BACKGROUND

Preservation of lip sensation is crucial in ablative surgery of mandibular tumors. When tumor control does not necessitate sacrifice of the inferior alveolar nerve (IAN), as in some cases of benign tumors of the lower jaw, attempts may be made to spare the nerve. The authors present and discuss their experience with an ultrasonic device in the treatment of benign tumors of the jaw in correspondence of the IAN.

MATERIALS AND METHODS

Five patients with tumoral lesions involving the IAN underwent surgery with an ultrasonic surgical device (Sonopet Omni Surgical System; Stryker, Kalamazoo, MI).

RESULTS

Fine, delicate movements allowed the surgeon to remove bone without damage to surrounding tissue. Three of 5 patients did not present intraoperative or postoperative complications that could be attributed to the Sonopet. Two cases were partial failures. In 1 case, postoperative dysesthesia was encountered, and in the other case, intraoperative transection of the nerve occurred.

CONCLUSION

The Sonopet ultrasonic bone curette proved to be highly useful in surgical procedures close to the IAN because it does not produce heat or cause mechanical injury to the neurovascular bundle. Application of this instrument may provide improved ability to preserve sensibility of the chin and lower lip in patients affected by lesions in proximity to the IAN.

Ultrasonic vibrations have been used for cutting in neurosurgery for decades. However, it is only in recent years that experimental devices have been used routinely for standard clinical applications in many fields of oral and maxillofacial surgery. Preservation of lip sensibility is important in oral function after ablative surgery. The lower lip is innervated by the inferior alveolar nerve (IAN). The IAN provides unilateral sensation to the teeth and, through the mental nerve, to the anterior labial mucosa and the skin from the commissure to the mental protuberance.

In the dental literature, it is generally claimed that the use of ultrasonic devices decreases the risk of damaging surrounding soft tissues and critical structures (nerves, vessels, and mucosa), particularly during osteotomies. In their works on IAN transposition, Meltzger (in sheep) and Bovi (in humans) observed that Piezoelectric devices, as opposed to conventional burs, have a lower rate of damage to soft tissue, specifically to neurovascular tissue.
In cases in which tumor control does not imply sacrifice of the IAN, as in some benign tumors of the lower jaw, attempts may be made to spare the nerve. This article presents and discusses experience with ultrasonic devices in surgery of benign tumors involving the IAN, as well as a case of an extremely rare neoplasm of the IAN.

MATERIALS AND METHODS

The design of this study was exempt from the approval of the local institutional review board. The Sonopet Omni Ultrasonic Surgical System (Stryker, Kalamazoo, MI) was used. The action of this bone curette consists of an ultrasonic frequency vibrating surgical tip produced by a Piezoelectric element exposed to alternate current.

The inclusion criterion for this prospective study was the presence of tumor lesions that were in contact with IAN.

Five patients (2 men, 3 women) were included in the study. The average age of the study population was 42.2 years (range 36-50 years, SD 5.58 years, median 42 years). Table 1 provides the characteristics of the study population.

RESULTS

Ultrasonic bone curettage occurred after gross high-speed drilling. A high-speed drill was preferred for resecting large amounts of bone because it required less time to complete gross bone ablation. Sonopet was used when the lesion or the bone to be drilled was close to the IAN.

Fine and delicate movements allowed the surgeon to remove bone without damaging surrounding tissues. Bone was easily resected with minimal pressure from the tip of the handpiece against the bone surface using simple scratching, as with a curette. No significant heat generation was observed. No dehiscences or infections occurred in any patient.

In this study population, 3 of 5 patients (Patients 2, 4, and 5) did not present any intraoperative or postoperative complications that could be attributed to the Sonopet. Two of 5 cases (Patients 1 and 3) were partial failures. In 1 case, postoperative dysesthesia was encountered; in the other case, intraoperative transection of the IAN occurred.
DISCUSSION

Ultrasonic surgery was developed in response to the need for greater precision and safety in bone surgery, compared with manual and motorized instruments. Ultrasonic surgical devices generally operate in a high-power, low-frequency range of 20 to 60 kHz for biological tissue cutting, ablation or fragmentation, and removal. A frequency from 25 to 29 kHz is used because micromovements that are created at this frequency (amplitude ranging from 60 to 210 μm) cut only mineralized tissue. Neurovascular tissue and other soft tissues are cut at frequencies higher than 50 kHz. These devices have gained widespread acceptance in dentistry, neuro-, orthopedic, ophthalmic, plastic, and maxillofacial surgeries.

In the dental literature, it is generally claimed that the use of ultrasonic devices decreases the risk of damaging surrounding critical structures (nerves, vessels, mucosa), particularly when performing osteotomies (Table 2). The Piezosurgery system (Mectron, Carasco, Italy) was the first ultrasonic lancet on the market. It is made of a generator of intermediate frequencies and a pump that enables irrigation. Experiences in the English dental literature are based exclusively on this kind of instrument. The parameters that are directly controlled by the operator, apart from manually applied pressure, are the pulse frequency (when available), the rate of delivery of coolant fluid, and applied power, which in some instruments is limited to 3 to 16 W and in others has a maximum of as much as 90 W. In most instruments, power is controlled by selecting the type of bone to be cut or the procedure to be performed. The peak-to-peak amplitude of tip oscillations, typically in the range of 30 to 200 μm perpendicular to the shaft of the working piece (some instruments also or exclusively oscillate along the shaft) ensures precise microabrasive incision.

Abbreviation: IAN, inferior alveolar nerve.

Sonopet ultrasonic bone curettes have been used successfully in ear, nose, and throat surgery, spine surgery, and neurosurgery. In maxillofacial surgery, the use of
Sonopet has been described for performing Le Fort I–type osteotomies\textsuperscript{36} and for establishing a guiding notch before completing sagittal split osteotomy.\textsuperscript{41} This ultrasonic surgical device comprises a power supply unit, foot switch, and handpiece. The handpiece weighs 110 g, is 140 mm in length from tip to angled section, and is 20 mm in thickness. The longitudinal vibration amplitude varies from 120 to 365 $\mu$m, and the ultrasonic frequency is 25 kHz. Longitudinal-torsional amplitude is also available for more effective bone cutting. The adjustable cooling irrigation fluid (20°C) emerges through the sheath near the tip of the handpiece. A suction device is attached that draws the tissue into or against the device for more effective ablation.

When tumor management does not require sacrifice of IAN, as in some cases of benign lower jaw tumors, attempts may be made to spare the nerve. This article presents and discusses experience with SONOPET in benign tumor surgery of the jaw in proximity to the IAN, as well as an extremely rare neoplasm of the IAN. The authors adopted this device because there was consistent literature on the treatment of intra- and extracranial neoplasms using the instrument.\textsuperscript{7, 51, 52 and 53} Bone removal may carry some risk to neural tissue. Indeed, any inadvertent contact of the rapidly rotating drill with the IAN may cause permanent damage to the nerve.\textsuperscript{2} Moreover, the use of a high-speed drill increases the temperature in the operative field and may affect the nerve, even in the absence of any mechanical compression.\textsuperscript{3 and 4}

Drilling in proximity of the IAN implies heat generation, problems in visualization, and, therefore, risk of neural damage. These limitations appear to be minimized with the Sonopet. As Nakase et al\textsuperscript{1} and Hadeishi et al\textsuperscript{5} have proposed, it was thought that the combined use of a drill followed by Sonopet could make bone removal easier, safer, and faster than using either alone. Furthermore, in various series, complications attributable to heat injury were not observed. This is probably due to automatic irrigation of cool saline solution.\textsuperscript{6} The ultrasonic bone curette resects bone through ultrasonic oscillation not rotation moments, and nerve tissue actually absorbs the oscillation.\textsuperscript{54} Thus, the risks of injuring the IAN should be prevented with this device. From what has been described in neurosurgery literature, the handpiece seems to allow fine control. This ultrasonic bone curette produces a minimal amount of bone dust compared with a typical drill. Furthermore, bone scraping is smooth and gradual, and it can be limited to the contact area.\textsuperscript{51}

In our series, 3 of 5 cases had no intraoperative or postoperative complications that could be attributed to the Sonopet. In these patients, the anatomy of the IAN canal was fully preserved within the tumor mass. The intervention was highly comparable to an IAN transposition, and, in accord with Nakase et al's claim, this device may reduce the surgical complication rate.\textsuperscript{1} This was especially true for tumors of nervous origin. Two of 5 cases were partial failures. In 1 case, we encountered postoperative dysesthesia, and intraoperative transection of the nerve occurred in the other case. Three hypotheses may explain the damage related to this specific treatment of jaw tumors. First, these 2 tumors were heterogeneous and had a nonlinear, inelastic, anisotropic character that varied throughout the mass. Second, the amount of collagen within these neoplasms is variable and unpredictable, and it is responsible for tensile strength of any tissue. Finally, apart from reporting that ultrasonic-curetted bone surfaces were less smooth than those drilled by a rotary diamond bur, Metzger et al\textsuperscript{49} provided evidence that epineurium lesions still occurred, but the nerve itself was not affected. In the case in which the nerve was damaged, we observed a true lack of an IAN bony canal and a histologically proved calcification of the epinevrium. The mechanical action on a harder-than-normal epinevrium might have indirectly caused damage to the underlying nerve.

Setting of the device apparatus seems difficult in cases like these because one must choose a definite work frequency, even though the texture of the mass is mixed and ultrasounds are absorbed unevenly. For these reasons, the results of jaw tumor removal close to the IAN are not fully predictable.
Ultrasonic bone curettes generally show other disadvantages. They require more time and do not seem suitable for resections of large amounts of bone.\(^1\)\(^,\)\(^2\) Moreover, in our experience, the angle of the Sonopet tip has to be as close to perpendicular as possible because the use of the working side of the tip may tear neural tissue. Therefore, the Sonopet does not automatically protect neural tissue, especially in a transoral approach.\(^2\) Finally, the cost of this device is significant, and thus its use might be limited to larger centers, perhaps shared among different departments (e.g., maxillofacial surgery; neurosurgery; and ear, nose, and throat).

The Sonopet ultrasonic bone curette was revealed to be highly useful in surgical procedures adjacent to the IAN. It avoids heat production and mechanical injury to the neurovascular bundle. Application of this instrument might provide improved ability to preserve sensibility of the chin and lower lip in patients affected by lesions in proximity to the IAN. The Sonopet could represent a valid alternative to standard surgical drills for IAN surgery. However, further studies are needed to confirm these results and to extend the possible uses of this system to other surgical procedures.
