for authors to refer to common journal metrics, such as the journal impact factor (JIF), the 5-year journal impact factor (5-JIF), the Scimago Journal Ranking (SJR) and the Eigenfactor (EF), to decide which journal is right for the proposed research. The JIF measures the average number of citations received by an article in a specific journal during a predefined timeframe (2 years for JIF and 5 years for 5-JIF). In contrast, the SJR and Eigenfactor use an original algorithm to appraise the number of citations received and consider the weight of the source of the citations.¹³ Authors choose a particular journal for a variety of reasons; one of the most important is the prestige or impact of the journal. Therefore, these metrics can provide a measure of the supposed quality of the published papers in a specific field.

Author metrics are used to track how often an author's work is cited and demonstrate the reach and impact of a researcher's work for use in grant applications, tenure, promotion, and performance reviews. An author's impact is frequently quantified in terms of the number of citations of their publications. A well-known author-level metric is the h-index, which is equal to the number of an author's publications (h) that have h or more citations¹⁴ (eg, if the h-index of a scientist is 50, it means that each of the 50 articles of the author has been cited at least 50 times).

Bibliometric analysis has been widely employed in several fields of dentistry,¹⁵⁻²² including orthodontics,²³⁻²⁷ but a study identifying and analyzing the most cited articles on CAT has not yet been performed.

The aim of the present bibliometric and visualized analysis is to assess and benchmark research performance, to identify significant trends and underinvestigated areas, and to rank influential men or women, institutions, papers, journals, and countries in the field of CAT. The analysis takes into account all of the aforementioned journal and author metrics.

MATERIAL AND METHODS

The study was designed to answer the following research question: *What are the most cited articles in the field of clear aligner treatment?* The research question was formulated according to the FINER (feasible, interesting, novel, ethical, relevant) criteria.²⁸

On March 22, 2020, a computerized database search was performed independently by 2 authors (S.F.G and G.V) to detect all the published papers about CAT. Because of its ability to provide a systematic citation search through multiple repositories,²⁹ the Web of Science Core Collection (Clarivate Analytics, Philadelphia,

Pa) was the source used to identify all potentially relevant studies regardless of the year, type of publication, or language.

The following complex search query was adopted without field restrictions:

((orthodont OR clear OR removable OR thermo-plastic) AND (aligner* OR "aligner* therap*" OR "aligner* treatment*")) OR Invisalign).*

Titles and abstracts were independently screened by 2 authors (S.F.G and G.V), who had been previously instructed how to use the Web of Science platform to assess the eligibility of the studies: articles not directly relevant to CAT were excluded.

The full records of the retrieved publications were downloaded or manually entered into Microsoft Excel spreadsheet software (Microsoft Corp, Redmond, Wash) by each author. The abstract of each article was analyzed manually to check its pertinence. The residual manuscripts were sorted in descending order according to their total number of citations, and among them, only the first 50 were listed. Cohen's kappa (κ) coefficient was calculated to measure the interrater agreement in the selection process.³⁰ The resulting κ coefficient was 1.0, showing perfect agreement. Any potential disagreement concerning the inclusion of studies would be resolved through discussion and consensus with a third author (C.T).

Bibliometric analysis

Three sets of parameters were independently collected for each article by 2 researchers (S.F.G and G.V): (1) article-based parameters (title, authors, journal, publication year, study design, total citations, average citation per year); (2) journal-based parameters (title, JIF 2018, 5-JIF, SJR, quartile, number of citations, number of manuscripts in top 50, EF), and (3) author-based parameters (name, affiliation/s, h-index, number of articles, authorship position, number of citations).

For the evaluation of the study design of each selected article, the authors used an adapted form, obtained from the classification of different study types proposed by Röhrig et al,³¹ integrated with the Cochrane Collaboration glossary definitions.

The JIF, the 5-JIF, and the EF score of each journal included in the list were identified using the Incites Journal Citation Reports (Clarivate Analytics) dataset.

Author's affiliations, country of origin, and h-index data were retrieved in the Scopus (Elsevier BV, Amsterdam, The Netherlands) database. The most productive institutions were identified using author-level fractional

counting³²; the total citations and the number of manuscripts in the top 50 were equally distributed among the number of their authors to obtain normalized results. All the collected data were subsequently analyzed using Graphpad Prism (version 8.4; GraphPad Software, La Jolla, San Diego, Calif) for descriptive statistics and chart making.

Visualized analysis

Keywords were extracted automatically from the dataset and used to construct a co-occurrence network on the basis of bibliographic data. Keywords were counted using full counting, meaning that each co-occurrence link had the same weight. To avoid redundancy, 2 authors (B.A and S.F.G) manually inspected and revised all the terms to collate a custom *thesaurus* (Supplementary Material). To include keywords in the analysis dataset, we set the requested minimum number of occurrences of keywords was set to 2. Thus, each identified keyword was tabled jointly with its occurrences and total link strength. VOSviewer (Centre for Science and Technology Studies, Leiden University, Leiden, The Netherlands) was used for keyword mapping. The generated networks consist of nodes, representing the keywords, and edges, representing the relationship between keywords. A distance-based approach was selected to display the network visually; the distance between 2 nodes would approximately indicate the relatedness of the nodes. Similar keywords were grouped in clusters.³³

Cluster resolution determines the level of detail of the clustering process. The higher the value, the higher the number of keyword subgroups created. The cluster resolution was set to 1.0, which means that small clusters were merged into larger clusters.

RESULTS

The search strategy applied returned a total of 378 papers. Only those unambiguously referred to CAT were used to create the list of the 50 most cited articles, and from those 50 papers, data were extracted. The articles listed were published from 2002 to 2017 inclusive; 2017 was the most frequently occurring publication year in the dataset. All the 50 articles included in the list were written in the English language.

The 50 most cited articles are shown in Table I, listed in descending order according to the total number of citations received. The number of citations collected by each article between 2002 and 2020 varied from 15 to 112, 1724 overall (mean, 34.48; standard deviation [SD], 20.93); the self-citation rate measured for the listed papers was 11%. The annual number of citations

collected by all 50 articles included in the list is increasing over time, as shown in Figure 1, from 6 in 2003 to 306 in 2019, with a peak in 2017 with 313 citations. Citations of the current year were not embedded in Figure 1 because they would represent a misleading trend.

Considering the total number of citations, the most-referenced paper, published in 2009 in the *American Journal of Orthodontics and Dentofacial Orthopedics*, is the clinical trial by Kravitz et al entitled “How well does Invisalign work? A prospective clinical study evaluating the efficacy of tooth movement with Invisalign.” The average number of citations per year range from 1.15 to 13.83 (mean, 3.87; SD, 2.45), and with regard to this parameter, the most-referenced paper, published in 2015 in *Angle Orthodontist*, is the systematic review by Rossini et al entitled “Efficacy of clear aligners in controlling orthodontic tooth movement: a systematic review.”

The majority of the listed papers were classified as clinical study (n = 14), followed by a cohort study (n = 8) and theoretical studies (n = 8). The type of study collecting the highest number of citations was the clinical trial (38%), followed by the cohort study (17%) and the systematic review (14%), as illustrated in Figure 2.

The 50 most cited papers were published in 15 journals, as shown in Table II. The majority of the listed journals (8 of 15) were classified as orthodontic journals. The journal with the most significant number of cited articles was the *American Journal of Orthodontics and Dentofacial Orthopedics* with 14 articles and 671 citations, followed by the *Angle Orthodontist* (with 14 articles and 410 citations) and the *European Journal of Orthodontics* (with 5 articles and 134 citations), as illustrated in Figure 3.

The JIF of scientific journals in which the 50 most cited articles were published varied from 0.181 to 4.440 (mean, 1.71; SD, 1.140), whereas the 5-JIF ranged from 0.457 to 5.183 (mean, 1.96; SD, 1.27). The journal with the highest JIF and 5-JIF is *Dental Materials*, with a single manuscript listed in the 50 most cited articles.

The SJR score varied from 1.94 to 0.25 (mean, 0.84; SD, 0.44) and the EF varied from 0.01853 to 0.00024 (mean, 0.00526; SD, 0.00587). In addition, considering these indicators, *Dental Materials* showed a higher score.

According to their SJR, 8 journals are positioned in the first quartile, 4 in the second quartile, and 3 in the third quartile.

The number of authors contributing to the 50 most cited articles on CAT is 195. The top 10 authors ranked per total citation numbers are listed in Table III. The

most-referenced author was Jung BA, an author of 4 papers, with a total number of 152 citations.

The h-index of each author varied from 1 to 78 (mean, 12.9; SD, 12.9); the first and the second position of the list were occupied by authors recognized with an h-index of 11, whereas the author in the third position had an h-index of 2.

The distribution of authors per country displayed a clear predominance in the United States ($n = 67$), followed by Italy ($n = 36$), and Germany ($n = 30$). The countries less represented were the United Kingdom, India, Sweden, and Denmark ($n = 1$).

Most of the authors are affiliated with no institutions ($n = 26$), followed by Johannes Gutenberg Universität Mainz ($n = 12$), Universität Göttingen ($n = 10$) and Ohio State University ($n = 10$) (Table IV).

Among the institutions, Albert Einstein College of Medicine of Yeshiva University had the highest author-weighted citations percentage (7.9%).

A total of 184 terms were automatically identified from the 50 most cited articles; of the 93 keywords obtained by merging the redundant terms through a custom thesaurus, 37 terms occurred a minimum of 2 times. A keyword cooccurrences map was generated, as shown in Figure 4. Cluster analysis on the basis of terms occurrence identified 5 clusters with 243 links and a total link strength of 466. The most representative keyword was *Invisalign*, with 25 occurrences and a total link strength of 104.

DISCUSSION

The introduction of clear aligners has been one of the greatest breakthroughs in orthodontic practice. The popularity of CAT has been steadily growing so that not even the uncertainty surrounding their capability to perform⁶⁻⁹ has hindered their large-scale adoption as observed by the relevant rise in market share in recent years.³⁴ This has sparked academic interest and resulted in a significant surge in research activities; CAT has turned into one of the most debated subjects among the orthodontic scientific community. Therefore, the main contribution of the present research was to define the main trends of academic activity.

According to the authors, the present study is the first bibliometric analysis exploring the 50 most cited articles in clear aligner orthodontics and one of the very few in the field of dentistry. The sample size was set to 50 manuscripts to provide a manageable and meaningful number of articles to be analyzed, according to several comparable published works.^{15,35,36}

Fig 1. The number of total citations per year (2003-2019).

Number of citations

From the available data, the authors identified a progressive increase in the number of citations over the years, along with a rising total number of publications in accordance with the growing interest in this subject (Fig 1). The improvements in aligner biomechanics and the common demand for esthetic treatments have encouraged the diffusion of the CAT and consequently have supported their academic attractiveness.

The majority of the articles included in this analysis were published from 2000 to 2010. It is reported that, on average, a scientific paper starts being cited 1 or

2 years after publication, reaching the maximum citation rate 7–10 years after publication³⁷ and that the highest recognition of relevant articles occurs during a chronological interval of 10–20 years.²³ Therefore, the potential impact of recently published papers is frequently underestimated. The average number of citations per year was the indicator used to identify the high potential impact of recently published articles that have had insufficient time to accumulate a large volume of total citations.³⁸ The indicator was calculated by dividing the total number of citations by the number of years since publication and was introduced to avoid any bias

Q, quartile.

arising from older manuscripts accruing a higher number of citations over time²⁰ and providing a fairer comparison for junior academics. Citations of the current year were not embedded in Figure 1 because they would represent a misleading trend.

The number of total citations obtained from the 50 most cited articles in CAT was still minimal compared with other medical disciplines in which a publication cited more than 400 times is considered a classic. In medical fields with limited research activity, the benchmark to qualify an article as a classic is 100 citations.¹¹

Considering the average number of citations in the orthodontic field, the 80 most cited papers published between 2000 and 2015 received an average number of citations of 116.2, with a peak of 274 citations.²⁵ Extending the timeframe from 1975 to 2011, the 100 most cited orthodontic articles collected an average number of citations of 126.54, with the most cited article receiving a total of 545 citations. In the present study, only 1 paper exceeds 100 citations (Kravitz et al, 2009), indicating that there is still a lack of research in the field.

Number of citations

Type of studies

The selected papers showed heterogeneity in analyzed topics as well as in study design. Most of the manuscripts were primary research papers (84.5%) with a predominance of clinical studies. Secondary research occurred less frequently in the present study (15.5%), despite it playing a key role in evidence-based decision-making by collecting and appraising all existing well-designed primary studies pertaining to a specific question.³⁷

Interestingly, these findings are in contrast with the dominant position occupied by secondary research in the hierarchy of evidence, the overall propensity of authors to cite articles conducted with great scientific rigor,^{39,40} and the increasing number of systematic reviews and meta-analyses in dentistry.^{41,42}

Some possible explanations can be surmised. There is a relatively small number of well-designed primary studies, as for instance, randomized controlled trials (RCTs), because conducting and monitoring an RCT is a challenging task, expensive⁴³ and time-

consuming^{43,44} and academic interest in CAT is relatively recent. In addition, when the usual treatment is assumed to be effective, randomization of patients into groups to be compared may even be considered unethical because it would mean exposing participants to potentially ineffective or harmful treatment.⁴⁵ Nevertheless, in an era focused on evidence-based medicine, studies accurately conducted and reported are what clinicians and patients deserve. The limited number of well-designed clinical trials on CAT could explain the high number of citations they collected.

It is reported that disproportionately more secondary research is conducted than primary research: synthesizing evidence from multiple sources requires fewer resources,⁴³ shorter time-frames, no procedures on human patients, and no ethical clearance.⁴² If primary studies, though well-designed, are insufficient, the systematic reviews, meta-analysis, and clinical practice guidelines will also potentially include primary studies that are both biased and performed without high methodological standards. For these reasons, only 22% of the

Fig 4. Network analysis of keywords co-occurrence. The size of the nodes represents the frequency of the keywords, with larger nodes indicating higher frequency. The thickness and the length of the edges indicate the closeness of the interactions between 2 nodes. The colors of the nodes of the keywords indicate the cluster to which keywords belong.

reviews, on average, reported adequate evidence for supporting clinical decisions in dentistry.⁴⁶

Nevertheless, “absence of evidence is not evidence of absence.”⁴⁷ Because research activities have intensified in recent years, substantial improvement of the quality of existing evidence is expected.

Journals

According to the results, 30% of the ranked articles were published in just 2 journals (*American Journal of Orthodontics and Dentofacial Orthopedics* and *Angle Orthodontics*), collecting more than half of the total citations (1081 of 1724). These outcomes demonstrate that a significant number of studies were concentrated in a limited core of journals, according to Bradford’s law.⁴⁸⁻⁵⁰

Authors tend to submit their works to the most prestigious journals,⁵¹ attracted by the enhanced visibility of the searched results and the higher probability of being cited. The most common measure of journal prestige is the JIF, defined as the frequency with which the *average*

article in a journal has been cited in the previous 2 years.⁵² Despite the wide recognition, the JIF is flawed because of considerable limitations. The most important is the time-constrained nature of the JIF is arguably sub-optimal because many important papers achieve their maximal scientific impact outside this timeframe.⁵³ The 5-JIF has been introduced to counterbalance this limitation,⁵⁴ extending the timeframe from 2 to 5 years.

The research field also influences the JIF: scientific productivity may vary according to the area of application. Furthermore, the number of authors, articles, and therefore citations, related to a research field⁵⁵ (popularity), the average number of references per article⁵⁶ (citation habits), and the timeframe between publication and citations peak⁵³ (citation dynamics) change from specialty to specialty.

Multidisciplinary journals usually tend to have a higher JIF than discipline-specific journals because of their broader readership and, consequently, a more significant number of citations.⁵² Accordingly, all the

ranked journals with a JIF greater than 2.0 are nonorthodontic. Nevertheless, the greater number of citations is sourced from journals specialized in orthodontics with a lower JIF but a broader readership and recognition within a specific research community.

The abuse of self-citations is another element that may substantially affect the JIF. The self-citation rate in the presented list was limited (11%), similar to the average reported in dentistry⁵⁷ and under the median self-citation rate of 12.7% emerging from a recent study.⁵⁸ This bias can be overcome by considering self-citation-free indices⁵⁹: The SJR⁶⁰ and the EF⁶¹ exclude self-citations and calculate, through algorithms, both the number of citations received by the journal and the value of the sources of the citations.⁵⁴ Both indicators also offer an extended timeframe (3 years for SJR; 5 years for EF). For these reasons, the use of these indicators should be encouraged in the academic world.

Authors, institutions, and countries

Metadata from all documents were used to reveal the most productive authors and the most impactful sources. The relevant number of authors (195) contributing to the top 50 papers listed suggested an average of more than 3 authors per article. Because there are a number of authors per document, it is difficult to determine the individual contribution and, consequently, the role of each author.⁶² Traditionally, in multiauthored papers, the first position is occupied by the major contributor, whereas the last position is reserved for the supervisor.⁶³ The corresponding author, in most articles, is situated in one of these positions.⁶² The most impactful authors in CAT rarely occupied a relevant position in the byline. Kravitz ND is the only contributor who appeared twice as the first author in the ranking of the most productive authors.

In addition to recording the total number of citations of each author, the number of articles authored, and their position in the author list, we investigated the relationship between a researcher's expertise and productivity.

The h-index is the bibliometric indicator examined: it quantifies the research performance of individual scientists, incorporating both quantity and visibility of publications.⁶⁴ The uneven distribution of h-index between authors of the top 50 papers listed indicates contributions from researchers with different academic experience.

The most cited articles were authored almost exclusively from the United States and Western Europe. A similar trend has been observed in citation analysis in other dental fields^{18-21,23,26} and other medical specialties. This trend may be explained by accumulative

geographic advantage, as citations originate more frequently from institutions located in the same country as where the author was based.⁶⁵ In addition, the United States can rely on a broad scientific community and generous science funding policies.⁶⁶ Indeed, the first and the second institutions with the most numbers of citations are located in the United States, in the state of New York (Albert Einstein College of Medicine of Yeshiva University) and Illinois (University of Illinois), respectively. In Europe, the University of Turin (Italy) is noteworthy for the number of citations.

Although the findings evidenced a collaboration between institutions, according to the increase of cross-institutional collaborations on coauthored papers documented in the literature,^{67,68} the highest number of citations is associated with authors without affiliation.⁶⁹

Author-level fractional counting was used for affiliation assessment: assigning coauthored publications fractionally to each coauthor will result in properly field-normalized results. The use of full counting could have resulted in bias by assigning the number of citations or number of manuscripts in coauthored publications multiple times (once for each coauthor).³²

Keywords

A network analysis of keyword cooccurrences is a tool for mapping the research domain in a specific field by examining the links between keywords.⁷⁰ Keywords are a set of terms enabling correct indexing in computerized databases, maximizing the sourcing of scientific literature.⁷¹

According to the keyword cooccurrences map, the bigger and centrally located nodes were filled by terms such as *Invisalign*, *Clear Aligners*, and *Orthodontic Tooth Movement*.

The keyword *Invisalign* had a significant weight in the keyword map probably because it represents the brand name of the most used clear aligners system, gaining the first-mover advantage. *Invisalign* is still the dominant player in terms of brand recognition, research and development, manufacturing, training, and sales regarding clear aligner therapies. Several companies are currently manufacturing aligners, with the number increasing every year.⁷²

Orthodontic tooth movement was the keyword reported in several studies investigating the predictability of specific outcomes (eg, distalization,⁷³ intrusion, extrusion, rotation). The efficacy of clear aligners has been a subject of ongoing debate since their introduction.^{9,74-76}

Given the tendency for CAT to evolve rapidly,¹ it is conceivable that the current predictability of treatment

outcomes could be higher than that which the literature has reported.

The occurrence of the term *physical properties* was significant, indicating the increasing interest in testing materials and exploring innovative solutions.⁷⁷ Orthodontic aligner performance is strongly influenced by the mechanical properties of the thermoformed material, such as by the intraoral environment.⁷⁸ All the polymers currently used showed a significant stress decay over time,⁷⁹ suggesting the need for a material able to yield greater initial stress values or slower stress decay over time.

Under the word *Biomechanics*, all the articles concerning the interaction between clear aligners and the tooth-periodontium complex were collected. The biological mechanism behind CAT does not differ from that of traditional appliances.⁸⁰ Intermittent forces applied with aligners respect the periodontium physiology and seem capable of inducing greater concentrations of orthodontic tooth movement biological markers.⁸⁰

Periodontal parameters were also extensively investigated in CAT literature. It was largely demonstrated that the use of removable appliances could mitigate the adverse effects of orthodontic treatment on periodontal health, allowing patients easier oral hygiene procedures.³ The keyword was significantly linked to terms related to fixed appliances, indicating the comparison of the impact of the 2 treatment options on the periodontium.

Limitations

Although the present study was designed to minimize all the potential shortcomings, it is crucial to highlight the existing limitations. Plausible omissions in articles included in the current work could be considered: comprehensive research was not performed, consulting 1 citation database only.

The most widely used citation-tracking databases include Web of Science, Scopus, and Google Scholar.⁸¹ No bibliometric database indexes every type of publication, and comprehensive coverage of research publications is not possible. The number of citations may fluctuate across databases. The use of each database directly impacts the bibliometric measures indexing different content and considering only citations within their collections.⁸²

Not considering other databases and the gray literature could potentially restrict the comprehensiveness of our search results.⁸¹ Furthermore, Web of Science does not automatically exclude self-citations. However, the self-citation rate of 11% identified in the present paper should

not jeopardize the results. The average self-citation rate in dental journals has been proven to be near 10%,⁵⁷ consistent with the data of the present study.

There are shortcomings in the study. Future research suggestions that address these limitations could be proposed. A wider search through more than 1 database and gray literature would be desirable. A statistical test to determine the potential correlation between the analyzed variables could also be attractive and useful.

CONCLUSIONS

Taken together, the evidence gathered from the present bibliometric and visualized analysis suggest the following:

1. The total number of articles in aligner orthodontics is rapidly increasing; the total number of citations among the 50 most cited papers about CAT is small despite the growing interest of the scientific community.
2. Advances in CAT depend on well-designed secondary researches or RCTs; a significant portion of the 50 most cited articles on CAT is represented by studies of lower position in evidence hierarchy.
3. Two leading journals published 30% of the most influential articles on CAT and collected more than half of the total number of citations.
4. Most of the papers are coauthored; individual researchers not belonging to an institution collected a noteworthy quantity of citations; not belonging to an institution could increase the risk of not-independent studies; academic involvement in the field should be encouraged.
5. The main topics, according to keyword mapping, are the predictability of diverse tooth movements, physical properties of materials, biomechanics, and the influence of CAT on periodontal health. For all those topics, well-designed studies are still lacking.

There is considerable room for the improvement and further development of CAT. Conclusions generated by this bibliometric analysis may be employed to guide further research in several areas of CAT. Because research activities have expanded over recent years, substantial advances can be expected soon, in addition to a significant improvement in research quality.
